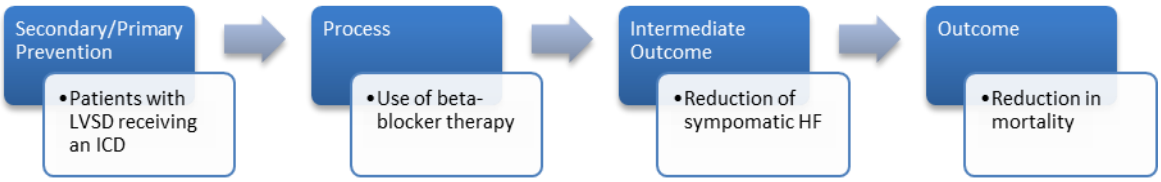
INTERMEDIATE OUTCOME, PROCESS, OR STRUCTURE PERFORMANCE MEASURE

1a.3. Briefly state or diagram the path between structure, process, intermediate outcome, and health outcomes. Include all the steps between the measure focus and the health outcome.



Beta-blockers reduce morbidity, mortality, and hospitalizations for patients with heart failure and left ventricular systolic dysfunction.

1a.3.1. What is the source of the systematic review of the body of evidence that supports the performance measure?

☒ Clinical Practice Guideline recommendation – ***complete sections 1a.4, and 1a.7***

☐ US Preventive Services Task Force Recommendation – ***complete sections 1a.5 and 1a.7***

☐ Other systematic review and grading of the body of evidence (*e.g., Cochrane Collaboration, AHRQ Evidence Practice Center*) – ***complete sections 1a.6 and 1a.7***

☐ Other – ***complete section 1a.8***

Please complete the sections indicated above for the source of evidence. You may skip the sections that do not apply.

1a.4. CLINICAL PRACTICE GUIDELINE RECOMMENDATION

1a.4.1. Guideline citation (*including date*) and **URL for guideline** (*if available online*):

Yancy CW, Jessup M, Bozkurt B, Butler J, Casey DE Jr, Drazner MH, Fonarow GC, Geraci SA, Horwich T, Januzzi JL, Johnson MR, Kasper EK, Levy WC, Masoudi FA, McBride PE, McMurray JJV, Mitchell JE, Peterson PN, Riegel B, Sam F, Stevenson LW, Tang WHW, Tsai EJ, Wilkoff BL. 2013 ACCF/AHA guideline for the management of heart failure: a report of the American College of Cardiology Foundation/American Heart Association Task Force on Practice Guidelines. http://content.onlinejacc.org/article.aspx?articleid=1147807

1a.4.2. Identify guideline recommendation number and/or page number and **quote verbatim, the specific guideline recommendation**.

2013 ACCF/AHA Guideline for the Management of Heart Failure (p. e169-170, 176, 195)

Stages of Heart Failure:

Stage A: At high risk for HF, but without structural heart disease or symptoms of Failure

Stage B: Structural heart disease, but without signs or symptoms of HF

Stage C: Structural heart disease with prior or current symptoms of HF

Stage D: Refractory HF requiring specialized interventions

p. e169

Stage B:

1. In all patients with a recent or remote history of MI or ACS and reduced EF, evidence-based beta blockers should be used to reduce mortality. **Class I: Level of Evidence: B**
2. Beta blockers should be used in all patients with a reduced EF to prevent symptomatic HF, even if they do not have a history of MI. **Class I: Level of Evidence: C**

p. e176:

Stage C:

3. Use of 1 of the 3 beta blockers proven to reduce mortality (e.g., bisoprolol, carvedilol, and sustained-release metoprolol succinate) is recommended for all patients with current or prior symptoms of HFrEF, unless contraindicated, to reduce morbidity and mortality. **Class I: Level of Evidence: A**

AHA/ACCF secondary prevention and risk reduction therapy for patients with coronary and other atherosclerotic vascular disease: 2011 update (p. 2435)

4. Beta-blocker therapy should be used in all patients with left ventricular systolic dysfunction (ejection fraction <40%) with heart failure or prior myocardial infarction, unless contraindicated. (Use should be limited to carvedilol, metoprolol succinate, or bisoprolol, which have been shown to reduce mortality.) **Class I: Level of Evidence: A**

1a.4.3. Grade assigned to the quoted recommendation <u>with definition</u> of the grade:

Guideline Statement # (see 1a.4.2 above)	Class of Recommendation/Level of Evidence (for definitions see 1a.4.4 below)

1	Class Ib
2	Class Ic
3	Class Ia
4	Class Ib
5	Class Ib
6	Class Ia

1a.4.4. Provide all other grades and associated definitions for recommendations in the grading system. (*Note: If separate grades for the strength of the evidence, report them in section 1a.7.*)

Class of Recommendation (COR) is an estimate of the size of the treatment effect considering risks versus benefits in addition to evidence and/or agreement that a given treatment or procedure is or is not useful/effective or in some situations may cause harm.

Class I: Procedure/Treatment should be performed/administered

Class IIa: It is reasonable to perform procedure/administer treatment

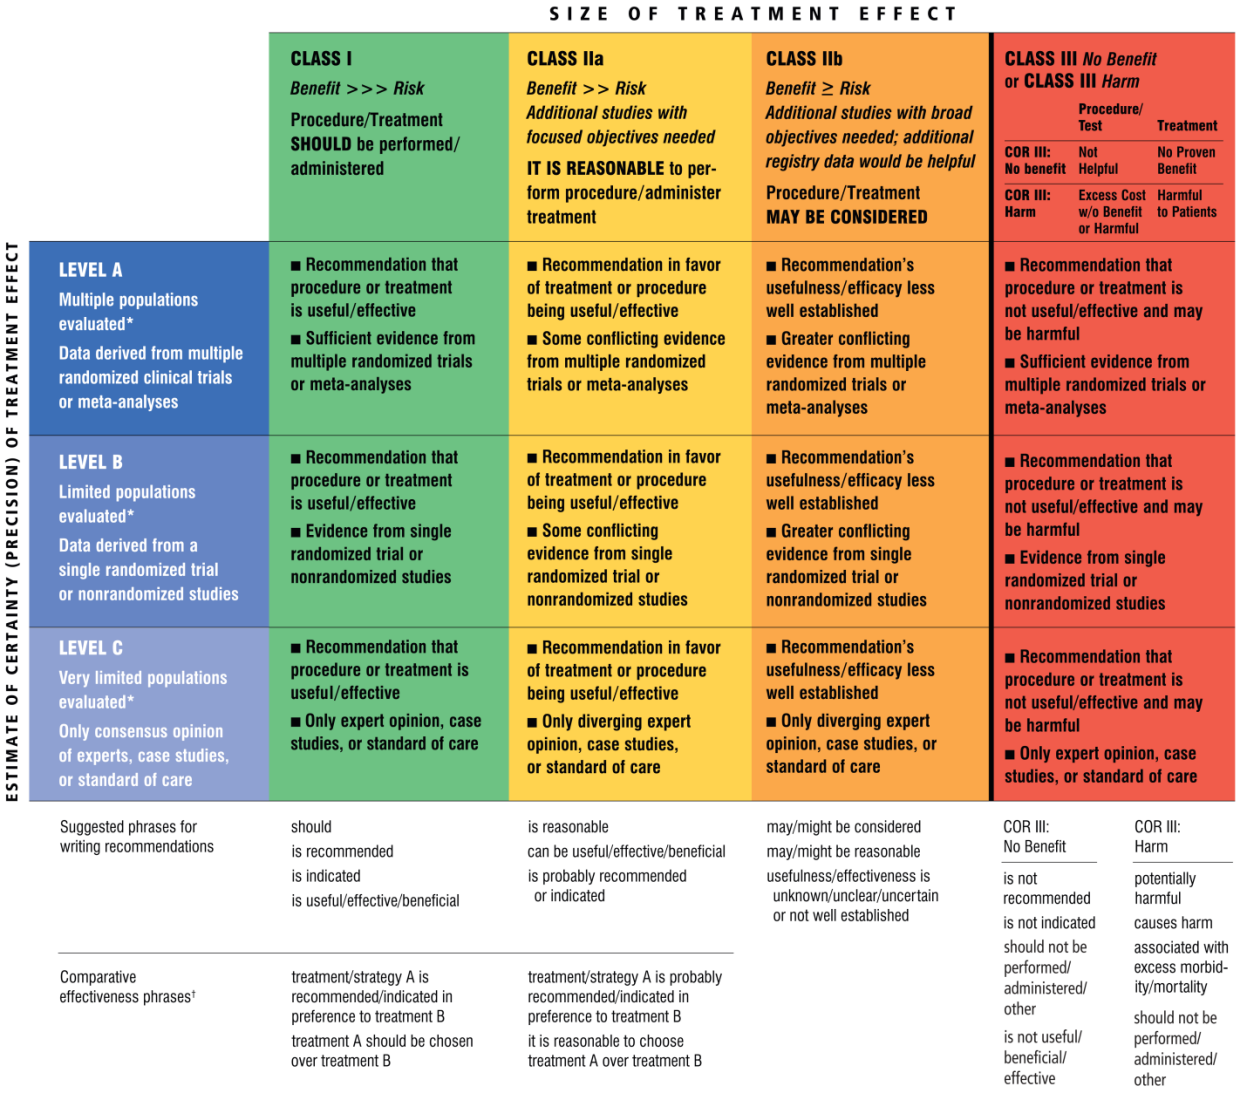
Class IIb: Procedure/Treatment may be considered

Class III: No benefit (Not helpful or No proven benefit)

Class III: Harm (Excess cost w/o benefit or Harmful to patients)

Specific COR definitions are included in Table 1 below.

Table 1. Applying Classification of Recommendation and Level of Evidence



Note: A recommendation with Level of Evidence B or C does not imply that the recommendation is weak. Many important clinical questions addressed in the guidelines do not lend themselves to clinical trials. Although randomized trials are unavailable, there may be a very clear clinical consensus that a particular test or therapy is useful or effective. *Data available from clinical trials or registries about the usefulness/efficacy in different subpopulations, such as sex, age, history of diabetes, history of prior myocardial infarction, history of heart failure, and prior aspirin use. †For comparative effectiveness recommendations (Class I and IIa; Level of Evidence A and B only), studies that support the use of comparator verbs should involve direct comparisons of the treatments or strategies being evaluated.

1a.4.5. Citation and URL for methodology for grading recommendations (*if different from 1a.4.1*)**:**

_____

1a.7. FINDINGS FROM SYSTEMATIC REVIEW OF BODY OF THE EVIDENCE SUPPORTING THE MEASURE

If more than one systematic review of the evidence is identified above, you may choose to summarize the one (or more) for which the best information is available to provide a summary of the quantity, quality, and consistency of the body of evidence. Be sure to identify which review is the basis of the responses in this section and if more than one, provide a separate response for each review.

1a.7.1. What was the specific structure, treatment, intervention, service, or intermediate outcome addressed in the evidence review?

2013 ACCF/AHA Guideline for the Management of Heart Failure

This guideline covers multiple management issues for the adult patient with Heart Failure (HF) including the guideline-directed medical therapy (GDMT) such as beta-blocker therapy.

1a.7.2. Grade assigned for the quality of the quoted evidence with definition of the grade:

An overall grade for the quality of evidence was not assigned. Rather, the quality of a study (or set of studies) supporting a recommendation was graded on an estimate of the certainty or precision of the treatment effect (see 1a.4.3).

Recommendations used to support this measure have a:

- Level of Evidence A: Data derived from multiple randomized clinical trials or meta- analyses. References used to determine level of evidence must be provided and cited with the recommendation.

OR

- Level of Evidence B: Data derived from a single randomized trial, or nonrandomized studies. References used to determine level of evidence must be provided and cited with the recommendation.

OR

- Level of Evidence C: Consensus opinion of experts, case studies, or standard of care.

1a.7.3. Provide all other grades and associated definitions for strength of the evidence in the grading system.

Level of Evidence (LOE) is an estimate of the certainty or precision of the treatment effect.

Level of Evidence A: Data derived from multiple randomized clinical trials or meta- analyses. References used to determine level of evidence must be provided and cited with the recommendation.

Level of Evidence B: Data derived from a single randomized trial, or nonrandomized studies. References used to determine level of evidence must be provided and cited with the recommendation.

Level of Evidence C: Consensus opinion of experts, case studies, or standard of care.

Specific LOE definitions are included in Table 1 in 1a.4.4.

1a.7.4. What is the time period covered by the body of evidence? (*provide the date range, e.g., 1990-2010*). Date range: An extensive evidence review was conducted through October 2011 and includes selected other references through April 2013.

QUANTITY AND QUALITY OF BODY OF EVIDENCE

1a.7.5. How many and what type of study designs are included in the body of evidence? (*e.g., 3 randomized controlled trials and 1 observational study*)

The body of evidence supporting the recommendations on beta-blocker therapy for patients with LVSD includes:

7 randomized controlled trials

1a.7.6. What is the overall quality of evidence <u>across studies</u> in the body of evidence? (*discuss the certainty or confidence in the estimates of effect particularly in relation to study factors such as design flaws, imprecision due to small numbers, indirectness of studies to the measure focus or target population*)

2013 ACCF/AHA Guideline for the Management of Heart Failure

All but one of the recommendations for this process is rated as Level of Evidence A or B, meaning that the data was derived from one or more RCTs or meta-analyses. Additional information on the overall quality of evidence across the RCTs is not provided.

ESTIMATES OF BENEFIT AND CONSISTENCY ACROSS STUDIES IN BODY OF EVIDENCE

1a.7.7. What are the estimates of benefit—magnitude and direction of effect on outcome(s) across studies in the body of evidence? (*e.g., ranges of percentages or odds ratios for improvement/ decline across studies, results of meta-analysis, and statistical significance*)

2013 ACCF/AHA Guideline for the Management of Heart Failure

p. e170:

CAD is a major risk factor for the development of HF and a key target for prevention of HF. The 5-year risk of developing HF after acute MI is 7% and 12% for men and women, respectively; for men and women between the ages of 40 and 69 and those >70 years of age, the risk is 22% and 25%, respectively. Current evidence supports the use of ACE inhibitors and (to a lower level of evidence) beta-blocker therapy to impede maladaptive LV remodeling in patients with stage B HF and low LVEF to improve mortality and morbidity.

In 1 study, losartan reduced adverse outcomes in a population with hypertension, and in another study of patients post-MI with low LVEF, valsartan was equivalent to captopril. Data with beta blockers are less convincing in a population with known CAD, although in 1 trial carvedilol therapy in patients with stage B and low LVEF was associated with a 31% relative risk reduction in adverse long-term outcomes. In patients with previously established structural heart disease, the administration of agents known to have negative inotropic properties such as non-dihydropyridine calcium channel blockers and certain antiarrhythmics should be avoided.

p. e176:

Three beta blockers have been shown to be effective in reducing the risk of death in patients with chronic HFrEF: bisoprolol and sustained-release metoprolol (succinate), which selectively block beta-1–receptors; and carvedilol, which blocks alpha-1–, beta-1–, and beta-2–receptors. Positive findings with these 3 agents, however, should not be considered a beta-blocker class effect. Bucindolol lacked uniform effectiveness across different populations, and short-acting metoprolol tartrate was less effective in HF clinical trials. Beta-1 selective blocker nebivolol demonstrated a modest reduction in the primary endpoint of all-cause mortality or cardiovascular hospitalization but did not affect mortality alone in an elderly population that included patients with HFpEF.

1a.7.8. What harms were studied and how do they affect the net benefit (benefits over harms)?

2013 ACCF/AHA Guideline for the Management of Heart Failure

p. e177:

Initiation of treatment with a beta blocker may produce 4 types of adverse reactions that require attention and management: fluid retention and worsening HF; fatigue; bradycardia or heart block; and hypotension. The

occurrence of fluid retention or worsening HF is not generally a reason for the permanent withdrawal of treatment. Such patients generally respond favorably to intensification of conventional therapy, and once treated, they remain excellent candidates for long-term treatment with a beta blocker. The slowing of heart rate and cardiac conduction produced by beta blockers is generally asymptomatic and thus requires no treatment; however, if the bradycardia is accompanied by dizziness or lightheadedness or if second- or third-degree heart block occurs, clinicians should decrease the dose of the beta blocker. Clinicians may minimize the risk of hypotension by administering the beta blocker and ACE inhibitor at different times during the day. Hypotensive symptoms may also resolve after a decrease in the dose of diuretics in patients who are volume depleted. If hypotension is accompanied by other clinical evidence of hypoperfusion, beta-blocker therapy should be decreased or discontinued pending further patient evaluation. The symptom of fatigue is multifactorial and is perhaps the hardest symptom to address with confidence. Although fatigue may be related to beta blockers, other causes of fatigue should be considered, including sleep apnea, overdiuresis, or depression.

UPDATE TO THE SYSTEMATIC REVIEW(S) OF THE BODY OF EVIDENCE

1a.7.9. If new studies have been conducted since the systematic review of the body of evidence, provide for <u>each</u> new study: 1) citation, 2) description, 3) results, 4) impact on conclusions of systematic review.

One RCT, one prospective cohort study, and two meta-analyses were published after the publication of the 2013 ACCF/AHA Guideline for the Management of Heart Failure.

Note: Text below for description and results is verbatim from the article abstract.

Peck KY, Lim YZ, Hopper I, Krum H. Medical therapy versus implantable cardioverter-defibrillator in preventing sudden cardiac death in patients with left ventricular systolic dysfunction and heart failure: a meta-analysis of >35,000 patients. Int J Cardiol. 2014: 173(2): 197-2003.

Description: Our meta-analysis included trials of >100 patients with reduced left ventricular ejection fraction (LVEF), i.e.,<40%. Fourteen randomized controlled trials met the criteria for meta-analysis, 10 involving medical therapies (angiotensin receptor blockers [ARBs], mineralocorticoid receptor antagonists [MRAs], ivabradine, n3-polyunsaturated fatty acid [PUFA], ferric carboxymaltose and aliskiren) and four involving ICDs. Results were pooled using the Mantel-Haenszel random effects method.

Results: Drug therapy (*n* = 36,172) reduced the risk of SCD overall (risk ratio (RR) = 0.89, 95% confidence interval (CI) = 0.82–0.98, *p* = 0.02) when compared to placebo. MRAs alone were most effective in reducing SCD (*n*= 11,032, RR = 0.79 [0.68–0.91], *p* = 0.001). ICD insertion greatly reduced SCD (*n* = 4,269, RR = 0.39 [0.30–0.51], *p* < 0.00001) compared with placebo. The difference in treatment effect between the ICD and drug therapy was significant (*p* < 0.002), and between ICD and MRAs (*p* < 0.002).

Al-Gobari M, El Khatib C, Pillion F, Gueyffier F. β-Blockers for the prevention of sudden cardiac death in heart failure patients: a meta-analysis of randomized controlled trials. BMC Cardiovasc Disord. 2014: 13:52.

Description: We conducted a meta-analysis of all randomized controlled trials examining the use of beta-blockers vs. placebo/control for the prevention of SCD in heart failure patients. We identified 30 trials, which randomized 24,779 patients to beta-blocker or placebo/control. Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines were followed. Eligible studies had to be randomized controlled trials and provide information on the incidence of sudden cardiac death in heart failure patients. Additional inclusion criteria included: treatment for >30 days and follow-up ≥3 months. Studies of patients<18 years, randomization to beta-blocker vs. an angiotensin converting enzyme (without placebo) and/or beta-blocker in both arms were excluded from the analysis. Pre-specified outcomes of interest included SCD, cardiovascular death (CVD), and all-cause mortality and were analyzed according to intention-to-treat.

Results: We found that beta-blockers are effective in the prevention of SCD [OR 0.69; 95% CI, 0.62-0.77, P<0.00001], cardiovascular death (CVD) [OR 0.71; 95% CI, 0.64-0.79, P<0.00001], and all-cause mortality [OR 0.67; 95% CI, 0.59-0.76, P<0.00001]. Based on the study analysis, 43 patients must be treated with a beta-blocker to prevent one SCD, 26 patients to prevent one CVD and 21 patients to prevent all-cause mortality in one year.

Conclusion: Beta-blockers reduce the risk of sudden cardiac death (SCD) by 31%, cardiovascular death (CVD) by 29% and all-cause mortality by 33%. These results confirm the mortality benefits of these drugs and they should be recommended to all patients similar to those included in the trials.

Fiuzat M, Wojdyla D, Kitzman D, Fleg J, Keteyian SJ, Kraus WE, Pina IL, Whellan D, O'Connor CM. Relationship of beta-blocker dose with outcomes in ambulatory heart failure patients with systolic dysfunction: results from the HF-ACTION (Heart Failure: A Controlled Trial Investigating Outcomes of Exercise Training) trial. J AM Coll Cardiol. 2012;60:208-15.

Description: The HF-ACTION trial was a randomized, multicenter trial enrolling 2,331 ambulatory HF patients with systolic dysfunction (New York Heart Association functional class II to IV, left ventricular ejection fraction <0.35) randomized to exercise training versus usual care, with median follow-up of 2.5 years. The BB dose at baseline was standardized with carvedilol equivalents and analyzed as a continuous variable and by discrete dose groups. The relationship between BB dose and the primary endpoint of all-cause mortality or all-cause hospitalization and other cardiovascular secondary endpoints was determined before and after adjustment for variables significantly associated with outcomes in the HF-ACTION cohort.

Results: Ninety-five percent of patients were receiving a BB. There was a significant inverse relationship between BB dose and all-cause death or hospitalization but not other cardiovascular endpoints after adjustment for other predictors of outcome, with a linear benefit up to the 50-mg daily dose. There was a significant association between BB dose and change in peak VO(2) at 3 months. There was no increase in bradycardia with higher doses of BB.

Bauters C, Lemesle G, Meurice T, Tricot O, de Groote P, Lamblin N. Prognostic impact of ß-blocker use in patients with stable coronary artery disease. Heart. 2014;100:1757-61.

Description: We analysed the data of 4184 outpatients included in a prospective cohort study on stable CAD. Two groups were formed based on ß-blocker use at enrollment. Two propensity score analyses were performed to control for differences in covariates: one with adjustment among the entire cohort, and the other with propensity score matching. The outcome variable was cardiovascular mortality after a 2-year follow-up.

Results: There were 3320 patients with ß-blocker use. Younger age, hypertension, diabetes, prior myocardial infarction, multivessel CAD, prior coronary revascularisation, prior stroke, prior hospitalisation for heart failure and a low LVEF were associated with ß-blocker use. Clinical follow-up data were obtained for 4149 patients (99.2%). When adjusted on propensity score, ß-blocker use was associated with a HR for cardiovascular mortality of 0.64 (0.42-0.98) in the whole cohort (p=0.04). After one-to-one propensity score matching, both groups (n=839 in each group) were well matched on covariates. The cardiovascular mortality rate in the propensity-matched cohort was significantly lower in patients with ß-blocker use with a HR of 0.43 (0.22-0.82) (p=0.011). Non-cardiovascular mortality was similar in both groups. These results were consistent across different subgroups.

Conclusions: In this observational study of patients with stable CAD, the use of ß-blockers was associated with a lower risk of cardiovascular mortality.

Impact on conclusions of systematic review: These studies and meta-analyses further support the recommendations and level of evidence ratings for this process of care.

1a.8 OTHER SOURCE OF EVIDENCE

If source of evidence is NOT from a clinical practice guideline, USPSTF, or systematic review, please describe the evidence on which you are basing the performance measure.

1a.8.1 What process was used to identify the evidence?

1a.8.2. Provide the citation and summary for each piece of evidence.

NATIONAL QUALITY FORUM—Evidence (subcriterion 1a)

Measure Number (*if previously endorsed*)**:** 1522

Measure Title: ACE/ARB Therapy at Discharge for ICD Implant Patients with LVSD

IF the measure is a component in a composite performance measure, provide the title of the Composite Measure here: 965 Patients with an ICD implant who receive ACE-I/ARB and beta blocker therapy at discharge

Date of Submission: Click here to enter a date

Instructions

- *For composite performance measures:*
  - *A separate evidence form is required for each component measure unless several components were studied together.*
  - *If a component measure is submitted as an individual performance measure, attach the evidence form to the individual measure submission.*
- Respond to all questions as instructed with answers immediately following the question. All information needed to demonstrate meeting the evidence subcriterion (1a) must be in this form. An appendix of *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 10 pages (*incudes questions/instructions*; minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the evidence for this measure meets NQF's evaluation criteria.

1a. Evidence to Support the Measure Focus

The measure focus is evidence-based, demonstrated as follows:

- Health outcome: [3] a rationale supports the relationship of the health outcome to processes or structures of care. Applies to patient-reported outcomes (PRO), including health-related quality of life/functional status, symptom/symptom burden, experience with care, health-related behavior.
- Intermediate clinical outcome: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured intermediate clinical outcome leads to a desired health outcome.
- Process: [5] a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured process leads to a desired health outcome.
- Structure: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured structure leads to a desired health outcome.
- Efficiency: [6] evidence not required for the resource use component.

Notes

3. Generally, rare event outcomes do not provide adequate information for improvement or discrimination; however, serious reportable events that are compared to zero are appropriate outcomes for public reporting and quality improvement.

4. The preferred systems for grading the evidence are the U.S. Preventive Services Task Force (USPSTF) grading definitions and methods, or

Grading of Recommendations, Assessment, Development and Evaluation (GRADE) guidelines.
5. Clinical care processes typically include multiple steps: assess → identify problem/potential problem → choose/plan intervention (with patient input) → provide intervention → evaluate impact on health status. If the measure focus is one step in such a multistep process, the step with the strongest evidence for the link to the desired outcome should be selected as the focus of measurement. Note: A measure focused only on collecting PROM data is not a PRO-PM.
6. Measures of efficiency combine the concepts of resource use and quality (see NQF's Measurement Framework: Evaluating Efficiency Across Episodes of Care; AQA Principles of Efficiency Measures).

1a.1.This is a measure of: (*should be consistent with type of measure entered in De.1*)

Outcome

☐ Health outcome: Click here to name the health outcome

☐Patient-reported outcome (PRO): Click here to name the PRO

PROs include HRQoL/functional status, symptom/symptom burden, experience with care, health-related behaviors

☐ Intermediate clinical outcome (*e.g., lab value*): Click here to name the intermediate outcome

☒ Process: ACE/ARB therapy for patients with LVSD receiving an ICD

☐ Structure: Click here to name the structure

☐ Other: Click here to name what is being measured

HEALTH OUTCOME/PRO PERFORMANCE MEASURE *If not a health outcome or PRO, skip to 1a.3*

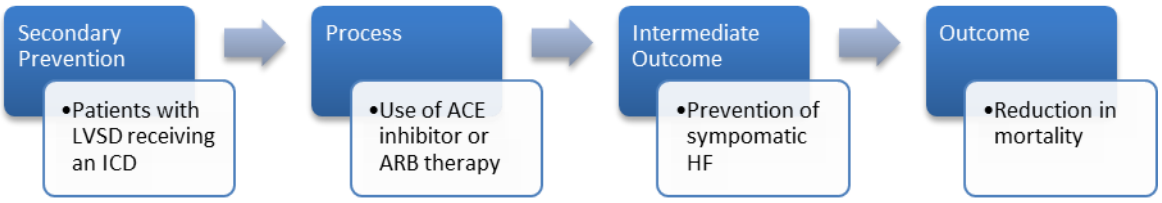
1a.2. Briefly state or diagram the path between the health outcome (or PRO) and the healthcare structures, processes, interventions, or services that influence it.

1a.2.1. State the rationale supporting the relationship between the health outcome (or PRO) to at least one healthcare structure, process, intervention, or service (*i.e., influence on outcome/PRO*).

Note: For health outcome/PRO performance measures, no further information is required; however, you may provide evidence for any of the structures, processes, interventions, or service identified above.

INTERMEDIATE OUTCOME, PROCESS, OR STRUCTURE PERFORMANCE MEASURE

1a.3. Briefly state or diagram the path between structure, process, intermediate outcome, and health outcomes. Include all the steps between the measure focus and the health outcome.



Angiotensin-converting enzyme (ACE) inhibitors and angiotensin-receptor antagonists/blockers (ARBs) reduce morbidity, mortality, and hospitalizations for patients with heart failure and left ventricular systolic dysfunction.

1a.3.1. What is the source of the systematic review of the body of evidence that supports the performance measure?

☒ Clinical Practice Guideline recommendation – ***complete sections 1a.4, and 1a.7***

☐ US Preventive Services Task Force Recommendation – ***complete sections 1a.5 and 1a.7***

☐ Other systematic review and grading of the body of evidence (*e.g., Cochrane Collaboration, AHRQ Evidence Practice Center*) – ***complete sections 1a.6 and 1a.7***

☐ Other – ***complete section 1a.8***

Please complete the sections indicated above for the source of evidence. You may skip the sections that do not apply.

1a.4. CLINICAL PRACTICE GUIDELINE RECOMMENDATION

1a.4.1. Guideline citation (*including date*) and **URL for guideline** (*if available online*):

Yancy CW, Jessup M, Bozkurt B, Butler J, Casey DE Jr, Drazner MH, Fonarow GC, Geraci SA, Horwich T, Januzzi JL, Johnson MR, Kasper EK, Levy WC, Masoudi FA, McBride PE, McMurray JJV, Mitchell JE, Peterson PN, Riegel B, Sam F, Stevenson LW, Tang WHW, Tsai EJ, Wilkoff BL. 2013 ACCF/AHA guideline for the management of heart failure: a report of the American College of Cardiology Foundation/American Heart Association Task Force on Practice Guidelines. http://content.onlinejacc.org/article.aspx?articleid=1147807

1a.4.2. Identify guideline recommendation number and/or page number and **quote verbatim, the specific guideline recommendation**.

2013 ACCF/AHA Guideline for the Management of Heart Failure (e169-170, 174-175, 195)

Stages of Heart Failure:

Stage A: At high risk for HF, but without structural heart disease or symptoms of Failure

Stage B: Structural heart disease, but without signs or symptoms of HF

Stage C: Structural heart disease with prior or current symptoms of HF

Stage D: Refractory HF requiring specialized interventions

Stage B recommendations (e169-170):

1. In all patients with a recent or remote history of MI or ACS and reduced EF, ACE inhibitors should be used to prevent symptomatic HF and reduce mortality. In patients intolerant of ACE inhibitors, ARBs are appropriate unless contraindicated. **Class I; Level of Evidence: A**
2. ACE inhibitors should be used in all patients with a reduced EF to prevent symptomatic HF, even if they do not have a history of MI. **Class I; Level of Evidence: A**

Stage C recommendations (e174-175):

3. ACE inhibitors are recommended in patients with HFrEF and current or prior symptoms, unless contraindicated, to reduce morbidity and mortality. **Class I; Level of Evidence: A**
4. ARBs are recommended in patients with HFrEF with current or prior symptoms who are ACE inhibitor intolerant, unless contraindicated, to reduce morbidity and mortality. **Class I; Level of Evidence: A**

AHA/ACCF secondary prevention and risk reduction therapy for patients with coronary and other atherosclerotic vascular disease: 2011 update (p. 2435)

5. ACE inhibitors should be started and continued indefinitely in all patients with left ventricular ejection fraction <40% and in those with hypertension, diabetes, or chronic kidney disease, unless contraindicated. **Class I; Level of Evidence: A**

6. The use of ARBs is recommended in patients who have heart failure or who have had a myocardial infarction with left ventricular ejection fraction □40% and who are ACE-inhibitor intolerant. **Class I; Level of Evidence: A**

1a.4.3. Grade assigned to the quoted recommendation with definition of the grade:

Guideline Statement # (see 1a.4.2 above)	Class of Recommendation/Level of Evidence (for definitions see 1a.4.4 below)
1	Class Ia
2	Class Ia
3	Class Ia
4	Class Ia
5	Class Ib
6	Class Ia
7	Class Ia

1a.4.4. Provide all other grades and associated definitions for recommendations in the grading system. (*Note: If separate grades for the strength of the evidence, report them in section 1a.7.*)

Class of Recommendation (COR) is an estimate of the size of the treatment effect considering risks versus benefits in addition to evidence and/or agreement that a given treatment or procedure is or is not useful/effective or in some situations may cause harm.

Class I: Procedure/Treatment should be performed/administered

Class IIa: It is reasonable to perform procedure/administer treatment

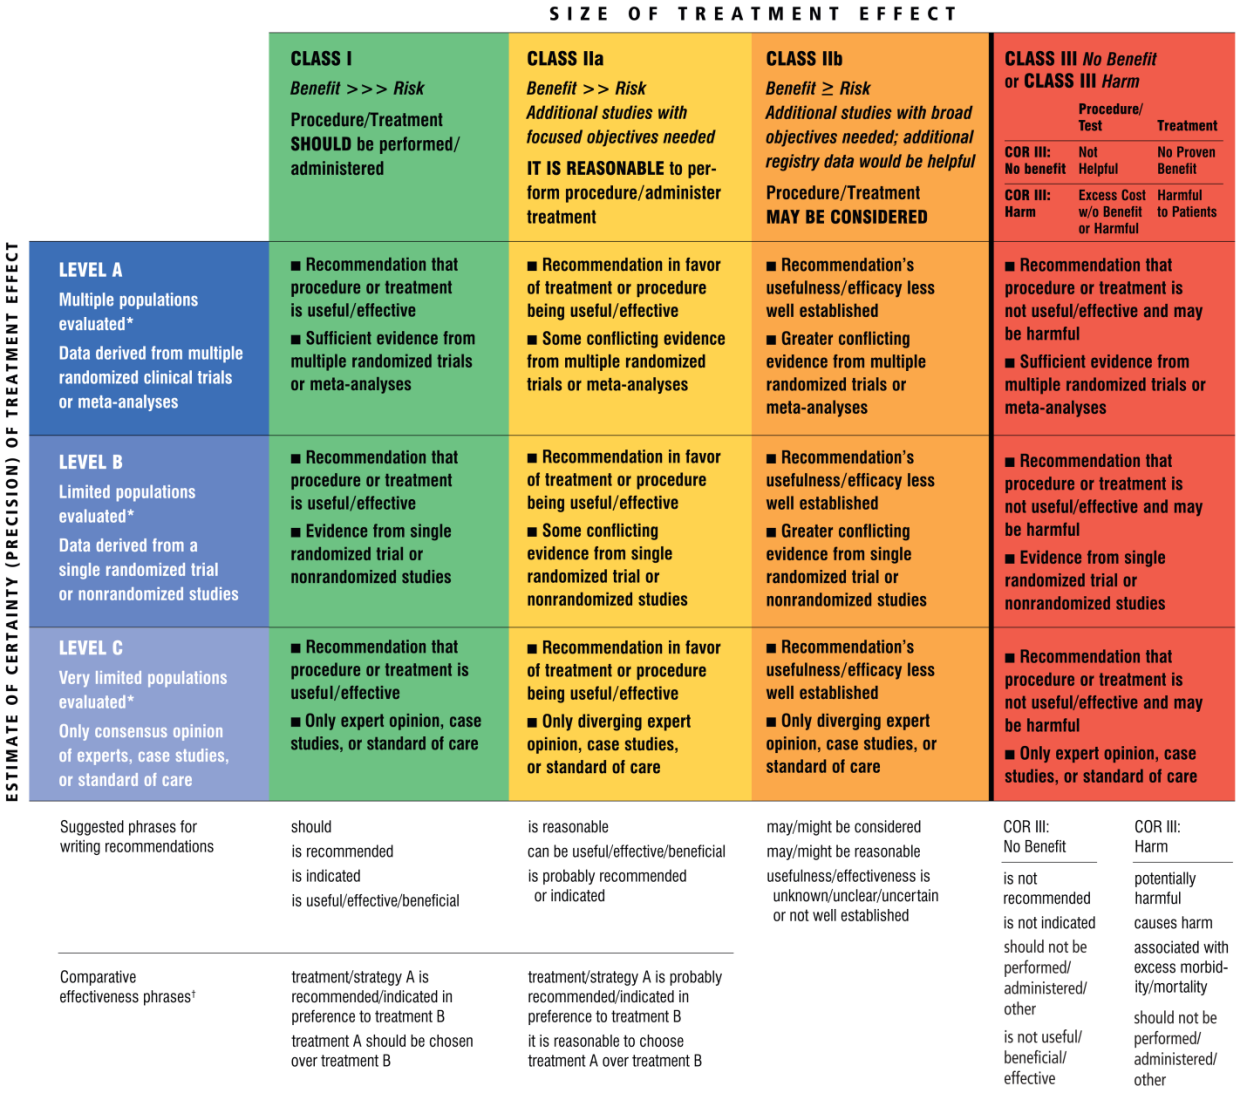
Class IIb: Procedure/Treatment may be considered

Class III: No benefit (Not helpful or No proven benefit)

Class III: Harm (Excess cost w/o benefit or Harmful to patients)

Specific COR definitions are included in Table 1 below.

Table 1. Applying Classification of Recommendation and Level of Evidence



Note: A recommendation with Level of Evidence B or C does not imply that the recommendation is weak. Many important clinical questions addressed in the guidelines do not lend themselves to clinical trials. Although randomized trials are unavailable, there may be a very clear clinical consensus that a particular test or therapy is useful or effective. *Data available from clinical trials or registries about the usefulness/efficacy in different subpopulations, such as sex, age, history of diabetes, history of prior myocardial infarction, history of heart failure, and prior aspirin use. †For comparative effectiveness recommendations (Class I and IIa; Level of Evidence A and B only), studies that support the use of comparator verbs should involve direct comparisons of the treatments or strategies being evaluated.

1a.4.5. Citation and URL for methodology for grading recommendations (*if different from 1a.4.1*)**:**

_____

1a.7. FINDINGS FROM SYSTEMATIC REVIEW OF BODY OF THE EVIDENCE SUPPORTING THE MEASURE

If more than one systematic review of the evidence is identified above, you may choose to summarize the one (or more) for which the best information is available to provide a summary of the quantity, quality, and consistency of the body of evidence. Be sure to identify which review is the basis of the responses in this section and if more than one, provide a separate response for each review.

1a.7.1. What was the specific structure, treatment, intervention, service, or intermediate outcome addressed in the evidence review?

2013 ACCF/AHA Guideline for the Management of Heart Failure

This guideline covers multiple management issues for the adult patient with Heart Failure (HF) including the guideline-directed medical therapy (GDMT) such as ACE inhibitor or ARB therapies.

1a.7.2. Grade assigned for the quality of the quoted evidence with definition of the grade:

An overall grade for the quality of evidence was not assigned. Rather, the quality of a study (or set of studies) supporting a recommendation was graded on an estimate of the certainty or precision of the treatment effect (see 1a.4.3).

Recommendations used to support this measure have a:

- Level of Evidence of A: Data derived from multiple randomized clinical trials or meta- analyses. References used to determine level of evidence must be provided and cited with the recommendation

OR

- Level of Evidence B: Data derived from a single randomized trial, or nonrandomized studies. References used to determine level of evidence must be provided and cited with the recommendation.

1a.7.3. Provide all other grades and associated definitions for strength of the evidence in the grading system.

Level of Evidence (LOE) is an estimate of the certainty or precision of the treatment effect.

Level of Evidence A: Data derived from multiple randomized clinical trials or meta- analyses. References used to determine level of evidence must be provided and cited with the recommendation.

Level of Evidence B: Data derived from a single randomized trial, or nonrandomized studies. References used to determine level of evidence must be provided and cited with the recommendation.

Level of Evidence C: Consensus opinion of experts, case studies, or standard of care.

Specific LOE definitions are included in Table 1 in 1a.4.4.

1a.7.4. What is the time period covered by the body of evidence? (*provide the date range, e.g., 1990-2010*). Date range: An extensive evidence review was conducted through October 2011 and includes selected other references through April 2013.

QUANTITY AND QUALITY OF BODY OF EVIDENCE

1a.7.5. How many and what type of study designs are included in the body of evidence? (*e.g., 3 randomized controlled trials and 1 observational study*)

2013 ACCF/AHA Guideline for the Management of Heart Failure

The body of evidence supporting the recommendations on ACE/ARB therapy includes:

15 randomized controlled trials (RCTs)

1a.7.6. What is the overall quality of evidence <u>across studies</u> in the body of evidence? (*discuss the certainty or confidence in the estimates of effect particularly in relation to study factors such as design flaws, imprecision due to small numbers, indirectness of studies to the measure focus or target population*)

2013 ACCF/AHA Guideline for the Management of Heart Failure

All but one of the recommendations for this process are rated as Level of Evidence A, meaning that the data was derived from multiple RCTs or meta-analyses. Additional information on the overall quality of evidence across the RCTs is not provided.

ESTIMATES OF BENEFIT AND CONSISTENCY ACROSS STUDIES IN BODY OF EVIDENCE

1a.7.7. What are the estimates of benefit—magnitude and direction of effect on outcome(s) <u>across studies</u> in the body of evidence? (*e.g., ranges of percentages or odds ratios for improvement/ decline across studies, results of meta-analysis, and statistical significance*)

2013 ACCF/AHA Guideline for the Management of Heart Failure

p. e170:

CAD is a major risk factor for the development of HF and a key target for prevention of HF. The 5-year risk of developing HF after acute MI is 7% and 12% for men and women, respectively; for men and women between the ages of 40 and 69 and those >70 years of age, the risk is 22% and 25%, respectively. Current evidence supports the use of ACE inhibitors and (to a lower level of evidence) beta-blocker therapy to impede maladaptive LV remodeling in patients with stage B HF and low LVEF to improve mortality and morbidity. At 3-year follow-up, those patients treated with ACE inhibitors demonstrated combined endpoints of reduced hospitalization or death, a benefit that extended up to a 12-year follow-up. ARBs are reasonable alternatives to ACE inhibitors.

p. e175-176:

In several placebo-controlled studies, long-term therapy with ARBs produced hemodynamic, neurohormonal, and clinical effects consistent with those expected after interference with the renin-angiotensin system. Reduced hospitalization and mortality have been demonstrated. ACE inhibitors remain the first choice for inhibition of the renin-angiotensin system in systolic HF, but ARBs can now be considered a reasonable alternative.

1a.7.8. What harms were studied and how do they affect the net benefit (benefits over harms)?

2013 ACCF/AHA Guideline for the Management of Heart Failure

p. e174-175:

The majority of the adverse reactions of ACE inhibitors can be attributed to the 2 principal pharmacological actions of these drugs: those related to angiotensin suppression and those related to kinin potentiation. Other types of adverse effects may also occur (e.g., rash and taste disturbances). Up to 20% of patients will experience an ACE inhibitor–induced cough. With the use of ACE inhibitors, particular care should be given to the patient's volume status, renal function, and concomitant medications. However, most HF patients (85% to 90%) can tolerate these drugs.

p. e176:

The risks of ARBs are attributed to suppression of angiotensin stimulation. These risks of hypotension, renal dysfunction, and hyperkalemia are greater when combined with another inhibitor of this neurohormonal axis, such as ACE inhibitors or aldosterone antagonists.

UPDATE TO THE SYSTEMATIC REVIEW(S) OF THE BODY OF EVIDENCE

1a.7.9. If new studies have been conducted since the systematic review of the body of evidence, provide for <u>each</u> new study: 1) citation, 2) description, 3) results, 4) impact on conclusions of systematic review.

One meta-analysis was published after the publication of the 2013 ACCF/AHA Guideline for the Management of Heart Failure.

Peck KY, Lim YZ, Hopper I, Krum H. Medical therapy versus implantable cardioverter-defibrillator in preventing sudden cardiac death in patients with left ventricular systolic dysfunction and heart failure: a meta-analysis of >35,000 patients. Int J Cardiol. 2014: 173(2): 197-2003.

Note: Text below for description and results is verbatim from the article abstract.

Description: Our meta-analysis included trials of >100 patients with reduced left ventricular ejection fraction (LVEF), i.e.,<40%. Fourteen randomized controlled trials met the criteria for meta-analysis, 10 involving medical therapies (angiotensin receptor blockers [ARBs], mineralocorticoid receptor antagonists [MRAs], ivabradine, n3-polyunsaturated fatty acid [PUFA], ferric carboxymaltose and aliskiren) and four involving ICDs. Results were pooled using the Mantel-Haenszel random effects method.

Results: Drug therapy (n = 36,172) reduced the risk of SCD overall (risk ratio (RR) = 0.89, 95% confidence interval (CI) = 0.82–0.98, p = 0.02) when compared to placebo. MRAs alone were most effective in reducing SCD (n= 11,032, RR = 0.79 [0.68–0.91], p = 0.001). ICD insertion greatly reduced SCD (n = 4,269, RR = 0.39 [0.30–0.51], p < 0.00001) compared with placebo. The difference in treatment effect between the ICD and drug therapy was significant (p < 0.002), and between ICD and MRAs (p < 0.002).

Impact on conclusions of systematic review: This meta-analysis further supports the recommendations and level of evidence ratings for this process of care.

1a.8 OTHER SOURCE OF EVIDENCE

If source of evidence is NOT from a clinical practice guideline, USPSTF, or systematic review, please describe the evidence on which you are basing the performance measure.

1a.8.1 What process was used to identify the evidence?

1a.8.2. Provide the citation and summary for each piece of evidence.

1. Evidence, Performance Gap, Priority – Importance to Measure and Report

Extent to which the specific measure focus is evidence-based, important to making significant gains in healthcare quality, and improving health outcomes for a specific high-priority (high-impact) aspect of healthcare where there is variation in or overall less-than-optimal performance. ***Measures must be judged to meet all subcriteria to pass this criterion and be evaluated against the remaining criteria.***

1a. Evidence to Support the Measure Focus – See attached Evidence Submission Form

965_Composite_all_evidence_submission_061715_submitted.docx

1b. Performance Gap

Demonstration of quality problems and opportunity for improvement, i.e., data demonstrating:

- considerable variation, or overall less-than-optimal performance, in the quality of care across providers; and/or
- disparities in care across population groups.

1b.1. Briefly explain the rationale for this measure *(e.g., the benefits or improvements in quality envisioned by use of this measure)*

This measure is intended to assess the extent to which eligible patients receive evidence-based medications that are indicated at hospital discharge following ICD placement. This measure focuses on processes of care that are supported by guidelines for optimal care for patients undergoing ICD placement.

1b.2. Provide performance scores on the measure as specified (current and over time) at the specified level of analysis. *(This is required for endorsement maintenance. Include mean, std dev, min, max, interquartile range, scores by decile. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities included). This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*

In the time period 2011-12, a total of 243,186 patients at 1552 hospitals were analyzed, and 195, 563 patients at 1606 hospitals in 2013-14. The distribution of the hospital performance was as follows:

2011 - 2012
Hospitals: n=1552
Patients: n=243186
Mean: 74%
Std Deviation: 16%
Percentiles
90th: 91%
75th (Quartile 3): 84%
50th (Median): 76%
25th (Quartile 1): 67%
10th: 56%

2013 - 2014
Hospitals: n=1606
Patients: n=195563

Mean: 78%
Std Deviation: 17%
Percentiles
90th: 97%
75th (Quartile 3): 89%
50th (Median): 79%
25th (Quartile 1): 71%
10th: 59%

1b.3. **If no or limited performance data on the measure as specified is reported in 1b2, then provide a summary of data from the literature that indicates opportunity for improvement or overall less than optimal performance on the specific focus of measurement.**
There is a demonstration for an opportunity for improvement based on the noted performance ranges.

1b.4. **Provide disparities data from the measure as specified (current and over time) by population group, e.g., by race/ethnicity, gender, age, insurance status, socioeconomic status, and/or disability.** *(This is required for endorsement maintenance. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities include.) This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*
See testing supplement for details.

1b.5. **If no or limited data on disparities from the measure as specified is reported in 1b4, then provide a summary of data from the literature that addresses disparities in care on the specific focus of measurement. Include citations.**
None

1c. High Priority (previously referred to as High Impact)

The measure addresses:

- a specific national health goal/priority identified by DHHS or the National Priorities Partnership convened by NQF; OR
- a demonstrated high-priority (high-impact) aspect of healthcare (e.g., affects large numbers of patients and/or has a substantial impact for a smaller population; leading cause of morbidity/mortality; high resource use (current and/or future); severity of illness; and severity of patient/societal consequences of poor quality).

1c.1. **Demonstrated high priority aspect of healthcare**
Affects large numbers, A leading cause of morbidity/mortality, Frequently performed procedure, High resource use, Severity of illness
1c.2. **If Other:**

1c.3. **Provide epidemiologic or resource use data that demonstrates the measure addresses a high priority aspect of healthcare. List citations in 1c.4.**
Optimal medical therapy is critical to ensure favorable patient outcomes following implantation of an implantable cardiac defibrillator (ICD) to prevent sudden cardiac death (SCD). Approximately 86 million American adults have 1 or more types of CVD. Over 30% of all deaths are related to CVD. Nearly 787,000 people in the U.S. died from heart disease, stroke and other cardiovascular diseases in 2011 or about one of every three deaths in America. ACE inhibitors have been shown to decrease morbidity, mortality, and hospitalizations for patients with heart failure and left ventricular systolic dysfunction. The efficacy of ARB therapy has been strengthened by several large-scale prospective randomized clinical trials demonstrating reduction in mortality and hospitalization for heart failure among patients with heart failure and LVSD. Refer to evidence supplement for additional details. Long term beta blocker therapy for patients with left systolic ventricular dysfunction (LVSD) can improve symptoms of heart failure, improve patient clinical status, and reduce hospitalizations and mortality. Lastly, the benefits of beta blocker therapy in patients with prior myocardial infarction without contraindications have been established for a wide range of

patient groups. Because the majority of patients undergoing ICD implantation have LVSD and/or have had a prior myocardial infarction, a substantial proportion of this population has an indication for chronic ACE/ARB and/or beta blocker therapy to improve outcomes.

1c.4. **Citations for data demonstrating high priority provided in 1a.3**

Bonow RO, Bennett S, Casey DE, Jr., et al. ACC/AHA clinical performance measures for adults with chronic heart failure: a report of the American College of Cardiology/American Heart Association Task Force on Performance Measures (Writing Committee to Develop Heart Failure Clinical Performance Measures) endorsed by the Heart Failure Society of America. J Am Coll Cardiol. 2005;46:1144-78.

1c.5. **If a PRO-PM (e.g. HRQoL/functional status, symptom/burden, experience with care, health-related behaviors), provide evidence that the target population values the measured PRO and finds it meaningful.** *(Describe how and from whom their input was obtained.)*

1d. Composite Quality Construct and Rationale

1d.1. **A composite performance measure is a combination of two or more component measures, each of which individually reflects quality of care, into a single performance measure with a single score.**

For purposes of NQF measure submission, evaluation, and endorsement, the following will be considered composites:

- Measures with two or more individual performance measure scores combined into one score for an accountable entity.
- Measures with two or more individual component measures assessed separately for each patient and then aggregated into one score for an accountable entity:
  - all-or-none measures (e.g., all essential care processes received, or outcomes experienced, by each patient); or
  - any-or-none measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient).

1d.1. Please identify the composite measure construction: all-or-none measures (e.g., all essential care processes received, or outcomes experienced, by each patient)

1d.2. **Describe the quality construct, including:**

- the overall area of quality
- included component measures and
- the relationship of the component measures to the overall composite and to each other.

This measure focuses on processes of care that recommended for optimal care for patients following ICD implantation. Each component of the measure has been shown in randomized clinical trials to impact clinical outcomes and represents a Class 1 guideline indication for the care of patients with left ventricular systolic dysfunction or prior myocardial infarction. Combining the individual process measures into a single composite provides patients, physicians, and hospitals with a perspective of the overall quality of medical therapy provided to patients undergoing ICD implantation. Hospitals with a gap in performance can investigate the individual components of the measure to identify specific opportunities for improvement. The content validity of this measure has been achieved by virtue of their consistency with strong guideline recommendations and the expertise of the individuals who developed this measure.

In addition, we conducted empiric analyses examining the association between performance on the composite measure and clinical outcomes including readmission and mortality at 6 months following device implantation (see testing supplement for

detailed results). We found that patients who were discharged on appropriate medical therapy were less likely to experience adverse outcomes compared with patients who were not discharged on appropriate medical therapy. Furthermore, fewer patients treated at high performing hospitals as determined by this composite experienced adverse outcomes compared with those treated at low performing hospitals

1d.3. **Describe the rationale for constructing a composite measure, including how the composite provides a distinctive or additive value over the component measures individually.**

This measure is intended to assess the extent to which eligible patients receive evidence-based medications that are indicated at hospital discharge following ICD implantation.

Composite performance measures have a variety of uses.

Data reduction. A large and growing array of individual indicators makes it possible for users to become overloaded with data. A composite measure reduces the information burden by distilling the available indicators into a simple summary.

Scope expansion. The information in a composite measure is highly condensed, making it feasible to track a broader range of metrics than would be possible otherwise. Composite measures have been described as a tool for making provider assessments more comprehensive

Provider performance valuation. Performance indicators are used for various decisions about providers, including the allocation of pay-for-performance incentives, designation of preferred provider status, and assignment of letter grades and star rating categories. If a decision is to be based on multiple indicators instead of a single indicator, a method of translating several variables into a single decision is needed. Composite measures serve this function by assigning providers to 1 position on a scale of

better-to-worse performance.

Given all these uses, NCDR believes that while we will continue to report these measures at the individual level there is a distinctive value of having a composite measure endorsed at NQF.

1d.4. **Describe how the aggregation and weighting of the component measures are consistent with the stated quality construct and rationale.**

Each of the components of this measure address appropriate medication prescribing at discharge for ICD patients.

2. Reliability and Validity—Scientific Acceptability of Measure Properties

Extent to which the measure, as specified, produces consistent (reliable) and credible (valid) results about the quality of care when implemented. ***Measures must be judged to meet the subcriteria for both reliability and validity to pass this criterion and be evaluated against the remaining criteria.***

2a.1. Specifications The measure is well defined and precisely specified so it can be implemented consistently within and across organizations and allows for comparability. eMeasures should be specified in the Health Quality Measures Format (HQMF) and the Quality Data Model (QDM).

De.5. **Subject/Topic Area** *(check all the areas that apply):*

Cardiovascular

De.6. **Cross Cutting Areas** *(check all the areas that apply):*

S.1. **Measure-specific Web Page** *(Provide a URL link to a web page specific for this measure that contains current detailed specifications including code lists, risk model details, and supplemental materials. Do not enter a URL linking to a home page or to general information.)*

N/A

S.2a. **If this is an eMeasure**, HQMF specifications must be attached. Attach the zipped output from the eMeasure authoring tool (MAT) - if the MAT was not used, contact staff. (Use the specification fields in this online form for the plain-language description of the specifications)
This is not an eMeasure **Attachment:**

S.2b. **Data Dictionary, Code Table, or Value Sets** *(and risk model codes and coefficients when applicable) must be attached. (Excel or csv file in the suggested format preferred - if not, contact staff)*
Attachment **Attachment:** icd_v2_datadictionary_codersdictionary_2-1-635246241637392049.pdf

S.3. **For endorsement maintenance**, please briefly describe any changes to the measure specifications since last endorsement date and explain the reasons.
No change since last endorsement.

S.4. **Numerator Statement** *(Brief, narrative description of the measure focus or what is being measured about the target population, i.e., cases from the target population with the target process, condition, event, or outcome)*
IF an OUTCOME MEASURE, state the outcome being measured. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
Patients who receive ACE/ARB and Beta blockers for which they are eligible.
1. ACE/ARB prescribed at discharge (if eligible for ACE/ARB as described in denominator)
AND
2. Beta blockers prescribed at discharge (if eligible for beta blockers as described in denominator)

S.5. **Time Period for Data** *(What is the time period in which data will be aggregated for the measure, e.g., 12 mo, 3 years, look back to August for flu vaccination? Note if there are different time periods for the numerator and denominator.)*
1 year

S.6. **Numerator Details** *(All information required to identify and calculate the cases from the target population with the target process, condition, event, or outcome such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
IF an OUTCOME MEASURE, describe how the observed outcome is identified/counted. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
If eligible for beta blocker and given, then code "Yes"
If eligible for beta blocker and not given, then code "No, not given"

If eligible for ACE/ARB and given, then code then "Yes"
If eligible for ACE/ARB and not given, then code "No, not given"

If any "No, not given" present, then performance not met. Else, performance met.

Note: Contraindicated and those participating in blinded studies are also considered as exceptions and performance met.

S.7. **Denominator Statement** *(Brief, narrative description of the target population being measured)*
All patients with an ICD implant surviving hospitalization who are eligible to receive any one of the two medication classes:
1) Eligiblility for ACE/ARB: Patients who have an ejection fraction (EF) of <40% AND do not have a documented contraindication to ACE/ARB documented
OR
2) Eligibility for beta blockers: Patients who do not have a documented contraindication to beta blocker therapy and have

either:

a. EF of <40% OR

b. a previous myocardial infarction (MI)

S.8. **Target Population Category** *(Check all the populations for which the measure is specified and tested if any):*
Populations at Risk

S.9. **Denominator Details** *(All information required to identify and calculate the target population/denominator such as definitions, specific data collection items/responses , code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
N/A

S.10. **Denominator Exclusions** *(Brief narrative description of exclusions from the target population)*
Discharge status of expired; not eligible for either ACE/ARB or beta blockers

S.11. **Denominator Exclusion Details** *(All information required to identify and calculate exclusions from the denominator such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
NCDR makes a clear distinction between absolute "Exclusions" (e.g., death, transfer) and relative "Exceptions", (e.g., contraindications). While patients with exclusions are always automatically removed from the denominator and numerator, exceptions allow clinicians the opportunity to identify an intervention/process/medication as not clinically indicated based on the unique patient scenario.
Each of the two medications incorporated into this composite may be coded as Yes (medication prescribed), No (medication not prescribed), Blinded (pt. involved in a clinical trial, medication type unavailable for data entry), and Contraindicated (used to capture many of the medical exceptions used in this measure).

S.12. **Stratification Details/Variables** *(All information required to stratify the measure results including the stratification variables, definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format with at S.2b)*
N/A

S.13. **Risk Adjustment Type** (Select type. Provide specifications for risk stratification in S.12 and for statistical model in S.14-15)
No risk adjustment or risk stratification
If other:

S.14. **Identify the statistical risk model method and variables** *(Name the statistical method - e.g., logistic regression and list all the risk factor variables. Note - risk model development and testing should be addressed with measure testing under Scientific Acceptability)*
N/A

S.15. **Detailed risk model specifications** *(must be in attached data dictionary/code list Excel or csv file. Also indicate if available at measure-specific URL identified in S.1.)*
Note: Risk model details (including coefficients, equations, codes with descriptors, definitions), should be provided on a separate worksheet in the suggested format in the Excel or csv file with data dictionary/code lists at S.2b.

S.15a. **Detailed risk model specifications** (*if not provided in excel or csv file at S.2b*)

S.16. **Type of score:**

Rate/proportion
If other:

S.17. **Interpretation of Score** *(Classifies interpretation of score according to whether better quality is associated with a higher score, a lower score, a score falling within a defined interval, or a passing score)*
Better quality = Higher score

S.18. **Calculation Algorithm/Measure Logic** *(Describe the calculation of the measure score as an ordered sequence of steps including identifying the target population; exclusions; cases meeting the target process, condition, event, or outcome; aggregating data; risk adjustment; etc.)*
1) Remove patients whose discharge status is expired
2) Check if given patient is eligible for 1 of the 2 medication therapies.
3) If eligible for at least 1 medication, then keep this patient.
4) If not eligible for any of the 2 medications, then patient is removed from eligibility.

If eligible for ACE/ARB and given, then code "Yes"
If eligible for ACE/ARB and not given, then code "No, not given"
If eligible for ACE/ARB but contraindicated, then code "contraindicated/blinded"

If eligible for Beta Blocker and given, then code then "Yes"
If eligible for Beta Blocker and not given, then code "No, not given"
If eligible for Beta Blocker but contraindicated, then code "contraindicated/blinded"

5) If any "No, not given" present, then performance not met. Else, performance met.

Although ineligible cases are removed from the denominator population for the performance calculation, the number of patients with valid exceptions should be calculated and reported along with performance rates to track variations in care and highlight possible areas of focus for QI.

If the patient does not meet the numerator and a valid exception is not present, this case represents a quality failure.

Missing data defaults to "performance not met" This measure assumes that missing documentation on the process results in a failure of meeting an evidence based therapy.

S.19. **Calculation Algorithm/Measure Logic Diagram URL or Attachment** *(You also may provide a diagram of the Calculation Algorithm/Measure Logic described above at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
No diagram provided

S.20. **Sampling** *(If measure is based on a sample, provide instructions for obtaining the sample and guidance on minimum sample size.)*
IF a PRO-PM, identify whether (and how) proxy responses are allowed.
N/A

S.21. **Survey/Patient-reported data** *(If measure is based on a survey, provide instructions for conducting the survey and guidance on minimum response rate.)*
IF a PRO-PM, specify calculation of response rates to be reported with performance measure results.
N/A

S.22. **Missing data** (specify how missing data are handled, e.g., imputation, delete case.)

Required for Composites and PRO-PMs.

Missing data defaults to "performance not met" This measure assumes that missing documentation on the process results in a failure of meeting a evidence based therapy.

S.23. **Data Source** *(Check ONLY the sources for which the measure is SPECIFIED AND TESTED).*
If other, please describe in S.24.
Electronic Clinical Data : Registry

S.24. **Data Source or Collection Instrument** *(Identify the specific data source/data collection instrument e.g. name of database, clinical registry, collection instrument, etc.)*

NATIONAL QUALITY FORUM—Composite Measure Testing (subcriteria 2a2, 2b2-2b6, 2d)

Composite Measure Title: Discharge Medications (ACE/ARB and beta blockers) in Eligible ICD Implant Patients
Date of Submission: Click here to enter a date
Composite Construction:
☐Two or more individual performance measure scores combined into one score
☐**All-or-none measures (e.g., all essential care processes received or outcomes experienced by each patient)**
☐Any-or-none measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient)

Instructions: Please contact NQF staff before you begin.

- If a component measure is submitted as an individual performance measure, the non-composite measure testing form must also be completed and attached to the individual measure submission.
- Measures must be tested for all the data sources and levels of analyses that are specified. ***If there is more than one set of data specifications or more than one level of analysis, contact NQF staff*** about how to

present all the testing information in one form.

- **For <u>all</u> composite measures, sections 1, 2a2, 2b2, 2b3, 2b5, and 2d must be completed.**
- **For composites with <u>outcome and resource use</u> measures**, section **2b4** also must be completed.
- If specified for **<u>multiple data sources/sets of specifications</u>** (e.g., claims and EHRs), section **2b6** also must be completed.
- Respond to <u>all</u> questions as instructed with answers immediately following the question. All information on testing to demonstrate meeting the subcriteria for reliability (2a2), validity (2b2-2b6), and composites (2d) must be in this form. An appendix for *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 25 pages (*incuding questions/instructions;* minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

<u>Note</u>: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the testing results for this measure meet NQF's evaluation criteria for testing.

2a2. Reliability testing [10] demonstrates the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise.

2b2. Validity testing [11] demonstrates that the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality.

2b3. Exclusions are supported by the clinical evidence; otherwise, they are supported by evidence of sufficient frequency of occurrence so that results are distorted without the exclusion; [12]
AND
If patient preference (e.g., informed decisionmaking) is a basis for exclusion, there must be evidence that the exclusion impacts performance on the measure; in such cases, the measure must be specified so that the information about patient preference and the effect on the measure is transparent (e.g., numerator category computed separately, denominator exclusion category computed separately). [13]

2b4. For outcome measures and other measures when indicated (e.g., resource use):

- **an evidence-based risk-adjustment strategy** (e.g., risk models, risk stratification) is specified; is based on patient factors that influence the measured outcome (but not factors related to disparities in care or the quality of care) and are present at start of care; [14,15] and has demonstrated adequate discrimination and calibration

OR

- rationale/data support no risk adjustment/ stratification.

2b5. Data analysis of computed measure scores demonstrates that methods for scoring and analysis of the specified measure allow for **identification of statistically significant and practically/clinically meaningful [16] differences in performance**;

OR

there is evidence of overall less-than-optimal performance.

2b6. If multiple data sources/methods are specified, there is demonstration they produce comparable results.

Composite 2d. For composite performance measures, empirical analyses support the composite construction approach and demonstrate that:

1) the component measures fit the quality construct and add value to the overall composite while achieving the related objective of parsimony to the extent possible; and
2) the aggregation and weighting rules are consistent with the quality construct and rationale while achieving the related objective of simplicity to the extent possible; and
3) the extent of missing data and how the specified handling of missing data minimizes bias (i.e., achieves scores that are an accurate reflection of quality).

Notes

10. Reliability testing applies to both the data elements and computed measure score. Examples of reliability testing for data elements include, but are not limited to: inter-rater/abstractor or intra-rater/abstractor studies; internal consistency for multi- item scales; test-retest for survey items. Reliability testing of the measure score addresses precision of measurement (e.g., signal-to-noise).

11. Validity testing applies to both the data elements and computed measure score. Validity testing of data elements typically analyzes agreement with another authoritative source of the same information. Examples of validity testing of the measure score include, but are not limited to: testing hypotheses that the measures scores indicate quality of care, e.g., measure scores are different for groups known to have differences in quality assessed by another valid quality measure or method; correlation of measure scores with another valid indicator of quality for the specific topic; or relationship to conceptually related measures (e.g., scores on process measures to scores on outcome measures). Face validity of the measure score as a quality indicator may be adequate if accomplished through a systematic and transparent process, by identified experts, and explicitly addresses whether performance scores resulting from the measure as specified can be used to distinguish good from poor quality.

12. Examples of evidence that an exclusion distorts measure results include, but are not limited to: frequency of occurrence, variability of exclusions across providers, and sensitivity analyses with and without the exclusion.

13. Patient preference is not a clinical exception to eligibility and can be influenced by provider interventions.

14. Risk factors that influence outcomes should not be specified as exclusions.

15. Risk models should not obscure disparities in care for populations by including factors that are associated with differences/inequalities in care, such as race, socioeconomic status, or gender (e.g., poorer treatment outcomes of African American men with prostate cancer or inequalities in treatment for CVD risk factors between men and women). It is preferable to stratify measures by race and socioeconomic status rather than to adjust out the differences.

16. With large enough sample sizes, small differences that are statistically significant may or may not be practically or clinically meaningful. The substantive question may be, for example, whether a statistically significant difference of one percentage point in the percentage of patients who received smoking cessation

counseling (e.g., 74 percent v. 75 percent) is clinically meaningful; or whether a statistically significant difference of $25 in cost for an episode of care (e.g., $5,000 v. $5,025) is practically meaningful. Measures with overall less-than-optimal performance may not demonstrate much variability across providers.

1. DATA/SAMPLE USED FOR ALL TESTING OF THIS MEASURE
Often the same data are used for all aspects of measure testing. In an effort to eliminate duplication, the first five questions apply to all measure testing. If there are differences by aspect of testing,(e.g., reliability vs. validity) be sure to indicate the specific differences in question 1.7.

1.1. What type of data was used for testing? (*Check all the sources of data identified in the measure specifications and data used for testing the measure. Testing must be provided for all the sources of data specified and intended for measure implementation. If different data sources are used for different components in the composite, indicate the component after the checkbox.*)

Measure Specified to Use Data From: (*must be consistent with data sources entered in S.23*)	**Measure Tested with Data From:**
☐ abstracted from paper record	☐ abstracted from paper record
☐ administrative claims	☐ administrative claims
☐ **clinical database/registry**	☐ **clinical database/registry**
☐ abstracted from electronic health record	☐ abstracted from electronic health record
☐ eMeasure (HQMF) implemented in EHRs	☐ eMeasure (HQMF) implemented in EHRs
☐ other: Click here to describe	☐ other: Click here to describe

1.2. If an existing dataset was used, identify the specific dataset (*the dataset used for testing must be consistent with the measure specifications for target population and healthcare entities being measured; e.g., Medicare Part A claims, Medicaid claims, other commercial insurance, nursing home MDS, home health OASIS, clinical registry*).

We propose to use the National Cardiovascular Data Registry for ICD Registry. This is a national quality improvement registry used in >1700 US hospitals. Some states and healthcare systems mandate participation, and participation is required as a condition for hospital reimbursement for Medicare beneficiaries receiving ICD therapy for primary prevention of sudden death. Rigorous quality standards are applied to the data and both quarterly and performance reports are generated for participating centers to track and improve their performance.

1.3. What are the dates of the data used in testing? Click here to enter date range
We have chosen to use different datasets to provide support for different aspects of the proposed measure.
Assessment of item-level reliability through the Audit Program: 01/2010-12/2010
All other forms of reliability testing: Jan 2013-Jun 2014
Hospital information about the Safety Net Hospital and %Medicaid are derived from AHA 2010 data.

1.4. What levels of analysis were tested? (*testing must be provided for all the levels specified and intended for measure implementation, e.g., individual clinician, hospital, health plan*)

Measure Specified to Measure Performance of: (*must be consistent with levels entered in item*	**Measure Tested at Level of:**
☐individual clinician	☐individual clinician
☐group/practice	☐group/practice

☐**hospital/facility/agency**	☐**hospital/facility/agency**
☐health plan	☐health plan
☐other: Click here to describe	☐other: Click here to describe

1.5. How many and which <u>measured entities</u> were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of measured entities included in the analysis (e.g., size, location, type); if a sample was used, describe how entities were selected for inclusion in the sample*)

For all the descriptive statistics for this measure except auditing:

Number of the measured entities (hospitals): 1,606

<u>Assessment of item-level reliability through the Audit Program:</u>

To assess inter-rater reliability of the extracted data elements that comprise this measure, data from 25 participating hospitals were reviewed by an independent contractor hired by ACCF.

1.6. How many and which <u>patients</u> were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of patients included in the analysis (e.g., age, sex, race, diagnosis); if a sample was used, describe how patients were selected for inclusion in the sample*)

The number of patients varies by testing type.

For all the descriptive statistics for this measure except auditing we used data submitted to the ICD Registry between January 2013 and June 2014. Note this reflects all data from all centers that met data quality standards irrespective of the case volume of participating hospitals. When we present information about hospital performance

* Hospital information about the Safety Net Hospital and %Medicaid are derived from AHA 2010 data.

Assessment of item-level reliability through the Audit Program:
To assess inter-rater reliability of the extracted data elements that comprise this measure, we reviewed 627 patients.

1.7. If there are differences in the data or sample used for different aspects of testing (e.g., reliability, validity, exclusions, risk adjustment), identify how the data or sample are different for each aspect of testing reported below.

There are different time periods and different descriptive statistics as noted in previous sections. The datasets, dates, number of measured entities, and number of admissions used in each type of testing are as follows:

For reliability testing (Section 2a2) using audit data: 01/2010 – 12/2010
For the split sample testing: 01/2013 – 06/2014

1.8 What were the patient-level sociodemographic (SDS) variables that were available and analyzed in the data or sample used? For example, patient-reported data (e.g., income, education, language), proxy variables when SDS data are not collected from each patient (e.g. census tract), or patient community characteristics (e.g. percent vacant housing, crime rate).

We do not currently collect many of the SDS variables examples listed above. However, we do collect data on race as well as insurance type.

2a2. RELIABILITY TESTING
2a2.1. What level of reliability testing was conducted?
Note*: Current guidance for composite measure evaluation states that reliability must be demonstrated for the composite performance measure score.*
☒ **Critical data elements used in the measure** (*e.g., inter-abstractor reliability; data element reliability must address ALL critical data elements*)
☐ **Performance measure score** (e.g., *signal-to-noise analysis*)

2a2.2. Describe the method of reliability testing and what it tests (*describe the steps—do not*

just name a method; what type of error does it test; what statistical analysis was used)

Split Sample Methodology

For the performance rates and disparities data, raw rates were calculated and a correlation coefficient was computed.

Assessment of item-level reliability through the Audit Program:

To assess inter-rater reliability of the extracted data elements that comprise this measure, 627 patients at 25 hospitals were reviewed by an independent contractor hired by ACCF.

Assessment of item-level reliability through the Audit Program:

The NCDR Data Quality Program ensures that data submitted to the NCDR are collected completely and in a valid manner. The NCDR Data Quality Program consists of 3 main components: data completeness, consistency, and accuracy. Completeness focuses on the proportion of missing data within fields, whereas consistency determines the extent to which logically related fields contain values consistent with other fields. Accuracy characterizes the agreement between registry data and the contents of original charts from the hospitals submitting data. Before entering the Enterprise Data Warehouse (EDW), all submissions are scored for file integrity and data completeness, receiving 1 of 3 scores that are transmitted back to facilities using a color-coding scheme. A "red light" means that a submission has failed because of file integrity problems such as excessive missing data and internally inconsistent data. Such data are not processed or loaded into the EDW. A "yellow light" status means that a submission has passed the integrity checks but failed in completeness according to predetermined thresholds. Such data are processed and loaded into the EDW but are not included in any registry aggregate computations until corrected. Facilities are notified about data submission problems and provided an opportunity to resubmit data. Finally, a "green light" means that a submission has passed all integrity and quality checks. Such submissions are loaded to the EDW. After passing the DQR, data are loaded into a common EDW that houses data from all registries and included for all registry aggregate computations. In a secondary transaction process, data are loaded into registry-specific, dimensionally modeled data marts.
A summary of the Program is noted under Table 1.

Table 1. Data Quality Program Overview

Methodology	• Nationwide program (i.e., all submitting participants in the United States) • Review of data submitted the previous year • Review of a subset of data elements that can rotate each year • Remote review of data combined with couple of onsite visit • Onsite visits are targeted based on the Data Outlier Program • Random selection of sites and records • Blinded data abstraction from medical charts • Inter-rater Reliability Assessment conducted to validate the audit findings • Adjudication step for participant to refute audit findings
Scope	• Review of hospital's medical records for related episodes of care • Assessment of complete submission (Comparison of two lists : hospital

	list of cases with specific billing codes versus NCDR submitted records)
Criteria for selecting sites/records	Remote audit : • Sites passing their quarterly DQR for 2 quarters within audited year • Sites submitting at least the number of records/sites being reviewed Onsite audit • Sites identified with an outlier and not contacted with the data outlier program
Scoring	NCDR uses a grading system for identifying the amount of agreement or matching between the data captured during the medical record review and data submitted to the NCDR.

2a2.3. What were the statistical results from reliability testing? (e*.g., percent agreement and kappa for the critical data elements; distribution of reliability statistics from a signal-to-noise analysis*)

Assessment of item-level reliability through the Audit Program:

CE #	field_Name	agreement rate	_KAPPA_	L_KAPPA	U_KAPPA	N levels
4170	Prior MI	0.815920398	0.60411	0.54118	0.66704	3
5000	LVEF Assessed	0.797678275	0.327125	0.245208	0.409041	3
6005	Procedure Type	0.978441128	0.955269	0.931311	0.979227	4
9045	ACE Inhibitor (Any)	0.883913765	0.755579	0.707206	0.803952	4
9100	ARB (Any)	0.922056385	0.729868	0.660493	0.799242	4
9110	Beta Blocker (Any)	0.933665008	0.658258	0.568486	0.748029	5

Assessment of item-level reliability through the Audit Program:

NCDR's Data Quality Program rotates the review of all the variables in the registry. ICD has over 300 elements that are reviewed on a 3 year rotating cycle. The elements required for this measure will be reviewed during the upcoming audit process. NCDR staff can provide kappa scores and percentage agreement scores upon completion of the cycle.

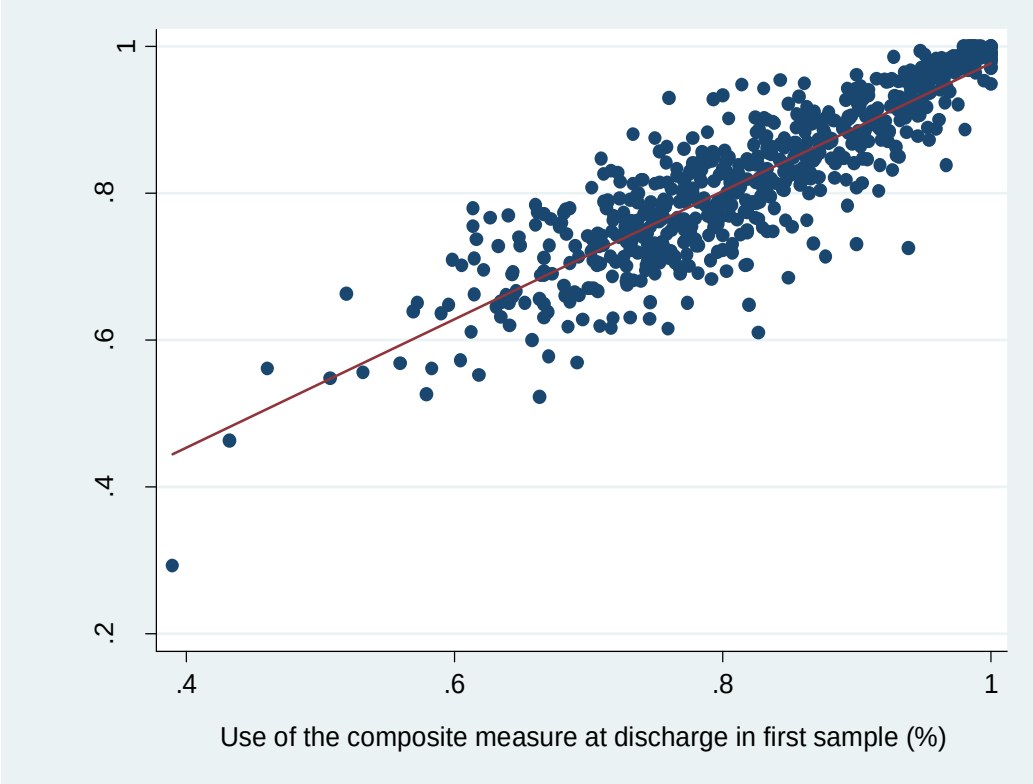
Split Sample Methodology:

Distribution of hospital performance on the composite measure within random split samples (minimum 50 cases in each sample)

Description	Randomly Split Samples	
	First (RAND=1) DCM	Second (RAND=0) DCM
N	707	684
Mean	0.8178	0.8200
Std Deviation	0.1089	0.1090
100% Max	1.0000	1.0000
75% Q3	0.9020	0.9087
50% Median	0.8199	0.8203
25% Q1	0.7414	0.7434

To evaluate the reliability of the measure, we randomly split the study cohort over the two year period (Jan 2013 to Jun 2014 combined) into two samples and restricted the cohort to hospitals that had a minimum of 50 cases in each split sample.

Results of the split sample testing are provided below. The 2 split samples were calculated during the same timeframe to avoid the potential for changes in hospital performance over time. After splitting the cohort into two random samples, we compared measure scores calculated at hospitals with at least 50 cases in both random samples. Of note, slightly less than half of participating hospitals met this volume threshold, and a few hospitals had more than 50 cases in one random sample but fewer than 50 in the other. The distribution of hospital performance was similar in the two samples (figure below), and there was an extremely high correlation between hospital performances assessed in the two samples (r 0.87949)



2a2.4 What is your interpretation of the results in terms of demonstrating reliability? (i.*e., what do the results mean and what are the norms for the test conducted?*)

Assessment of item-level reliability through the Audit Program:

These kappa scores were calculated with a 95% CI. By convention, a kappa > .70 is considered acceptable inter-rater reliability (Landis 1977). We used the scale below for our analysis.

0: No better than chance
0.01-0.20: Slight
0.21-0.40: Fair
0.41-0.60: Moderate
0.61-0.80: Substantial
0.81-1.0: Almost perfect

(Reference: Landis J, Koch G, The measurement of observer agreement for categorical data, *Biometrics*, 1977; 33:159-174.)

The kappa score for all medication elements demonstrate substantial or almost perfect reliability. Some of the measure elements have justifiable reasons for a lower kappa and percentage agreement scores. The element "LVEF Assessed" is not always known. Moreover, there are multiple data elements at different times during hospitalization. Therefore, it is difficult to assess which

score is the correct score. Nevertheless, this element is actively discussed on monthly registry site manager calls and NCDR' s educational annual conference.

Split Sample Methodology

The figure above shows the scatterplot of the distribution of hospital performance for ICD composite measure at discharge when assessed in randomly split samples. Overall hospital performance in one random sample was strongly correlated with hospital performance in the other split sample (r=0.87949), which is consistent with a highly reliable measure.

2b2. VALIDITY TESTING

Note*: Current guidance for composite measure evaluation states that validity should be demonstrated for the composite performance measure score. If not feasible for initial endorsement, acceptable alternatives include assessment of content or face validity of the composite OR demonstration of validity for each component. Empirical validity testing of the composite measure score is expected by the time of endorsement maintenance.*

2b2.1. What level of validity testing was conducted?

☐**Composite performance measure score**

☐**Empirical validity testing**

☐**Systematic assessment of face validity of performance measure score as an indicator** of quality or resource use (*i.e., is an accurate reflection of performance on quality or resource use and can distinguish good from poor performance*)

☐**Systematic assessment of content validity**

☐**Validity testing for component measures** *(check all that apply)*

Note*: applies to ALL component measures, unless already endorsed or are being submitted for individual endorsement.*

☐**Endorsed (or submitted) as individual performance measures**

☐**Critical data elements** (*data element validity must address ALL critical data elements*)

☐**Empirical validity testing of the component measure score(s)**

☐**Systematic assessment of face validity of component measure score(s) as an indicator** of quality or resource use (*i.e., is an accurate reflection of performance on quality or resource use and can distinguish good from poor performance*)

2b2.2. For each level checked above, describe the method of validity testing and what it tests (*describe the steps—do not just name a method; what was tested, e.g., accuracy of data elements compared to authoritative source, relationship to another measure as expected; what statistical analysis was used)*

Systematic assessment of content validity:

Content validity of this process was achieved by the specialized expertise of those individuals who developed this measure as well as the structured discussions that the group conducted. For this particular topic those individuals who were involved in identifying the key attributes and variables for this process measure were leaders and experts in the field of electrophysiology. Serial phone

calls were held to both define the eligible population and given process. These clinical leaders are noted below.

NCDR Clinical Measures workgroup ensured the measure demonstrated an opportunity for improvement, had strong clinical evidence, and was a reliable and valid measure. These members included Drs. Jeptha Curtis (Chair), Frederick Masoudi, John Rumsfeld, Mark Kremers, and Matthew Reynolds.

NCDR Scientific Quality and Oversight Committee—a committee that served as the primary resource for crosscutting scientific and quality of care methodological issues. These members included Drs. Frederick Masoudi (Chair) , David Malenka, Thomas Tsai, Matthew Reynolds, David Shahian, John Windle, Fred Resnic, John Moore, Deepak Bhatt, James Tcheng, Jeptha Curtis, Paul Chan, Matthew Roe, and John Rumsfeld.

Lastly the 16 member NCDR Management Board and 31member ACCF Board of Trustees reviewed and approved these measures for submission to NQF.

Evidence:

ACE/ARB

ACE inhibitors reduce morbidity, mortality, and hospitalizations for patients with heart failure and left ventricular systolic dysfunction. The efficacy of ARB therapy has been strengthened by several large-scale prospective randomized clinical trials demonstrating lower rates of death and heart failure hospitalization among patients with heart failure and LVSD. Consensus clinical guidelines include strong recommendations for ACE inhibitors for all patients with HF due to LV systolic dysfunction unless they have a contraindication to their use or have been shown to be unable to tolerate treatment with these drugs. ACE inhibitors remain the first choice for inhibition of the renin-angiotensin system in chronic HF, but ARBs are considered a reasonable alternative. Even if the patient has responded favorably to the diuretic, treatment with ACE inhibitor or ARBs should be initiated and maintained in patients who can tolerate them, because they have been shown to favorably influence the long-term prognosis of HF

Beta Blocker-MI

The benefits of beta blocker therapy in patients with prior myocardial infarction without contraindications have been established for a wide range of patient groups. The greatest benefits are seen in patients with the greatest baseline risk: those with impaired ventricular function or ventricular arrhythmias and those who do not undergo reperfusion. The benefits of beta-blocker therapy for secondary prevention are well established.

Beta Blocker-LVSD

Long term beta blocker therapy for patients with left systolic ventricular dysfunction (LVSD) can improve symptoms of heart failure, improve patient clinical status, and reduce hospitalizations and mortality.

All this research demonstrates that this measure contributes to improved intermediate outcomes and important outcomes such as reductions in hospitalizations and mortality rates.

Empiric assessment of content validity:

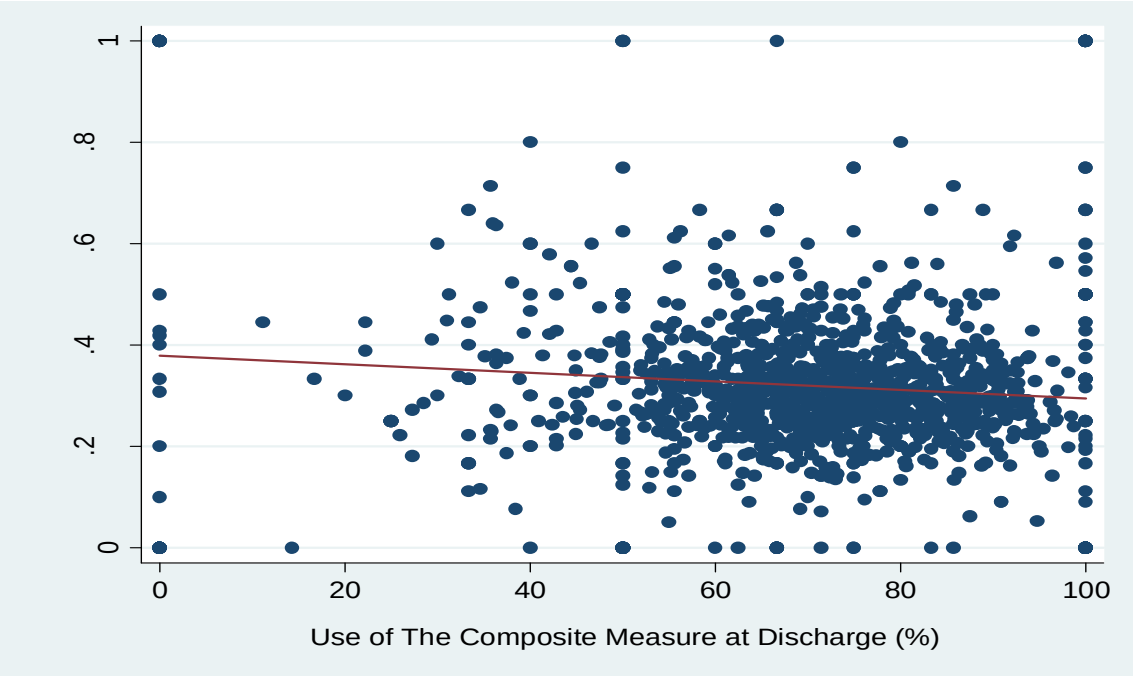
As noted in the measure application, we conducted empiric analyses to assess the association of patient and hospital performance on the composite measure with adverse outcomes, specifically mortality and readmission at 6 months following hospital discharge. To conduct these analyses we used a sample of patients for whom these outcomes were available. This consisted of 93971 Medicare fee-for-service patients at least 65 years of age who underwent ICD implantation in 2010 or 2011. Our outcomes of interest included all-cause mortality, all-cause readmission, and the combination of the 2 at 6 months following hospital discharge. We examined the proportion of patients who experienced these outcomes stratified by whether or not they were discharged on appropriate medical therapy. In addition, we conducted analyses at the hospital level examining the association between hospital-level performance on the measure and the combination of mortality or readmission at 6 months.

2b2.3. What were the statistical results from validity testing? (*e.g., correlation; t-test*)

Patient-level results are shown below. Overall, a significantly smaller proportion of patients discharged on appropriate medical therapy died or were readmitted within 6 months of hospital discharge.

Description	Use of Medications				P
	No		Yes		
	#	%	#	%	
Composite Measure	**25217**		**68754**		
6 month mortality	2408	9.55	3720	5.41	<0.001
6 month readmission	8587	34.05	18643	27.12	<0.001
6 month mortality or readmission	9148	36.28	19504	28.37	<0.001

Hospital-level results are shown below. The figure shows the association between rate of death or readmission within 6 months of discharge, with the use of the composite measure at discharge. Hospital performance on the composite discharge medication measure were significantly correlated with the combined outcome of death or readmission such that patients treated at hospitals that performed better on the measure had better unadjusted outcomes that those treated at hospitals that performed worse on the measure (correlation coefficient (-0.0998), $p<0.001$).



2b2.4. What is your interpretation of the results in terms of demonstrating validity? (i.*e., what do the results mean and what are the norms for the test conducted?*

These findings support the validity of the composite discharge medication measure. At both the patient and hospital level, performance on the measure was associated with better outcomes at 6 months following discharge.

Threats to Validity:

Information Bias: There should be little concern for information bias since the care process is objective and there is a low likelihood of misreporting the given care process. Additionally, since there is only 1 data source that is used for NCDR inpatient registries thus mitigating this potential threat.

Missing Data Bias: Because of the large amount of data typically contained in registries, it is not feasible to meet the stringent requirements used in clinical trials. However, unlike with administrative claims data, data fields in a registry must be assessed for completeness, consistency, and accuracy to support the central activities of the registry. The NCDR Data Quality Program consists of 3 main components: data completeness, consistency, and accuracy. Completeness

focuses on the proportion of missing data within fields, whereas consistency determines the extent to which logically related fields contain values consistent with other fields. Accuracy characterizes the agreement between registry data and the contents of original charts from the hospitals submitting data. The thresholds for all critical elements in a performance measure are set high to ensure data completeness and consistency for the overall calculation of the performance measure. Therefore it is unlikely missing data bias would threaten the validity properties.

Selection Bias: In January 2005 the Centers for Mediare and Medicaid Services (CMS) expanded the covered indications for primary prevention ICDs to incorporate the findings from published literature. As part of this expansion, CMS mandated that a national registry be formed to compile data on Medicare patients implanted with primary prevention ICDs to confirm the appropriateness of ICD utilization in this patient population. CMS selected the NCDR ICD Registry as the mandated national registry in October 2005 and enrollment opened on January 1, 2006. As the CMS-mandated registry for hospitals that perform ICD implantation procedures, the ICD Registry essentially requires all hospitals that receive Medicare funding, to a participant of the NCDR Registry. This limits the potential for selection bias. Additionally, based on the entity and patient descriptive statistics, there does not appear to be certain subgroups of hospitals or patients who are excluded. Lastly, the exclusion frequencies did not appear to be unusually high.

Confounding Bias: No empirical testing was performed since this metric is neither an outcome or resource use measure.

2b3. EXCLUSIONS ANALYSIS

Note: *Applies to the composite performance measure, as well all component measures unless they are already endorsed or are being submitted for individual endorsement.*

NA ☐no exclusions — *skip to section 2b4*

2b3.1. Describe the method of testing exclusions and what it tests (*describe the steps—do not just name a method; what was tested, e.g., whether exclusions affect overall performance scores; what statistical analysis was used*)

The only exclusions for this measure are noted under S.10. (Discharge status of expired; not eligible for either ACE/ARB or beta blockers). These exclusions are relatively rare and firmly supported by the clinical rationale.

2b3.2. What were the statistical results from testing exclusions? (*include overall number and percentage of individuals excluded, frequency distribution of exclusions across measured entities, and impact on performance measure scores*)

Exclusions	Patient Stays		Facilities	
Total	**665983**	**100.0**	**1709**	**100.0**
Discharge not in 2013 and 2014	420784	63.2	96	5.6
Remaining	**245199**	**36.8**	**1613**	**94.4**
Died during hospital	710	0.3	0	0.0
Remaining	**244489**	**99.7**	**1613**	**100.0**
Not eligible to the composite measure	48926	20.0	7	0.4
Study Cohort	**195563**	**80.0**	**1606**	**99.6**
The composite measure at discharge	159321	81.47	1589	98.94

2b3.3. What is your interpretation of the results in terms of demonstrating that exclusions are needed to prevent unfair distortion of performance results? (*i.e., the value outweighs the burden of increased data collection and analysis. Note: **If patient preference is an exclusion**, the measure must be specified so that the effect on the performance score is transparent, e.g., scores with and without exclusion*)

As noted above, there are no 'discretionary' exclusions. All exclusions are necessary to the accurate calculation of performance on the composite measure. For example, patients need to survive to discharge to be eligible for the measure. Similarly, it would be inappropriate to calculate the measure among patients ineligible for the medications.

2b4. RISK ADJUSTMENT/STRATIFICATION FOR OUTCOME OR RESOURCE USE MEASURES
Note: *Applies to all outcome or resource use component measures, unless already endorsed or are being submitted for individual endorsement.*
If not an intermediate or health outcome, or PRO-PM, or resource use measure, skip to section 2b5.

2b4.1. What method of controlling for differences in case mix is used? *(check all that apply)*
☐**Endorsed (or submitted) as individual performance measures**
☐**No risk adjustment or stratification**
☐**Statistical risk model**
☐**Stratification by risk categories**
☐**Other,** Click here to enter description

2b4.2. If an outcome or resource use component measure is not risk adjusted or stratified, provide rationale and analyses to demonstrate that controlling for differences in patient characteristics (case mix) is not needed to achieve fair comparisons across measured entities.
N/A

2b4.3. Describe the conceptual/clinical and statistical methods and criteria used to select patient factors used in the statistical risk model or for stratification by risk (*e.g., potential factors identified in the literature and/or expert panel; regression analysis; statistical significance of p<0.10; correlation of x or higher; patient factors should be present at the start of care and not related to disparities*)

N/A

2b4.4. What were the statistical results of the analyses used to select risk factors?

N/A

2b4.5. Describe the method of testing/analysis used to develop and validate the adequacy of the statistical model or stratification approach (*describe the steps—do not just name a method; what statistical analysis was used*)

N/A

Provide the statistical results from testing the approach to controlling for differences in patient characteristics (case mix) below.
if stratified, skip to 2b4.9

2b4.6. Statistical Risk Model Discrimination Statistics (*e.g., c-statistic, R-squared*)**:**
N/A

2b4.7. Statistical Risk Model Calibration Statistics (*e.g., Hosmer-Lemeshow statistic*):
N/A

2b4.8. Statistical Risk Model Calibration – Risk decile plots or calibration curves:
N/A

2b4.9. Results of Risk Stratification Analysis:
N/A

2b4.10. What is your interpretation of the results in terms of demonstrating adequacy of controlling for differences in patient characteristics (case mix)? (i.*e., what do the results mean and what are the norms for the test conducted?*)
N/A

***2b4.11. Optional Additional Testing for Risk Adjustment** (*not required, but would provide additional support of adequacy of risk model, e.g., testing of risk model in another data set; sensitivity analysis for missing data; other methods*)
N/A

2b5. IDENTIFICATION OF STATISTICALLY SIGNIFICANT & MEANINGFUL DIFFERENCES IN PERFORMANCE
Note: *Applies to the composite performance measure.*
Across stratified analyses based on sex, age, race, and proportion of patients who are insured through Medicaid, we found significant overlap in the distribution of hospital performance.

2b5.1. Describe the method for determining if statistically significant and clinically/practically meaningful differences in performance measure scores among the measured entities can be identified (*describe the steps—do not just name a method; what statistical analysis was used? Do not just repeat the information provided related to performance gap in 1b)*
We examined variation in hospital performance for the composite measure based on sex, age, race, and the proportion of patients who are insured through Medicaid to identify meaningful differences.

2b5.2. What were the statistical results from testing the ability to identify statistically significant and/or clinically/practically meaningful differences in performance measure scores across measured entities? (e.g., *number and percentage of entities with scores that were statistically significantly different from mean or some benchmark, different from expected; how was meaningful difference defined*)

Across stratified analyses based on sex, age, race, and proportion of patients who are insured through Medicaid, we found significant overlap in the distribution of hospital performance.

2b5.3. What is your interpretation of the results in terms of demonstrating the ability to identify statistically significant and/or clinically/practically meaningful differences in performance across measured entities? (i.*e., what do the results mean in terms of statistical and meaningful differences?*)

Given the gaps in care, there continues to be an opportunity for improvement.

2b6. COMPARABILITY OF PERFORMANCE SCORES WHEN MORE THAN ONE SET OF SPECIFICATIONS *Note:* *Applies to all component measures, unless already endorsed or are being submitted for individual endorsement.*
If only one set of specifications for each component, this section can be skipped.

Note*: This criterion is directed to measures with more than one set of specifications/instructions (e.g., one set of specifications for how to identify and compute the measure from medical record abstraction and a different set of specifications for claims or eMeasures). It does not apply to measures that use more than one source of data in one set of specifications/instructions (e.g., claims data to identify the denominator and medical record abstraction for the numerator).* ***If comparability is not demonstrated, the different specifications should be submitted as separate measures.***

2b6.1. Describe the method of testing conducted to demonstrate comparability of performance scores for the same entities across the different data sources/specifications (*describe the steps—do not just name a method; what statistical analysis was used*)

N/A

2b6.2. What were the statistical results from testing comparability of performance scores for the same entities when using different data sources/specifications? (*e.g., correlation, rank order*)

N/A

2b6.3. What is your interpretation of the results in terms of demonstrating comparability of performance measure scores for the same entities across the different data sources/specifications? (i.*e., what do the results mean and what are the norms for the test conducted?*)

N/A

2d. EMPIRICAL ANALYSIS TO SUPPORT COMPOSITE CONSTRUCTION APPROACH
Note: *If empirical analyses do not provide adequate results—or are not conducted—justification must be provided and accepted in order to meet the must-pass criterion of Scientific Acceptability of Measure Properties. Each of the following questions has instructions if there is no empirical analysis.*

2d1. Empirical analysis demonstrating that the component measures fit the quality construct, add value to the overall composite, and achieve the object of parsimony to the extent possible.

We believe the content validity of this measure has been achieved by virtue of the noted expertise of those individuals who developed this measure. The individual components of the composite have

already shown to impact clinical outcomes. However the empirical analysis demonstrating the individual component measures fit the overall quality construct is currently being researched. The testing will focus on construct validation which will test the hypothesis on the theory of the construct that following these processes for patients with ICD implantations lead to better outcomes. This research is expected to ultimately be published in the medical literature.

2d1.1 Describe the method used (*describe the steps—do not just name a method; what statistical analysis was used; if no empirical analysis, provide justification)*

2d1.2. What were the statistical results obtained from the analysis of the components? (e.g., *correlations, contribution of each component to the composite score, etc.*; *if no empirical analysis, identify the components that were considered and the pros and cons of each*)

2d1.3. What is your interpretation of the results in terms of demonstrating that the components included in the composite are consistent with the described quality construct and add value to the overall composite? (i.*e., what do the results mean in terms of supporting inclusion of the components; if no empirical analysis, provide rationale for the components that were selected)*

2d2. Empirical analysis demonstrating that the aggregations and weighting rules are consistent with the quality construct and achieve the objective of simplicity to the extent possible

2d2.1 Describe the method used (*describe the steps—do not just name a method; what statistical analysis was used; if no empirical analysis, provide justification)*

2d2.2. What were the statistical results obtained from the analysis of the aggregation and weighting rules? (e.g., *results of sensitivity analysis of effect of different aggregations and/or weighting rules; if no empirical analysis, identify the aggregation and weighting rules that were considered and the pros and cons of each*)

2d2.3. What is your interpretation of the results in terms of demonstrating the aggregation and weighting rules are consistent with the described quality construct? (i.*e., what do the results mean in terms of supporting the selected rules for aggregation and weighting; if no empirical analysis, provide rationale for the selected rules for aggregation and weighting*)

2d3. Empirical analysis demonstrating that the approach for handling missing data minimizes bias (*i.e., achieves scores that are an accurate reflection of quality*)**.**
Note: *Applies to the overall composite measure; the focus is on missing data rather than exclusions, which are considered in 2b3.*
The composite discharge medication measure is specified such that cases with missing data are assumed to have not met the metric. The performance ranges throughout this application reflect this approach. By following this method, the scores should be a true depiction of performance

scores.

2d3.1. What is the overall frequency of missing data and the distribution of missing data across providers?

As noted above, there are no "discretionary" exclusions. All exclusions are necessary to the accurate calculation of performance of the measure. See section 2b3.2.

2d3.2. Describe the method used to compare approaches for handling missing data (*describe the steps—do not just name a method; what statistical analysis was used; if no empirical analysis, provide justification)*

Missing data defaults to "performance not met". This measure assumes that missing documentation on the process results in a failure of meeting a evidence based therapy.

2d3.3. What were the statistical results obtained from the analysis of missing data? (e.g., *results of sensitivity analysis of effect of various rules for missing data; if no empirical analysis, identify the approaches for handling missing data that were considered and pros and cons of each*)

No empirical analysis was performed. However, it was felt that the method employed would minimize the potential for gaming.

2d3.4. What is your interpretation of the results in terms of demonstrating that the approach used for missing data minimizes bias? (i.*e., what do the results mean in terms of supporting the selected approach for missing data; if no empirical analysis, provide rationale for the selected approach for missing data*)

Given the low frequency of exclusions, we do not believe that the exclusions have any impact on the validity, accuracy or interpretability of this measure. The exclusions have little potential for bias especially given the ICD Data Quality Program audits all essentially performance measure elements on a 3 year cycle and would detect misclassifications of patient records.

3. Feasibility

Extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

3a. Byproduct of Care Processes

For clinical measures, the required data elements are routinely generated and used during care delivery (e.g., blood pressure, lab test, diagnosis, medication order).

3a.1. Data Elements Generated as Byproduct of Care Processes.

generated by and used by healthcare personnel during the provision of care, e.g., blood pressure, lab value, medical condition, Coded by someone other than person obtaining original information (e.g., DRG, ICD-9 codes on claims)

If other:

3b. Electronic Sources

The required data elements are available in electronic health records or other electronic sources. If the required data are not in electronic health records or existing electronic sources, a credible, near-term path to electronic collection is specified.

3b.1. **To what extent are the specified data elements available electronically in defined fields?** *(i.e., data elements that are needed to compute the performance measure score are in defined, computer-readable fields)*
ALL data elements are in defined fields in electronic clinical data (e.g., clinical registry, nursing home MDS, home health OASIS)

3b.2. **If ALL the data elements needed to compute the performance measure score are not from electronic sources, specify a credible, near-term path to electronic capture, OR provide a rationale for using other than electronic sources.**

3b.3. **If this is an eMeasure, provide a summary of the feasibility assessment in an attached file or make available at a measure-specific URL.**
No feasibility assessment **Attachment:**

3c. Data Collection Strategy

Demonstration that the data collection strategy (e.g., source, timing, frequency, sampling, patient confidentiality, costs associated with fees/licensing of proprietary measures) can be implemented (e.g., already in operational use, or testing demonstrates that it is ready to put into operational use). For eMeasures, a feasibility assessment addresses the data elements and measure logic and demonstrates the eMeasure can be implemented or feasibility concerns can be adequately addressed.

3c.1. **Describe what you have learned/modified as a result of testing and/or operational use of the measure regarding data collection, availability of data, missing data, timing and frequency of data collection, sampling, patient confidentiality, time and cost of data collection, other feasibility/implementation issues.**
IF a PRO-PM, consider implications for both individuals providing PROM data (patients, service recipients, respondents) and those whose performance is being measured.
Availability:
Participating hospitals report patient demographics, medical history, risk factors, hospital presentation, initial cardiac status, procedural details, medications, laboratory values and in-hospital complications. All of the data elements are routinely generated and acquired during the delivery of standard cardiac care to this patient population. Electronic extraction of data recorded as part of the procedure expedites data collection. This strategy offers point of care collection and minimizes time and cost. Institutions can manually report using a free web-based tool or automate the reporting by using certified software developed by third-party vendors. The data elements required for this measure are readily available within the patient's medical record or can be attained without undue burden within the hospital. Most data elements exist in a structured format within patient's electronic health record.

Sampling:
There is no sampling of patient data allowed within the contractual terms of participation in the ICD Registry in

NCDR. Section 2.b of the NCDR Master Agreement with participants includes 'Participant Responsibilities': "b. Use of ACCF Data Set and ACCF-Approved Software. Participant will submit a data record on each patient who receives medical care and who is eligible for inclusion in the Registries in which Participant is participating under this Agreement." Adult patients, ages 18 years and older, who have an ICD implanted. Patients are selected for inclusion by reviewing existing medical records and no direct interaction with the patient will be required outside of the normal course of care. There will be no discrimination or bias with respect to inclusion on the basis of sex, race, or religion.

Patient confidentiality:

Patient confidentiality is preserved as the data are in aggregate form. The ICD Registry dataset, comprised of approximately 320, data elements was created by a panel of experts using available ACC-AHA guidelines, data elements and definitions, and other evidentiary sources. Private health information (PHI), such as social security number, is collected. The intent for collection of PHI is to allow for registry interoperability and the potential for future generation of patient-level drill downs in Quality and Outcomes Reports. Registry sites can opt out of transmitting direct identifiers to the NCDR, however, so inclusion of direct identifiers in the registry is at the discretion of the registry participants themselves. When using the NCDR web-based data collection tool, direct identifiers are entered but a partition between the data collection process and the data warehouse maintains the direct identifiers separate from the analysis datasets. The minimum level of PHI transmitted to the ACCF when a participant opts out of submitting direct identifiers meets the definition of a Limited Dataset as such term is defined by the Health Insurance Portability and Accountability Act of 1996.

Data collection within the NCDR conforms to laws regarding protected health information. Patient confidentiality is of utmost concern. The proposed measure does not include a patient survey. Physician and/or institutional confidentiality are maintained by de-identified dashboard reports. There is no added procedural risk to patients through involvement in the ICD Registry. No testing, time, risk, or procedures beyond those required for routine care will be imposed. The primary risk associated with this measure is the potential for a breach of patient confidentiality. The ACCF has established a robust plan for ensuring appropriate and commercially reasonable physical, technical, and administrative safeguards are inplace to mitigate such risks.

Data are maintained on secure servers with appropriate safeguards in place. The project team periodically reviews all activities involving protected health information to ensure that such safeguards including standard operating procedures are being followed. The procedure for notifying the ACCF of any breach of confidentiality and immediate mitigation standards that need to be followed is communicated to participants. ACCF limits access to Protected Health Information, and to equipment, systems, and networks that contain, transmit, process or store Protected Health Information, to employees who need to access the PHI for purposes of performing ACCF's obligations to participants who are in a contractual relationship with the ACCF. All PHI are stored in a secure facility or secure area within ACCF's facilities which has separate physical controls to limit access, such as locks or physical tokens. The secured areas are monitored 24 hours per day, 7 days per week, either by employees or agents of ACCF by video surveillance, or by intrusion detection systems.

Each participant who has access to the NCDR website must have a unique identifier. The password protected webpages have implement inactivity time-outs. Encryption of wireless network data transmission and authentication of wireless devices containing NCDR Participant's information ACCF's network is required. Protected Health Information may only be transmitted off of ACCF's premises to approved parties, which shall mean: A subcontractor who has agreed to be bound by the terms of the Business Associate Agreement between the ACCF and the NCDR Participant.

Time of Data collection:
1 Full time employee can enter on average roughly 1200 patient records per year
(citation: ACC Marketing Intelligence Team)

3c.2. **Describe any fees, licensing, or other requirements to use any aspect of the measure as specified** *(e.g., value/code set, risk model, programming code, algorithm)*.
The ACCF's program the National Cardiovascular Data Registry (NCDR) provides evidence based solutions for cardiologists and other medical professionals committed to excellence in cardiovascular care. NCDR hospital participants receive confidential benchmark reports that include access to measure macro specifications and micro specifications, the eligible patient population, exclusions, and model variables (when applicable). In addition to hospital sites, NCDR Analytic and Reporting Services provides consenting hospitals' aggregated data reports to interested federal and state regulatory agencies, multi-system provider groups, third-party payers, and other organizations that have an identified quality improvement initiative that supports NCDR-participating facilities. Lastly, the ACCF also allows for licensing of the measure specifications outside of the Registry.
It should be noted that the centers already have to participate in this specific registry for reimbursement purposes so that currently almost all hospitals that implant ICDs in Medicare populations already participate. Hence there is no additional cost.
Measures that are aggregated by ACCF and submitted to NQF are intended for public reporting and therefore there is no charge for a standard export package. However, on a case by case basis, requests for modifications to the standard export package will be available for a separate charge.

4. Usability and Use

Extent to which potential audiences (e.g., consumers, purchasers, providers, policy makers) are using or could use performance results for both accountability and performance improvement to achieve the goal of high-quality, efficient healthcare for individuals or populations.

4a. Accountability and Transparency

Performance results are used in at least one accountability application within three years after initial endorsement and are publicly reported within six years after initial endorsement (or the data on performance results are available). If not in use at the time of initial endorsement, then a credible plan for implementation within the specified timeframes is provided.

4.1. **Current and Planned Use**

NQF-endorsed measures are expected to be used in at least one accountability application within 3 years and publicly reported within 6 years of initial endorsement in addition to performance improvement.

Planned	Current Use (for current use provide URL)
Public Reporting Quality Improvement with	

Benchmarking (external benchmarking to multiple organizations) Quality Improvement (Internal to the specific organization) Not in use	

4a.1. **For each CURRENT use, checked above, provide:**

- Name of program and sponsor
- Purpose
- Geographic area and number and percentage of accountable entities and patients included

N/A, not being publicly reported.

4a.2. **If not currently publicly reported OR used in at least one other accountability application (e.g., payment program, certification, licensing) what are the reasons?** (*e.g., Do policies or actions of the developer/steward or accountable entities restrict access to performance results or impede implementation?*)

N/A, not being publicly reported.

4a.3. **If not currently publicly reported OR used in at least one other accountability application, provide a credible plan for implementation within the expected timeframes -- any accountability application within 3 years and publicly reported within 6 years of initial endorsement.** (*Credible plan includes the specific program, purpose, intended audience, and timeline for implementing the measure within the specified timeframes. A plan for accountability applications addresses mechanisms for data aggregation and reporting.*)

ACC is committed to implementing this measure. ACC is an authorized organization to receive CMS data through the ResDAC application process. Unfortunately, it has been determined by ResDAC that this authorization does not permit use of CMS for performance measure reporting purposes, either to hospitals or for public display. ACC is currently in process of applying to be a Qualified Entity. It is unclear if this pathway will permit measure implementation. ACC also is commenting on and tracking proposed language in 21st Century Cures legislation, which does appear to create a pathway for use of CMS data for this type of reporting purpose.

4b. Improvement

Progress toward achieving the goal of high-quality, efficient healthcare for individuals or populations is demonstrated. If not in use for performance improvement at the time of initial endorsement, then a credible rationale describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.

4b.1. **Progress on Improvement. (Not required for initial endorsement unless available.)**

Performance results on this measure (current and over time) should be provided in 1b.2 and 1b.4. Discuss:

- **Progress (trends in performance results, number and percentage of people receiving high-quality healthcare)**
- **Geographic area and number and percentage of accountable entities and patients included**

Trends: Data presented below identify the improving trend shown by participating hospitals in prescribing each of the three medications within this composite measure. While the top 10% of performers saw slight performance improvement, the hospitals in the lower percentiles (below the median) improved significantly.

The two tables below indicate aggregated hospital performance results in 2009 (second table) and aggregated hospital performance results for this composite during Jan 2011-Dec 2012 (first table listed below)

2011 - 2012
Hospitals: n=1552
Patients: n=243186
Mean: 74%
Std Deviation: 16%
Percentiles
90th: 91%
75th (Quartile 3): 84%
50th (Median): 76%
25th (Quartile 1): 67%
10th: 56%

2013 - 2014
Hospitals: n=1606
Patients: n=195563
Mean: 78%
Std Deviation: 17%
Percentiles
90th: 97%
75th (Quartile 3): 89%
50th (Median): 79%
25th (Quartile 1): 71%
10th: 59%

Geographic area and number and percentage of accountable entities and patients included

Geographic area: This registry data captures hospital data from the United States as well as territories. The United States data are included in the aggregate. Other country data are excluded from national aggregates for the purpose of reporting.
Number of accountable entities:1552 for calendar years 2011-2012; 1606 for calendar years 2013-14.
Patients included: 243186 for calendar years 2011-2012; 195563 for calendar years 2013-2014

4b.2. **If no improvement was demonstrated, what are the reasons? If not in use for performance improvement at the time of initial endorsement, provide a credible rationale that describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.**
Improvements were demonstrated.

4c. Unintended Consequences

The benefits of the performance measure in facilitating progress toward achieving high-quality, efficient healthcare for individuals or populations outweigh evidence of unintended negative consequences to individuals or populations (if such evidence exists).

4c.1. **Were any unintended negative consequences to individuals or populations identified during testing; OR**

has evidence of unintended negative consequences to individuals or populations been reported since implementation? If so, identify the negative unintended consequences and describe how benefits outweigh them or actions taken to mitigate them.

Inaccuracies may occur if certified vendors export data incorrectly, in transmission of data from medical record to a paper form and then to the online data collection tool. Some sites may over-code medication exclusions.
A vendor certification process has been established to ensure high quality data collection and submission.
The NCDR Data Quality Program is in place to assess reliability of data abstraction. For additional details about the NCDR Data Quality Program please see testing supplement.

5. Comparison to Related or Competing Measures

If a measure meets the above criteria and there are endorsed or new related measures (either the same measure focus or the same target population) or competing measures (both the same measure focus and the same target population), the measures are compared to address harmonization and/or selection of the best measure.

5. Relation to Other NQF-endorsed Measures

Are there related measures (conceptually, either same measure focus or target population) or competing measures (conceptually both the same measure focus and same target population)? If yes, list the NQF # and title of all related and/or competing measures.

Yes

5.1a. **List of related or competing measures (selected from NQF-endorsed measures)**

0066 : Coronary Artery Disease (CAD): Angiotensin-Converting Enzyme (ACE) Inhibitor or Angiotensin Receptor Blocker (ARB) Therapy - Diabetes or Left Ventricular Systolic Dysfunction (LVEF < 40%)
0070 : Coronary Artery Disease (CAD): Beta-Blocker Therapy-Prior Myocardial Infarction (MI) or Left Ventricular Systolic Dysfunction (LVEF <40%)
0071 : Persistence of Beta-Blocker Treatment After a Heart Attack
0081 : Heart Failure (HF): Angiotensin-Converting Enzyme (ACE) Inhibitor or Angiotensin Receptor Blocker (ARB) Therapy for Left Ventricular Systolic Dysfunction (LVSD)
0083 : Heart Failure (HF): Beta-Blocker Therapy for Left Ventricular Systolic Dysfunction (LVSD)
0117 : Beta Blockade at Discharge
0236 : Coronary Artery Bypass Graft (CABG): Preoperative Beta-Blocker in Patients with Isolated CABG Surgery
0594 : Post MI: ACE inhibitor or ARB therapy

5.1b. **If related or competing measures are not NQF endorsed please indicate measure title and steward.**

Note also 0696: STS composite score. section 5.1a. has noted this has been de-endorsed, but after re-confirming with the NQF Quality Positioning System, believe this measure is still endorsed.

5a. Harmonization

The measure specifications are harmonized with related measures;

OR

The differences in specifications are justified

5a.1. **If this measure conceptually addresses EITHER the same measure focus OR the same target population as NQF-endorsed measure(s):**
Are the measure specifications completely harmonized?
No

5a.2. **If the measure specifications are not completely harmonized, identify the differences, rationale, and impact on interpretability and data collection burden.**
We believe the aforementioned measures are not in direct competition with measure 0965. In all cases the measure focuses on the same process, but different target population. Surgical (CABG): 0117, 0236, 0696 HF: 0083, 0081 CAD and outpatient focused: 0070, 0066 AMI: 0071 AMI, hypertension, heart failure, and diabetes: 0594 While ACC's ICD Registry does capture patient history, risk factors, and other ailments, the focus of the Registry surrounds the clinical conditions of the implantation of an ICD, dual chamber, or CRT-D device. Secondly, the Registry does not capture hypertension as an element.

5b. Competing Measures

The measure is superior to competing measures (e.g., is a more valid or efficient way to measure);
OR
Multiple measures are justified.

5b.1. **If this measure conceptually addresses both the same measure focus and the same target population as NQF-endorsed measure(s):**
Describe why this measure is superior to competing measures (e.g., a more valid or efficient way to measure quality); OR provide a rationale for the additive value of endorsing an additional measure. (Provide analyses when possible.)

Appendix

A.1 Supplemental materials may be provided in an appendix. All supplemental materials (such as data collection instrument or methodology reports) should be organized in one file with a table of contents or bookmarks. If material pertains to a specific submission form number, that should be indicated. Requested information should be provided in the submission form and required attachments. There is no guarantee that supplemental materials will be reviewed.

Additional Information

Ad.1 **Workgroup/Expert Panel involved in measure development**

Provide a list of sponsoring organizations and workgroup/panel members' names and organizations. Describe the members' role in measure development.

For this particular topic those individuals who were involved in identifying the key attributes and variables for this process measure were leaders and experts in the field of electrophysiology. Serial phone calls were held to both define the eligible population and given process. These clinical leaders are noted below.

NCDR Clinical Subworkgroup ensured the measure demonstrated an opportunity for improvement, had strong clinical evidence, and was a reliable and valid measure. These members included Drs. Jeptha Curtis (Chair), Frederick Masoudi, John Rumsfeld, Matt Reynolds, and Mark Kremers.

NCDR Scientific Quality and Oversight Committee—a committee that served as the primary resource for crosscutting scientific and quality of care methodological issues. These members included Drs. Frederick Masoudi (Chair) , David Malenka, Thomas Tsai, Matthew Reynolds, David Shahian, John Windle, Fred Resnic, John Moore, Deepak Bhatt, James Tcheng, Jeptha Curtis, Paul Chan, Matthew Roe, and John Rumsfeld.

Measure Developer/Steward Updates and Ongoing Maintenance

Ad.2 **Year the measure was first released:** 2011

Ad.3 **Month and Year of most recent revision:** 02, 2015

Ad.4 **What is your frequency for review/update of this measure?** With dataset revisions and based on new evidence.

Ad.5 **When is the next scheduled review/update for this measure?** 2016

Ad.7 **Disclaimers:** ACC realizes the various NCDR endorsed measures are not readily available on their own main webpage. However, ACCF plans to update their main webpage (acc.org) to include the macrospecifications of the NQF endorsed measures. ACC hopes to work collaboratively with NQF to create a consistent and standard format would be helpful for various end users. In the interim, the supplemental materials include the details needed to understand this model. In addition, interested parties are always able to contact comment@acc.org to reach individuals at the ACC Quality Measurement Team.

Ad.8 **Additional Information/Comments:** ACC appreciates the opportunity to submit measures for this NQF endorsement maintenance project.

MEASURE WORKSHEET

This document summarizes the evaluation of the measure as it progresses through NQF's Consensus Development Process (CDP). The information submitted by measure developers/stewards is included after the Brief Measure Information, Preliminary Analysis, and Pre-meeting Public and Member Comments sections.

Brief Measure Information

NQF #: 2396
De.2. **Measure Title:** Carotid artery stenting: Evaluation of Vital Status and NIH Stroke Scale at Follow Up
Co.1.1. **Measure Steward:** American College of Cardiology
De.3. **Brief Description of Measure:** Proportion of patients with carotid artery stenting procedures who had follow up performed for evaluation of Vital Status and neurological assessment with an NIH Stroke Scale (by an examiner who is certified by the American Stroke Association) Occurring between day 21 and the end of day 60 after the procedure. (Days 21-60 inclusive)
1b.1. **Developer Rationale:** This measure is important to determine the number of patients that are being followed after a carotid artery stent procedure. Specifically vital status and if a NIHSS were completed at follow-up.

S.4. **Numerator Statement:** Patient Status (alive or Deceased) at follow-up AND Neurologic status with an assessment using the NIH Stroke Scale (by an examiner who is certified by the American Stroke Association) AND Discharge Status (alive or Deceased)
S.7. **Denominator Statement:** Count of CARE Registry patients that had a carotid artery stenting procedure
S.10. **Denominator Exclusions:** Patients with a discharge status of deceased
Patients with was an acute, evolving stroke and dissection during the episode of care

De.1. **Measure Type:** Process
S.23. **Data Source:** Electronic Clinical Data : Registry
S.26. **Level of Analysis:** Facility, Population : National

IF Endorsement Maintenance – Original Endorsement Date: Most Recent Endorsement Date:

Preliminary Analysis

The preliminary analysis was developed in response to recommendations from NQF's Consensus Task Force and measurement stakeholders as a way to enhance and streamline the measures evaluation and voting processes. The preliminary analysis will help to guide the Standing Committee evaluation of each measure by summarizing the measure developer submission, guide measure evaluation discussion, and identify topic areas for additional input. **NQF staff would like to stress that the preliminary analysis is intended to be used as a guide to facilitate the Committee's discussion and evaluation.**

Criteria 1: Importance to Measure and Report

1a. Evidence

1a. Evidence. The evidence requirements for a *process* measure is that it is based on a systematic review (SR) and grading of the body of empirical evidence where the specific focus of the evidence matches what is being measured.

The developer provides the following evidence for this process measure:

- This is facility- and population-level measure calculates the proportion of patients with carotid artery stenting (CAS) procedures who had follow up performed for evaluation of Vital Status and neurological assessment with an NIH Stroke Scale (NIHSS) between 21 and 60 days inclusive after the procedure by an examiner who is certified by the American Stroke Association.
- The evidence finds higher recurrent stenosis after carotid artery stenting than carotid endartectomy requiring stroke symptom assessment with a reliable and standardized tool, NIHSS. They also state mortality and stroke are common within 2 years post-CAS, and more common immediately following CAS. The developer provides a

consensus recommendation – categorized as a guideline in the submission – with 7 articles for attaining facility & operator procedure competence (no grading is assigned). This document recommends post-procedural follow-up and monitoring using standardized tools and definitions, with a neurologic assessment performed by a qualified and NIH Stroke Scale-certified individual for all patients undergoing carotid stenting. The developer also provides a clinical guideline (Class IIa) that recommends *noninvasive imaging* 1 month, 6 months, and annually after carotid revascularization. Grading is based on the 2010 Methodology Manual and Policies From the ACCF/AHA Task Force on Practice Guideline. Thirty-day post-CAS neurological raassessment with NIHSS certified examiner is recommended.

- The developer provides the Quantity/Quality/Consistency for the imaging clinical guideline, and they also include a 2013 article outlining comprehensive stroke center quality metrics, though this measure does not appear in the article.
- A process to outcomes logic diagram states reassessment 30-days after CAS with NIHSS assists in determining the disability caused by the stroke and guides patient-specific treatment planning. The evidence states disability reassessment with NIHSS should 30 days post-CAS, while the specifications state "between 21 and 60 days" inclusive.

Questions for the Committee:

- *For process measures:*
  - *Is the evidence directly applicable to the process of care being measured?*
  - *Is the process of care proximal and closely related to desired outcomes?*
- *For possible exception to the evidence criteria:*
  - *Are there, or could there be, performance measures of a related health outcome, OR evidence-based intermediate clinical outcomes, intervention/treatment?*
  - *Is there evidence of a systematic assessment of expert opinion beyond those involved in developing the measure?*
  - *Does the SC agree that it is acceptable (or beneficial) to hold providers accountable without empiric evidence?*

1b. Gap in Care/Opportunity for Improvement and 1b. Disparities

1b. Performance Gap. The performance gap requirements include demonstrating quality problems and opportunity for improvement.

- The developer provides the following performance table of NCDR CARE Registry from 2007Q1 through 2013 Q1 demonstrating gaps in care:

	Total	Both Vital and NIHSS at F/U		
	n = 18212	1 n = 7220	0 n = 10992	P-Value
Followup Measures				
Has_vital	12883 (70.74%)	7220 (100.00%)	5663 (51.52%)	< 0.001
has_nihss	7220 (39.64%)	7220 (100.00%)	0 (0.00%)	< 0.001

- It is not clear if the "has nihss" includes patients who were deceased at the time of the follow-up (21 to 60 days inclusive post-CAS).
- The developer also provides post-CAS morbidity and mortality data, as well as stroke and stroke mortality data.
- Disparities data is also provided by age, sex, and race, as well as multiple clinical findings (e.g., comorbidities, testing and medications). The developer also provides data on hospital type and rural/suburban hospital characteristics. Insurance status & type are captured on the measure data collection tool.

Questions for the Committee:

- *Is there a gap in care that warrants a national performance measure?*
- *If no disparities information is provided, are you aware of evidence that disparities exist in this area of healthcare?*
- *Should this measure be indicated as disparities sensitive?*

1c. Priority

1c. High Priority (previously "High Impact") requires measures to address national health goal/priority or a demonstrated high-impact aspect of care.

- *Beginning in 2015, priority is no longer an NQF measure evaluation criterion.*

Committee pre-evaluation comments

Criteria 1: Importance to Measure and Report (including 1a, 1b, 1c)

1. ***Committee's Overview Comments***:
   - The developer provides a consensus recommendation – categorized as a guideline – with 7 articles for attaining facility and operator procedure competence (no grading is assigned). It appears to be in the category of expert opinion Level of evident: C primary source of recommendation was consensus opinion, case studies or standard of care
   - The measure looks at the important point of evaluating Vital status and NIHSS stroke evaluation post carotid artery stenting.
   - The cited evidence does not appear to support the measure focus.

1a. ***Committee's Comments on Evidence to Support Measure Focus:***
   - Clinical Practice Guideline Recommendation Monitoring 1a of outcomes with independent post-procedural neurological assessment using standardized instruments and definitions is critically important to ensure high-quality intervention and patient safety. Institutions offering carotid stent placement must have a quality assurance program specifically designed to assess the results of carotid interventions in their locale. The integrity and accuracy of outcome reporting is reliant on the incorporation of mandatory independent and objective neurologic assessment by a qualified and NIH Stroke
   - Facility and population level measure looking at CAS patients who had a Vital status evaluation and NIHSS evalution at 21-60 days.
     - The restenosis rate after CAS as compared to CEA doesn't necessarily correlate with stroke rate.
     - Some of the articles presented for support the measure are dated.
   - The evidence cites a higher rate of recurrent carotid artery stenosis >70% after carotid stenting than endarterectomy during a 2-year follow-up period. This is not directly applicable to this process measure, which assesses rates of 21-to-60-day follow-up with a neurological assessment (standardized NIHSS stroke scale) performed by an examiner certified by the American Stroke Association (ASA) and ascertainment of mortality status.
   - The process of care does not seem proximal, nor closely related to desired outcomes (lower rates of recurrent stenosis and stroke).
   - I am not aware of any logical basis for possible exception to the evidence criterion, with respect to performance measures of a related health outcome or evidence-based intermediate clinical outcomes, intervention, or treatment. The developers cite general support from the ASA and Society of Vascular and Interventional Neurology for quality of care metrics for comprehensive stroke centers as relevant expert opinion.
   - I consider it to be generally unacceptable to hold providers accountable for measure performance without empirical evidence of benefit from improving performance on the measure.

1b. ***Committee's Comments on Performance Gap:***
   - Overall considerable variation or less than optimal performance in the quality of care and disparities in care across population groups.
   - The performance gap would be that all patients undergoing CAS have Vital and NIHSS evaluation. The perfomance table provided is not clear and does not delineate if deceased patients were included in followup.
   - The developers cite performance rates of 0-100%, which would appear to warrant a national performance measure, if other measure criteria were met.
   - I did not see in the application and am not aware of evidence for significant disparities in care.
   - I do not think it should be indicated as disparities sensitive.

1c. ***Committee's Comments on Composite Performance Measure:***
   - Not Applicable
   - Not clearly stated.
   - The numerator elements of this measure (vitality status and neurological assessment) are logically constructed performance measures, with a reasonably well articulated rationale. However this does not appear to be a true

composite measure, since the only element within clinician control in the timeframe is the neurological assessment.

Criteria 2: Scientific Acceptability of Measure Properties

2a. Reliability

2a1. Reliability Specifications

2a1. Specifications requires the measure, as specified, to produce consistent (reliable) and credible (valid) results about the quality of care when implemented.

- This is a hospital/acute care facility level measure that requires documentation of a completed NIHSS assessment between 21 and 60 days inclusive post-CAS procedure by an American Stroke Association certified examiner.
- The developer is encouraged to clarify the denominator population as patients age is not provided in the specifications, though the narrative in section 3c.1 states adult patients, 18 years and older.
- The denominator exclusions include patients with a discharge status of deceased, and patients with an acute, evolving stroke and dissection during the episode of care. It is not clear if the episode of care is at any time during the hospitalization when the CAS was performed, or at any time after the CAS was performed.
- The developer should clarify if documentation of deceased vital status prior to the 21 to 60 days inclusive follow-up is considered as a performed quality action (equals a performance pass).
- The evidence and collection tool provided states the NIHSS should be conducted by someone other than the operator for the current procedure, and by an American Stroke Association certified examiner. It is not clear how these characteristics are assessed.
- The data collection tool appears to allows patient reasons (e.g., patient refusal, patient unavailable and other) for no follow-up, which does not appear in the specifications.
- A brief calculation algorithm is provided.

Questions for the Committee:

- *Are all the data elements clearly defined? Are all appropriate clinical concepts included?*
- *Is the logic or calculation algorithm clear?*
- *Is it likely this measure can be consistently implemented?*

2a2. Reliability Testing Testing attachment

2a2. Reliability testing demonstrates if the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise enough to distinguish differences in performance across providers.

- The developer provides 2 types of reliability testing including the signal-to-noise facility-level testing of the measure score for facilities who completed neurological function testing, and a test-retest methodology to test data element reliability of patient characteristics only.
  The signal-to-noise analysis, which is appropriate for this type of measure, differentiates the true difference between measured entities (the signal) to random measurement error (the noise). A value of 0 indicates that all variation is due to measurement error and a value of 1 indicates that all variation is due to real differences in between hospital performance. A value of 0.7 is often regarded as a minimum acceptable reliability value. The table demonstrates very high reliability and is provided based on CAS procedural volumes, with reliability increasing in higher volumes.

Level	Signal-to-Noise
All, >10 Procedures	.984
>Q1 (>55 Procedures)	.986

>Q2 (>91 Procedures)	.989
>Q3 (>161 Procedures)	.993
>Average (>131 Procedures)	.992

- The developers also used a test-retest of assess the accuracy of the data collection methodology and applicable patient characteristic data elements entered into the CARE registry including age, gender, race, smoking, history of PAD, diabetes, chronic lung disease & dyslipidemia. To construct the test/retest, developers identified 449 patient during the testing period with 2 procedures in facilities completing >30 procedures to produce more reliable estimates of the data elements. Data elements included in this testing that are not applicable to measure calculation, are used to testing accuracy and reproducibility of data collection.
- Data element definitions and differences are provided for each data element. Age, gender and race did not vary between the test/retest populations, and smoking, history of PAD, diabetes, chronic lung disease & dyslipidemia variation were < 2.7%.
- Patients with missing data were not included in either of the tests.

Questions for the Committee:

- *Does limiting testing to > 30 procedures per facility impact the measure reliability?*
- *Is the test sample adequate to generalize for widespread implementation?*
- *Do the results demonstrate sufficient reliability so that differences in performance can be identified?*

2b. Validity

2b1. Validity: Specifications

2b1. Validity Specifications. This section should determine if the measure specifications are consistent with the evidence.

- The measure specifications allow for follow-up and NIHSS reassessment between 21-60 days inclusive, and the evidence states 30 days.
- NIHSS completed by a certified examiner who is not the CAS operator is not included in the measure.

Question for the Committee:

- *Are the specifications consistent with the evidence?*

2b2. Validity testing

2b2. Validity Testing should demonstrate the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality.

- The developer provided content validity stating numerous studies assess the comparative effectiveness of stenting vs. surgery for carotid occlusion on the outcomes of myocardial infarction, death and stroke.
- The developer provided face validity by expert cardiologist panel who actively perform CAS and carotid endartectomy procedures including leading experts in the field and vetted the measure with 3 committees and the 16 member NCDR Management Board and 31 member ACCF Board of Trustees prior to NQF submission.
- No formal statistical validity tests were provided.

Questions for the Committee:

- *Do the face and content validity provided demonstrate the measure has sufficient validity so that conclusions about quality can be made?*
- *Do you agree that the score from this measure as specified is an indicator of quality?*

2b3-2b7. Threats to Validity

2b3. Exclusions:

- The exclusions include patients deceased at discharge and patients with an acute, evolving stroke and

dissection.

- The developer does not provide statistical testing methods and results from excluding patients with an acute stroke. Instead the developer provides a table that shows the differences in clinical characteristics of those with an acute evolving stroke as compared with those treated for stable carotid disease.

Questions for the Committee:

- *Are the exclusions consistent with the evidence?*
- *Are any patients or patient groups inappropriately excluded from the measure?*
- *Are the exclusions/exceptions of sufficient frequency and variation across providers to be needed (and outweigh the data collection burden)?*

2b4. Risk adjustment:

- This measure is not risk adjusted.

2b5. Meaningful difference:

- The developer notes an association between procedural volume and follow up rates; higher volume centers perform substantially greater than poor performing centers. The developer also states that performance rates range from 0% to 100% therefore it is feasible for hospitals to assess all of their patients and NQF endorsement of this measure would increase hospitals' commitment.

Question for the Committee:

- *Does this measure identify meaningful differences about quality?*

2b6. Comparability of data sources/methods:

- This is not applicable as there is only one data source/specification for this measure.

2b7. Missing Data

- The developer describes the NCDR Data Quality Report that assesses for data completeness (missing data), and consistency and accuracy (integrity), scoring provided data with 3 "light" levels: Red lights (submission failure for integrity and completeness check – data not processed), yellow lights (passed for integrity and fails completeness – requires data resubmission), and green lights (passed all quality checks and included for aggregate computations). No sampling of NCDR patient data is allowed as registry inclusion mandates 100% consecutive patients.

Committee pre-evaluation comments

Criteria 2: Scientific Acceptability of Measure Properties (including all 2a, 2b, and 2d)

2a1. &2b1.: ***Committee's Comments on Reliability-Specifications:***

- Measure is well defined and specified. Should produce consistent, reliable results about quality of care. Reliability testing for the elements assessed appeared consistent and accurate in the Care Registery.
- Data elements are not clearly defined.
- The measure data elements lack clarity for the denominator (age, method of ascertaining ASA examiner certification and non-procedure-operator status of the conductor of the NIHSS tool, and credit status for documentation of death prior to 21 days are missing).
- The algorithm is clear, but seems oversimplified.
- It seems unlikely that the measure can be consistently implemented.

2a2.: ***Committee's Comments on Reliability-Testing:***

- Big variation s in collection of 30 day outcomes in hospitals from 0 to 100%.
- The patients included did test with an overall .992 reliability on a sigal to noise analysis. However, patients with missing data were not included in the testing.
- Limiting testing to facilities performing >30 procedures probably inflates the measure reliability.
- I am unsure whether the test sample of 449 patients is sufficient for widespread implementation.
- The results appear to be sufficiently reliable to identify differences in performance.

2b1.: ***Committee's Comments on Validity-Specifications***:

- Measure was shared with a noted panel of expert cardiologists wh participate regularly in carotid artery stenting

procedures. All members of the committee reported that the measures appear to be a good indication of positive outcome in CAS procedures.
- Specifications are not consistent with the evidence.
- The specifications seem inconsistent with the evidence for the non-CAS operator being the certified examiner. I think the 21-60 day timeframe is a reasonable window around the 30-day expert opinion point. (The evidence actually comes from a 2-year timeframe for inferior stenting restenosis outcome.)

2b2.: ***Committee's Comments on Validity-Testing:***
- There was content validity from prior studies and expert consensus bit no statistical validity was provided.
- The face and content validity arguments are based on expert opinion only and do not appear to support validity of the measure as a quality indicator.

2b3-7.: ***Committee's Comments on Threats to Validity:***
- The exclusions are significant and patients or patient groups may be excluded form the the measure.
- The measure is not risk adjusted
- The exclusions make sense, but there is no analysis of the effects of the exclusions. It is unclear whether the exclusions/exceptions are frequent enough and/or vary enough across providers to be needed and worth the data collection burden.
- It is unclear whether this measure identifies meaningful differences in quality of post-CAS care.
- This measure is not risk adjusted.
- The measure would appear to address meaningful differences in quality, based on their reporting a performance range of 0-100%.
- Ironically, I found no data on the potential effect of missing data.
- This was not presented as a composite measure.

2d.: ***Committee's Comments on Composite Performance Measure:***
- Not Applicable

Criterion 3. Feasibility

3. Feasibility is the extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

- The data source used to collect and calculate measure performance is the NCDR Care Registry. The developer states that ALL data elements are in defined fields in electronic clinical data, and may be collected via third-party vendors. The specifications are available in the public domain.
- Though it is not apparent, it is assumed the post-discharge data is captured by the facility reporting the measure.
- The developer provides the data collection strategy including costs and fees noting for calendar year 2014 the annual pricing for hospitals, NCDR Analytic and Reporting Services, and licensing of measure specifications ranges from $2900-$50,000.

Questions for the Committee:
- *Are the required data elements routinely generated and used during care delivery?*
- *Are the required data elements available in electronic form, e.g., EHR or other electronic sources?*
- *Is the data collection strategy ready to be put into operational use?*

Committee pre-evaluation comments
Criteria 3: Feasibility

3.: ***Committee's Comments on Feasibility:***
- By Product of care
- The data can be obtained from the NCDR CARE registry. In using the registry for projects in the past, there is a likelihood that not all the data was captures.
- It is unclear whether the ASA examiner certification status of the conductor of the NIHSS tool is routinely generated and used during care delivery. The developers did not specify how this data entry and verification of

this key element would be handled.
- Most, but probably not all required data elements are available in electronic form.
- It appears to be dubious whether the data collection strategy is fully ready to be put into operational use.

Criterion 4: Usability and Use

4. Usability and Use evaluate the extent to which audiences (e.g., consumers, purchasers, providers, policymakers) use or could use performance results for both accountability and performance improvement activities.

- It is unclear if the measure is currently or planned for use with ACC's CARE Registry of the National Cardiovascular Data Registry (NCDR).
- The measure is not currently publicly reported but the developers state that the plan is for this measure to be publicly reported in the future. The developer provides a plan for future use/ implementation and are applying to be a CMS Qualified Entity to allow developers access to CMS reporting. Further clarification is needed.
- The measure may be used for quality improvement purposes.
- The developer states there are no unintended consequence identified for the measure.

***Questions for the Committee**:*
- *Is the measure publicly reported?*
- *How can the performance results be used to further the goal of high-quality, efficient healthcare?*
- *Do the benefits of the measure outweigh any potential unintended consequences?*

Committee pre-evaluation comments

Criteria 4: Usability and Use

4.: ***Committee's Comments on Usability and Use:***
- Public Reporting is planned. Current use is quality improvement.
- Not currently publicly reported, but plans for being a CMS Qualified entity in the future to allow for reporting is possible. The actual utilizaiton of this measure should be further clarified.
- The measure is not currently publicly reported, and it is unclear whether it will be used by the NCDR.
- The developers say that the ACC is committed to implementing this measure, but they also say that CMS data cannot be used for performance measure reporting to hospitals or the public.
- It is unclear how the performance results would be used to further the goal of high quality efficient healthcare.
- The benefits of the measure are unclear.
- The developers identified no unintended consequences, and I can think of none, but since unintended consequences are often unanticipated, that does not say much.

Criterion 5: Related and Competing Measures

- The developer provided no related or competing measures.

Pre-meeting public and member comments

-

NATIONAL QUALITY FORUM—Evidence (subcriterion 1a)

Measure Title Carotid artery stenting: Evaluation of Vital Status and NIH Stroke Scale at Follow Up

IF the measure is a component in a composite performance measure, provide the title of the Composite Measure here: Click here to enter composite measure title

Date of Submission: 12/18/ 2013

Instructions

- *For composite performance measures:*
  - *A separate evidence form is required for each component measure unless several components were studied together.*
  - *If a component measure is submitted as an individual performance measure, attach the evidence form to the individual measure submission.*
- Respond to all questions as instructed with answers immediately following the question. All information needed to demonstrate meeting the evidence subcriterion (1a) must be in this form. An appendix of *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 10 pages (*incudes questions/instructions*; minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the evidence for this measure meets NQF's evaluation criteria.

Subcriterion 1a. Evidence to Support the Measure Focus

The measure focus is a health outcome or is evidence-based, demonstrated as follows:

- Health outcome:[3] a rationale supports the relationship of the health outcome to processes or structures of care.
- Intermediate clinical outcome, Process,[4] or Structure: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence[5] that the measure focus leads to a desired health outcome.
- Patient experience with care: evidence that the measured aspects of care are those valued by patients and for which the patient is the best and/or only source of information OR that patient experience with care is correlated with desired outcomes.
- Efficiency:[6] evidence for the quality component as noted above.

Notes

3. Generally, rare event outcomes do not provide adequate information for improvement or discrimination; however, serious reportable events that are compared to zero are appropriate outcomes for public reporting and quality improvement.
4. Clinical care processes typically include multiple steps: assess → identify problem/potential problem → choose/plan intervention (with patient input) → provide intervention → evaluate impact on health status. If the measure focus is one step in such a multistep process, the step with the strongest evidence for the link to the desired outcome should be selected as the focus of measurement.
5. The preferred systems for grading the evidence are the U.S. Preventive Services Task Force (USPSTF) grading definitions and methods, or Grading of Recommendations, Assessment, Development and Evaluation (GRADE) guidelines.
6. Measures of efficiency combine the concepts of resource use and quality (NQF's Measurement Framework: Evaluating Efficiency Across Episodes of Care; AQA Principles of Efficiency Measures).

1a.1.This is a measure of:

Outcome

☐ Health outcome: Click here to name the health outcome

Health outcome includes patient-reported outcomes (PRO, i.e., HRQoL/functional status, symptom/burden, experience with care, health-related behaviors)

☐ Intermediate clinical outcome: Click here to name the intermediate outcome

☒ Process: 30 Day Follow-up Assessment of Stroke/Death after Carotid Artery Stent Revascularization

☐ Structure: Click here to name the structure

☐ Other: Click here to name what is being measured

HEALTH OUTCOME PERFORMANCE MEASURE *If not a health outcome, skip to 1a.3*

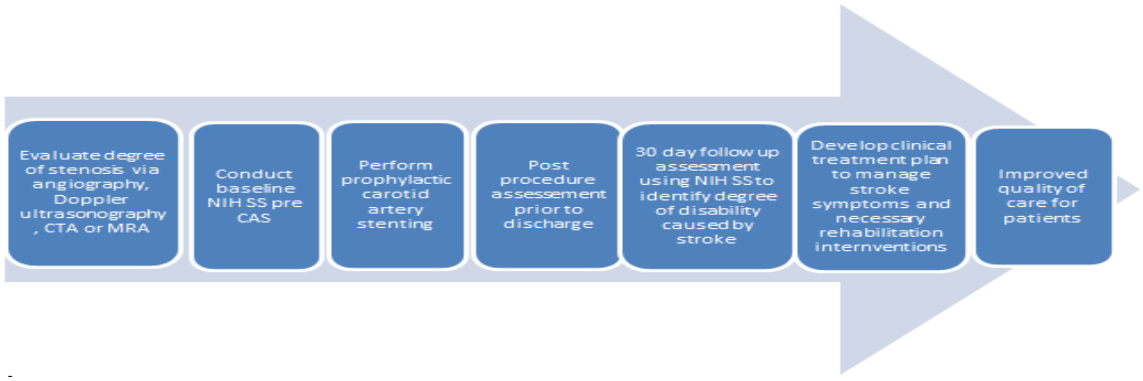
1a.2. Briefly state or diagram the linkage between the health outcome (or PRO) and the healthcare structures, processes, interventions, or services that influence it.

1a.2.1. State the rationale supporting the relationship between the health outcome (or PRO) and at least one healthcare structure, process, intervention, or service.

Note: For health outcome performance measures, no further information is required; however, you may provide evidence for any of the structures, processes, interventions, or service identified above.

INTERMEDIATE OUTCOME, PROCESS, OR STRUCTURE PERFORMANCE MEASURE

1a.3. Briefly state or diagram the linkages between structure, process, intermediate outcome, and health outcomes. Include all the steps between the measure focus and the health outcome.



1a.3.1. What is the source of the systematic review of the body of evidence that supports the performance measure?

☒ Clinical Practice Guideline recommendation – ***complete sections 1a.4, and 1a.7***

☐ US Preventive Services Task Force Recommendation – ***complete sections 1a.5 and 1a.7***

☐ Other systematic review and grading of the body of evidence (*e.g., Cochrane Collaboration, AHRQ Evidence Practice Center*) – ***complete sections 1a.6 and 1a.7***

☒ Other – ***complete section 1a.8***

Please complete the sections indicated above for the source of evidence. You may skip the sections that do not apply.

1a.4. CLINICAL PRACTICE GUIDELINE RECOMMENDATION

1a.4.1. Guideline citation (including date) and **URL for guideline** (if available online):

#2) Brott TG, Halperin JL, Abbara S, et al. 2011 ASA/ACCF/AHA/AANN/AANS/ACR/ASNR/CNS/SAIP/SCAI/SIR/SNIS/SVM/SVS Guideline on the Management of Patients With Extracranial Carotid and Vertebral Artery Disease: A Report of the American College of Cardiology Foundation/American Heart Association Task Force on Practice Guidelines, and the American Stroke Association, American Association of Neuroscience Nurses, American Association of Neurological Surgeons, American College of Radiology, American Society of Neuroradiology, Congress of Neurological Surgeons, Society of Atherosclerosis Imaging and Prevention, Society for Cardiovascular Angiography and Interventions, Society of Interventional Radiology, Society of NeuroInterventional Surgery, Society for Vascular Medicine, and Society for Vascular Surgery Developed in Collaboration With the American Academy of Neurology and Society of Cardiovascular Computed Tomography. J Am Coll Cardiol. 2011;57(8):e16-e94.URL for guideline: http://content.onlinejacc.org/article.aspx?articleid=1144187

1a.4.2. Identify guideline recommendation number and/or page number and **quote verbatim, the specific guideline recommendation**.

#1) Page 9 of 10 “Monitoring of outcomes with independent post-procedural neurological assessment using standardized instruments and definitions is critically important to ensure high-quality intervention and patient safety. Institutions offering carotid stent placement must have a quality assurance program specifically designed to assess the results of carotid interventions in their locale. The integrity and accuracy of outcome reporting is reliant on the incorporation of mandatory independent and objective neurologic assessment by a qualified and NIH Stroke Scale-certified individual for all patients undergoing carotid stenting”.

#2) Page 40 of 79, e55 “Noninvasive imaging of the extracranial carotid arteries is reasonable 1 month, 6 months, and annually after revascularization to assess patency and exclude the development of new or contralateral lesions. Once stability has been established over an extended period, surveillance at extended intervals may be appropriate. Termination of surveillance is reasonable when the patient is no longer a candidate for intervention”.

1a.4.3. Grade assigned to the quoted recommendation with definition of the grade:

#1) No grade assigned

#2) Class IIa,(Definition of Class IIa: Weight of evidence/opinion is in favor of usefulness/ efficacy. IT IS REASONABLE to perform procedure/administer treatment.

1a.4.4. Provide all other grades and associated definitions for recommendations in the grading system.
(*Note: If separate grades for the strength of the evidence, report them in section 1a.7.*)

#1) No grades in Competence Statement

#2) See table below.

ESTIMATE OF CERTAINTY (PRECISION) OF TREATMENT EFFECT	CLASS I *Benefit >>> Risk* Procedure/Treatment **SHOULD** be performed/ administered	CLASS IIa *Benefit >> Risk* *Additional studies with focused objectives needed* **IT IS REASONABLE** to perform procedure/administer treatment	CLASS IIb *Benefit ≥ Risk* *Additional studies with broad objectives needed; additional registry data would be helpful* Procedure/Treatment **MAY BE CONSIDERED**	CLASS III *No Benefit* or CLASS III *Harm* Procedure/ Test / Treatment COR III: No benefit / Not Helpful / No Proven Benefit COR III: Harm / Excess Cost w/o Benefit or Harmful / Harmful to Patients
LEVEL A Multiple populations evaluated* Data derived from multiple randomized clinical trials or meta-analyses	■ Recommendation that procedure or treatment is useful/effective ■ Sufficient evidence from multiple randomized trials or meta-analyses	■ Recommendation in favor of treatment or procedure being useful/effective ■ Some conflicting evidence from multiple randomized trials or meta-analyses	■ Recommendation's usefulness/efficacy less well established ■ Greater conflicting evidence from multiple randomized trials or meta-analyses	■ Recommendation that procedure or treatment is not useful/effective and may be harmful ■ Sufficient evidence from multiple randomized trials or meta-analyses
LEVEL B Limited populations evaluated* Data derived from a single randomized trial or nonrandomized studies	■ Recommendation that procedure or treatment is useful/effective ■ Evidence from single randomized trial or nonrandomized studies	■ Recommendation in favor of treatment or procedure being useful/effective ■ Some conflicting evidence from single randomized trial or nonrandomized studies	■ Recommendation's usefulness/efficacy less well established ■ Greater conflicting evidence from single randomized trial or nonrandomized studies	■ Recommendation that procedure or treatment is not useful/effective and may be harmful ■ Evidence from single randomized trial or nonrandomized studies
LEVEL C Very limited populations evaluated* Only consensus opinion of experts, case studies, or standard of care	■ Recommendation that procedure or treatment is useful/effective ■ Only expert opinion, case studies, or standard of care	■ Recommendation in favor of treatment or procedure being useful/effective ■ Only diverging expert opinion, case studies, or standard of care	■ Recommendation's usefulness/efficacy less well established ■ Only diverging expert opinion, case studies, or standard of care	■ Recommendation that procedure or treatment is not useful/effective and may be harmful ■ Only expert opinion, case studies, or standard of care
Suggested phrases for writing recommendations	should is recommended is indicated is useful/effective/beneficial	is reasonable can be useful/effective/beneficial is probably recommended or indicated	may/might be considered may/might be reasonable usefulness/effectiveness is unknown/unclear/uncertain or not well established	COR III: No Benefit is not recommended is not indicated should not be performed/ administered/ other is not useful/ beneficial/ effective
Comparative effectiveness phrases†	treatment/strategy A is recommended/indicated in preference to treatment B treatment A should be chosen over treatment B	treatment/strategy A is probably recommended/indicated in preference to treatment B it is reasonable to choose treatment A over treatment B		COR III: Harm potentially harmful causes harm associated with excess morbidity/mortality should not be performed/ administered/ other

1a.7. FINDINGS FROM SYSTEMATIC REVIEW OF BODY OF THE EVIDENCE SUPPORTING THE MEASURE

1a.7.1. What was the specific structure, treatment, intervention, service, or intermediate outcome addressed in the evidence review?

The evidence review focused on the importance of 30 day follow up assessment for this patient population to determine morbidity in terms of incidence and prevalence of stroke and mortality that may be associated with carotid artery revascularization via stenting.

1a.7.2. Grade assigned for the quality of the quoted evidence with definition of the grade:

Level of Evidence: C (Definition of Evidence Level C: primary source of the recommendation was consensus opinion, case studies, or standard of care).

1a.7.3. Provide all other grades and associated definitions for strength of the evidence in the grading system.

Guideline #2) listed in section 1.a. 4.2

Evidence Level A: data were derived from multiple randomized clinical trials or meta-analyses.

Evidence Level B: data were derived from a single randomized trial or nonrandomized studies.

1a.7.4. What is the time period covered by the body of evidence? (*provide the date range, e.g., 1990-2010*).
Date range: 2001 - 2006

QUANTITY AND QUALITY OF BODY OF EVIDENCE

1a.7.5. How many and what type of study designs are included in the body of evidence? (*e.g., 3 randomized controlled trials and 1 observational study*)

One multinational, prospective, randomised study of 1,214 patients.

1a.7.6. What is the overall quality of evidence across studies in the body of evidence? (*discuss the certainty or confidence in the estimates of effect particularly in relation to study factors such as design flaws, imprecision due to small numbers, indirectness of studies to the measure focus or target population*)

Certainty or confidence in the estimates (verbatim from Eckstein et al.,cited below)

In both the intention-to-treat and per-protocol analyses the Kaplan-Meier estimates of ipsilateral ischaemic strokes up to 2 years after the procedure and any periprocedural stroke or death do not differ between the carotid artery stenting and the carotid endarterectomy groups (intention to treat 9.5%vs 8.8%; hazard ratio (HR) 1.10, 95%CI 0.75 to 1.61; log-rank p=0.62; per protocol 9.4%vs 7.8%; HR 1.23, 95%CI 0.82 to 1.83; log-rank p=0.31).

In both the intention-to-treat and per-protocol populations, recurrent stenosis of 70% or more is significantly more frequent in the carotid artery stenting group compared with the carotid endarterectomy group, with a life-table estimate of 10.7% versus 4.6% (p=0.0009) and 11.1% versus 4.6% (p=0.0007), respectively.

Eckstein H.H., Ringleb P., Allenberg J.R.; Results of the Stent-Protected Angioplasty versus Carotid Endarterectomy (SPACE) study to treat symptomatic stenoses at 2 years: a multinational, prospective, randomised trial. *Lancet Neurol*. 7 2008:893-902.

Indirectness of studies to the measure focus

The guidelines cited in 1a.4.1. stress the importance of follow up to be conducted upon this patient population. While indirectly implied, it can be considered a natural aspect of this follow up process to determine the mortality status of a patient for this follow up visit. In addition to mortality status, this measure requires the NIH Stroke Scale to be performed during the follow up visit. This can also be an implied aspect of the follow up exam assessing for morbidity.

ESTIMATES OF BENEFIT AND CONSISTENCY ACROSS STUDIES IN BODY OF EVIDENCE

1a.7.7. What are the estimates of benefit—magnitude and direction of effect on outcome(s) across studies in the body of evidence? (*e.g., ranges of percentages or odds ratios for improvement/ decline across studies, results of meta-analysis, and statistical significance*)

Only two incidences of recurrent stenoses after carotid artery stenting led to neurological symptom. After 2 years' follow-up, the rate of recurrent ipsilateral ischaemic strokes reported in the SPACE trial is similar for both treatment groups

1a.7.8. What harms were studied and how do they affect the net benefit (benefits over harms)?

One outcome identified by this study is that the incidence of recurrent carotid stenosis at 2 years (identified by ultrasound), was significantly higher after carotid artery stenting then when a CEA was performed. This reinforces the importance of continued follow up on this patient population.

UPDATE TO THE SYSTEMATIC REVIEW(S) OF THE BODY OF EVIDENCE

1a.7.9. If new studies have been conducted since the systematic review of the body of evidence, provide for each new study: 1) citation, 2) description, 3) results, 4) impact on conclusions of systematic review.

1a.8 OTHER SOURCE OF EVIDENCE

If source of evidence is NOT from a clinical practice guideline, USPSTF, or systematic review, please describe the evidence on which you are basing the performance measure.

In a Statement for Healthcare Professionals From the American Heart Association/American Stroke Association and endorsed by the Society of Vascular and Interventional Neurology, several metrics were proposed intended to provide a framework for standardized data collection at comprehensive stroke centers (CSCs) to facilitate local quality improvement efforts and to allow for analysis of pooled data from different CSCs that may lead to development of national performance standards for CSCs in the future.

1a.8.1 What process was used to identify the evidence?

A literature search was performed of the medical database www.UpToDate.com and the American Heart Association/American Stroke Associate Stroke [http://stroke.ahajournals.org] webpage using keywords: "Carotid Artery Stenosis" and "Follow Up".

1a.8.2. Provide the citation and summary for each piece of evidence.

The following is quoted verbatim from the reference cited.

Reference: Leifer D, Bravata DM, Connors JJ 3rd, Hinchey JA, Jauch EC, Johnston SC, Latchaw R, Likosky W, Ogilvy C, Qureshi AI, Summers D, Sung GY, Williams LS, Zorowitz R; on behalf of the American Heart Association Special Writing Group of the Stroke Council, Atherosclerotic Peripheral Vascular Disease Working Group, Council on Cardiovascular Surgery and Anesthesia, and Council on Cardiovascular Nursing. Metrics for measuring quality of care in comprehensive stroke centers: detailed follow-up to Brain Attack Coalition comprehensive stroke center recommendations: a statement for healthcare professionals from the American Heart Association/American Stroke Association. Stroke. 2011;42: Retrieved from http://stroke.ahajournals.org/content/early/2011/01/13/STR.0b013e318208eb99.full.pdf+html on December 4, 2013

Metric 10

Percentage of patients undergoing carotid endarterectomy (CEA), or carotid angioplasty or stenting, with stroke or death within 30 days of the procedure.

Numerator: Number of patients who have a stroke or die within 30 days of CEA, or who have carotid angioplasty or stenting performed because of atherosclerotic disease.

Denominator: Total number of patients who undergo CEA or who undergo carotid angioplasty or stenting because of atherosclerotic disease.

The metric should be calculated for all procedures taken together and separately for the following groups of patients:

(1) symptomatic patients undergoing endarterectomy;

(2) symptomatic patients undergoing carotid angioplasty or stenting;

(3) asymptomatic patients undergoing endarterectomy; and

(4) asymptomatic patients undergoing carotid angioplasty or stenting.

Strokes should be included if they meet the clinical definition of a focal neurological deficit that persists for > or equal to 24 hours without other cause or if there is a focal deficit that lasts for a shorter period of time but is associated with an appropriately located acute ischemic lesion on MRI. Clinically silent acute lesions detected on diffusion-weighted MRI should not be included as complications, because they are likely to be common when MRI is performed, although their incidence and clinical significance are uncertain. Patients with confusion or encephalopathy who have multiple punctate lesions that together may explain their clinical findings should also be included as having had a stroke. Published clinical trials about complications after carotid procedures and other interventions have typically used clinical stroke as the end point and other ongoing trials also are using clinical end points. This definition of stroke will apply to this metric and subsequent ones.

This metric is limited to patients with atherosclerotic disease to ensure that the metric encompasses a uniform population of patients.

Justification: The AHA/ASA guidelines for patients with recent TIA or ischemic stroke within the past 6 months and ipsilateral severe (70% to 99%) carotid artery stenosis recommend endarterectomy by a surgeon with a perioperative morbidity and mortality rate of <6% ***(Class I; Level of Evidence A)***. For patients with recent TIA or ischemic stroke and ipsilateral moderate (50% to 69%) carotid stenosis, CEA is recommended, depending on patient-specific factors such as age, sex, comorbidities, and severity of initial symptoms if the perioperative morbidity and mortality risk is estimated to be <6% ***(Class I; Level of Evidence B)***.

Among patients with symptomatic severe stenosis (>70%) in whom either the stenosis is difficult to access surgically, medical conditions are present that greatly increase the risk for surgery, or other specific circumstances exist such as radiation-induced stenosis or restenosis after CEA, the use of carotid angioplasty and stent placement is not inferior to endarterectomy and may be considered ***(Class IIb; Level of Evidence B)***. The procedure is reasonable when performed by operators with established periprocedural morbidity and mortality rates of 4% to 6% ***(Class IIa; Level of Evidence B)***.

The role of carotid angioplasty/stenting in asymptomatic patients has not been established. The AHA/ASA "Guidelines for the Primary Prevention of Stroke" state, "The usefulness of CAS [carotid angioplasty/stenting] as an alternative to CEA in asymptomatic patients at high risk for the surgical procedure is uncertain ***(Class IIb;***

Level of Evidence C)." In this setting, if centers choose to perform carotid angioplasty/stenting on asymptomatic patients, the 30-day rate of stroke and death should be tracked separately for such patients and monitored carefully.

The recommended end point to be ascertained after carotid angioplasty and stent placement is any stroke or death within 30 days, to remain consistent with the data collected for CEA. This end point has been used in trials of carotid angioplasty and stenting. For comparable patients, the complication rate for stenting should be similar to that for endarterectomy if stenting is to be a reasonable option. In particular, the complication rate should be expected to be between 4% and 6% for symptomatic >70% stenosis. If carotid angioplasty and stenting are performed, therefore, careful attention must be paid to complication rates, so it is important for CSCs to monitor these rates.

The risk of stroke and death after carotid revascularization are important and can substantially influence the net benefit of the procedure. Assessment and reporting of the "outcome" of stroke for carotid revascularization procedures is not consistent in the absence of a clinical assessment using a standardized stroke scale, or by using claims data. A class IIa, LOE: C guideline advises noninvasive imaging of the extracranial carotid arteries be performed at 1 month, 6 months, and annually after revascularization to assess patency and exclude the development of new or contralateral lesions, it can be implied that patients will have a clinic/office follow-up visits as a follow-up to revascularization procedures. This office visit provides the opportunity for appropriate clinical assessment for key revascularization endpoints, including stroke or death. A process measure that uses a standard assessment of neurologic function, by an examiner who is certified by the American Stroke Association, is a measure that provides feedback on the ability to clearly and accurately assess for, capture and report the incidence of stroke after carotid revascularization procedures. The NIHSS is both reliable and valid, and has become a standard stroke impairment scale for use in both clinical trials and as part of clinical care in the United States [6].

When centers that perform carotid revascularization properly assess patients for adverse events (particularly for stroke) after carotid revascularization, they trigger further evaluation, if necessary. If the 30 day NIH stroke scale is (1) changed from baseline; or (2) abnormal in absence of a baseline, pre-procedure exam, then there should be some documentation on whether or not the abnormal stroke scale represents a new clinical neurological event, and should result in an evaluation by a neurologist.

According to the CARE Registry institutional outcomes reports, the median length of stay for CAS and CEA procedures is one day. This short hospital stay reflects difficulty in reporting "in-hospital" stroke outcomes as a relevant measure. Following carotid artery stenting, patients are typically discharged in one to two days. In a study that evaluated the timing of complications following CAS, 53% of postoperative events/complications occurred within 6 hours of CAS, 5.3% between 6 and 12 hours, 8% between 12 and 24 hours, and 34.2% >24 hours post procedure [1]. Late events >24 hours were access-site-related and neurologic events.

The primary endpoints of major contemporary trials used 30 day events (stroke, MI* or death) and included neurologic evaluation to identify stroke. Based on trial endpoints, 30 day outcomes have greater importance. Post-procedure stroke is one of the major adverse outcomes from carotid artery stenting and carotid endarterectomy. For example, this was the major outcome in the recent CREST trial, a randomized comparison of carotid artery stenting and surgical endarterectomy. A recent meta-analysis by Murad et al. summarized the results of 13 randomized controlled trials to assess the comparative effectiveness of stenting vs. surgery for carotid occlusion on the outcomes of myocardial infarction, death and stroke [13]. The latter of these

outcomes are proposed to serve as a process measure for quantifying the quality of carotid revascularization by this measure.

There is a sound clinical rationale for systematically measuring the outcomes of carotid revascularization. First, without knowing the outcomes, a hospital cannot know if it is applying its treatment in a safe and effective manner. Given how infrequently current providers assess the 30-day survival and stroke outcomes, it is obvious that more than half of these hospitals have no foundation with which to assess the quality of their care. We have proposed a process measure, merely assessing the stroke-free survival of treated patients, because without more clear ascertainment of outcomes it is not possible to provide risk-adjusted comparisons across centers and provide clear benchmarks of performance to identify hospitals that have the opportunity to improve. Second, as the country seeks to support the use of evidence-based medicine, the majority of the evidence in carotid disease comes from clinical trials. However, many of the trials establishing the benefits of carotid revascularization require that centers document a certain success rate, without complications of stroke or death, before the center can participate in a clinical trial. If a center does not know its rate, it will not know whether or not the benefits observed in a clinical trial apply to their practice. Finally, for patients to be adequately informed about the risks and benefits of treatment, hospitals need to have reliable data to share with their patients. By collecting, analyzing and reporting the outcomes of treatment, hospitals will be much better able to provide their patients the information that they need to make a treatment decision.

Stroke is the second leading cause of all hospital admissions among older patients and the leading reason for neurology-related admissions. From 1999 to 2009, the number of inpatient discharges from short stay hospitals with stroke as the first-listed diagnosis has remained stable with 961,000 discharges in 1999 and 971,000 discharges in 2009 (National Heart, Lung, and Blood Institute [NHLBI] tabulation, National Hospital Discharge Survey [NHDS], National Center for Health Statistics [NCHS]). Correspondingly, stroke death rates fell by 24% from 1994 to 2004. This decline suggests that there have been general improvements in the management of patients with acute stroke, decreases in the severity of stroke and/or improved detection or coding of milder stroke cases. Part of the decline in hospital stroke mortality may be due to the shorter length of stay resulting in more out of hospital death. The greatest risk of mortality for patients with stroke occurs in the first 30 days, with case-fatality rates ranging from 8% to 20% for ischemic stroke, with substantially higher rates for stroke due to subarachnoid or intracerebral hemorrhage (as high as 50%). The immediate cause of death in more than 60% of stroke cases is thought to be related to complications of the stroke itself. After the first week, cardiac causes, pneumonia, pulmonary embolism, sepsis, and other medical complications account for the majority of the stroke-related mortality. In 2008, approximately 46% of all stroke deaths occurred in the hospital (unpublished NHLBI tabulation of NCHS 2008 Mortality Data Set). The annual U.S. economic burden of stroke is estimated at $20.4 billion for direct and $53.6 billion indirect costs. [7]

1. Evidence, Performance Gap, Priority – Importance to Measure and Report

Extent to which the specific measure focus is evidence-based, important to making significant gains in healthcare quality, and improving health outcomes for a specific high-priority (high-impact) aspect of healthcare where there is variation in or overall less-than-optimal performance. ***Measures must be judged to meet all subcriteria to pass this criterion and be evaluated against the remaining criteria.***

1a. Evidence to Support the Measure Focus – See attached Evidence Submission Form
Evidence_Supplement_CARE_Registry_FollowUp_Stroke_Mortality_Assessment_20131218v2.docx

1b. Performance Gap

Demonstration of quality problems and opportunity for improvement, i.e., data demonstrating:

- considerable variation, or overall less-than-optimal performance, in the quality of care across providers; and/or
- disparities in care across population groups.

1b.1. **Briefly explain the rationale for this measure** *(e.g., the benefits or improvements in quality envisioned by use of this measure)*
This measure is important to determine the number of patients that are being follow-ed after a carotid artery stent procedure. Specifically vital status and if a NIHSS were completed at follow-up.

1b.2. **Provide performance scores on the measure as specified (current and over time) at the specified level of analysis.** *(This is required for endorsement maintenance. Include mean, std dev, min, max, interquartile range, scores by decile. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities included). This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*

1b.3. **If no or limited performance data on the measure as specified is reported in 1b2, then provide a summary of data from the literature that indicates opportunity for improvement or overall less than optimal performance on the specific focus of measurement.**

1b.4. **Provide disparities data from the measure as specified (current and over time) by population group, e.g., by race/ethnicity, gender, age, insurance status, socioeconomic status, and/or disability.** *(This is required for endorsement maintenance. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities include.) This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*

1b.5. **If no or limited data on disparities from the measure as specified is reported in 1b4, then provide a summary of data from the literature that addresses disparities in care on the specific focus of measurement. Include citations.**
Many patients after a carotid artery stenting procedure are lost to follow-up.

1c. High Priority (previously referred to as High Impact)

The measure addresses:

- a specific national health goal/priority identified by DHHS or the National Priorities Partnership convened by NQF; OR
- a demonstrated high-priority (high-impact) aspect of healthcare (e.g., affects large numbers of patients and/or has a substantial impact for a smaller population; leading cause of morbidity/mortality; high resource use (current and/or future); severity of illness; and severity of patient/societal consequences of poor quality).

1c.1. **Demonstrated high priority aspect of healthcare**
Frequently performed procedure, Patient/societal consequences of poor quality
1c.2. **If Other:**

1c.3. **Provide epidemiologic or resource use data that demonstrates the measure addresses a high priority aspect of healthcare. List citations in 1c.4.**

1c.4. **Citations for data demonstrating high priority provided in 1a.3**

1c.5. **If a PRO-PM (e.g. HRQoL/functional status, symptom/burden, experience with care, health-related behaviors), provide evidence that the target population values the measured PRO and finds it meaningful.** *(Describe how and from whom their input was obtained.)*
This is not a PRO-PM.

2. Reliability and Validity—Scientific Acceptability of Measure Properties

Extent to which the measure, as specified, produces consistent (reliable) and credible (valid) results about the quality of care when implemented. ***Measures must be judged to meet the subcriteria for both reliability and validity to pass this criterion and be evaluated against the remaining criteria.***

2a.1. Specifications The measure is well defined and precisely specified so it can be implemented consistently within and across organizations and allows for comparability. eMeasures should be specified in the Health Quality Measures Format (HQMF) and the Quality Data Model (QDM).

De.5. **Subject/Topic Area** *(check all the areas that apply):*
Cardiovascular, Cardiovascular : Ischemic Heart Disease, Coronary Artery Disease, Neurology : Stroke/Transient Ischemic Attack (TIA)

De.6. **Cross Cutting Areas** *(check all the areas that apply):*
Prevention : Screening

S.1. **Measure-specific Web Page** *(Provide a URL link to a web page specific for this measure that contains current detailed specifications including code lists, risk model details, and supplemental materials. Do not enter a URL linking to a home page or to general information.)*

S.2a. **If this is an eMeasure**, HQMF specifications must be attached. Attach the zipped output from the eMeasure authoring tool (MAT) - if the MAT was not used, contact staff. (Use the specification fields in this online form for the plain-language description of the specifications)
This is not an eMeasure **Attachment:**

S.2b. **Data Dictionary, Code Table, or Value Sets** *(and risk model codes and coefficients when applicable) must be attached. (Excel or csv file in the suggested format preferred - if not, contact staff)*
No data dictionary **Attachment:**

S.3. **For endorsement maintenance**, please briefly describe any changes to the measure specifications since last endorsement date and explain the reasons.
Measure not previously endorsed

S.4. **Numerator Statement** *(Brief, narrative description of the measure focus or what is being measured about the target population, i.e., cases from the target population with the target process, condition, event, or outcome)*
IF an OUTCOME MEASURE, state the outcome being measured. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
Neurologic status with an assessment using the NIH Stroke Scale (by an examiner who is certified by the American Stroke Association) AND Discharge Status (alive or Deceased)

S.5. **Time Period for Data** *(What is the time period in which data will be aggregated for the measure, e.g., 12 mo, 3 years, look back to August for flu vaccination? Note if there are different time periods for the numerator and denominator.)*
1 year for numerator and denomiator

S.6. **Numerator Details** *(All information required to identify and calculate the cases from the target population with the target process, condition, event, or outcome such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
IF an OUTCOME MEASURE, describe how the observed outcome is identified/counted. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
Field Name: Patient Follow-up Performed Seq No: 9000
Definition: Indicate whether patient follow-up was performed for the procedure. The recommended timeframe for follow-up is 30 days. Occurring between day 21 and the end of day 60 after the procedure. (Days 21-60 inclusive)

1=Yes

Field Name: Follow-Up Date Seq No: 9002
Definition: Indicate the date of follow-up. The recommended timeframe for follow-up is 30 days. Occurring between day 21 and the end of day 60 after the procedure. (Days 21-60 inclusive)

Field Name: Follow Up NIH Stroke Scale Administered Seq No: 9010
Definition: Indicate if the National Institutes of Health Stroke Scale (NIHSS) was administered during follow-up.

1=Yes

Follow-up NIH Stroke Scale Examiner Certified Seq No: 9014
Definition: Indicate the date the National Institutes of Health Stroke Scale (NIHSS) was administered during the follow-up period.
Note - Recommended timeframe to administer NIHSS is within 30 days after the current procedure.
Definition: Indicate if the NIH Stroke Scale examiner who administered the follow-up stroke scale is certified to administer the stroke scale exam. The Stroke Scale assessment should be conducted by someone other than the operator for the current procedure.

1=Yes

Field Name: Follow-up NIH Stroke Scale Examiner Certified Seq No: 9014
Definition: Indicate the date the National Institutes of Health Stroke Scale (NIHSS) was administered during the follow-up period.
Note - Recommended timeframe to administer NIHSS is within 30 days Occurring between day 21 and the end of day 60 after the procedure. (Days 21-60 inclusive)after the current procedure.

Examiner certified= yes
Supporting definitions:
The Stroke Scale assessment should be conducted by someone other than the operator for the current procedure.
Note - NIHSS examiners may become certified through the American Stroke Association.
NIH Stroke Scale Certification is currently available online free of charge: http://learn.heart.org/ihtml/application/student /interface.heart2/nihss.html

Field Name: Patient Status Seq No: 9100
Definition: Indicate if the patient is alive or deceased.

Alive (1) or deceased (2)

S.7. Denominator Statement *(Brief, narrative description of the target population being measured)*
Count of CARE Registry patients that had a carotid artery stenting procedure

S.8. Target Population Category *(Check all the populations for which the measure is specified and tested if any):*
Populations at Risk

S.9. Denominator Details *(All information required to identify and calculate the target population/denominator such as definitions, specific data collection items/responses , code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
Patients undergoing a carotid artery stent procedure

S.10. Denominator Exclusions *(Brief narrative description of exclusions from the target population)*
Patients deceased at discharge
Patients with was an acute, evolving stroke and dissection

S.11. Denominator Exclusion Details *(All information required to identify and calculate exclusions from the denominator such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
Field Name: Discharge Status Seq No: 8010
Definition: Indicate whether the patient was alive or deceased at discharge from the hospitalization during which the procedure occurred.
Alive=2

Field Name: Spontaneous Carotid Artery Dissection Seq No: 5060
Definition: Indicate if the patient has had a spontaneous carotid artery dissection prior to the current procedure.

1=Yes

Field Name: Acute Evolving Stroke Seq No: 4340
Definition: Indicate if the patient has experienced an acute evolving stroke with ischemia which is ongoing and progressing at the time of the procedure. Acute evolving stroke includes all of the following:
1. Any sudden development of neurological deficits attributable to cerebral ischemia and/or infarction.
2. Onset of symptoms occurring within prior three days and ongoing at time of procedure.
3. The event is marked by progressively worsening symptoms.
Note: Possible symptoms include, but are not limited to the following: numbness or weakness of the face or body; difficulty speaking or understanding; blurred or decreased vision; dizziness; or loss of balance and coordination.

1=Yes

S.12. Stratification Details/Variables *(All information required to stratify the measure results including the stratification variables, definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format with at S.2b)*
The measure is not stratified.

S.13. Risk Adjustment Type (Select type. Provide specifications for risk stratification in S.12 and for statistical model in S.14-15)
No risk adjustment or risk stratification
If other:

S.14. Identify the statistical risk model method and variables *(Name the statistical method - e.g., logistic regression and list all the risk factor variables. Note - risk model development and testing should be addressed with measure testing under Scientific Acceptability)*
No risk adjustment.

S.15. Detailed risk model specifications *(must be in attached data dictionary/code list Excel or csv file. Also indicate if available at measure-specific URL identified in S.1.)*
Note: Risk model details (including coefficients, equations, codes with descriptors, definitions), should be provided on a separate worksheet in the suggested format in the Excel or csv file with data dictionary/code lists at S.2b.

S.15a. Detailed risk model specifications (*if not provided in excel or csv file at S.2b*)

S.16. Type of score:
Rate/proportion

If other:

S.17. Interpretation of Score *(Classifies interpretation of score according to whether better quality is associated with a higher score, a lower score, a score falling within a defined interval, or a passing score)*
Better quality = Higher score

S.18. Calculation Algorithm/Measure Logic *(Describe the calculation of the measure score as an ordered sequence of steps including identifying the target population; exclusions; cases meeting the target process, condition, event, or outcome; aggregating data; risk adjustment; etc.)*

Patient Follow-up is performed and the Follow-up NIH Stroke Scale is administered

The Procedure date of the CAS procedure and the Follow-up Date are equal to or greater than 21 days and less than or equal to 60 days and the follow-up status is deceased or the NIH Stroke Scale is captured.

All patient undergoing a carotid artery stenting, excluding those with an in hospital spontaneous dissection, an acute evolving stroke or discharge status of deceased.

S.19. **Calculation Algorithm/Measure Logic Diagram URL or Attachment** *(You also may provide a diagram of the Calculation Algorithm/Measure Logic described above at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
No diagram provided

S.20. **Sampling** *(If measure is based on a sample, provide instructions for obtaining the sample and guidance on minimum sample size.)*
IF a PRO-PM, identify whether (and how) proxy responses are allowed.

S.21. **Survey/Patient-reported data** *(If measure is based on a survey, provide instructions for conducting the survey and guidance on minimum response rate.)*
IF a PRO-PM, specify calculation of response rates to be reported with performance measure results.
Not a PRO=PM measure.

S.22. **Missing data** (specify how missing data are handled, e.g., imputation, delete case.)
Required for Composites and PRO-PMs.

S.23. **Data Source** *(Check ONLY the sources for which the measure is SPECIFIED AND TESTED).*
If other, please describe in S.24.
Electronic Clinical Data : Registry

S.24. **Data Source or Collection Instrument** *(Identify the specific data source/data collection instrument e.g. name of database, clinical registry, collection instrument, etc.)*
IF a PRO-PM, identify the specific PROM(s); and standard methods, modes, and languages of administration.
NCDR Care Registry

S.25. **Data Source or Collection Instrument** *(available at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
Available at measure-specific web page URL identified in S.1

S.26. **Level of Analysis** *(Check ONLY the levels of analysis for which the measure is SPECIFIED AND TESTED)*
Facility, Population : National

S.27. **Care Setting** *(Check ONLY the settings for which the measure is SPECIFIED AND TESTED)*
Hospital/Acute Care Facility
If other:

S.28. **COMPOSITE Performance Measure** - Additional Specifications *(Use this section as needed for aggregation and weighting rules, or calculation of individual performance measures if not individually endorsed.)*
Not a composite performance measure

2a. Reliability – See attached Measure Testing Submission Form
2b. Validity – See attached Measure Testing Submission Form
ACC_NCDR_CARE_Followup_Assessment_Testing_Supplement_101713v2.docx

NATIONAL QUALITY FORUM—Measure Testing (subcriteria 2a2, 2b2-2b6)

Measure Title: Carotid artery stenting: Evaluation of Vital Status and NIH Stroke Scale at Follow Up
Date of Submission: Click here to enter a date
Type of Measure: Process

☐ Composite – ***STOP – use composite testing form***	☐ Outcome (*including PRO-PM*)
☐ Cost/resource	☒ Process
☐ Efficiency	☐ Structure

Instructions

- Measures must be tested for all the data sources and levels of analyses that are specified. ***If there is more than one set of data specifications or more than one level of analysis, contact NQF staff*** about how to present all the testing information in one form.
- **For all measures, sections 1, 2a2, 2b2, 2b3, and 2b5 must be completed.**
- **For outcome and resource use measures**, section **2b4** also must be completed.
- If specified for **multiple data sources/sets of specificaitons** (e.g., claims and EHRs), section **2b6** also must be completed.
- Respond to all questions as instructed with answers immediately following the question. All information on testing to demonstrate meeting the subcriteria for reliability (2a2) and validity (2b2-2b6) must be in this form. An appendix for *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 20 pages (*incuding questions/instructions;* minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the testing results for this measure meet NQF's evaluation criteria for testing.

2a2. Reliability testing [10] demonstrates the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise.

2b2. Validity testing [11] demonstrates that the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality.

2b3. Exclusions are supported by the clinical evidence; otherwise, they are supported by evidence of sufficient frequency of occurrence so that results are distorted without the exclusion; [12]

AND

If patient preference (e.g., informed decision making) is a basis for exclusion, there must be evidence that the exclusion impacts performance on the measure; in such cases, the measure must be specified so that the information about patient preference and the effect on the measure is transparent (e.g., numerator category computed separately, denominator exclusion category computed separately). [13]

2b4. For outcome measures and other measures when indicated (e.g., resource use):

- **an evidence-based risk-adjustment strategy** (e.g., risk models, risk stratification) is specified; is based on patient factors that influence the measured outcome (but not factors related to disparities in care or the quality of care) and are present

at start of care; [14,15] and has demonstrated adequate discrimination and calibration

OR

- rationale/data support no risk adjustment/ stratification.

2b5. Data analysis of computed measure scores demonstrates that methods for scoring and analysis of the specified measure allow for **identification of statistically significant and practically/clinically meaningful [16] differences in performance**;

OR

there is evidence of overall less-than-optimal performance.

2b6. If multiple data sources/methods are specified, there is demonstration they produce comparable results.

Notes

10. Reliability testing applies to both the data elements and computed measure score. Examples of reliability testing for data elements include, but are not limited to: inter-rater/abstractor or intra-rater/abstractor studies; internal consistency for multi-item scales; test-retest for survey items. Reliability testing of the measure score addresses precision of measurement (e.g., signal-to-noise).

11. Validity testing applies to both the data elements and computed measure score. Validity testing of data elements typically analyzes agreement with another authoritative source of the same information. Examples of validity testing of the measure score include, but are not limited to: testing hypotheses that the measures scores indicate quality of care, e.g., measure scores are different for groups known to have differences in quality assessed by another valid quality measure or method; correlation of measure scores with another valid indicator of quality for the specific topic; or relationship to conceptually related measures (e.g., scores on process measures to scores on outcome measures). Face validity of the measure score as a quality indicator may be adequate if accomplished through a systematic and transparent process, by identified experts, and explicitly addresses whether performance scores resulting from the measure as specified can be used to distinguish good from poor quality.

12. Examples of evidence that an exclusion distorts measure results include, but are not limited to: frequency of occurrence, variability of exclusions across providers, and sensitivity analyses with and without the exclusion.

13. Patient preference is not a clinical exception to eligibility and can be influenced by provider interventions.

14. Risk factors that influence outcomes should not be specified as exclusions.

15. Risk models should not obscure disparities in care for populations by including factors that are associated with differences/inequalities in care, such as race, socioeconomic status, or gender (e.g., poorer treatment outcomes of African American men with prostate cancer or inequalities in treatment for CVD risk factors between men and women). It is preferable to stratify measures by race and socioeconomic status rather than to adjust out the differences.

16. With large enough sample sizes, small differences that are statistically significant may or may not be practically or clinically meaningful. The substantive question may be, for example, whether a statistically significant difference of one percentage point in the percentage of patients who received smoking cessation counseling (e.g., 74 percent v. 75 percent) is clinically meaningful; or whether a statistically significant difference of $25 in cost for an episode of care (e.g., $5,000 v. $5,025) is practically meaningful. Measures with overall less-than-optimal performance may not demonstrate much variability across providers.

1. DATA/SAMPLE USED FOR ALL TESTING OF THIS MEASURE

Often the same data are used for all aspects of measure testing. In an effort to eliminate duplication, the first five questions apply to all measure testing. If there are differences by aspect of testing,(e.g., reliability vs. validity) be sure to indicate the specific differences in question 1.7.

1.1. What type of data was used for testing? (*Check all the sources of data identified in the measure specifications and data used for testing the measure. Testing must be provided for all the sources of data specified and intended for measure implementation.* ***If different data sources are used for the numerator and denominator, indicate N [numerator] or D [denominator] after the checkbox.***)

Measure Specified to Use Data From: (***must be consistent with data sources entered in S.23***)	**Measure Tested with Data From:**
☐ abstracted from paper record	☐ abstracted from paper record
☐ administrative claims	☐ administrative claims
☒ clinical database/registry	☒ clinical database/registry
☐ abstracted from electronic health record	☐ abstracted from electronic health record
☐ eMeasure (HQMF) implemented in EHRs	☐ eMeasure (HQMF) implemented in EHRs
☐ other: Click here to describe	☐ other: Click here to describe

1.2. If an existing dataset was used, identify the specific dataset (*the dataset used for testing must be consistent with the measure specifications for target population and healthcare entities being measured; e.g., Medicare Part A claims, Medicaid claims, other commercial insurance, nursing home MDS, home health OASIS, clinical registry*).

We propose to use a clinical registry, the National Cardiovascular Data Registry CARE Registry. This is a national quality improvement registry that is currently participated in by >180 US hospitals. Rigorous quality standards are applied to the data and both quarterly and ad hoc performance reports are generated for participating centers to track and improve their performance.

1.3. What are the dates of the data used in testing? Calendar Year2007Q1-2013Q1

1.4. What levels of analysis were tested? (*testing must be provided for all the levels specified and intended for measure implementation, e.g., individual clinician, hospital, health plan*)

Measure Specified to Measure Performance of: (***must be consistent with levels entered in item S.26***)	**Measure Tested at Level of:**
☐ individual clinician	☐ individual clinician
☐ group/practice	☐ group/practice
☒ hospital/facility/agency	☒ hospital/facility/agency
☐ health plan	☐ health plan
☐ other: Click here to describe	☐ other: Click here to describe

1.5. How many and which <u>measured entities</u> were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of measured entities included in the analysis (e.g., size, location, type); if a sample was used, describe how entities were selected for inclusion in the sample*)

A cohort of the NCDR CARE Registry (2007Q1 and 2013 Q1) was used to establish the prevalence of neurological function testing. We restricted our analyses to those hospitals that performed 30 or more carotid revascularization procedures to improve the precision of our estimates. To examine the test-restest validity of the measured data elements, we expanded the time window of CARE from 2007-2013 to identify patients with 2 or more procedures.

1.6. How many and which <u>patients</u> were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of patients included in the analysis (e.g., age, sex, race, diagnosis); if a sample was used, describe how patients were selected for inclusion in the sample*)

We included a total of 18,212 patients. The process measure we assessed was vital status and the presences of an NIH Stroke Scale (NIHSS) assessment at 30 days after their procedure. The only exclusion for this measure would be patients who are acutely having a stroke at the time of treatment, as it is not feasible to distinguish whether or not 30-day neurological outcomes were due to the presenting stroke, or treatment. The characteristics of the patients, stratified by collection of their outcomes data, is provided below:

	Total	Both Vital and NIHSS at F/U		
	n = 18212	1 n = 7220	0 n = 10992	P-Value

1.7. If there are differences in the data or sample used for different aspects of testing (e.g., reliability, validity, exclusions, risk adjustment), identify how the data or sample are different for each aspect of testing reported below.

We used 2012 data to assess the prevalence of complete follow-up. We used all available data from 3007-2013 to assess the test-retest reliability of the data elements used to describe patient characteristics. We also restricted this test-retest cohort to those hospitals that performed >30 procedures over this time period so as to provide more reliable estimates of the reproducibility of these data elements.

2a2. RELIABILITY TESTING

***Note**: If accuracy/correctness (validity) of data elements was empirically tested, separate reliability testing of data elements is not required – in 2a2.1 check critical data elements; in 2a2.2 enter "see section 2b2 for validity testing of data elements"; and skip 2a2.3 and 2a2.4.*

2a2.1. What level of reliability testing was conducted? (*may be one or both levels*)

☐ **Critical data elements used in the measure** (*e.g., inter-abstractor reliability; data element reliability must address ALL critical data elements*)

☒ **Performance measure score** (e.g., *signal-to-noise analysis*)

Level	Signal-to-Noise
All, >10 Procedures	.984
>Q1 (>55 Procedures)	.986
>Q2 (>91 Procedures)	.989
>Q3 (>161 Procedures)	.993
>Average (>131 Procedures)	.992

2a2.2. For each level checked above, describe the method of reliability testing and what it tests (*describe the steps—do not just name a method; what type of error does it test; what statistical analysis was used*)

2a2.3. For each level checked above, what were the statistical results from reliability testing? (e.*g., percent agreement and kappa for the critical data elements; distribution of reliability statistics from a signal-to-noise*

analysis)

We compared, among centers reporting greater than 30 cases (n=XX) between 2007-2013, the accuracy of data elements entered into the CARE registry. This approach enabled us to examine 2 independent abstractions of data for the same patient. For certain characteristics that would not change (e.g. gender), we would expect near perfect reproducibility. For other characteristics (e.g. diabetes) we would expect that any patient diagnosed with diabetes on the first visit should also have diabetes recorded on the second visit. It is, however, clinically plausible that someone could be diagnosed with diabetes between their first and second visit, so the emergence of diabetes on the second visit is not necessarily an 'error' and no interpretation is made for these scenarios.

There were 449 patients in the CARE registry that had 2 procedures between 2007-2013. Important data elements, support the overall validity of the registry, are provided below:

Age, as defined by date of birth, did not differ in any of the cases.

Gender did not vary in any of the patient records.

Race did not vary in any of the records.

Smoking had minimal inconsistencies. There were 3 patients (0.67%) who were categorized as current smokers on their 1st procedure and never smokers on their 2nd procedure. There were 9 patients (2.0%) listed as former smokers on their 1st visit and never smokers on their 2nd procedure.

History of Peripheral Artery Disease was noted in 11 patients (2.4%) at the time of their 1st procedure, but not at the time of their 2nd.

Diabetes was noted in 6 patients (1.3%) at the time of their 1st procedure, but not at the time of their 2nd.

Chronic Lung Disease was noted in 7 patients (1.6%) at the time of their 1st procedure, but not at the time of their 2nd.

Dyslipidemia was noted in 12 patients (2.7%) at the time of their 1st procedure, but not at the time of their 2nd.

2a2.4 What is your interpretation of the results in terms of demonstrating reliability? (i.*e., what do the results mean and what are the norms for the test conducted?*)

For the elements that we were able to assess, we believe that the results reported in the NCDR CARE record are consistent and accurate. There was not an independent audit performed for the CARE registry, but we observed <3% 'mistakes' in 1 of the records for patients who had 2 procedures reported in the CARE Registry.

2b2. VALIDITY TESTING

2b2.1. What level of validity testing was conducted? (*may be one or both levels*)

☐ **Critical data elements** (*data element validity must address ALL critical data elements*)

☐ **Performance measure score**

- ☐ **Empirical validity testing**
- ☐ **Systematic assessment of face validity of <u>performance measure score</u> as an indicator** of quality or

resource use (*i.e., is an accurate reflection of performance on quality or resource use and can distinguish good from poor performance*)

2b2.2. For each level checked above, describe the method of validity testing and what it tests (*describe the steps—do not just name a method; what was tested, e.g., accuracy of data elements compared to authoritative source, relationship to another measure as expected; what statistical analysis was used)*

Content validity of this outcome – post-procedure stroke is one of the major adverse outcomes from carotid artery stenting and carotid endarterectomy. For example, this was the major outcome in the recent CREST trial, a randomized comparison of carotid artery stenting and surgical endarterectomy. A recent meta-analysis by Bangalore and colleagues (Arch Nerol 201; 68:172-84) summarized the results of 13 randomized controlled trials to assess the comparative effectiveness of stenting vs. surgery for carotid occlusion on the outcomes of myocardial infarction, death and stroke. The latter 2 of these outcomes are proposed to serve as a process measure for quantifying the quality of carotid revascularization by this measure.

There is a very sound clinical rationale for systematically measuring the outcomes of carotid revascularization. First, without knowing the outcomes, a hospital cannot know if it is applying its treatment in a safe and effective manner. Given how infrequently current providers assess the 30-day survival and stroke outcomes, it is obvious that more than half of these hospitals have no foundation with which to assess the quality of their care. We have proposed a process measure, merely assessing the stroke-free survival of treated patients, because without clearer ascertainment of outcomes it is not possible to provide risk-adjusted comparisons across centers and provide clear benchmarks of performance to identify hospitals that have the opportunity to improve. Second, as the country seeks to support the use of evidence-based medicine, the majority of the evidence in carotid disease comes from clinical trials. However, many of the trials establishing the benefits of carotid revascularization require that centers document a certain success rate, without complications of stroke or death, before the center can participate in a clinical trial. If a center does not know its rate, it will not know whether or not the benefits observed in a clinical trial apply to their practice. Finally, for patients to be adequately informed about the risks and benefits of treatment, hospitals need to have reliable data to share with their patients. By collecting, analyzing and reporting the outcomes of treatment, hospitals will be much better able to provide their patients the information that they need to make a treatment decision.

Face Validity of this outcome- As expressed in the application, this measure was shared with a noted panel of expert cardiologist who participate regularly in carotid artery stenting procedures. All members of the committee reported that the measures appears to be a good indication of a positive outcome in carotid artery stenting procedures.

In developing this measure, the ACC consulted with leading experts in the field and vetted the process measure with the following committees. The individuals within specific committees and workgroups are noted below:

NCDR Strategic Quality and Oversight Committee— an ACC leadership oversight committee that serves as the primary resource for crosscutting scientific and quality of care methodological issues – ensured the data dictionaries and metrics are consistent across registries. They also reviewed and approved the methodology and results of the bleeding outcome and model.
These members include Dr. Frederick Masoudi (chair) , Dr. David Malenka, Dr. Thomas Tsai, Dr. Matthew Reynolds,Dr. David Shahian, Dr. John Windle, Dr. Fred Resnic, Dr. John Moore, Dr. Deepak Bhatt, Dr. James Tcheng, Dr. Jeptha Curtis, Dr. Paul Chan, Dr. Matt Roe, and Dr. John Rumsfeld

NCDR Clinical SubWorkgroup is a designated set of experts that oversees this NQF application. Prior to submission, it ensures there is variation in care, disparities data, and that the measure is a true reflection of quality care at a particular site and can also be used to improve quality. This committee included Dr. Jeptha Curtis (chair), Dr. Frederick Masoudi, Dr. John Rumsfeld, Dr. Christopher White, and Dr. Thomas Tsai.

NCDR CARE/PVI Transition Committee provides strategic direction for the Registry and ensures the measures submitted to NQF met key criterion such as reliability, feasibility, and that there is compelling evidence base behind the development and implementation of this measure, which included Christopher White (Chair), Kalon Ho, Ken Rosenfield, Bobby Yeh, Michael Jaff, Thomas Tsai, P. Michael Grossman, Herbert Aronow, H. Vernon Anderson

Lastly the 16 member NCDR Management Board and 31member ACCF Board of Trustees approved these measures for submission to NQF.

2b2.3. What were the statistical results from validity testing? (*e.g., correlation; t-test*)

As this measure is being proposed primarily on the basis of its content validity, as described above, there are no empiric results from formal validity testing.

2b2.4. What is your interpretation of the results in terms of demonstrating validity? (i.*e., what do the results mean and what are the norms for the test conducted?*)

As described above, we believe that acquiring the short-term outcomes of carotid revascularization is a critical foundation for assessing and improving care. The CARE registry provides the infrastructure to enter and analyze these data, if collected. An approved performance measure will increase the acquisition of these data and enable quality to be assessed and improved.

_____

2b3. EXCLUSIONS ANALYSIS

NA ☐ no exclusions — *skip to section 2b4*

2b3.1. Describe the method of testing exclusions and what it tests (*describe the steps—do not just name a method; what was tested, e.g., whether exclusions affect overall performance scores; what statistical analysis was used*)

The only proposed exclusion is for patients being treated in the context of an acute evolving stroke. This is a distinct clinical setting from the treatment of stable carotid disease. Moreover, the neurological results are likely to be strongly influenced by the presenting stroke, more so than the revascularization procedure that they receive.

2b3.2. What were the statistical results from testing exclusions? (*include overall number and percentage of individuals excluded, frequency distribution of exclusions across measured entities, and impact on performance measure scores*)

The Table below shows the differences in clinical characteristics of those with an acute evolving stroke as compared with those treated for stable carotid disease:

ex	Frequency	Percent	Cumulative Frequency	Cumulative Percent
0	16616	91.24	16616	91.24
AES	491	2.70	17107	93.93
Spont Dis	182	1.00	17289	94.93
Hosp <30 procs	923	5.07	18212	100.00

2b3.3. What is your interpretation of the results in terms of demonstrating that exclusions are needed to prevent unfair distortion of performance results? (*i.e., the value outweighs the burden of increased data collection and analysis. Note: **If patient preference is an exclusion**, the measure must be specified so that the effect on the performance score is transparent, e.g., scores with and without exclusion*)

Given the 2 very distinct populations, we believe that a measure of the survival and neurological outcomes at 30 days is an internally consistent, clinically-interpretable measure that does not suffer from excluding those with an acute ischemic stroke.

2b4. RISK ADJUSTMENT/STRATIFICATION FOR OUTCOME OR RESOURCE USE MEASURES

If not an intermediate or health outcome, or PRO-PM, or resource use measure, skip to section 2b5.

2b4.1. What method of controlling for differences in case mix is used?

☒ **No risk adjustment or stratification**

☐ **Statistical risk model with** Click here to enter number of factors **risk factors**

☐ **Stratification by** Click here to enter number of categories **risk categories**

☐ **Other,** Click here to enter description

2b4.2. If an outcome or resource use measure is not risk adjusted or stratified, provide rationale and analyses to demonstrate that controlling for differences in patient characteristics (case mix) is not needed to achieve fair comparisons across measured entities.

Not applicable.

2b4.3. Describe the conceptual/clinical and statistical methods and criteria used to select patient factors used in the statistical risk model or for stratification by risk (*e.g., potential factors identified in the literature and/or expert panel; regression analysis; statistical significance of p<0.10; correlation of x or higher; patient factors should be present at the start of care and not related to disparities*)

Not applicable.

2b4.4. What were the statistical results of the analyses used to select risk factors?

Not applicable.

2b4.5. Describe the method of testing/analysis used to develop and validate the adequacy of the statistical model or stratification approach (*describe the steps—do not just name a method; what statistical analysis was used*)

Not applicable.

Provide the statistical results from testing the approach to controlling for differences in patient characteristics (case mix) below.
if stratified, skip to 2b4.9

Not applicable.

2b4.6. Statistical Risk Model Discrimination Statistics (*e.g., c-statistic, R-squared*)**:**

Not applicable.

2b4.7. Statistical Risk Model Calibration Statistics (*e.g., Hosmer-Lemeshow statistic*):

Not applicable.

2b4.8. Statistical Risk Model Calibration – Risk decile plots or calibration curves:

Not applicable.

2b4.9. Results of Risk Stratification Analysis:

Not applicable.

2b4.10. What is your interpretation of the results in terms of demonstrating adequacy of controlling for differences in patient characteristics (case mix)? (i*.e., what do the results mean and what are the norms for the test conducted*)

Not applicable.

***2b4.11. Optional Additional Testing for Risk Adjustment** (*not required, but would provide additional support of adequacy of risk model, e.g., testing of risk model in another data set; sensitivity analysis for missing data; other methods*)

Not applicable.

2b5. IDENTIFICATION OF STATISTICALLY SIGNIFICANT & MEANINGFUL DIFFERENCES IN PERFORMANCE
2b5.1. Describe the method for determining if statistically significant and clinically/practically meaningful differences in performance measure scores among the measured entities can be identified (*describe the steps—do not just name a method; what statistical analysis was used? Do not just repeat the information provided related to performance gap in 1b)*

We observed marked variation in the collection of 30-day outcomes data across hospitals. Among 180 hospitals performing carotid revascularization in 17,289 patients in 2012, the range of hospital's collection of 30-day outcomes varied from 0% to 100%. Hospitals with <30 procedures were excluded. The interquartile ranges were 0-3.2%, 3.2-26.6%, 26.6-59.3% and 59.3-100%. The variation in patient characteristics, by quartile, is provided below:

2b5.2. What were the statistical results from testing the ability to identify statistically significant and/or clinically/practically meaningful differences in performance measure scores across measured entities? (e.g., *number and percentage of entities with scores that were statistically significantly different from mean or some benchmark, different from expected; how was meaningful difference defined*)

We observed that patient characteristics of hospitals in the lower performance quartiles or outcomes reporting did not differ substantially from a clinical perspective, other than that their patients were more likely to be symptomatic within the past 6 months with worse NIHSS and modified Rankin Scores pre-procedurally and that they trended to treat larger vessels when performing stenting. We also noted a strong association between procedural volume and follow-up rates, with the average procedural volume at the best performing hospitals being substantially greater than poorer performing sites.

2b5.3. What is your interpretation of the results in terms of demonstrating the ability to identify statistically significant and/or clinically/practically meaningful differences in performance across measured entities? (i*.e., what do the results mean in terms of statistical and meaningful differences?*)

The acquisition of outcomes data by hospitals after performing carotid revascularization could not be more broad ranging, from never to always assessing patients' outcomes. As described in Section 2b2.2, knowing and hospital's performance is essential for providing safe, evidence-based, patient-centered care. Importantly, since some hospitals understanding a were able to assess the survival and neurological outcomes of all of their patients, it is currently feasible to do so.

2b6. COMPARABILITY OF PERFORMANCE SCORES WHEN MORE THAN ONE SET OF SPECIFICATIONS
***If only one set of specifications, this section can be skipped*.**

Note: *This criterion is directed to measures with more than one set of specifications/instructions (e.g., one set of specifications for how to identify and compute the measure from medical record abstraction and a different set of specifications for claims or eMeasures). It does not apply to measures that use more than one source of data in one set of specifications/instructions (e.g., claims data to identify the denominator and medical record abstraction for the numerator).* ***If comparability is not demonstrated, the different specifications should be submitted as separate measures.***

2b6.1. Describe the method of testing conducted to demonstrate comparability of performance scores for the same entities across the different datasources/specifications (*describe the steps—do not just name a*

method; what statistical analysis was used)

We are not proposing alternative methods for data collection or performance assessment.

2b6.2. What were the statistical results from testing comparability of performance scores for the same entities when using different data sources/specifications? (*e.g., correlation, rank order*)

Not applicable.

2b6.3. What is your interpretation of the results in terms of demonstrating comparability of performance measure scores for the same entities across the different data sources/specifications? (i.*e., what do the results mean and what are the norms for the test conducted*)

Not applicable.

3. Feasibility

Extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

3a. Byproduct of Care Processes

For clinical measures, the required data elements are routinely generated and used during care delivery (e.g., blood pressure, lab test, diagnosis, medication order).

3a.1. **Data Elements Generated as Byproduct of Care Processes.**
Generated or collected by and used by healthcare personnel during the provision of care (e.g., blood pressure, lab value, diagnosis, depression score), Abstracted from a record by someone other than person obtaining original information (e.g., chart abstraction for quality measure or registry)
If other:

3b. Electronic Sources

The required data elements are available in electronic health records or other electronic sources. If the required data are not in electronic health records or existing electronic sources, a credible, near-term path to electronic collection is specified.

3b.1. **To what extent are the specified data elements available electronically in defined fields?** *(i.e., data elements that are needed to compute the performance measure score are in defined, computer-readable fields)*
ALL data elements are in defined fields in electronic clinical data (e.g., clinical registry, nursing home MDS, home health OASIS)

3b.2. **If ALL the data elements needed to compute the performance measure score are not from electronic sources, specify a credible, near-term path to electronic capture, OR provide a rationale for using other than electronic sources.**

3b.3. **If this is an eMeasure, provide a summary of the feasibility assessment in an attached file or make available at a measure-specific URL.**
No feasibility assessment **Attachment:**

3c. Data Collection Strategy

Demonstration that the data collection strategy (e.g., source, timing, frequency, sampling, patient confidentiality, costs associated with fees/licensing of proprietary measures) can be implemented (e.g., already in operational use, or testing demonstrates that it is ready to put into operational use). For eMeasures, a feasibility assessment addresses the data elements and measure logic and demonstrates the eMeasure can be implemented or feasibility concerns can be adequately addressed.

3c.1. Describe what you have learned/modified as a result of testing and/or operational use of the measure regarding data collection, availability of data, missing data, timing and frequency of data collection, sampling, patient confidentiality, time and cost of data collection, other feasibility/implementation issues.
IF a PRO-PM, consider implications for both individuals providing PROM data (patients, service recipients, respondents) and those whose performance is being measured.
Participating hospitals report patient demographics, medical history, risk factors, hospital presentation, initial cardiac status, procedural details, medications, laboratory values and in-hospital outcomes. The majority of the required data elements are routinely generated and acquired during the delivery of standard cardiac care to this patient population. Electronic extraction of data recorded as part of the procedure expedites data collection. This strategy offers point of care collection and minimizes time and cost. Institutions can manually report using a free web-based tool or automate the reporting by using certified software developed by third-party vendors. The data elements required for this measure are readily available within the patient's medical record or can be attained without undue burden within the hospital. Most data elements exist in a structured format within patient's electronic health record.

The NCDR Data Quality Program consists of 3 main components: data completeness, consistency, and accuracy. Completeness focuses on the proportion of missing data within fields, whereas consistency determines the extent to which logically related fields contain values consistent with other fields. Accuracy characterizes the agreement between registry data and the contents of original charts from the hospitals submitting data.

The Data Quality Report (DQR) consists of registry-specific algorithms that require predetermined levels of completeness and consistency for submitted data fields. Before entering the Enterprise Data Warehouse (EDW), all submissions are scored for file integrity and data completeness, receiving 1 of 3 scores that are transmitted back to facilities using a color coding scheme. A "red light" means that a submission has failed because of file integrity problems such as excessive missing data and internally inconsistent data. Such data are not processed or loaded into the EDW. A "yellow light" status means that a submission has passed the integrity checks but failed in completeness according to predetermined thresholds. Such data are processed and loaded into the EDW but are not included in any registry aggregate computations until corrected. Facilities are notified about data submission problems and provided an opportunity to resubmit data. Finally, a "green light" means that a submission has passed all integrity and quality checks. Such submissions are loaded to the EDW. After passing the DQR, data are loaded into a common EDW that houses data from all registries and included for all registry aggregate computations. In a secondary transaction process, data are loaded into registry-specific, dimensionally modeled data marts.

There is no sampling of patient data allowed within the contractual terms of participation in the CARE Registry in NCDR. The registry is designed to include 100 percent of consecutive adult patients who undergo a carotid revascularization procedure at participating institutions. Section 2.b of the NCDR Master Agreement with participants includes 'Participant Responsibilities': "b. Use of ACCF Data Set and ACCF-Approved Software. Participant will submit a data record on each patient who receives medical care and who is eligible for inclusion in the Registries in which Participant is participating under this Agreement." Adult patients, ages 18 years and older, who have an carotid revascularization procedure. Patients are selected for inclusion by reviewing existing medical records and no direct interaction with the patient will be required outside of the normal course of care. There will be no discrimination or bias with respect to inclusion on the basis of sex, race, or religion.
Patient confidentiality is preserved as the data are in aggregate form. The Care Registry dataset, comprised of approximately 250, data elements was created by a panel of experts using available ACC-AHA guidelines, data elements and definitions, and other evidentiary sources. Private health information (PHI), such as social security number, is collected. The intent for collection of PHI is to allow for registry interoperability and the potential for future generation of patient-level drill downs in Quality and Outcomes Reports. Registry sites can opt out of transmitting direct identifiers to the NCDR, however, so inclusion of direct identifiers in the registry is at the discretion of the registry participants themselves. When using the NCDR web-based data collection tool, direct identifiers are entered but a partition between the data collection process and the data warehouse maintains the direct identifiers separate from the analysis datasets. The minimum level of PHI transmitted to the ACCF when a participant opts out of submitting direct identifiers meets the definition of a Limited Dataset as such term is defined by the Health Insurance Portability and Accountability Act of 1996.
Data collection within the NCDR conforms to laws regarding protected health information. Patient confidentiality is of utmost concern with all metrics. The proposed measure does not include a patient survey. Physician and/or institutional confidentiality CARE Registry. No testing, time, risk, or procedures beyond those required for routine care will be imposed. The primary risk associated with this measure is the potential for a breach of patient confidentiality. The ACCF has established a robust plan for ensuring appropriate and commercially reasonable physical, technical, and administrative safeguards are in place to mitigate such risks.

Data are maintained on secure servers with appropriate safeguards in place. The project team periodically reviews all activities involving protected health information to ensure that such safeguards including standard operating procedures are being followed.

The procedure for notifying the ACCF of any breach of confidentiality and immediate mitigation standards that need to be followed is communicated to participants. ACCF limits access to Protected Health Information, and to equipment, systems, and networks that contain, transmit, process or store Protected Health Information, to employees who need to access the PHI for purposes of performing ACCF's obligations to participants who are in a contractual relationship with the ACCF. All PHI are stored in a secure facility or secure area within ACCF's facilities which has separate physical controls to limit access, such as locks or physical tokens. The secured areas are monitored 24 hours per day, 7 days per week, either by employees or agents of ACCF by video surveillance, or by intrusion detection systems.

Each participant who has access to the NCDR website must have a unique identifier. The password protected webpages have implemented inactivity time-outs. Encryption of wireless network data transmission and authentication of wireless devices containing NCDR Participant's information ACCF's network is required. Protected Health Information may only be transmitted off of ACCF's premises to approved parties, which shall mean: A subcontractor who has agreed to be bound by the terms of the Business Associate Agreement between the ACCF and the NCDR Participant.

3c.2. **Describe any fees, licensing, or other requirements to use any aspect of the measure as specified** *(e.g., value/code set, risk model, programming code, algorithm)*.
The ACCF's program the National Cardiovascular Data Registry (NCDR) provides evidence based solutions for cardiologists and other medical professionals committed to excellence in cardiovascular care. NCDR hospital participants receive confidential benchmark reports that include access to measure macro specifications and micro specifications, the eligible patient population, exclusions, and model variables (when applicable). In addition to hospital sites, NCDR Analytic and Reporting Services provides consenting hospitals' aggregated data reports to interested federal and state regulatory agencies, multi-system provider groups, third-party payers, and other organizations that have an identified quality improvement initiative that supports NCDR-participating facilities. Lastly, the ACCF also allows for licensing of the measure specifications outside of the Registry. For calendar year 2014 the annual pricing for hospitals, NCDR Analytic and Reporting Services, and licensing of measure specifications ranges from $2900-$50,000.
Measures that are aggregated by ACCF and submitted to NQF are intended for public reporting and therefore there is no charge for a standard export package. However, on a case by case basis, requests for modifications to the standard export package will be available for a separate charge.

There is no added procedural risk to patients through their hospital's involvement in the CARE Registry. No testing, time, risk, or procedures beyond those required for routine care will be imposed.

4. Usability and Use

Extent to which potential audiences (e.g., consumers, purchasers, providers, policy makers) are using or could use performance results for both accountability and performance improvement to achieve the goal of high-quality, efficient healthcare for individuals or populations.

4a. Accountability and Transparency

Performance results are used in at least one accountability application within three years after initial endorsement and are publicly reported within six years after initial endorsement (or the data on performance results are available). If not in use at the time of initial endorsement, then a credible plan for implementation within the specified timeframes is provided.

4.1. **Current and Planned Use**
NQF-endorsed measures are expected to be used in at least one accountability application within 3 years and publicly reported within 6 years of initial endorsement in addition to performance improvement.

Planned	Current Use (for current use provide URL)
Public Reporting	Quality Improvement with Benchmarking (external benchmarking to multiple organizations)

	CARE Registry https://www.ncdr.com/webncdr/care/

4a.1. **For each CURRENT use, checked above, provide:**

- Name of program and sponsor
- Purpose
- Geographic area and number and percentage of accountable entities and patients included

CARE Registry of the National Cardiovascular Data Registry of the American College of Cardiology

4a.2. **If not currently publicly reported OR used in at least one other accountability application (e.g., payment program, certification, licensing) what are the reasons?** (*e.g., Do policies or actions of the developer/steward or accountable entities restrict access to performance results or impede implementation?*)
Plan is to publically report in the future.

4a.3. **If not currently publicly reported OR used in at least one other accountability application, provide a credible plan for implementation within the expected timeframes -- any accountability application within 3 years and publicly reported within 6 years of initial endorsement.** (*Credible plan includes the specific program, purpose, intended audience, and timeline for implementing the measure within the specified timeframes. A plan for accountability applications addresses mechanisms for data aggregation and reporting.*)
ACC is committed to implementing this measure. ACC is an authorized organization to receive CMS data through the ResDAC application process. Unfortunately, it has been determined by ResDAC that this authorization does not permit use of CMS for performance measure reporting purposes, either to hospitals or for public display. ACC is currently in process of applying to be a Qualified Entity. It is unclear if this pathway will permit measure implementation. ACC also is commenting on and tracking proposed language in 21st Century Cures legislation, which does appear to create a pathway for use of CMS data for this type of reporting purpose.

4b. Improvement

Progress toward achieving the goal of high-quality, efficient healthcare for individuals or populations is demonstrated. If not in use for performance improvement at the time of initial endorsement, then a credible rationale describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.

4b.1. **Progress on Improvement. (Not required for initial endorsement unless available.)**
Performance results on this measure (current and over time) should be provided in 1b.2 and 1b.4. Discuss:

- **Progress (trends in performance results, number and percentage of people receiving high-quality healthcare)**
- **Geographic area and number and percentage of accountable entities and patients included**

Not available, initial endorsement

4b.2. **If no improvement was demonstrated, what are the reasons? If not in use for performance improvement at the time of initial endorsement, provide a credible rationale that describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.**

4c. Unintended Consequences

The benefits of the performance measure in facilitating progress toward achieving high-quality, efficient healthcare for individuals or populations outweigh evidence of unintended negative consequences to individuals or populations (if such evidence exists).

4c.1. **Were any unintended negative consequences to individuals or populations identified during testing; OR has evidence of unintended negative consequences to individuals or populations been reported since implementation? If so, identify the negative unintended consequences and describe how benefits outweigh them or actions taken to mitigate them.**
There were no unintended consequences identified.

5. Comparison to Related or Competing Measures

If a measure meets the above criteria and there are endorsed or new related measures (either the same measure focus or the same target population) or competing measures (both the same measure focus and the same target population), the measures are compared to address harmonization and/or selection of the best measure.

5. Relation to Other NQF-endorsed Measures
Are there related measures (conceptually, either same measure focus or target population) or competing measures (conceptually both the same measure focus and same target population)? If yes, list the NQF # and title of all related and/or competing measures.
No

5.1a. **List of related or competing measures (selected from NQF-endorsed measures)**

5.1b. **If related or competing measures are not NQF endorsed please indicate measure title and steward.**

5a. Harmonization

The measure specifications are harmonized with related measures;
OR
The differences in specifications are justified

5a.1. **If this measure conceptually addresses EITHER the same measure focus OR the same target population as NQF-endorsed measure(s):**
Are the measure specifications completely harmonized?
Yes

5a.2. **If the measure specifications are not completely harmonized, identify the differences, rationale, and impact on interpretability and data collection burden.**

5b. Competing Measures

The measure is superior to competing measures (e.g., is a more valid or efficient way to measure);
OR
Multiple measures are justified.

5b.1. **If this measure conceptually addresses both the same measure focus and the same target population as NQF-endorsed measure(s):**
Describe why this measure is superior to competing measures (e.g., a more valid or efficient way to measure quality); OR provide a rationale for the additive value of endorsing an additional measure. (Provide analyses when possible.)
No competing measures.

Appendix

A.1 Supplemental materials may be provided in an appendix. All supplemental materials (such as data collection instrument or methodology reports) should be organized in one file with a table of contents or bookmarks. If material pertains to a specific submission form number, that should be indicated. Requested information should be provided in the submission form and required attachments. There is no guarantee that supplemental materials will be reviewed.

Brief Measure Information

NQF #: 2712
Measure Title: Statin Use in Persons with Diabetes
Measure Steward: Pharmacy Quality Alliance (PQA, Inc.)
Brief Description of Measure: The percentage of patients ages 40 – 75 years who were dispensed a medication for diabetes that receive a statin medication.
Developer Rationale: The American College of Cardiology/American Heart Association (ACC/AHA) guidelines recommend moderate- to high-intensity statin therapy for primary prevention for persons aged 40-75 years with diabetes (class I recommendation). Guideline: 2013 ACC/AHA Guideline on Treatment of Blood Cholesterol to Reduce Atherosclerotic Cardiovascular Risk in Adults: a Report of the American College of Cardiology/American Heart Association Task Force on Practice Guidelines. (1)

The measure reflects this new clinical guideline and will promote appropriate treatment of patients with diabetes (age 40-75) to reduce their risk of cardiovascular disease and complications.

Prescription claims data are used as a proxy for diabetes diagnosis in this measure as well as other PQA and HEDIS measures. Medical data used in testing confirmed that the denominator criteria of two prescription claims for a hypoglycemic agent identified a population where a great majority had a diagnosis of diabetes during the measurement year. These criteria also included very few persons with select conditions (i.e., polycystic ovarian syndrome, gestational diabetes or diabetes secondary to another condition) that were considered for exclusion from the measure.
This measure uses only prescription claims as a source of data resulting in the inability to identify individuals with contraindications to statin therapy or other medical exceptions. Therefore the performance rate goal for this measure is not intended to reach 100%.

Stone NJ, Robinson J, Lichtenstein AH, Bairey Merz CN, Blum CB, Eckel RH, Goldberg AC, Gordon D, Levy D, Lloyd-Jones DM, McBride P, Schwartz JS, Shero ST, Smith SC Jr, Watson K, Wilson PWF. 2013 ACC/AHA guideline on the treatment of blood cholesterol to reduce atherosclerotic cardiovascular risk in adults: a report of the American College of Cardiology/American Heart Association Task Force on Practice Guidelines. Circulation. 2013;00:000–000. Accessed 2/3/2014 http://circ.ahajournals.org/content/early/2013/11/11/01.cir.0000437738.63853.7a.full.pdf

Numerator Statement: The number of patients in the denominator who received a prescription fill for a statin or statin combination during the measurement year.
Denominator Statement: The denominator includes subjects aged 41 years – 75 years as of the last day of the measurement year who are continuously enrolled during the measurement period. Subjects include patients who were dispensed two or more prescription fills for a hypoglycemic agent during the measurement year.
Denominator Exclusions: Patients in Hospice (Medicare Part D) are excluded from this measure. Medicare prescription claims for persons in hospice are not covered by Part D.

Measure Type: Process
Data Source: Administrative claims
Level of Analysis: Health Plan, Population : National
Is this an eMeasure? ☐ Yes ☒ No **If Yes, was it re-specified from a previously endorsed measure?** ☐ Yes ☐ No

☐ **Is this a MAINTENANCE measure submission?** ☐ Yes ☒ **No, this is a NEW measure submission.**
For a MAINTENANCE, what is the Original Endorsement Date: N/A **Most Recent Endorsement Date: N/A**

Preliminary Analysis

The preliminary analysis was developed in response to recommendations from NQF's Consensus Task Force and measurement stakeholders as a way to enhance and streamline the measures evaluation and voting processes. The preliminary analysis will help to guide the Standing Committee evaluation of each measure by summarizing the measure developer submission, guide measure evaluation discussion, and identify topic areas for additional input. **NQF staff would like to stress that the preliminary analysis is intended to be used as a guide to facilitate the Committee's discussion and evaluation.**

Criteria 1: Importance to Measure and Report

1a. Evidence

1a. Evidence. The evidence requirements for an *process* measure is that it is based on a systematic review (SR) and grading of the body of empirical evidence where the specific focus of the evidence matches what is being measured

The developer provides the following evidence for this process measure:

- This is a health plan-level process that calculates the percentage of patients ages 40 – 75 years who were dispensed a medication for diabetes that receive a statin medication.
- The developer provides the path from initiating statin therapy in patients with diabetes to a reduction in the risk of atherosclerotic cardiovascular disease.
- The measure is based on an ACC/AHA guideline for the primary prevention in individuals with diabetes. The evidence for this guideline was graded Level A, Class 1.
- Developers provided a summary of the quantity, quality, and consistency of the evidence.

Questions for the Committee:

- *Is the evidence directly applicable to the process being measured?*
- *Is the process proximal and closely related to desired outcomes?*
- *For possible exception to the evidence criteria:*
  - *Are there, or could there be, performance measures of a related health outcome?*
  - *Is there evidence of a systematic assessment of expert opinion beyond those involved in developing the measure?*
  - *Does the SC agree that it is acceptable (or beneficial) to hold providers accountable without empiric evidence?*

1b. Gap in Care/Opportunity for Improvement and 1b. Disparities

1b. Performance Gap. The performance gap requirements include demonstrating quality problems and opportunity for improvement.

- The developer provided 2012 and 2013 data for the following health plans, though individual descriptive statistics are not provided by year and insurance type for 2012:

	Type of plan	# of patients(N)	Min	Max	Mean	SD	IQR
2012	Medicare	1,807,725	59.1%	67.6%	62.8%	6.6%	-
	Commercial	16,615,029					
	Medicaid	665,715					
2013	Medicare Part D	23,185,246	66.1%	100%	72.5%	8.3%	6.2%

- The developer provided additional information on the Medicare Drug Benefit: The Medicare Drug Benefit is provided by private prescription drug plans (PDPs) that offer drug-only coverage, or through Medicare Advantage health plans that offer both prescription drug and health care coverage (known as MA-PDs). Currently there are 23.9 million lives in PDPs and 15.3 million lives in MA-PDs:
  - Medicare PDP – 61%
  - Medicare MA-PDP – 39%
- The disparities data provided by the developer includes the rates for the Low Income Subsidy (LIS) population; disparities data from the literature was not provided.
- The developer provided 2012 data for 3 insurance types and 2015 (Jan-Mar) data for eight Part D contracts for the Low Income Subsidy (LIS) and non-LIS population:

	Type of plan	Rate

2012	Medicare	73.6%
	Commercial	60.4%
	Medicaid	59.1%
2015	Medicare Part D: LIS	67.3%
	Medicare Part D: Non-Lis	67.1%

- The developer states LIS is a subsidy paid by the Federal government to the drug plan for Medicare beneficiaries who need extra help with their prescription drug costs due to limited income and resources. Medicare beneficiaries apply for the LIS with the Social Security Administration or their State Medicaid agency. The following groups automatically qualify for LIS without applying:
  - Full–benefit dual eligible (Medicare and Medicaid eligible)
  - Supplemental Security Income recipients
  - Medicare beneficiaries who participate in the Medicare Saving Programs
  - QMB – qualified Medicare beneficiary
  - SLMB – specified low-income Medicare beneficiary
  - QI – qualifying individual

Questions for the Committee:

- *Is there a gap in care that warrants a national performance measure?*
- *Is the SC aware of additional evidence that disparities exist in this area of healthcare?*
- *Should this measure be indicated as disparities sensitive?*

1c. Priority

1c. High Priority (previously "High Impact") requires measures to address national health goal/priority or a demonstrated high-impact aspect of care.

- *Beginning in 2015, priority is no longer an NQF measure evaluation criterion.*

Committee pre-evaluation comments

Criteria 1: Importance to Measure and Report (including 1a, 1b, 1c)

1. ***Committee's Overview Comments***:
   - There has been a significant body of literature over the years to support the concept that people with diabetes have better outcomes with lower cholesterol; and that statins appear to have additional protective properties beyond that of cholesterol reduction alone.
   - Health Outcome
     - Intermediate clinical outcome
     - Process
     - Structure
     - Efficiency

1a. ***Committee's Comments on Evidence to Support Measure Focus:***

- This process identifies persons with diabetes via prescriptions for a hypoglycemic agent and then identifies subsequent statin use. The use of a statin in this population may lead to a reduction of risk in cardiovascular complications.

1b. ***Committee's Comments on Performance Gap:***

- Yes. While there has been a much greater recognition of the value of statin therapy among specialists and PCPs, the adherence has not been at the level that is appropriate. Much of this gap may have come from the over concern for statin induced myopathy so that patients and doctors have had an over concern about the use of statins with diabetes.
- Not provided. This is a missed opportunity because many minority women have higher risks for diabetes, thus cardiovascular disease.

1c. ***Committee's Comments on Composite Performance Measure:***

- Not a composite measure
- The NQF Measure 0729 is a Related measure. It is Optimal Diabetes Care - Cholesterol Statin Use Component. The Measure Steward is MN Community Measurement.

Criteria 2: Scientific Acceptability of Measure Properties

2a. Reliability

2a1. Reliability Specifications

2a1. Specifications requires the measure, as specified, to produce consistent (reliable) and credible (valid) results about the quality of care when implemented.

- The measure assess the percentage of patients ages 40 – 75 years diagnosed with diabetes who were dispensed a statin medication. To be included in the denominator, patients must be 41 years by the end of the measurement year.
- The measure uses prescription administrative claims data which is available electronically. The eligible medications used to calculate the numerator/denominator are provided.
- The measure uses diabetic medications as proxy information for a diagnosis of diabetes. As the measure exclusively uses prescription administrative claims data (i.e., clinical data is not collected) to calculate performance, this measure does *not* assess diabetic patients who are treated non-pharmaceutically, patients with a contradiction to statins (e.g., allergy, intolerance, refusal), diabetic patients with cholesterol monitored and within normal limits, nor patients who are exclusively taking over-the-counter cholesterol-lowering medications.
- Patients with gestational diabetes, steroid-induced diabetes, and poly-cystic ovarian disease may be prescribed hypoglycemic agents and are not excluded from the measure.
- The measure description states "a" single medication identifies patients as diabetic, while rationale and the calculation algorithm state "two prescription claims for a hypoglycemic agent identified a population where a great majority had a diagnosis of diabetes".
- Those persons receiving hospice care at any point during the measurement year are excluded, though the developer notes a limitation to this exclusion because hospital enrollment data may not be routinely available to non-Medicare plans, such as Medicaid and Commercial lines of business.
- The measure is stratified by insurance type: Commercial, Medicaid, and Medicare, and it is not risk adjusted.
- A clear calculation algorithm for the measure is provided. The measure is not risk adjusted.

Questions for the Committee:

- *Should all hospice patients be excluded, including those from non-Medicare plans?*
- *Should all patients prescribed hypoglycemic agents be prescribed statins?*
- *Are all the data elements clearly defined? Are all appropriate codes included?*
- *Is the logic or calculation algorithm clear?*
- *Is it likely this measure can be consistently implemented?*

2a2. Reliability Testing Testing attachment

2a2. Reliability testing demonstrates if the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise enough to distinguish differences in performance across providers.

- The developer used signal to noise analysis with a mixed effect logistic regression model to examine the variability in performance measure score at the health plan level, which is the unit of analysis specified for the prescription-only claims measure. The developer used a signal to noise methodology other than The Reliability of Provider Profiling (2009) familiar to the Committee. The developer states this type of reliability testing is appropriate for this type of measure, and that the testing differentiates the true difference between measured entities (the signal) to random measurement error (the noise). The developer tested (and rejected) the null hypothesis that performance does not vary across the units being measured. From their findings, observed performance variation is at least partly due to true differences (i.e. signal) and is not entirely due to random statistical variation (i.e. noise), though the developer should provide further

interpretation and quantification of the results. The developer is encouraged to provide clarification for reliability testing methods and results.

- A likelihood-ratio (LR) test was also performed to determine if a model with random effects would fit the data better than a standard logistic regression model without random effects. This test was conducted with the Medicare Part D Prescription Drug Event (PDE) data described in sections 1.2- 1.7. It does not include Medicare Advantage, Medicaid & Commercial insurance data. The developer is encouraged to provide clarification for reliability testing methods and results.

Table 1. Mixed Effect Logistic Regression Model, Statin Use in Persons with Diabetes measure rate comparison across Part D plans

	Coefficient	Standard Error	Z	p-value
Intercept	1.018	0.009	110.56	<0.001
	Estimate	**Standard Error**	**95% Confidence Interval**	
Random Effects	0.224	0.008	0.210	0.239

- The developer states these results indicate that there are significant differences in performance measure scores between plans, which allows for discrimination between high performing plans and low performing plans. The developer reports that based on these results, the measure is considered to be reliable.
- The testing methodology and results are pending review.

Questions for the Committee:

- *Is the test sample adequate to generalize for widespread implementation?*
- *Do the results demonstrate sufficient reliability so that differences in performance can be identified?*

2b. Validity

2b1. Validity: Specifications

2b1. Validity Specifications. This section should determine if the measure specifications are consistent with the evidence.

- The clinical practice guideline supporting this measure recommends the use of statin therapy in persons with diabetes 40 to 75 years of age.

Question for the Committee:

- *Are the specifications consistent with the evidence?*
- *Do the evidence state patients with gestational diabetes, steroid-induced diabetes, and poly-cystic ovarian disease should be prescribed statins?*

2b2. Validity testing

2b2. Validity Testing should demonstrate the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality.

- Face Validity - The developers provide a 7 step consensus based measure development and testing process, and state that 34 of the 38 (89.5%) members of the PQA Workgroup who developed the SUPD measure, agreed that the measure could differentiate the quality of care.

Questions for the Committee:

- *Is the test sample adequate to generalize for widespread implementation?*
- *Do the results demonstrate sufficient validity so that conclusions about quality can be made?*

○ *Do you agree that the score from this measure as specified is an indicator of quality?*

2b3-2b7. Threats to Validity

2b3. Exclusions:

- Those persons receiving hospice care at any point during the measurement year are excluded. No testing was performed on this exclusion, as the data source, prescription claims data, do not contain claims for persons that are in hospice care.
- The developer notes a limitation to this exclusion because hospital enrollment data may not be routinely available to non-Medicare plans such as Medicaid and Commercial lines of business.

Questions for the Committee:

- *Should all hospice patients be excluded, including those from non-Medicare plans?*
- *Should patients with gestational diabetes, Steroid-induced diabetes, and poly-cystic ovarian disease be excluded from the measure?*
- *Are the exclusions consistent with the evidence?*
- *Are any patients or patient groups inappropriately excluded from the measure?*
- *Are the exclusions/exceptions of sufficient frequency and variation across providers to be needed (and outweigh the data collection burden)?*

2b4. Risk adjustment:

- This process measure is not risk adjusted.

2b5. Meaningful difference:

- The overall mean performance on this measure varied between health plans: 59.1% (Medicaid) to 73.6% (Medicare) in 2012. The rates for 2013 also showed significant variation for Medicare Part D from 66.07% to 100% (SD = 8.31%).

Question for the Committee:

○ *Does this measure identify meaningful differences about quality?*

2b6. Comparability of data sources/methods:

- This is not appropriate as the measure is not specified for multiple data source.

2b7. Missing Data

- All data elements required to calculate the measure are available in the prescription claims; no missing data was found.

Committee pre-evaluation comments

Criteria 2: Scientific Acceptability of Measure Properties (including all 2a, 2b, and 2d)

2a1. &2b1.: ***Committee's Comments on Reliability-Specifications:***

- The concern that I have is in the definition of diabetes used in this measure as being medication managed. This means those individuals with diabetes not on medications are not included in the numerator or denominator. This is different than the determinations of diabetes used by NCQA where at least two separate claims with the ICD codes for diabetes may be used for the inclusion of people with diabetes. As a result this measure is somewhat distorted.
- Reliability testing demonstrates the measure data elements are repeatable producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is procise.

2a2.: ***Committee's Comments on Reliability-Testing:***

- The measure has been used sufficiently to have reliability for the measured population
- Reliable data points used, populations included increased substantially over time.

2b1.: ***Committee's Comments on Validity-Specifications***:

- As in the section above. The limitation of people on pharmacologic therapy for diabetes means that these are likely to be people with greater degrees of glucose intolerance, and are more likely to be people who would be medication compliant. So the measure is valid for its defined population but not valid for all diabetic people.
- The Validity testing demonstrates that the measure data elements are correct and/or the measure scores correctly reflects the quality of care provided adequately identifying differences in quality.

2b2.: ***Committee's Comments on Validity-Testing:***

- This has been considered a standard and valid measure---but only for the population of people with diabetes who are on mediation management.
- Critical data elements used in readability testing.

2b3-7.: ***Committee's Comments on Threats to Validity:***

- The reliability and validity of prescription claims data tested and each one evaluate 4d in the literature and deemed reliable and valid for this measure.
- As above. The risk adjustment of people not on medication for their diabetes means that the population being measured is different than the population of all people with diabetes. This may mean that if the population included all diabetics the results may be different. Confounding factors for non-prescription of medication may include:
  1. Severity of glucose intolerance.
  2. Medication adherence.
  3. Social determinant such as access to care, numeracy and literacy

2d.: ***Committee's Comments on Composite Performance Measure:***

- Not Applicable

Criterion 3. Feasibility

3. Feasibility is the extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

- The data source is electronically abstracted from administrative claims and readily available from health plan prescription claims data and enrollment data.
- Health plans already obtain prescription claims data for payment therefore there is no extra burden/cost in the collection of data for this measure.
- The developer states organizations must obtain permission to use this measure and they may require a license, though no details or costs are provided.

Questions for the Committee:

- *Are the required data elements routinely generated and used during care delivery?*
- *Are the required data elements available in electronic form, e.g., EHR or other electronic sources?*
- *Is the data collection strategy ready to be put into operational use?*

Committee pre-evaluation comments

Criteria 3: Feasibility

3.: ***Committee's Comments on Feasibility:***

- This has been an existing measure so is quite feasible
- Data Elements generated as byproduct of care process.

Criterion 4: Usability and Use

4. Usability and Use evaluate the extent to which audiences (e.g., consumers, purchasers, providers, policymakers) use

or could use performance results for both accountability and performance improvement activities.

- The measure is currently reported by CMS to all Medicare Part D health plan sponsors in the monthly Patient Safety Reports for quality improvement.
- URAC is planning to add this measure as an exploratory measure to their accreditation programs for Community Pharmacy, PBM, and Mail Service.
- CMS is considering this measure as a new 2017 display measure (using 2015 data) and as a possible 2018 Star Rating measure (using 2016 data).
- The developers state no unintended consequences were identified during testing of this measure.

***Questions for the Committee**:*

- *Is the measure publicly reported?*
- *How can the performance results be used to further the goal of high-quality, efficient healthcare?*
- *Do the benefits of the measure outweigh any potential unintended consequences?*

Committee pre-evaluation comments

Criteria 4: Usability and Use

4.: ***Committee's Comments on Usability and Use:***

- As an accountability measure, it has been applied to clinical practices, integrated delivery systems and to health plans--all of which have some ability to impact the results through their actions.
- Expected to be used in at least one accountability application within 3 years and publicly reported in 6 years.

Criterion 5: Related and Competing Measures

- 0729: Optimal Diabetes Care- Cholesterol Statin Use Component
- The developer states that the measure specifications are not harmonized because 2712 is a health plan measure that addresses only appropriate use of statins in diabetics age 40-75 while 0729 is a clinician level composite measure that addresses various aspects of care for patients with IVD.

Pre-meeting public and member comments

Comment by: Ashish R. Trivedi, Pharm.D.
Organization: SPI-Lilly

Comment#5113: Lilly is supportive of the direction of the new guidelines focused on treating and reducing cardiovascular risk (vs treating to LDL-C targets) in patients with diabetes, who represent a large population of patients at substantially increased risk for ASCVD (atherosclerosis cardiovascular disease) events [Stone et al, 2013]. However, we would like to point out that comprehensive and routine lipoprotein lipid assessment is still an integral part of managing risk in patients with ASCVD [Jacobson et al, 2015]. In addition, clinical trial data indicates significant residual cardiovascular risk in ASCVD patients treated with statins, even in the setting of optimal LDL-C reduction (eg, <70 mg/dL and <100 mg/dL), thus highlighting the need to consider alternative CV risk reduction algorithms beyond the focus on LDL-C levels and/or the use of statins [Cannon et al 2004, LaRosa et al 2005, Pedersen et al 2005].

NATIONAL QUALITY FORUM—Evidence (subcriterion 1a)

Measure Number (*if previously endorsed*)**:** Click here to enter NQF number

Measure Title: Statin Use in Persons with Diabetes

IF the measure is a component in a composite performance measure, provide the title of the Composite Measure here: Click here to enter composite measure #/ title

Date of Submission: 6/29/2015

Instructions

- *For composite performance measures:*
  - *A separate evidence form is required for each component measure unless several components were studied together.*
  - *If a component measure is submitted as an individual performance measure, attach the evidence form to the individual measure submission.*
- Respond to all questions as instructed with answers immediately following the question. All information needed to demonstrate meeting the evidence subcriterion (1a) must be in this form. An appendix of *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 10 pages (*incudes questions/instructions*; minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the evidence for this measure meets NQF's evaluation criteria.

1a. Evidence to Support the Measure Focus

The measure focus is evidence-based, demonstrated as follows:

- Health outcome: [3] a rationale supports the relationship of the health outcome to processes or structures of care. Applies to patient-reported outcomes (PRO), including health-related quality of life/functional status, symptom/symptom burden, experience with care, health-related behavior.
- Intermediate clinical outcome: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured intermediate clinical outcome leads to a desired health outcome.

- Process: [5] a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured process leads to a desired health outcome.
- Structure: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured structure leads to a desired health outcome.
- Efficiency: [6] evidence not required for the resource use component.

Notes

3. Generally, rare event outcomes do not provide adequate information for improvement or discrimination; however, serious reportable events that are compared to zero are appropriate outcomes for public reporting and quality improvement.

4. The preferred systems for grading the evidence are the U.S. Preventive Services Task Force (USPSTF) grading definitions and methods, or Grading of Recommendations, Assessment, Development and Evaluation (GRADE) guidelines.

5. Clinical care processes typically include multiple steps: assess → identify problem/potential problem → choose/plan intervention (with patient input) → provide intervention → evaluate impact on health status. If the measure focus is one step in such a multistep process, the step with the strongest evidence for the link to the desired outcome should be selected as the focus of measurement. Note: A measure focused only on collecting PROM data is not a PRO-PM.

6. Measures of efficiency combine the concepts of resource use and quality (see NQF's Measurement Framework: Evaluating Efficiency Across Episodes of Care; AQA Principles of Efficiency Measures).

1a.1.This is a measure of: (*should be consistent with type of measure entered in De.1*)

Outcome

☐ Health outcome: Click here to name the health outcome

☐Patient-reported outcome (PRO): Click here to name the PRO

PROs include HRQoL/functional status, symptom/symptom burden, experience with care, health-related behaviors

☐ Intermediate clinical outcome (*e.g., lab value*): Click here to name the intermediate outcome

☒ Process: The percentage of patients ages 40 – 75 years who were dispensed a medication for diabetes that receive a statin medication.

☐ Structure: Click here to name the structure

☐ Other: Click here to name what is being measured

HEALTH OUTCOME/PRO PERFORMANCE MEASURE *If not a health outcome or PRO, skip to 1a.3*

1a.2. Briefly state or diagram the path between the health outcome (or PRO) and the healthcare structures, processes, interventions, or services that influence it.

1a.2.1. State the rationale supporting the relationship between the health outcome (or PRO) to at least one healthcare structure, process, intervention, or service (*i.e., influence on outcome/PRO*).

Note: For health outcome/PRO performance measures, no further information is required; however, you may provide evidence for any of the structures, processes, interventions, or service identified above.

INTERMEDIATE OUTCOME, PROCESS, OR STRUCTURE PERFORMANCE MEASURE

1a.3. Briefly state or diagram the path between structure, process, intermediate outcome, and health outcomes. Include all the steps between the measure focus and the health outcome.

For people aged 40-75, there are considerable potential benefits from initiating stain therapy, especially for those with a cardiovascular risk factor such as diabetes. This process measure identifies persons with diabetes via prescriptions for a hypoglycemic agent and then identifies subsequent statin use. The use of a statin in this population may lead to a reduction of risk in cardiovascular complications.

1a.3.1. What is the source of the systematic review of the body of evidence that supports the performance measure?

☒ Clinical Practice Guideline recommendation – ***complete sections 1a.4, and 1a.7***

☐ US Preventive Services Task Force Recommendation – ***complete sections 1a.5 and 1a.7***

☐ Other systematic review and grading of the body of evidence (*e.g., Cochrane Collaboration, AHRQ Evidence Practice Center*) – ***complete sections 1a.6 and 1a.7***

☐ Other – ***complete section 1a.8***

Please complete the sections indicated above for the source of evidence. You may skip the sections that do not apply.

1a.4. CLINICAL PRACTICE GUIDELINE RECOMMENDATION

1a.4.1. Guideline citation (*including date*) and **URL for guideline** (*if available online*):

Stone NJ, Robinson J, Lichtenstein AH, Bairey Merz CN, Blum CB, Eckel RH, Goldberg AC, Gordon D, Levy D, Lloyd-Jones DM, McBride P, Schwartz JS, Shero ST, Smith SC Jr, Watson K, Wilson PWF. 2013 ACC/AHA guideline on the treatment of blood cholesterol to reduce atherosclerotic cardiovascular risk in adults: a report of the American College of Cardiology/American Heart Association Task Force on Practice Guidelines. *Circulation.* 2013;00:000–000. Accessed 6/2/2015
http://circ.ahajournals.org/content/early/2013/11/11/01.cir.0000437738.63853.7a.full.pdf

1a.4.2. Identify guideline recommendation number and/or page number and **quote verbatim, the specific guideline recommendation**.

Page 31 of the guidelines state:

"4.5. Primary Prevention in Individuals with Diabetes**:** A high level of evidence supports the use of moderate-intensity statin therapy in persons with diabetes 40 to 75 years of age. The only trial of high-intensity statin therapy in primary prevention was performed in a population without diabetes. However, a high level of evidence was considered for event with statin therapy reduction in individuals with a ≥7.5% estimated 10-year ASCVD risk (Section 4.6) who did not have diabetes to recommend high-intensity statin therapy preferentially for individuals with diabetes and a ≥7.5% estimated 10-year ASCVD risk (Section 4.7). This consideration for those with diabetes 40 to 75 years of age recognizes that these

individuals are at substantially increased lifetime risk for ASCVD events and death. Moreover, individuals with diabetes experience greater morbidity and worse survival following the onset of clinical ASCVD.

In persons with diabetes <40 or >75 years of age, statin therapy should be individualized based on considerations of ASCVD risk reduction benefits, the potential for adverse effects and drug-drug interactions, and patient preferences (Figure 4)."

ASCVD = atherosclerotic cardiovascular disease

1a.4.3. Grade assigned to the quoted recommendation with definition of the grade:

The National Heart, Lung, and Blood Institute (NHLBI) Grading methodology was used for this recommendation. This guideline is graded A, which is defined as: Strong recommendation - There is high certainty based on evidence that the net benefit is substantial.

1a.4.4. Provide all other grades and associated definitions for recommendations in the grading system.

(*Note: If separate grades for the strength of the evidence, report them in section 1a.7.*)

The following table contains the grades and associated definitions for grading system recommendations:

Grade	Strength of Recommendation*
A	**Strong recommendation** There is high certainty based on evidence that the net benefit† is substantial.
B	**Moderate recommendation** There is moderate certainty based on evidence that the net benefit is moderate to substantial, or there is high certainty that the net benefit is moderate.
C	**Weak recommendation** There is at least moderate certainty based on evidence that there is a small net benefit.
D	**Recommendation against** There is at least moderate certainty based on evidence that it has no net benefit or that risks/harms outweigh benefits.
E	**Expert opinion ("There is insufficient evidence or evidence is unclear or conflicting, but this is what the Work Group recommends.")** Net benefit is unclear. Balance of benefits and harms cannot be determined because of no evidence, insufficient evidence, unclear evidence, or conflicting evidence, but the Work Group thought it was important to provide clinical guidance and make a recommendation. Further research is recommended in this area.

N	**No recommendation for or against ("There is insufficient evidence or evidence is unclear or conflicting.")** Net benefit is unclear. Balance of benefits and harms cannot be determined because of no evidence, insufficient evidence, unclear evidence, or conflicting evidence, and the Work Group thought no recommendation should be made. Further research is recommended in this area.

*In most cases, the strength of the recommendation should be closely aligned with the quality of the evidence; however, under some circumstances, there may be valid reasons for making recommendations that are not closely aligned with the quality of the evidence (e.g., strong recommendation when the evidence quality is moderate, like smoking cessation to reduce CVD risk or ordering an ECG as part of the initial diagnostic work-up for a patient presenting with possible MI). Those situations should be limited and the rationale explained clearly by the Work Group.

†Net benefit is defined as benefits minus risks/harms of the service/intervention

1a.4.5. Citation and URL for methodology for grading recommendations (*if different from 1a.4.1*)**:**

See citation in 1a.4.1; pages 6-8

1a.4.6. If guideline is evidence-based (rather than expert opinion), are the details of the quantity, quality, and consistency of the body of evidence available (e.g., evidence tables)?

☒ Yes → ***complete section 1a.7***

☐ No → ***report on another systematic review of the evidence in sections 1a.6 and 1a.7; if another review does not exist, provide what is known from the guideline review of evidence in 1a.7***

1a.5. UNITED STATES PREVENTIVE SERVICES TASK FORCE RECOMMENDATION

1a.5.1. Recommendation citation (*including date*) and **URL for recommendation** (*if available online*):

1a.5.2. Identify recommendation number and/or page number and **quote verbatim, the specific recommendation**.

1a.5.3. Grade assigned to the quoted recommendation with definition of the grade:

1a.5.4. Provide all other grades and associated definitions for recommendations in the grading system.
(*Note: the grading system for the evidence should be reported in section 1a.7.*)

1a.5.5. Citation and URL for methodology for grading recommendations (*if different from 1a.5.1*)**:**

Complete section 1a.7

1a.6. OTHER SYSTEMATIC REVIEW OF THE BODY OF EVIDENCE

1a.6.1. Citation (*including date*) and **URL** (*if available online*):

1a.6.2. Citation and URL for methodology for evidence review and grading (*if different from 1a.6.1*)**:**

Complete section 1a.7

1a.7. FINDINGS FROM SYSTEMATIC REVIEW OF BODY OF THE EVIDENCE SUPPORTING THE MEASURE

If more than one systematic review of the evidence is identified above, you may choose to summarize the one (or more) for which the best information is available to provide a summary of the quantity, quality, and consistency of the body of evidence. Be sure to identify which review is the basis of the responses in this section and if more than one, provide a separate response for each review.

1a.7.1. What was the specific structure, treatment, intervention, service, or intermediate outcome addressed in the evidence review?

The treatment addressed in the evidence review is moderate-intensity statin therapy for adults 40 to 75 years of age with diabetes mellitus.

1a.7.2. Grade assigned for the quality of the quoted evidence with definition of the grade:

The quality of the quoted evidence is graded using the American College of Cardiology/American Heart Association (ACC/AHA) Level of Evidence (LOE) grading system. The evidence was graded a Level A, Class 1.

The estimate of the precision of the treatment effect is graded Level A. This is defined as: Multiple (3-5) population risk strata evaluated; general consistency of direction and magnitude of effect.

The size of the treatment effect is graded Class 1. This is defined as: Benefit >>> Risk. No additional studies are needed. Procedure/treatment should be performed/administered.

1a.7.3. Provide all other grades and associated definitions for strength of the evidence in the grading system.

The following table contains the grades and associated definitions for grading the strength of the evidence:

Grade	Estimate of the precision of the treatment effect

A	Multiple (3-5) population risk strata evaluated; general consistency of direction and magnitude of effect.
B	Limited (2-3) population risk strata evaluated.
C	Very limited (1-2) population risk strata evaluated.
Grade	**Size of treatment effect**
Class I	Benefit >>> Risk. No additional studies are needed. Procedure/treatment should be performed/administered.
Class IIa	Benefit >> Risk. Additional studies with focused objectives are needed. It is reasonable to perform procedure/administer treatment.
Class IIb	Benefit ≥ Risk. Additional studies with broad objectives are needed; additional registry data would be helpful. It is not unreasonable to perform procedure/administer treatment.
Class III	Risk ≥ Benefit. No additional studies are needed. Procedure/treatment should not be performed/administered since it is not helpful and may be harmful.

1a.7.4. What is the time period covered by the body of evidence? (*provide the date range, e.g., 1990-2010*).
Date range: 1998-2010

QUANTITY AND QUALITY OF BODY OF EVIDENCE

1a.7.5. How many and what type of study designs are included in the body of evidence? (*e.g., 3 randomized controlled trials and 1 observational study*)

Five (5) studies were included in the body of evidence for this recommendation. Three (3) studies are randomized control trials (RCT). Two studies are meta-analyses of RCTs, one that included 26 trials and one that included 14 trials.

1a.7.6. What is the overall quality of evidence <u>across studies</u> in the body of evidence? (*discuss the certainty or confidence in the estimates of effect particularly in relation to study factors such as design flaws, imprecision due to small numbers, indirectness of studies to the measure focus or target population*)

The overall quality of the evidence across studies is graded using the ACC/AHA Level of Evidence (LOE) grading system. The evidence was graded a Level A, Class 1.

The estimate of the precision of the treatment effect is graded Level A. This is defined as: Multiple (3-5) population risk strata evaluated; general consistency of direction and magnitude of effect.

The size of the treatment effect is graded Class 1. This is defined as: Benefit >>> Risk. No additional studies are needed. Procedure/treatment should be performed/administered.

The populations included in the studies included the intended target population of this measure, persons with diabetes 40 to 75 years of age. The quality of the evidence, estimate of the precision of the treatment effect and size of the treatment effect each received the highest grading, providing a high degree of confidence.

ESTIMATES OF BENEFIT AND CONSISTENCY ACROSS STUDIES IN BODY OF EVIDENCE

1a.7.7. What are the estimates of benefit—magnitude and direction of effect on outcome(s) across studies in the body of evidence? (*e.g., ranges of percentages or odds ratios for improvement/ decline across studies, results of meta-analysis, and statistical significance*)

In the RCTs reviewed, initiation of moderate to high intensity therapy is a critical factor in reducing arteriosclerotic cardiovascular disease (ASCVD) events.

The review of the RCTs showed that statin use reduced the incidence of major coronary and vascular events, with a relative risk (RR) range of 0.63 to 0.82 (*P* range from 0.003 to 0.001). Statin use also reduced the mortality rate, with a RR range from 0.63 to 0.90 (*P* range from 0.059 to 0.001).

1a.7.8. What harms were studied and how do they affect the net benefit (benefits over harms)?

Adverse events were studied across the RCTs that were reviewed. One meta-analysis found that adverse events were generally mild, but 17 RCTs reported on increased risk of development of incident diabetes [Odds Ratio (OR) 1.09; 95% CI 1.02–1.17, $P = 0.001$, $I^2 = 11\%$]. One study found that there was no significant difference in the incidence of malignant neoplasms or other serious adverse events, while another found that there was no evidence that reduction of LDL cholesterol with a statin increased cancer incidence (RR per 1.0 mmol/L LDL cholesterol reduction 1.00, 95% CI 0.96–1.04), cancer mortality (RR 0.99, 95% CI 0.93–1.06), or other non-vascular mortality. Across studies, the findings were consistent with the findings that that the benefit of stain therapy greatly exceeds any known risks.

UPDATE TO THE SYSTEMATIC REVIEW(S) OF THE BODY OF EVIDENCE

1a.7.9. If new studies have been conducted since the systematic review of the body of evidence, provide for each new study: 1) citation, 2) description, 3) results, 4) impact on conclusions of systematic review.

NA

1a.8 OTHER SOURCE OF EVIDENCE

If source of evidence is NOT from a clinical practice guideline, USPSTF, or systematic review, please describe the evidence on which you are basing the performance measure.

1a.8.1 What process was used to identify the evidence?

NA

1a.8.2. Provide the citation and summary for each piece of evidence.

NA

1. Evidence, Performance Gap, Priority – Importance to Measure and Report

Extent to which the specific measure focus is evidence-based, important to making significant gains in healthcare quality, and improving health outcomes for a specific high-priority (high-impact) aspect of healthcare where there is variation in or overall less-than-optimal performance. ***Measures must be judged to meet all subcriteria to pass this criterion and be evaluated against the remaining criteria.***

1a. Evidence to Support the Measure Focus – See attached Evidence Submission Form
SUPD_Template_MeasSubm_Evidence_FINAL_062615.docx

1b. Performance Gap

Demonstration of quality problems and opportunity for improvement, i.e., data demonstrating:

- considerable variation, or overall less-than-optimal performance, in the quality of care across providers; and/or
- disparities in care across population groups.

1b.1. **Briefly explain the rationale for this measure** *(e.g., the benefits or improvements in quality envisioned by use of this measure)*
The American College of Cardiology/American Heart Association (ACC/AHA) guidelines recommend moderate- to high-intensity statin therapy for primary prevention for persons aged 40-75 years with diabetes (class I recommendation).
Guideline: 2013 ACC/AHA Guideline on Treatment of Blood Cholesterol to Reduce Atherosclerotic Cardiovascular Risk in Adults: a Report of the American College of Cardiology/American Heart Association Task Force on Practice Guidelines. (1)

The measure reflects this new clinical guideline and will promote appropriate treatment of patients with diabetes (age 40-75) to reduce their risk of cardiovascular disease and complications.

Prescription claims data are used as a proxy for diabetes diagnosis in this measure as well as other PQA and HEDIS measures. Medical data used in testing confirmed that the denominator criteria of two prescription claims for a hypoglycemic agent identified a population where a great majority had a diagnosis of diabetes during the measurement year. These criteria also included very few persons with select conditions (i.e., polycystic ovarian syndrome, gestational diabetes or diabetes secondary to another condition) that were considered for exclusion from the measure.
This measure uses only prescription claims as a source of data resulting in the inability to identify individuals with contraindications to statin therapy or other medical exceptions. Therefore the performance rate goal for this measure is not intended to reach 100%.

1. Stone NJ, Robinson J, Lichtenstein AH, Bairey Merz CN, Blum CB, Eckel RH, Goldberg AC, Gordon D, Levy D, Lloyd-Jones DM, McBride P, Schwartz JS, Shero ST, Smith SC Jr, Watson K, Wilson PWF. 2013 ACC/AHA guideline on the treatment of blood cholesterol to reduce atherosclerotic cardiovascular risk in adults: a report of the American College of Cardiology/American Heart Association Task Force on Practice Guidelines. Circulation. 2013;00:000–000. Accessed 2/3/2014 http://circ.ahajournals.org/content/early/2013/11/11/01.cir.0000437738.63853.7a.full.pdf

1b.2. **Provide performance scores on the measure as specified (current and over time) at the specified level of analysis.** *(This is required for endorsement maintenance. Include mean, std dev, min, max, interquartile range, scores by decile. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities included).*

This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.
Testing results for this measure was performed on data for calendar years 2012 and 2013.

For the 2012 data, results were calculated for one Medicare plan (N=1,807,725), one Commercial plan (N=16,615,029) and one Medicaid plan (N=665,715). The measure rates ranged from 59.1% to 67.6%, with a mean of 62.8% and a standard deviation of 6.6%.

For the 2013 data, results were calculated for 736 Medicare Part D plans (N=23,185,246). The measure rates range from 66.1% to 100%, with a mean of 72.5% and a standard deviation of 8.3%. The Interquartile Range (IQR) is 6.2%.

1b.3. **If no or limited performance data on the measure as specified is reported in 1b2, then provide a summary of data from the literature that indicates opportunity for improvement or overall less than optimal performance on the specific focus of measurement.**
N/A

1b.4. **Provide disparities data from the measure as specified (current and over time) by population group, e.g., by race/ethnicity, gender, age, insurance status, socioeconomic status, and/or disability.** *(This is required for endorsement maintenance. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities include.) This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*
For calendar year 2012, the measure rates were calculated by three different insurance types. The rate for the Commercial insurance population is 60.4%. The rate for the Medicare population is 73.6%, and the rate for the Medicaid population is 59.1%.

Data from January-March 2015 for eight (8) Part D contracts show that the measure rate for the Low Income Subsidy (LIS) population is 67.3%, while the rate in the Non-LIS population is 67.1%.

Definition: Medicare Low Income Subsidy (LIS)
A subsidy paid by the Federal government to the drug plan for Medicare beneficiaries who need extra help with their prescription drug costs due to limited income and resources. Medicare beneficiaries apply for the LIS with the Social Security Administration or their State Medicaid agency.

The following groups automatically qualify for LIS without applying:
- Full–benefit dual eligible's (Medicare and Medicaid eligible)
- Supplemental Security Income recipients
- Medicare beneficiaries who participate in the Medicare Saving Programs
  - QMB – qualified Medicare beneficiary
  - SLMB – specified low-income Medicare beneficiary
  - QI – qualifying individual

1b.5. **If no or limited data on disparities from the measure as specified is reported in 1b4, then provide a summary of data from the literature that addresses disparities in care on the specific focus of measurement. Include citations.**
N/A

1c. High Priority (previously referred to as High Impact)
The measure addresses:
- a specific national health goal/priority identified by DHHS or the National Priorities Partnership convened by NQF; OR
- a demonstrated high-priority (high-impact) aspect of healthcare (e.g., affects large numbers of patients and/or has a substantial impact for a smaller population; leading cause of morbidity/mortality; high resource use (current and/or future); severity of illness; and severity of patient/societal consequences of poor quality).

1c.1. **Demonstrated high priority aspect of healthcare**
Affects large numbers, A leading cause of morbidity/mortality
1c.2. **If Other:**

1c.3. **Provide epidemiologic or resource use data that demonstrates the measure addresses a high priority aspect of healthcare. List citations in 1c.4.**
This measure addresses two highly prevalent diseases, diabetes and cardiovascular disease (CVD). There are 29 million people in the

United States with diabetes, 9.3% of the population. (1) Cardiovascular disease is the leading cause of death in the United States.(2) Diabetes is a significant risk factor for CVD and diabetes can be viewed as a high-risk state for CVD, similar to having coronary heart disease.(3) The ACC/AHA Guidelines indicate that persons with diabetes who are 40-75 years of age are at increased risk of developing atherosclerotic cardiovascular disease events and statin therapy is used to decrease this risk. (4)

PQA testing data from CMS and a commercial database also demonstrates that the measure addresses a large number of people. In a commercial population of around 16 million, there were 1.3 million people meeting the measure denominator. Nearly 5 million Medicare beneficiaries met the denominator criteria of a total population of 23 million.

1c.4. **Citations for data demonstrating high priority provided in 1a.3**

1c.5. **If a PRO-PM (e.g. HRQoL/functional status, symptom/burden, experience with care, health-related behaviors), provide evidence that the target population values the measured PRO and finds it meaningful.** *(Describe how and from whom their input was obtained.)*
N/A

2. Reliability and Validity—Scientific Acceptability of Measure Properties

Extent to which the measure, as specified, produces consistent (reliable) and credible (valid) results about the quality of care when implemented. ***Measures must be judged to meet the subcriteria for both reliability and validity to pass this criterion and be evaluated against the remaining criteria.***

2a.1. Specifications The measure is well defined and precisely specified so it can be implemented consistently within and across organizations and allows for comparability. eMeasures should be specified in the Health Quality Measures Format (HQMF) and the Quality Data Model (QDM).

De.5. **Subject/Topic Area** *(check all the areas that apply):*
Cardiovascular : Hyperlipidemia, Endocrine : Diabetes

De.6. **Cross Cutting Areas** *(check all the areas that apply):*
Health and Functional Status

S.1. **Measure-specific Web Page** *(Provide a URL link to a web page specific for this measure that contains current detailed specifications including code lists, risk model details, and supplemental materials. Do not enter a URL linking to a home page or to general information.)*

S.2a. **If this is an eMeasure**, HQMF specifications must be attached. Attach the zipped output from the eMeasure authoring tool

(MAT) - if the MAT was not used, contact staff. (Use the specification fields in this online form for the plain-language description of the specifications)
This is not an eMeasure **Attachment:**

S.2b. **Data Dictionary, Code Table, or Value Sets** *(and risk model codes and coefficients when applicable) must be attached. (Excel or csv file in the suggested format preferred - if not, contact staff)*
No data dictionary **Attachment:**

S.3. **For endorsement maintenance**, please briefly describe any changes to the measure specifications since last endorsement date and explain the reasons.
N/A

S.4. **Numerator Statement** *(Brief, narrative description of the measure focus or what is being measured about the target population, i.e., cases from the target population with the target process, condition, event, or outcome)*
IF an OUTCOME MEASURE, state the outcome being measured. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
The number of patients in the denominator who received a prescription fill for a statin or statin combination during the measurement year.

S.5. **Time Period for Data** *(What is the time period in which data will be aggregated for the measure, e.g., 12 mo, 3 years, look back to August for flu vaccination? Note if there are different time periods for the numerator and denominator.)*
The measurement period is generally a 12 month calendar year and extends through the last day of the enrollment period or until death or disenrollment.

S.6. **Numerator Details** *(All information required to identify and calculate the cases from the target population with the target process, condition, event, or outcome such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
IF an OUTCOME MEASURE, describe how the observed outcome is identified/counted. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
The number of patients in the denominator who received a prescription fill for a statin or statin combination during the measurement year. Statin medications for this measure include: lovastatin, rosuvastatin, fluvastatin, atorvastatin, pravastatin, pitavastatin, simvastatin. Statin combination medications for this measure include: niacin & lovastatin, atorvastatin & amlodipine, niacin & simvastatin, sitagliptin & simvastatin, ezetimibe & simvastatin, ezetimibe & atorvastatin. Note: The active ingredients are limited to oral formulations only.

S.7. **Denominator Statement** *(Brief, narrative description of the target population being measured)*
The denominator includes subjects aged 41 years – 75 years as of the last day of the measurement year who are continuously enrolled during the measurement period. Subjects include patients who were dispensed two or more prescription fills for a hypoglycemic agent during the measurement year.

S.8. **Target Population Category** *(Check all the populations for which the measure is specified and tested if any):*
Populations at Risk, Populations at Risk : Dual eligible beneficiaries, Populations at Risk : Individuals with multiple chronic conditions

S.9. **Denominator Details** *(All information required to identify and calculate the target population/denominator such as definitions, specific data collection items/responses , code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
Subjects are included if they are age 41-75 at the end of the measurement year. Subjects should be continuously enrolled during the measurement period. To determine continuous enrollment using enrollment data, for a Medicaid beneficiary for whom enrollment is verified monthly, the member may not have more than a 1-month gap in coverage (i.e., a member whose coverage lapses for 2 months [60 consecutive days] is not considered continuously enrolled). Subjects are included in the denominator if they were dispensed two or more prescription fills for a hypoglycemic agent during the measurement year. Hypoglycemic medications for this measure include:

Biguanides and Biguanide Combination Products: Metformin, pioglitazone & metformin, rosiglitazone & metformin, repaglinide & metformin, sitagliptin & metformin IR & SR, saxagliptin & metformin SR, linagliptin & metformin, glyburide & metformin, glipizide & metformin, alogliptin & metformin

Sulfonylureas and Sulfonylurea Combination Products: chlorpropamide, glipizide & metformin, glimepiride, glipizide, glyburide & metformin, glyburide, rosiglitazone & glimepiride, pioglitazone & glimepiride, tolazamide, tolbutamide

Meglitinides and Meglitinide Combination Products: nateglinide, repaglinide, repaglinide & metformin

Alpha- Glucosidase Inhibitors: acarbose, miglitol

Thiazolidinediones and Thiazolidinedione Combination Products: pioglitazone, pioglitazone & glimepiride, pioglitazone & metformin, rosiglitazone, rosiglitazone & glimepiride, rosiglitazone & metformin, alogliptin & pioglitazone

Incretin Mimetic Agents: exenatide, dulaglutide, liraglutide, albiglutide

Amylin Analogs: pramlintide

DPP-IV Inhibitors and DPP-IV Inhibitor Combination Products: sitagliptin, linagliptin, alogliptin, saxagliptin, alogliptin & metformin, alogliptin & pioglitazone, linagliptin & metformin, sitagliptin & metformin IR & SR, saxagliptin & metformin SR, sitagliptin & simvastatin

Insulins: insulin aspart, insulin aspart Protamine & Aspart, insulin detemir, insulin glargine, insulin glulisine, insulin isophane & regular human insulin, insulin isophane (human N), insulin lispro, insulin lispro Protamine & Insulin lispro, insulin regular (human R), insulin regular (human) inhalation powder

Sodium glucose co-transporter2 (SGLT2) Inhibitors: canagliflozin, dapagliflozin, emapaglifozin

Note: Excludes nutritional supplement/dietary management combination products.

S.10. Denominator Exclusions *(Brief narrative description of exclusions from the target population)*
Those persons receiving hospice care at any point during the measurement year.
The exclusion uses enrollment data.

S.11. Denominator Exclusion Details *(All information required to identify and calculate exclusions from the denominator such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
Hospice status may not be identifiable in all non-Medicare prescription drug plan benefits. The exclusion will be for any person receiving hospice care during the measurement year. It is a limitation of the measure if enrollment data for line of business (e.g. Medicaid, Commercial) does not routinely include this information and therefore cannot use the exclusion in the measure calculation.
Limitation: Hospice enrollment data may not be routinely available to non-Medicare plans such as Medicaid and Commercial lines of business

S.12. Stratification Details/Variables *(All information required to stratify the measure results including the stratification variables, definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format with at S.2b)*
This measure will be stratified by insurance product line. Rates for Commercial, Medicaid, and Medicare will be reported separately.

S.13. Risk Adjustment Type (Select type. Provide specifications for risk stratification in S.12 and for statistical model in S.14-15)
No risk adjustment or risk stratification
If other:

S.14. Identify the statistical risk model method and variables *(Name the statistical method - e.g., logistic regression and list all the risk factor variables. Note - risk model development and testing should be addressed with measure testing under Scientific Acceptability)*
N/A

S.15. Detailed risk model specifications *(must be in attached data dictionary/code list Excel or csv file. Also indicate if available at measure-specific URL identified in S.1.)*

Note: Risk model details (including coefficients, equations, codes with descriptors, definitions), should be provided on a separate worksheet in the suggested format in the Excel or csv file with data dictionary/code lists at S.2b.

S.15a. **Detailed risk model specifications** (*if not provided in excel or csv file at S.2b*)
N/A

S.16. **Type of score:**
Rate/proportion
If other:

S.17. **Interpretation of Score** *(Classifies interpretation of score according to whether better quality is associated with a higher score, a lower score, a score falling within a defined interval, or a passing score)*
Better quality = Higher score

S.18. **Calculation Algorithm/Measure Logic** *(Describe the calculation of the measure score as an ordered sequence of steps including identifying the target population; exclusions; cases meeting the target process, condition, event, or outcome; aggregating data; risk adjustment; etc.)*
Denominator Calculation:
Step 1: Identify the eligible population that is 41-75 years of age as of the last day of the measurement period and that are continuously enrolled in the drug plan.
Step 2: Exclude any person that is in hospice (Medicare Part D)
Step 3: Identify those patients in Step 2 who were dispensed two or more prescription fills for a hypoglycemic agent during the measurement year.
The number of patients identified in Step 3 is the denominator for the measure.

Numerator Calculation:

Step 4: Of those patients identified in Step 3, identify the patients who received one or more prescription fills for a statin or statin combination during the measurement year.
The number of patients identified by completing Step 4 represents the numerator for this measure.

Step 5: Divide the numerator by the denominator and then multiply by 100 to obtain the rate (as a percentage) for the measure.

S.19. **Calculation Algorithm/Measure Logic Diagram URL or Attachment** *(You also may provide a diagram of the Calculation Algorithm/Measure Logic described above at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
No diagram provided

S.20. **Sampling** *(If measure is based on a sample, provide instructions for obtaining the sample and guidance on minimum sample size.)*
IF a PRO-PM, identify whether (and how) proxy responses are allowed.
N/A

S.21. **Survey/Patient-reported data** *(If measure is based on a survey, provide instructions for conducting the survey and guidance on minimum response rate.)*
IF a PRO-PM, specify calculation of response rates to be reported with performance measure results.
N/A

S.22. **Missing data** (specify how missing data are handled, e.g., imputation, delete case.)
Required for Composites and PRO-PMs.
N/A

S.23. **Data Source** *(Check ONLY the sources for which the measure is SPECIFIED AND TESTED).*
If other, please describe in S.24.
Administrative claims

S.24. **Data Source or Collection Instrument** *(Identify the specific data source/data collection instrument e.g. name of database, clinical registry, collection instrument, etc.)*
IF a PRO-PM, identify the specific PROM(s); and standard methods, modes, and languages of administration.
Health plan (e.g., Medicare, Medicaid, other) prescription claims data. Health Plan member enrollment information. This measure is intended to be reported by prescription drug plans that only have prescription claims and enrollment data.

S.25. **Data Source or Collection Instrument** *(available at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
No data collection instrument provided

S.26. **Level of Analysis** *(Check ONLY the levels of analysis for which the measure is SPECIFIED AND TESTED)*
Health Plan, Population : National

S.27. **Care Setting** *(Check ONLY the settings for which the measure is SPECIFIED AND TESTED)*
Pharmacy
If other:

S.28. **COMPOSITE Performance Measure** - Additional Specifications *(Use this section as needed for aggregation and weighting rules, or calculation of individual performance measures if not individually endorsed.)*
N/A

NATIONAL QUALITY FORUM—Measure Testing (subcriteria 2a2, 2b2-2b7)

Measure Number (*if previously endorsed*)**:** Click here to enter NQF number
Measure Title: Statin Use in Persons with Diabetes
Date of Submission: 6/29/2015
Type of Measure:

☐Composite – ***STOP – use composite testing form***	☐Outcome (*including PRO-PM*)
☐Cost/resource	XProcess
☐Efficiency	☐Structure

Instructions

- Measures must be tested for all the data sources and levels of analyses that are specified. ***If there is more than one set of data specifications or more than one level of analysis, contact NQF staff*** about how to present all the testing information in one form.
- **For all measures, sections 1, 2a2, 2b2, 2b3, and 2b5 must be completed.**
- **For outcome and resource usemeasures**, section **2b4** also must be completed.
- If specified for **multiple data sources/sets of specificaitons** (e.g., claims andEHRs), section **2b6** also must be completed.
- Respond to all questions as instructedwith answers immediately following the question. All information on testing to demonstrate meeting the subcriteria for reliability (2a2) and validity (2b2-2b6) must be in this form. An appendix for *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 20 pages (*incuding questions/instructions;* minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

- For information on the most updated guidance on how to address sociodemographic variables and testing in this form refer to the release notes for version 6.6 of the Measure Testing Attachment.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the testing results for this measure meet NQF's evaluation criteria for testing.

2a2.Reliability testing[10] demonstrates the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise. For **PRO-PMs and composite performance measures**, reliability should be demonstrated for the computed performance score.

2b2.Validity testing[11] demonstrates that the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality. For **PRO-PMs and composite performance measures**, validity should be demonstrated for the computed performance score.

2b3. Exclusions are supported by the clinical evidence; otherwise, they are supported by evidence of sufficient frequency of occurrence so that results are distorted without the exclusion; [12]

AND

If patient preference (e.g., informed decision-making) is a basis for exclusion, there must be evidence that the exclusion impacts performance on the measure; in such cases, the measure must be specified so that the information about patient preference and the effect on the measure is transparent (e.g., numerator category computed separately, denominator exclusion category computed separately). [13]

2b4.For outcome measures and other measures when indicated (e.g., resource use):

- **an evidence-based risk-adjustment strategy** (e.g., risk models, risk stratification) is specified; is based on patient factors (including clinical and sociodemographic factors) that influence the measured outcome and are present at start of care; [14,15] and has demonstrated adequate discrimination and calibration

OR

- rationale/data support no risk adjustment/ stratification.

2b5. Data analysis of computed measure scores demonstrates that methods for scoring and analysis of the specified measure allow for **identification of statistically significant and practically/clinically meaningful**[16]**differences in performance**;

OR

there is evidence of overall less-than-optimal performance.

2b6.If multiple data sources/methods are specified, there is demonstration they produce comparable results.

2b7. For **eMeasures, composites, and PRO-PMs** (or other measures susceptible to missing data),analyses identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias.

Notes

10. Reliability testing applies to both the data elements and computed measure score. Examples of reliability testing for data elements include, but are not limited to: inter-rater/abstractor or intra-rater/abstractor studies; internal consistency for multi-item scales; test-retest for survey items. Reliability testing of the measure score addresses precision of measurement (e.g., signal-to-noise).

11. Validity testing applies to both the data elements and computed measure score. Validity testing of data elements typically analyzes agreement with another authoritative source of the same information. Examples of validity testing of the measure score include, but are not limited to: testing hypotheses that the measures scores indicate quality of care, e.g., measure scores are different for groups known to have differences in quality assessed by another valid quality measure or method; correlation of measure scores with another valid indicator of quality for the specific topic; or relationship to conceptually related measures (e.g., scores on process measures to scores on outcome measures). Face validity of the measure score as a quality indicator may be adequate if accomplished through a systematic and transparent process, by identified experts, and explicitly addresses whether performance scores resulting from the measure as specified can be used to distinguish good from poor quality.

12. Examples of evidence that an exclusion distorts measure results include, but are not limited to: frequency of occurrence, variability of exclusions across providers, and sensitivity analyses with and without the exclusion.

13. Patient preference is not a clinical exception to eligibility and can be influenced by provider interventions.

14. Risk factors that influence outcomes should not be specified as exclusions

15. With large enough sample sizes, small differences that are statistically significant may or may not be practically or clinically meaningful. The substantive question may be, for example, whether a statistically significant difference of one percentage point in the percentage of patients who received smoking cessation counseling (e.g., 74 percent v. 75 percent) is clinically meaningful; or whether a statistically significant difference of $25 in cost for an episode of care (e.g., $5,000 v. $5,025) is practically meaningful. Measures with overall less-than-optimal performance may not demonstrate much variability across providers.

1. DATA/SAMPLE USED FOR ALL TESTING OF THIS MEASURE

Often the same data are used for all aspects of measure testing. In an effort to eliminate duplication, the first five questions apply to all measure testing. If there are differences byaspect of testing,(e.g., reliability vs. validity) be sure to indicate the specific differences in question 1.7.

1.1. What type of data was used for testing? (*Check all the sources of data identified in the measure specifications and data used for testing the measure. Testing must be provided forall the sources of data specified and intended for measure implementation.* ***If different data sources are used for the numerator and denominator, indicate N [numerator] or D [denominator] after the checkbox.***)

Measure Specified to Use Data From: (***must be consistent with data sources entered in S.23***)	**Measure Tested with Data From:**
☐abstracted from paper record	☐abstracted from paper record
X administrative claims	X administrative claims
☐clinical database/registry	☐clinical database/registry
☐abstracted from electronic health record	☐abstracted from electronic health record
☐eMeasure (HQMF) implemented in EHRs	☐eMeasure (HQMF) implemented in EHRs
☐other: Click here to describe	☐other: Click here to describe

1.2. If an existing dataset was used, identify the specific dataset (*the dataset used for testing must be consistent with the measure specifications for target population and healthcare entities being measured; e.g., Medicare Part A claims, Medicaid claims, other commercial insurance, nursing home MDS, home health OASIS, clinical registry*).

For 2012, the data were derived from three data sources. The first is the Truven Health MarketScan® Commercial Claims and Encounters Database. These data represent the health services of approximately 139 million employees, dependents, and retirees in the United States with primary coverage through privately insured fee-for-service, point-of-service, or capitated health plans. There were more than 40 million lives in the database in for 2012.

The second was The MarketScan Medicare Supplemental and Coordination of Benefits Database (Medicare Supplemental Database). This database represents over 8.3 million lives and had more than 3.3 million covered lives in 2012. The database includes the Medicare-covered portion of payment (represented as Coordination of Benefits Amount, or COB), the employer-paid portion, and any out-of-pocket patient expenses. The data elements in this database are the same as those appearing in the Commercial Database, but pertain to patients with Medicare supplemental insurance.

The third data source is the MarketScan Medicaid Multi-State Database, which contains the medical, surgical and prescription drug experience of more than 19 million Medicaid enrollees from multiple states. It includes records of inpatient services, inpatient admissions, outpatient services, and prescription drug claims, as well as information about long term care and other medical care. Data on eligibility, service, and provider type are also included. There were more than 5 million lives in the database in 2012.

For 2013, the data used for testing came from ***three data sources***. For identification of prescription drugs, the Medicare Part D Prescription Drug Event (PDE) claims were used. To identify dates of birth and continuous enrollment, the Common Medicare Environment (CME) data source was used. To identify hospice enrollment, the Medicare Enrollment Database (EDB) was used.

1.3. What are the dates of the data used in testing? Two years of data were used for testing, from two different data sources. The years included calendar year 2012 and calendar year 2013.

1.4. What levels of analysis were tested? (*testing must be provided for<u>all</u> the levels specified and intended for measure implementation, e.g., individual clinician, hospital, health plan*)

Measure Specified to Measure Performance of: (***must be consistent with levels entered in item S.26***)	**Measure Tested at Level of:**
☐ individual clinician	☐ individual clinician
☐group/practice	☐group/practice
☐hospital/facility/agency	☐hospital/facility/agency
X health plan	X health plan
☐other: Click here to describe	☐other: Click here to describe

1.5. How many and which <u>measured entities</u> were included in the testing and analysis(by level of analysis and data source)? (*identify the number and descriptive characteristics of measured entities included in the analysis (e.g., size, location, type); if a sample was used, describe how entities were selected for inclusion in the sample*)

For the calendar year 2012 data, the testing analysis included 25 health plans, including a national convenience sample of privately insured fee-for-service, point-of-service, capitated health plans, Medicare and Medicaid plans. The size and characteristics of the population are included at the patient level in 1.6.

For the calendar year 2013 data, the testing analysis included a convenience sample of 736 Medicare Part D prescription drug plans. The size and characteristics of the population are included at the patient level in 1.6.

1.6. How many and which <u>patients</u> were included in the testing and analysis(by level of analysis and data source)? (*identify the number and descriptive characteristics of patients included in the analysis (e.g., age, sex, race, diagnosis); if a sample was used, describe how patients were selected for inclusion in the sample*)

For calendar year 2012, a total of 19,088,469 patients age 40-75 were included in the testing and analysis. This data can be stratified by insurance type, gender, and age. Of all patients, 16,615,029 (87.0%) are enrolled in a Commercial health insurance plan, 1,807,725 (9.5%) are enrolled in Medicare, and 665,715 (3.5%) are enrolled in Medicaid. Of all patients, 9,018,357 (47.2%) are male, and 10,070,112 (52.8%) are female. Patients by age group included 17,261,150 (90.4%) age 40-64 years, and 1,827,319 (9.6%) age 65-75.

For calendar year 2013, a total of 22,145,248 patients age 40-75 were included in the testing and analysis. This data can be stratified by gender and age. Of all patients, 9,943,095 (44.9%) are male, and 12,202,153 (55.1%) are female. Patients by age group included 5,743,719 (25.9%) age 40-64 years, and 16,401,529 (74.1%) age 65-75.

1.7. If there are differences in the data or sample used for different aspects of testing (e.g., reliability, validity, exclusions, risk adjustment), identify how the data or sample are different for each aspect of testing reported below.
N/A

1.8 What were the patient-level sociodemographic (SDS) variables that were available and analyzed in the data or sample used? For example, patient-reported data (e.g., income, education, language), proxy variables when SDS data are not collected from each patient (e.g. census tract), or patient community characteristics (e.g. percent vacant housing, crime rate).

No patient level or proxy sociodemographic status (SDS) variables were analyzed in the 2012 and 2013 testing data. We reviewed patient-level Low Income Subsidy (LIS) data from January-March 2015 for eight (8) Part D contracts, which showed that the measure rate for the LIS population is not significantly different from the rate in the Non-LIS population (67.3% vs 67.1%, respectively.)

2a2. RELIABILITY TESTING
***<u>Note</u>**: If accuracy/correctness (validity) of data elements was empirically tested, separate reliability testing of data elements is not required – in 2a2.1 check critical data elements; in 2a2.2 enter "see section 2b2 for validity testing of data elements"; and skip 2a2.3 and 2a2.4.*

2a2.1. What level of reliability testing was conducted? (*maybe one or both levels*)
Critical data elements used in the measure (*e.g., inter-abstractor reliability; data element reliability must address ALL critical data elements*)
X Performance measure score (e.g., *signal-to-noise analysis*)

2a2.2. For each level checked above, describe the method of reliability testing and what it tests (*describe the steps—do not just name a method; what type of error does it test; what statistical analysis was used*)

<u>Performance Measure Score</u>

Using a mixed effect logistic regression model with varying intercept, a signal to noise analysis was conducted to examine the variability in performance measure score at the plan level, which is the unit of analysis specified

for this measure. This test was conducted with the Medicare PDE data described in sections 1.2- 1.7. This test examines the variance in performance measure score between plans compared to the variance in performance measure score for individuals within plans, and models the individual's SUPD rate based on the varying plan mean. A likelihood-ratio (LR) test was also performed to determine if a model with random effects would fit the data better than a standard logistic regression model without random effects.

2a2.3. For each level of testing checked above, what were the statistical results from reliability testing? (e.*g., percent agreement and kappa for the critical data elements; distribution of reliability statistics from a signal-to-noise analysis*)

The results of the mixed effect model are outlined in Table 1.

Table 1. Mixed Effect Logistic Regression Model, Statin Use in Persons with Diabetes measure rate comparison across Part D plans

	Coefficient	**Standard**	**Z**	**p-value**
Intercept	1.018	0.009	110.56	<0.001
	Estimate	**Standard**	**95% Confidence Interval**	
Random Effects	0.224	0.008	0.210	0.239

The p-value for the likelihood ratio test was <0.001.

2a2.4 What is your interpretation of the results in terms of demonstrating reliability? (i.*e., what do the results mean and what are the norms for the test conducted?*)

Performance Measure Score

The mixed effect logistic regression model results show that the standard deviation of the intercept term is significantly different from zero (0.224), and is also supported by the 95% confidence interval, which does not contain 0. In addition, the likelihood-ratio test shows that the varying intercept model (which allows SUPD rates to vary across contracts) fits the observed data better than a standard logistic regression model without random effects (which restricts all contracts to have the same average SUPD rate) with the p-value of <0.001; significant at alpha=0.05.

These results indicate that there are significant differences in performance measure scores between plans, which allows for discrimination between high performing plans and low performing plans. Based on these results, the SUPD measure is considered to be reliable.

2b2. VALIDITY TESTING

2b2.1. What level of validity testing was conducted? (*may be one or both levels*)

☐ **Critical data elements** (*data element validity must address ALL critical data elements*)

☐**Performance measure score**

☐**Empirical validity testing**

X **Systematic assessment of face validity of performance measure score as an indicator** of quality or

resource use (*i.e., is an accurate reflection of performance on quality or resource use and can distinguish good from poor performance*)

2b2.2. For each level of testing checked above, describe the method of validity testing and what it tests (*describe the steps—do not just name a method; what was tested, e.g., accuracy of data elements compared to authoritative source, relationship to another measure as expected; what statistical analysis was used)*

PQA uses a transparent, consensus-based measure development and testing process. The process used in 2014 to develop the measure, Statin Use in Persons with Diabetes (SUPD), is outlined below:

Step 1: The PQA Adherence workgroup identified this measure concept as appropriate for development into a fully specified performance measure during their February 2014 meeting. Workgroups typically focus on specific aspects of the medication-use system and/or specific therapeutic areas for the basis of a measure concept. In this case the workgroup focused on the ACC/AHA Guidelines that recommend diabetic patients age 40-75y/o receive statin medications to reduce their risk of cardiovascular disease. The workgroup included representatives of PQA members with interest in medication use measures and clinical expertise. The workgroup used a consensus-based approach to specify all aspects of the measure concept.

During the process of development, the workgroup invited a guest speaker to provide information about the ACC/AHA guidelines and to answer questions about specific technical specifications in the measure concept as it was being developed. The guest speaker was Joseph Saseen, PharmD Professor in the Departments of Clinical Pharmacy and Family Medicine at the University of Colorado Anchutz Medical Campus. Dr. Saseen is on the Board of Directors for the National Lipid Association and the Board of Pharmacy Specialties, and also is Director of the American College of Clinical Pharmacy Academy Career Advancement program.

After several months of meetings, the SUPD measure concept was developed and recommended (by vote) to the PQA Quality metrics Expert Panel (QMEP) for further evaluation. The voting results (June 23, 2014) by the workgroup were:

34 people voted in favor of recommending the concept to the QMEP
2 people voted against the recommendation
2 people abstained from voting

Step 2: The QMEP reviewed the measure concept on July 2, 2014 to provide an initial assessment of the key properties of performance measures (i.e., feasibility, usability and scientific validity). Measure concepts that are rated highly on these key properties will be tested.

QMEP voted unanimously in favor of testing the measure concept (13-0)

Step 3: The draft SUPD measure was provided to PQA member organizations for their comments prior to preparing technical specifications for pilot testing. The QMEP reviewed the member comments and then reviewed the testing plan based on this all-member feedback. Specific questions addressed in the testing plan included what criteria best identified diabetic patients (denominator) using only prescription claims data and understanding how many people would be in the denominator with contraindications to statin medications.

Step 4: PQA asked two member organizations to test the draft measure. The testing partner implemented the draft technical specifications with their existing datasets and provided a report to PQA that detailed testing results and recommendations for modifications of the technical specifications.

Step 5: The QMEP reviewed the testing results (October 8, 2014) and assessed the feasibility and scientific validity of the draft performance measure, SUPD.

The QMEP vote unanimous in favor of recommending the measure to the PQA membership for endorsement consideration (vote 15-0)

Step 6: Following the QMEP recommendation, the SUPD measure was posted on the PQA web site for member review. Written comments were requested via email, and a conference call for member organizations was held November 5, 2014 to address any questions. This process allows members to discuss their views on the measures in advance of the voting period.

Step 7: PQA member organizations voted on the endorsement of this performance measure in November, 2014. Of the PQA membership that voted, 89% voted to endorse the measure. (56 out of 63 voting member organizations)

2b2.3. What were the statistical results from validity testing? (*e.g., correlation; t-test*)

Of the 38 members of the PQA Workgroup that identified and developed the SUPD measure, 89.5% agreed that the measure had face validity, and recommended that the PQA Quality Measures Expert Panel (QMEP) consider it. After reviewing the measure concept specifications and testing results, 100% of the QMEP members recommended the measure to move forward to be endorsed by PQA membership. After review, 89% of PQA members agreed that the measure should be endorsed.

2b2.4. What is your interpretation of the results in terms of demonstrating validity? (i.*e., what do the results mean and what are the norms for the test conducted?*)

Based upon the rigorous PQA measure development process designed to assure face validity, and the high rate of consensus from the PQA Workgroup, QMEP, and PQA members, this measure has been determined to have face validity.

2b3. EXCLUSIONS ANALYSIS
NA ☐ no exclusions—*skip to section 2b4*

2b3.1. Describe the method of testing exclusions and what it tests (*describe the steps—do not just name a method; what was tested, e.g., whether exclusions affect overall performance scores; what statistical analysis was used*)

Patients in hospice are excluded from this measure. No testing was performed on this exclusion, as the data source, prescription claims data, do not contain claims for persons that are in hospice care.

2b3.2. What were the statistical results from testing exclusions? (*include overall number and percentage of individuals excluded, frequency distribution of exclusions across measured entities, and impact on performance measure scores*)
N/A

2b3.3. What is your interpretation of the results in terms of demonstrating that exclusions are needed to prevent unfair distortion of performance results?(*i.e., the value outweighs the burden of increased data collection and analysis. Note: **If patient preference is an exclusion**, the measure must be specified so that the effect on the performance score is transparent, e.g., scores with and without exclusion*)
N/A

2b4. RISK ADJUSTMENT/STRATIFICATION FOR OUTCOME OR RESOURCE USE MEASURES

If not an intermediate or health outcome, or PRO-PM, or resource use measure, skip to section 2b5.

2b4.1./S13What method of controlling for differences in case mix is used?

☐ **No risk adjustment or stratification**

☐**Statistical risk model with** Click here to enter number of factors**risk factors**

☐**Stratification by** Click here to enter number of categories**risk categories**

☐**Other,** Click here to enter description

2b4.1.2. If an outcome or resource use measure is not risk adjusted or stratified, provide rationale and analyses to demonstrate that controlling for differences in patient characteristics (case mix) is not needed to achieve fair comparisons across measured entities.

2b4.2/S14. Identify the statistical risk model variables (Name the statistical method – e.g., logistic regression and list all the risk factor variables.

2b4.2.1/S15. Detailed risk model specifications including coefficients, equations, codes with descriptors, definitions(may be attached in an Excel or cvs file)

2b4.3. Describe the conceptual/clinical and statistical methods and criteria used to select patient factors (clinical factors or sociodemographic factors) used in the statistical risk model or for stratification by risk(*e.g., potential factors identified in the literature and/or expert panel; regression analysis; statistical significance of p<0.10; correlation of x or higher; patient factors should be present at the start of care*)

2b4.4a. What were the statistical results of the analyses used to select risk factors?

2b4.4b. Describe the analyses and interpretation resulting in the decision to select SDS factors (e.g. prevalence of the factor across measured entities, empirical association with the outcome, contribution of unique variation in the outcome, assessment of between-unit effects and within-unit effects)

2b4.5. Describe the method of testing/analysis used to develop and validate the adequacy of the statistical model or stratification approach (*describe the steps—do not just name a method; what statistical analysis was used*)

Provide the statistical results from testing the approach to controlling for differences in patient characteristics (case mix) below.

If stratified, skip to 2b4.9

2b4.6. Statistical Risk Model Discrimination Statistics (*e.g., c-statistic, R-squared*)**:**

2b4.7. Statistical Risk Model Calibration Statistics(*e.g., Hosmer-Lemeshow statistic*):

2b4.8. Statistical Risk Model Calibration – Risk decile plots or calibration curves:

2b4.9. Results of Risk Stratification Analysis:

2b4.10. What is your interpretation of the results in terms of demonstrating adequacy of controlling for differences in patient characteristics (case mix)? (i.*e., what do the results mean and what are the norms for the test conducted*)
N/A

2b4.11.Optional Additional Testing for Risk Adjustment(*not required, but would provide additional support of adequacy of risk model, e.g., testing of risk model in another data set; sensitivity analysis for missing data; other methods that were assessed*)

2b5. IDENTIFICATION OF STATISTICALLY SIGNIFICANT & MEANINGFUL DIFFERENCES IN PERFORMANCE

2b5.1. Describe the method for determining if statistically significant and clinically/practically meaningful differences in performance measure scores among the measured entities can be identified (*describe the steps—do not just name a method; what statistical analysis was used? Do not just repeat the information provided related to performance gap in 1b)*

To assess significant differences in measure rates, we used 2013 Medicare Part D data for 736 plan contracts, and calculated the distribution mean, median, standard deviation, and interdecile range. These statistics are reported below in 2b5.2, Tables 1 and 2.

Data from the 2012 Truven Health MarketScan® Databases were also analyzed to assess differences between Medicare, Commercial and Medicare plans. Using a test of proportions, a p-value was calculated to determine if there are statistically significant differences in measure rates between health plans. Comparisons were made for differences in rates between Medicare and Medicaid, Medicare and Commercial, and Commercial and Medicaid (2b5.2, Table 3).

2b5.2. What were the statistical results from testing the ability to identify statistically significant and/or clinically/practically meaningful differences in performance measure scores across measured entities? (e.g., *number and percentage of entities with scores that were statistically significantly different from mean or some benchmark, different from expected; how was meaningful difference defined*)

Table 1. Variation in SUPD Measure Rates -2013 Medicare Part D data

Mean	Median	Standard Deviation
72.45	72.57%	8.31%

Table 2. Interdecile Range of SUPD Measure Rates -2013 Medicare Part D data

10th Percentile	66.07%
20th Percentile	68.49%

30th Percentile	70.45%
40th Percentile	71.53%
50th Percentile	72.57%
60th Percentile	73.46%
70th Percentile	74.81%
80th Percentile	76.61%
90th Percentile	80.23%
100th Percentile	100.00%
Interdecile Range	14.17%

Table 3. SUPD Measure rates, by insurance type – 2012 Truven Health MarketScan® Databases

Insurance Type	Measure Rate	p-value Medicare vs. Medicaid	p-value Medicare vs. Commercial	p-value: Medicaid vs. Commercial
Medicare	73.6%	<0.0001	<0.0001	
Medicaid	59.1%	<0.0001		<0.0001
Commercial	60.4%		<0.0001	<0.0001

2b5.3. What is your interpretation of the results in terms of demonstrating the ability to identify statistically significant and/or clinically/practically meaningful differences in performance across measured entities? (i.*e., what do the results mean in terms of statistical and meaningful differences?*)

The measure rates for the 2013 data showed significant variation, with a standard deviation of 8.31%. The 10th percentile rate was 66.07%, the maximum rate was 100%, and the interdecile range was 14.17%. The 2012 data demonstrated statistically significant differences in measure rates between heath plan types (P<0.0001 for all comparisons). The measure rates ranged from 59.1% in the Medicaid population to 73.6% in the Medicare population. This variation shows meaningful differences in whether patients aged 40-75 with diabetes are receiving statins.

2b6. COMPARABILITY OF PERFORMANCE SCORES WHEN MORE THAN ONE SET OF SPECIFICATIONS

If only one set of specifications, this section can be skipped.

- Only one set of specifications is provided for this measure.

Note: *This criterion is directed to measures with more than one set of specifications/instructions (e.g., one set of specifications for how to identify and compute the measure from medical record abstraction and a different set of specifications for claims or eMeasures). It does not apply to measures that use more than one source of data in one set of specifications/instructions (e.g., claims data to identify the denominator and medical record abstraction for the numerator).* ***Comparability is not required when comparing performance scores with and***

without SDS factors in the risk adjustment model. However, if comparability is not demonstrated for measures with more than one set of specifications/instructions, the different specifications (e.g., for medical records vs. claims) should be submitted as separate measures.

2b6.1. Describe the method of testing conducted to demonstrate comparability of performance scores for the same entities across the different data sources/specifications (*describe the steps—do not just name a method; what statistical analysis was used*)
N/A

2b6.2. What were the statistical results from testing comparability of performance scores for the same entities when using different data sources/specifications?(*e.g., correlation, rank order*)
N/A

2b6.3. What is your interpretation of the results in terms of demonstrating comparability of performance measure scores for the same entities across the different data sources/specifications?(i.*e., what do the results mean and what are the norms for the test conducted*)
N/A

2b7. MISSING DATA ANALYSIS AND MINIMIZING BIAS

2b7.1. Describe the method of testing conducted to identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias(*describe the steps—do not just name a method; what statistical analysis was used*)

With the utilization of prescription claims data as the data source for this measure, the dispensing information (including medication, days supply and quantity dispensed) is available for each patient. The requirements to utilize this measure include medication (National Drug Code, or NDC), days supply and prescription fill date.

Since each of these data elements are available via prescription claims data, it is not expected—nor was it found—that missing data would result. Age is derived from the date of birth in the enrollment data. The date of birth in the CMS Medicare Enrollment Database (EDB) is considered to largely be valid and reliable since it determines eligibility for enrollment and payment of services.

2b7.2. What is the overall frequency of missing data, the distribution of missing data across providers, and the results from testing related to missing data? (*e.g.,results of sensitivity analysis of the effect of various rules for missing data/nonresponse; if no empirical sensitivity analysis, identify the approaches for handling missing data that were considered and pros and cons of each*)

The frequency of missing data is zero for the current analysis.

2b7.3. What is your interpretation of the results in terms of demonstrating that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias**?** (i.*e., what do the results mean in terms of supporting the selected approach for missing data and what are the norms for the test conducted;if no empirical analysis, provide rationale for the selected approach for missing data*)

As stated above, no missing data was found through testing, nor would missing data be expected to occur in the future. Therefore, performance results would not be biased, as prescription claims data provides the data elements necessary to calculate the measure rate.

3. Feasibility

Extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

3a. Byproduct of Care Processes

For clinical measures, the required data elements are routinely generated and used during care delivery (e.g., blood pressure, lab test, diagnosis, medication order).

3a.1. **Data Elements Generated as Byproduct of Care Processes.**

Other

If other: Prescription claims data

3b. Electronic Sources

The required data elements are available in electronic health records or other electronic sources. If the required data are not in electronic health records or existing electronic sources, a credible, near-term path to electronic collection is specified.

3b.1. **To what extent are the specified data elements available electronically in defined fields?** *(i.e., data elements that are needed to compute the performance measure score are in defined, computer-readable fields)*

ALL data elements are in defined fields in electronic claims

3b.2. **If ALL the data elements needed to compute the performance measure score are not from electronic sources, specify a credible, near-term path to electronic capture, OR provide a rationale for using other than electronic sources.**

3b.3. **If this is an eMeasure, provide a summary of the feasibility assessment in an attached file or make available at a measure-specific URL.**

Attachment:

3c. Data Collection Strategy

Demonstration that the data collection strategy (e.g., source, timing, frequency, sampling, patient confidentiality, costs associated with fees/licensing of proprietary measures) can be implemented (e.g., already in operational use, or testing demonstrates that it is ready to put into operational use). For eMeasures, a feasibility assessment addresses the data elements and measure logic and demonstrates the eMeasure can be implemented or feasibility concerns can be adequately addressed.

3c.1. **Describe what you have learned/modified as a result of testing and/or operational use of the measure regarding data collection, availability of data, missing data, timing and frequency of data collection, sampling, patient confidentiality, time and cost of data collection, other feasibility/implementation issues.**

IF a PRO-PM, consider implications for both individuals providing PROM data (patients, service recipients, respondents) and those whose performance is being measured.

Prescription claims data is required for payment to health plans, so there is no extra burden or cost in the collection of the data. There have been no feasibility issues with the use of this measure.

3c.2. **Describe any fees, licensing, or other requirements to use any aspect of the measure as specified** *(e.g., value/code set, risk model, programming code, algorithm)*.

PQA develops and maintains numerous performance measures related to the medication use system. The Measures are the proprietary property of PQA, and it is in the interest of PQA to protect and promote the appropriate use of the Measures. PQA may approve an organization's use of the Measures; however, no organization may use the Measures without first obtaining permission from PQA prior to using the Measures. Certain uses of the Measures are only approved with a licensing agreement from PQA that specifies the terms of use and the licensing fee. PQA reserves the right to determine the conditions under which it will approve and/or license the Measures.

Licenses are granted on a year-to-year basis. PQA reserves the right to audit the licensee's use of the Measures and may revoke a license if it is determined that the licensee has used the Measures in a manner that is outside the scope of permitted use that was specified in the licensing agreement.

Licensees using PQA measures for commercial purposes are required to pay a fee. The licensing fee may be structured as a fixed annual amount or as a variable amount that is dependent on the volume of utilization of the Measures. As a benefit of membership, PQA members who use the Measures only for internal quality improvement initiatives (i.e., self-assessment) will not be assessed a licensing fee.

4. Usability and Use

Extent to which potential audiences (e.g., consumers, purchasers, providers, policy makers) are using or could use performance results for both accountability and performance improvement to achieve the goal of high-quality, efficient healthcare for individuals or populations.

4a. Accountability and Transparency

Performance results are used in at least one accountability application within three years after initial endorsement and are publicly reported within six years after initial endorsement (or the data on performance results are available). If not in use at the time of initial endorsement, then a credible plan for implementation within the specified timeframes is provided.

4.1. Current and Planned Use

NQF-endorsed measures are expected to be used in at least one accountability application within 3 years and publicly reported within 6 years of initial endorsement in addition to performance improvement.

Planned	Current Use (for current use provide URL)
Public Reporting Regulatory and Accreditation Programs	Quality Improvement (Internal to the specific organization) Medicare Part D Patient Safety Reportsty http://www.cms.gov/Medicare/Prescription-Drug-Coverage/PrescriptionDrugCovGenIn/index.html?redirect=/PrescriptionDrugCovGenIn/06_PerformanceData.asp

4a.1. For each CURRENT use, checked above, provide:

- Name of program and sponsor
- Purpose
- Geographic area and number and percentage of accountable entities and patients included

Name of program: Medicare Part D Patient Safety Reports
Purpose: Quality improvement and monitoring
Geographic area – National; nearly 700 health plan sponsor contracts

4a.2. If not currently publicly reported OR used in at least one other accountability application (e.g., payment program, certification, licensing) what are the reasons? (*e.g., Do policies or actions of the developer/steward or accountable entities restrict access to performance results or impede implementation?*)

The measure is new (endorsed by PQA membership in November 2014) and is being further evaluated by Medicare Part D. It is currently being reported by CMS to all Medicare Part D health plan sponsors in the monthly Patient Safety Reports. The reports are based on 2015 prescription drug event (PDE) information.
URAC is planning to add this measure as an exploratory measure to their accreditation programs for Community Pharmacy, PBM, and Mail Service.

4a.3. If not currently publicly reported OR used in at least one other accountability application, provide a credible plan for implementation within the expected timeframes -- any accountability application within 3 years and publicly reported within 6 years of initial endorsement. (*Credible plan includes the specific program, purpose, intended audience, and timeline for*

implementing the measure within the specified timeframes. A plan for accountability applications addresses mechanisms for data aggregation and reporting.)
CMS is considering this measure as a new 2017 display measure (using 2015 data) and as a possible 2018 Star Rating measure (using 2016 data).
Source: Memorandum April 2015: Announcement of Calendar Year 2016 Medicare Advantage Capitation Rates and Medicare Advantage and Part D Payment Policies and Final Call Letter. Attachment VII: 2016 Call Letter Pg 111
http://www.cms.gov/Medicare/Health-Plans/MedicareAdvtgSpecRateStats/index.html

4b. Improvement

Progress toward achieving the goal of high-quality, efficient healthcare for individuals or populations is demonstrated. If not in use for performance improvement at the time of initial endorsement, then a credible rationale describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.

4b.1. **Progress on Improvement. (Not required for initial endorsement unless available.)**
Performance results on this measure (current and over time) should be provided in 1b.2 and 1b.4. Discuss:

- **Progress (trends in performance results, number and percentage of people receiving high-quality healthcare)**
- **Geographic area and number and percentage of accountable entities and patients included**

N/A

4b.2. **If no improvement was demonstrated, what are the reasons? If not in use for performance improvement at the time of initial endorsement, provide a credible rationale that describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.**
N/A

4c. Unintended Consequences

The benefits of the performance measure in facilitating progress toward achieving high-quality, efficient healthcare for individuals or populations outweigh evidence of unintended negative consequences to individuals or populations (if such evidence exists).

4c.1. **Were any unintended negative consequences to individuals or populations identified during testing; OR has evidence of unintended negative consequences to individuals or populations been reported since implementation? If so, identify the negative unintended consequences and describe how benefits outweigh them or actions taken to mitigate them.**
No negative consequences were incurred by individuals or populations during the testing nor has any evidence of unintended negative consequences to individuals or populations been demonstrated.

5. Comparison to Related or Competing Measures

If a measure meets the above criteria and there are endorsed or new related measures (either the same measure focus or the same target population) or competing measures (both the same measure focus and the same target population), the measures are compared to address harmonization and/or selection of the best measure.

5. Relation to Other NQF-endorsed Measures
Are there related measures (conceptually, either same measure focus or target population) or competing measures (conceptually both the same measure focus and same target population)? If yes, list the NQF # and title of all related and/or competing measures.
Yes

5.1a. **List of related or competing measures (selected from NQF-endorsed measures)**

5.1b. **If related or competing measures are not NQF endorsed please indicate measure title and steward.**
The following NQF endorsed measure was not included on the drop down above:

NQF Measure 0729: Optimal Diabetes Care- Cholesterol Statin Use Component
Measure Steward: MN Community Measurement

5a. Harmonization

The measure specifications are harmonized with related measures;

OR

The differences in specifications are justified

5a.1. **If this measure conceptually addresses EITHER the same measure focus OR the same target population as NQF-endorsed measure(s):**

Are the measure specifications completely harmonized?

No

5a.2. **If the measure specifications are not completely harmonized, identify the differences, rationale, and impact on interpretability and data collection burden.**

Differences between measures 0729 and 2712: The composite measure, 0729, addresses A1c, blood pressure, statin use, tobacco non-use and daily aspirin or anti-platelet use for patients with diagnosis of ischemic vascular disease. Measure 2712 addresses one specific aspect of appropriate medication use, statin medications in a population with diabetes age 40-75. The composite measure, 0729, is reported at the clinician level and uses data from the medical record. Measure 2712 is reported at the health plan level is based on prescription claims data. The composite measure 0729 includes diabetic patients 18-75 years, while measure 2712 only includes diabetic patients age 40-75 years. While the intent and basis of the measures are similar, there are some differences in the measure specification. These differences are due to the accessibility of clinical data for measure 0729 including LDL, allergies, diagnosis etc. Rationale: The rationales of the measures are similar as they address the same guideline but in different settings of care. Impact on interpretability: These measures will be interpreted differently since one (0729) is a composite measure of diabetes care used by clinicians in an ambulatory setting. The other measure (2712) is specific to statin use in a limited age group of diabetics and will be used by health plans and pharmacists. Data collection burden: There will be no additional level of burden as the data used in measure 2712 is prescription claims data and administrative data that are already collected by the health plan.

5b. Competing Measures

The measure is superior to competing measures (e.g., is a more valid or efficient way to measure);

OR

Multiple measures are justified.

5b.1. **If this measure conceptually addresses both the same measure focus and the same target population as NQF-endorsed measure(s):**

Describe why this measure is superior to competing measures (e.g., a more valid or efficient way to measure quality); OR provide a rationale for the additive value of endorsing an additional measure. (Provide analyses when possible.)

N/A

Appendix

A.1 Supplemental materials may be provided in an appendix. All supplemental materials (such as data collection instrument or methodology reports) should be organized in one file with a table of contents or bookmarks. If material pertains to a specific submission form number, that should be indicated. Requested information should be provided in the submission form and required attachments. There is no guarantee that supplemental materials will be reviewed.

PQA QMEP members´ role: The PQA Quality Metrics Expert Panel (QMEP) is charged with evaluating the measure concepts proposed by the PQA workgroups and prioritizing the measure concepts for specification and testing. The Panel reviews comments from PQA members on draft measures to determine whether modifications should be made or what variations should be considered during testing. The QMEP reviews the results of the pilot-testing of the draft measures and makes final recommendations to the PQA membership regarding endorsement of the draft measures. The Panel is comprised of persons who have clinical or other technical expertise related to quality measurement. The members are invited to serve on the QMEP by PQA's senior measurement development team. The composition of the QMEP reflects PQA's membership.

Members of the 2014 QMEP include:

Steven Burch	GSK
Catherine Coast	Highmark
Lynn Deguzman	Kaiser Perm
Chris Dezii	BMS
Chris DuPaul	CVS/Caremark

MEASURE WORKSHEET

This document summarizes the evaluation of the measure as it progresses through NQF's Consensus Development Process (CDP). The information submitted by measure developers/stewards is included after the Brief Measure Information, Preliminary Analysis, and Pre-meeting Public and Member Comments sections.

To navigate the links in the worksheet: Ctrl + click link to go to the link; ALT + LEFT ARROW to return

Brief Measure Information

NQF #: 2740
Measure Title: Proportion of Patients with coronary artery disease (CAD) that have a Potentially Avoidable Complication (during the episode time window)
Measure Steward: Health Care Incentives Improvement Institute Inc. (HCI3)
Brief Description of Measure: Percent of adult population aged 18 + years who triggered an episode of coronary artery disease (CAD), are followed for at least one-year, and have one or more potentially avoidable complications (PACs). PACs may occur any time during the episode time window. Please reference attached document labeled NQF_CAD_all_codes_risk_adjustment_06.30.15.xls, in the tabs labeled PACs I-9 and PAC I-10 for a list of code definitions of PACs relevant to CAD.
We define PACs as one of two types:
(1) Type 1 PACs - PACs directly related to the index condition: Patients are considered to have a PAC, if they receive services during the episode time window for any of the complications directly related to CAD, such as for hypotension, cardiac arrest, fluid and electrolyte disturbances etc.
(2) Type 2 PACs - PACs suggesting Patient Safety Failures: Patients are also considered to have a PAC, if they receive services during the episode time window for any of the complications related to patient safety failures such as for sepsis, infections, phlebitis, deep vein thrombosis, pressure sores etc..
All relevant admissions in a patient with CAD are considered potentially avoidable and flagged as PACs.
PACs are counted as a dichotomous (yes/no) outcome. If a patient had one or more PACs, they get counted as a "yes" or a 1. The enclosed workbook labeled NQF_CAD_all_codes_risk_adjustment_06.30.15.xls serves as an example. The tab labeled PAC overview gives the percent of CAD episodes that have a PAC and the tab labeled "PAC drill down" gives the types of PACs and their frequencies in CAD episodes within this dataset.
The information is based on a two-year claims database from a large regional commercial insurer. The database had over 3.2 million covered lives and over $25.9 billion in "allowed amounts" for claims costs. The database is an administrative claims database with medical as well as pharmacy claims.
Developer Rationale:
1d.3.
Each individual PAC, when measured in isolation, provides a very limited picture of the performance of the provider(s) who are managing or co-managing the care of the patient. However, looking at all the PACs that may occur individually or concurrently in a patient with a given episode provides a comprehensive picture of the care received by the patient for that particular condition or illness.

Additionally, the frequency of occurrence of individual PACs may be so low that it may require very high sample sizes from individual providers to achieve any meaningful and reliable comparisons. But aggregating all the PACs into a single quality metric creates meaningful scores that can be compared across providers even with relatively smaller sample sizes.

Additionally, a comprehensive measure is easier to explain to the average consumer. From a patient's point of view, any bad outcome has an impact on their health with respect to return to work, functional limitations and need for additional support. If a provider has a high PAC rate with regards to one component PAC but not the other PACs, the impact on the patient is still adverse. In selecting providers, individual component PAC scores would mean nothing to a patient, but aggregating it to a comprehensive quality score could be a measure of "all-cause" harms and easier to interpret and act on.

1b.1. Measures associated to potentially avoidable complication (PAC) have been used as comprehensive outcomes measures since 2007 for several conditions and procedures (de Brantes 2010) (Joynt 2013) (James 2013). In 2011, following the NQF endorsement of these measures for certain acute medical conditions (AMI, Pneumonia and Stroke), and for chronic conditions, they were adopted for

various purposes, including the creation of related measures (NQF – Measure #1550). Some commercial payers have used them as a means for tracking outcomes (Yong 2010) and for tiering providers for pay for performance programs (BCBSNC). In addition, some provider organizations have used them in quality improvement efforts by homing in on the detailed specifications of the measures to reveal opportunities for care improvement (CALPERS – link below). Identification of PACs has spurred provider innovation (Bundled Payment Summit 2015) for practice re-engineering, to create proactive care pathways, and to focus on areas of high variability (McVary 2010). Some employers are also using measures of avoidable complications as public measures of quality (Colorado Business Group on Health) given the research that demonstrated the potential efficacy of these measures to differentiate provider quality and cost (Hibbard 2012). In fact in a series of focus groups led by Judy Hibbard and colleagues, the researchers found that the very framing of potentially avoidable complications as an indicator of potential harm, is an effective way of communicating the quality of care. And when measures of PACs were presented in conjunction with price, consumers intuitively accepted the logical relationship between low PACs – fewer "defects" – and lower price.

Accountability for and measurement of PACs occurs at the practice, medical group, provider system or purchaser/payer level. PAC rates are calculated as absolute values. For example, a health plan would report that 60% of its plan members with CAD incurred PACs in the study time window. The objective of the measure is to encourage the unit being measured to progressively reduce that amount over time. In addition, comparisons of PAC rates across plans or provider systems should be encouraged and publicly reported. An organization that uses the measure should be able to identify the leading causes of PACs and implement improvements to existing processes that will decrease PACs. There are several tools available for provider systems and health plans to impact PAC rates. These include care coordination across care settings; post-discharge planning and patient follow- up, active care management, sharing medical record data between care settings and providers, total quality management within hospitals and active reduction of patient safety failures. Reducing PACs has the potential to significantly improve the overall level of quality.

Creating a single measure of accountability for physicians and hospitals tied to gaps in quality is likely to yield much improved outcomes for patients. A measure of accountability for health plans helps them review trends over time and work with physicians and hospitals to improve the ways in which they engage patients using more optimal care management and care coordination (Cassel 2014). In addition, PAC measures could be used as a surrogate for quality in a consumer transparency tool to differentiate providers with regards to their performance.

Moreover, since these measures are claims based, there is minimal added burden for collecting the data, and it also avoids potential gaming that may occur for other measures that require reporting information to registries. Although use of administrative claims data in identifying conditions and measuring provider quality has been questioned, there are several studies in literature that acknowledge validity of its use (Normand 2007) (Quan 2009). Until more readily available data are at hand, use of administrative data to measure provider performance has steadily increased (Miller 2001), (NQF Quality Positioning System). Interestingly, in the current fee for service system, services for most PACs are rewarded by continued payment (except the CMS defined "never events") and hence to our advantage, adverse events surface in billing data. Claims based PAC measures; therefore serve as an alternative method to track adverse outcomes that do occur (Leibson 2008).

Numerator Statement: Outcome: Number of patients who triggered an episode of coronary artery disease (CAD), are followed for at least one-year, and had one or more potentially avoidable complications (PACs) during the episode time window.
Denominator Statement: Adult patients aged 18 years and above who triggered an episode of coronary artery disease (CAD) and are followed for at least one-year.
Denominator Exclusions: Denominator exclusions include exclusions of either "patients" or "claims" based on the following criteria:
1. "Patients" excluded are those that do not meet the enrollment criteria. If patient has an enrollment gap for more than 30 days during the episode time window, it is considered as an enrollment gap
2. "Patients" are also excluded if the cost of the episode is an outlier at greater than 99th percentile or less than 1st percentile value for all episodes. This is another way to ensure that episodes are complete as well as they do not bring in random noise into the analysis due to inappropriate codes or services.
3. "Claims" are excluded from the CAD measure if they are considered not relevant to CAD care.

Measure Type: Composite, Outcome
Data Source: Administrative claims
Level of Analysis: Clinician : Group/Practice, Clinician : Team
Is this an eMeasure? ☐ **Yes** ☒ **No** **If Yes, was it re-specified from a previously endorsed measure?** ☐ **Yes** ☐ **No**

1d.1. **Composite Measure Construction:** any-or-none measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient)any-or-none measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient)
Component Measures (if endorsed or submitted for endorsement): n/a. The individual complications are considered measurable components

Is this a MAINTENANCE measure submission? ☐ **Yes** ☒ **No, this is a NEW measure submission.**
For MAINTENANCE, state the Original Endorsement Date: n/a **Most Recent Endorsement Date:** n/a

Preliminary Analysis

The preliminary analysis was developed in response to recommendations from NQF's Consensus Task Force and measurement stakeholders as a way to enhance and streamline the measures evaluation and voting processes. The preliminary analysis will help to guide the Standing Committee evaluation of each measure by summarizing the measure developer submission, guide measure evaluation discussion, and identify topic areas for additional input. **NQF staff would like to stress that the preliminary analysis is intended to be used as a guide to facilitate the Committee's discussion and evaluation.**

Criteria 1: Importance to Measure and Report

1a. Evidence

1a. Evidence. The evidence requirements for this *health outcomes* measure include providing rationale that supports the relationship of the health outcome to processes or structures of care. The guidance for evaluating clinical evidence asks if the there is a relationship between the measured health outcome and at least one clinical action is identified and if it is supported by the stated rationale. For a composite measure, the developer must discuss the reasoning for the composite quality constructs, the rationale for constructing, & aggregation and weighting of measure components.

- This new risk-adjusted (by age, gender and clinical co-morbidities) outcomes composite measure assesses the proportion (rate) of adult patients with Coronary Artery Disease (CAD) with *at least one* Potentially Avoidable Complications (PAC) within 12 months of CAD triggered claims data. Based on NQF's criteria, this measure is considered an "any or none" composite measure that assesses if 1 or more PACs or "care defects" have occurred for the index episode. For this composite measure, the individual complications considered the measurable components. PACs are classified in two types: 1) related to CAD, and 2) related to Patient Safety Failures. The2 PAC types are combined into a single "any or none" (bimodal "yes" or "no") PAC rate. PACs are considered unwarranted health outcomes that combine concepts from AHRQ PSIs, PQIs and the CMS HACs and episode-specific PACs into index episode all-cause patient harms rate.
- The developer links primary & secondary prevention care gaps, poor patient education, poor care coordination and poor follow-up increase unnecessary ER visits, hospitalizations, readmissions, and mortalities to increased PACs, and state that PACs for CAD patients should occur rarely in well-managed patients.
- The evidence for Patient Safety Failure PACs is described to be within the influence of the measured entity, though the rationale for selecting some of the identified PACs is not clear (e.g., post procedural fever, oral bisphosphonates, hallucinations). The developer provides an extensive list of comorbidities as risk factor for increased PAC potential, though the severity is not captured in consistently within the claims data.
- In addition to linking processes of care to outcomes, the developer provides an extensive PAC literature review in sections 1a.2. and 1a.2.1. for CAD, Patient Safety Failures & processes of care.
- The developer discusses the rationale for constructing, aggregation and equal weighting for the measure.

Questions for the Committee:

- *Does sufficient evidence exist connecting Patient Safety Failures to the CAD index episode?*
- *Does sufficient evidence exist between the measured health outcome and at least one clinical action identified and supported by the stated rationale?*

1b. Gap in Care/Opportunity for Improvement and 1b. Disparities

1b. Performance Gap. The performance gap requirements include demonstrating quality problems and opportunity for improvement.

- The developer identifies significant CAD prevalence data as the leading cause of US mortalities, as well as BOOST and the Dartmouth Atlas Project CAD readmission rates.
- PAC performance gaps are calculated from PROMETHEUS administrative claims data from April 1, 2012 - December 17, 2014, for providers with ≥ 10 attributable index episodes. The data includes 468 of 5840 (8.0%) providers from 31,093 of 63,972 (48.6%) index episodes in 3,258,706 unique beneficiaries).

Unadjusted PAC Rates:		**Risk-Standardized PAC Rates (RSPR):**	
Median (IQR):	40.0% (29.9%, 54.8%)	Median (IQR):	40.1% (32.6%, 47.5%)
Range:	0% -100%	Range:	0% - 84%

- Descriptive data on the patient, provider and payer are not provided. The developer provides "Overview" and "Drill Down" PAC rates in the spreadsheet demonstrating gap, though PAC rates for individual complications are not provided.
- The developer does not provide data on disparities.

Questions for the Committee:

- *Is there a gap in care that warrants a national performance measure?*
- *If no disparities information is provided, are you aware of evidence that disparities exist in this area of healthcare?*
- *Should this measure be indicated as disparities sensitive?*

1c. Priority

1c. High Priority (previously "High Impact") requires measures to address national health goal/priority or a demonstrated high-impact aspect of care.

- *Beginning in 2015, priority is no longer an NQF measure evaluation criterion.*

Committee pre-evaluation comments

Criteria 1: Importance to Measure and Report (including 1a, 1b, 1c)

1. ***Committee's Overview Comments***:
   - This is an outcome measure. The developers DO NOT Present any evidence of this measure being performed in pilot or research setting.

1a. ***Committee's Comments on Evidence to Support Measure Focus:***

- Not Applicable

1b. ***Committee's Comments on Performance Gap:***

- Performance Gap presented for outcomes in CAD but not with this composite measure.

1c. ***Committee's Comments on Composite Performance Measure:***

- I did not find this measure clearly presented with respect to performance.

Criteria 2: Scientific Acceptability of Measure Properties

2a. Reliability

2a1. Reliability Specifications

2a1. Specifications requires the measure, as specified, to produce consistent (reliable) and credible (valid) results about the quality of care when implemented.

- The measure assesses the rate of patients with 1 or more PAC(s) during index episodes. This new risk adjusted outcomes measure is specified for use at the clinician group and team levels of analyses.
- The measure exclusively uses electronically available administrative claims data to calculation the measure score, and for this measure, better care equals lower scores.
- The developer states that non-patient-related PACs as controllable by provider processes without further analysis as other influencers that may contribute to PAC rates beyond the patient and provider (e.g., payer, access, suppliers, etc.).
- Patient- and claims- based exclusions are provided to promote the availability and consistency of claims data capture, including payer enrollment requirements, cost outliers of < 1% or > 99%, and claims not relevant to CAD.
- Developers provide administrative claims data for CAD & PAC (CAD- & Patient Safety Failure-related) triggers, and describe a complete 12-month episode time window. A calculation algorithm is provided.
- ICD-9 & ICD-10 codes are provided. ICD-10 descriptions & the ICD-10 conversion methodology are not provided.
- A conceptual risk model and statistical method using logistic regression model for determining the probability of a patient incurring a PAC are provided. After adjusting for patient-related factors, the developers state the remaining

PAC variance is due to factors potentially controlled by the provider during and after hospitalization. "Predicted" coefficients from the risk adjustment models are summed to give predicted probabilities of PAC occurrence.

Questions for the Committee:

- *Are all the data elements clearly defined? Are all appropriate codes included?*
- *Is the logic or calculation algorithm clear?*
- *Is it likely this measure can be consistently implemented?*

2a2. Reliability Testing Testing attachment

2a2. Reliability testing demonstrates if the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise enough to distinguish differences in performance across providers.

- The developer tested reliability at the performance measure score, and used a beta-binomial model and a signal-to-noise analysis, which is appropriate for this type of measure, to differentiate the true difference between measured entities (the signal) to random measurement error (the noise). A value of 0 indicates that all variation is due to measurement error and a value of 1 indicates that all variation is due to real differences in between *provider* performance. A value of 0.7 is often regarded as a minimum acceptable reliability value.
- The measure is specified for CAD patients ≥ 18 years, though the testing sample includes patients 18 through 64 years.
- Providers with < 10 CAD episodes were excluded from reliability testing, though the measure is specified for patient without episode restrictions. A sample of 468 of 5840 (8.0%) providers and 31,093 of 63,972 (48.6%) CAD episodes were included in the testing, for patients with a mean age of 56.4 (18-64 years) with 27% being female.
- The developer states, "Minimum sample size requirements for PAC measures are a function of the reliability testing of the measures on every dataset on which the measures are applied. Our research suggests that minimum sample sizes to achieve high degrees of reliability in the measures are a function of the dataset analyzed, and as such may vary from dataset to dataset. One should not infer that a minimum sample size achieved in one dataset will apply to another." The developer also states that very high sample sizes are to achieve any meaningful and reliable comparisons.
- A patient may have more than one condition-specific concurrent episode with claims applied to both episodes. If an inpatient claim corresponds to a procedure index episode and to a condition index episode, the claim would be assigned to the procedure index episode, rather than the condition index episode (e.g., for a claim that corresponds to both index episodes of CAD & CABG, the claim would be assigned to CABG).
- Patient with missing gender were excluded from the denominator, and no other missing data was identified.
- Reliability results are provided in the table below, as well as in great detail in the accompanied spreadsheet with median (IQR) results demonstrating median reliability of 0.73 (0.61,0.83) for ≥ 10 providers, increasing with the number of episodes per provider. For reliability analysis, providers were restricted to the minimum of 10 CAD episodes, though all episodes were included in the risk model.
- The developer provides a supplementary fact sheet (available for review on SharePoint) requiring a minimum of 21 index episodes for absolute reliability, and a minimum of 10 index episodes for median reliability of > 0.7.

Reliability Scores	Minimum # Episodes Per Provider		
	>=10	>=25	>=50
# of Providers (%)	468 (100)	171 (37)	80 (17)
Median (IQR)	0.73 (0.61,0.83)	0.85 (0.79,0.91)	0.92 (0.88,0.95)
Range	0.50-1.00	0.72-0.99	0.84-0.99

The table provides a summary reliability scores minimum sample size thresholds. Complete results are provided in the workbook entitled, NQF_CAD_all_codes_risk_adjustment_06.30.15.xls, under the "ProviderAttribution Reliability" tab.

Questions for the Committee:

- *Reliability testing was conducted only for those providers with at least 10 episodes. Can differences in performance*

be identified for providers with fewer than 10 episodes? For patients ≥ 65 years?

- *Should the measure be specified to include only those providers with at least 10 episodes?*
- *Is the test sample adequate to generalize for widespread implementation?*
- *Do the results demonstrate sufficient reliability so that differences in performance can be identified?*

2b. Validity

2b1. Validity: Specifications

2b1. Validity Specifications. This section should determine if the measure specifications are consistent with the evidence.

- Because this is an outcome measure, the rationale that is presented for subcriterion 1a does not necessarily have to address all of the variables used to calculate the measure.
- The measure uses a statistical risk model with 170 risk factors and episode-specific subtypes/severity markers including age, gender and clinical comorbidities, on at least 10 claims to determine "stable" covariates and assess comorbidity or procedure impact on the PAC. All covariates must be present prior to an episode trigger. No formal covariate analysis was conducted to select risk factors beyond the present on a minimum of 10 claims threshold. The developer describes the heterogeneity of the provided data sets as crucial to ensure measure validity, and the accuracy and completeness of the data sets.
- The developers did not provide disparities data, an exploration of a conceptual relation to SDS, or empirical testing of SDS factors in the risk model.

Question for the Committee:

- *Are the specifications consistent with the evidence?*
- *Are these variables available and generally accessible for the measured patient population?*

2b2. Validity testing

2b2. Validity Testing should demonstrate the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality.

- The developer conducted systematic assessment of face validity for the performance measure score for validity testing in numerous ways, including the use of monthly multi-specialty clinical working groups and focus groups, and face validity comparisons of the measure to other national accountability measures, as well as additional literature for the measure & PAC development process.
- No empiric results are provided for the face validity tests described above.

Questions for the Committee:

- *Is the test sample adequate to generalize for widespread implementation?*
- *Do the results demonstrate sufficient validity so that conclusions about quality can be made?*
- *Do you agree that the score from this measure as specified is an indicator of quality?*
- *Is there evidence of a systematic assessment of expert opinion beyond those involved in developing the measure?*

2b3-2b7. Threats to Validity

2b3. Exclusions:

- The developer describes patient- (demographic, enrollment or low/high claims cost) and claims-based (due to missing or non-relevant data) exclusions for the measure. They further state nearly half of the original population of CAD patients was removed from the denominator with applied exclusions.
- A significant number of patients were eliminated from the measure due to exclusion criteria, including 31,093 of 63,972 CAD (48.6%) episodes (in 3,258,706 unique beneficiaries) and 468 of 5840 (8.0%) providers.

Questions for the Committee:

- *Are high cost outliers (> 99%) exclusions an opportunity to identify PACs?*
- *Does the high number of exclusions restrict the measure use?*
- *Are the exclusions consistent with the evidence?*
- *Are any patients or patient groups inappropriately excluded from the measure?*
- *Are the exclusions/exceptions of sufficient frequency and variation across providers to be needed (and outweigh the data collection burden)?*

2b4. Risk adjustment:

- The risk model (detailed in the accompanied spreadsheet) includes 170 factors and subtypes including age, gender, 12-month enrollment markers, co-morbidities, and episode severity markers.
- No SDS factors beyond age and gender were included in the risk-adjustment approach. The developers note that race was not available for analysis, and no description of the of the conceptual relationships between patient sociodemographic factors, patient clinical factors, quality of care, and the outcomes (PAC rates) were provided, nor do they discuss the availability of SDS variables.
- Logistic regression was used to model the probability of at least one PAC during an episode. The reasoning for no additional modeling performed is described.
- The performance of the model was determined with a split sample method by estimating the model coefficients using a development dataset (80% of the sample) and applying those coefficients to a validation dataset (20% of the sample). C-statistics for the development and validation samples with c-statistic results of 0.803 and 0.792, respectively. C-statistics measures the extent of a statistical model to discriminate between a patient with and without PAC, with an ability to predict if a PAC is or is not present about 75% of the time. A c-statistic of 0.50 indicates the model is no better than random prediction, implying that the patient risk factors do not predict variation in the outcome; conversely, a c-statistic of 1.0 indicates perfect prediction, implying patients' outcomes can be predicted completely by their risk factors, and physicians and hospitals play little role in patients' outcomes. Generally, models with c-statistic values of at least 0.7 are considered good.
- Both Hosmer-Lemeshow Goodness-of-Fit statistics and risk-decide plots were provided to indicate model fit. Results from the Hosmer-Lemeshow test suggest that the fit is not good; however, this test is sensitive to the number of groupings and sample sizes. Results from the risk decile plot indicate that the predicted PAC rates are similar to the observed PAC rates across all deciles of risk. The developer states the model demonstrates strong predictive power.

Questions for the Committee:

- *Is the Committee aware of conceptual relationship(s) between additional patient-level SDS factors, patient clinical factors, quality of care, and PACs (other than gender and age)? If so, what data might be available to allow an empirical analysis of these relationships?*
- *Is an appropriate risk-adjustment strategy included in the measure?*
- *Are the candidate and final variables included in the risk adjustment model adequately described for the measure to be implemented?*
- *Are all of the risk adjustment variables present at the start of care? If not, describe the rationale provided.*

2b5. Meaningful difference:

- The developer presents PAC rates across providers and also providers adjusting for differences in patient severity in a ratio of observed to expected attributable episodes to PACS accounting for patient severity, and calculates estimates from the risk model, for risk-standardized PAC rates for the provider.

Summary of Unadjusted and Adjusted Performance Scores Across Providers:

PAC Rates	Minimum # Episodes Per Provider	
	>=10	>=25
Unadjusted		
Median (IQR)	40% (30%, 55%)	39% (32%, 51%)
Range	0%-100%	8%-94%

Adjusted (RSPR)*		
Median (IQR)	40% (33%, 47%)	41% (34%, 46%)
Range	0%-84%	11%-71%

***RSPR = Risk Standardized PAC Rate**

Please refer to the NQF_CAD_all_codes_risk_adjustment_06.30.15.xls workbook under the "ProviderAttribution Reliability" tab to see specific results for each provider.

Question for the Committee:

- *Does this measure identify meaningful differences about quality?*

2b6. Comparability of data sources/methods:

- As there is only one data source used for measure calculation (administrative claims), comparability of data sources or methods is not applicable.

2b7. Missing Data

- No formal analysis of missing data is provided. As the measure assesses the rate of patients with PACs, rather than the rate of PACs per index episode, the total number of PACs is not included in the PAC rate.
- Patient with missing gender were excluded from the denominator, and no other missing data was identified.
- The developers state the under-coding of claims is unavoidable in the current DRG payment structure which could lead to under capture or missing PACs.

2d. Empirical Analysis to Support Composite Construction

- As an "any or none" composite, the individual complications are considered measurable components of the composite. Frequency and distribution statistics are provided in the PAC Overview and PAC Drill Down tabs in the measure spreadsheet, which detail PAC types and subtypes. The identification of individual PACs are not provided (e.g., sepsis, unattended falls, DVT).
- PACs are counted as a dichotomous (yes/no) outcome. If a patient had one or more PACs, they get counted as a "yes" or a 1. Since our premise is that all PACs are potentially avoidable, we adopted the approach to count all PACs and give them equal weights. The overall composite score results in the quality construct that could be measured and interpreted.
- The developer states that no formal analysis was performed on missing data. For details, see 2b7 above.

Committee pre-evaluation comments

Criteria 2: Scientific Acceptability of Measure Properties (including all 2a, 2b, and 2d)

2a1. &2b1.: ***Committee's Comments on Reliability-Specifications:***

- I did not find the Risk methodology clearly defined.

2a2.: ***Committee's Comments on Reliability-Testing:***

- Testing done on a small number of providers

2b1.: ***Committee's Comments on Validity-Specifications***:

- Developer stated face validity but no pilot data presented.

2b2.: ***Committee's Comments on Validity-Testing:***

- No data presented

2b3-7.: ***Committee's Comments on Threats to Validity:***

- Not Applicable

2d.: ***Committee's Comments on Composite Performance Measure:***

- Not Applicable

Criterion 3. Feasibility

3. Feasibility is the extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

- All measure elements are readily available in electronic sources via administrative claims data, and coded by someone other than the person obtaining the original information (e.g., DRG, ICD-9 codes on claims).
- The developer provides an excel spreadsheet attachment including claims coding for diagnoses, visits, hospitalizations, post-acute facility stays, procedures, laboratory tests and procedures/surgeries, for CAD & PAC triggers, and describe the time window for measuring PACs as 12 months following a CAD episode triggers, as well as a decision tree for measure calculation and implementation.
- The measure specifications, metadata and calculation algorithms are available free of charge on the developer's website. Limited analytics are planned at no cost to the end user.
- This is not an eMeasure.

Questions for the Committee:

- *Are the required data elements routinely generated and used during care delivery?*
- *Are the required data elements available in electronic form, e.g., EHR or other electronic sources?*
- *Is the data collection strategy ready to be put into operational use?*

Committee pre-evaluation comments

Criteria 3: Feasibility

3.: ***Committee's Comments on Feasibility:***

- I do not think this is feasible in current environment.

Criterion 4: Usability and Use

4. Usability and Use evaluate the extent to which audiences (e.g., consumers, purchasers, providers, policymakers) use or could use performance results for both accountability and performance improvement activities.

- This is a newly developed claims measure is currently used in accountability programs for payers, states, and planned for public reporting, professional certification or recognition programs, and external quality improvement for benchmarking purposes.
- The developer states that PAC measures provide a foundation for the relationship between healthcare quality and cost and assist in the exploration of practice reengineering and alternative payment models, act as indicators of potential harm, and is spurring the development of private-based analytics software for further outcomes exploration. No public improvement rates are available due to recent implementation and variation in PAC definitions have also modified, though the provided PROMETHEUS data suggest wide variation in performance and improvement opportunities. Payer and Provider improvement use perspectives are also outlined.
- The developer stated they identified no unintended consequences, though they also state the measure used in small volumes may be used for QI purposes, though they may produce unreliable performance scores. They further state that under-coding or "gaming" of claims is unavoidable in the current DRG payment structure could be an unintended consequences of the measure, and payers calculating the measures even with inadequate sample sizes and using the results to penalize providers could lead to invalid provider comparisons.
- If the measure was theoretically to be used for accountability purposes to "ding" the measured entity, further exploration of PAC antecedents and the measured entity is warranted, especially with small group practices and very small PAC rates. In the original testing sample of 5840 providers, when providers with fewer than 10 CAD episodes were eliminated from analysis due to less reliable estimates with small numbers, 468 (8.0%) remained for analysis.

Questions for the Committee:

- *Is the measure publicly reported?*
- *How can the performance results be used to further the goal of high-quality, efficient healthcare?*

- *Should PAC measures also include the clinician: group in the analysis or include population-level only entities?*
- *Do the benefits of the measure outweigh any potential unintended consequences?*

Committee pre-evaluation comments

Criteria 4: Usability and Use

4.: ***Committee's Comments on Usability and Use:***

- Tools will need to be developed for this to be practical.

Criterion 5: Related and Competing Measures

5.1a. List of related or competing measures (selected from NQF-endorsed measures)

0337 : Pressure Ulcer Rate (PDI 2)
0450 : Perioperative Pulmonary Embolism or Deep Vein Thrombosis Rate (PSI 12)
0705 : Proportion of Patients Hospitalized with Stroke that have a Potentially Avoidable Complication (during the Index Stay or in the 30-day Post-Discharge Period)
0708 : Proportion of Patients Hospitalized with Pneumonia that have a Potentially Avoidable Complication (during the Index Stay or in the 30-day Post-Discharge Period)
0709 : Proportion of patients with a chronic condition that have a potentially avoidable complication during a calendar year.
1789 : Hospital-Wide All-Cause Unplanned Readmission Measure (HWR)

5.1b. If related or competing measures are not NQF endorsed please indicate measure title and steward.

-0531 Patient Safety for Selected Indicators (Composite Measure, endorsed) (AHRQ)
-CMS defined hospital acquired conditions (HACs) are a subset of our PACs. We have pain-stakingly matched the definitions to provide as much consistency as possible. http://www.cms.

Pre-meeting public and member comments

-

NATIONAL QUALITY FORUM—Evidence (subcriterion 1a)

Measure Number (*if previously endorsed*)**:** 2740

Measure Title: Proportion of Patients with coronary artery disease (CAD) that have a Potentially Avoidable Complication (during the episode time window)

IF the measure is a component in a composite performance measure, provide the title of the Composite Measure here: Click here to enter composite measure #/ title

Date of Submission: 6/30/2015

Instructions

- *For composite performance measures:*
  - *A separate evidence form is required for each component measure unless several components were studied together.*
  - *If a component measure is submitted as an individual performance measure, attach the evidence form to the individual*

measure submission.

- Respond to all questions as instructed with answers immediately following the question. All information needed to demonstrate meeting the evidence subcriterion (1a) must be in this form. An appendix of *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 10 pages (*incudes questions/instructions*; minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the evidence for this measure meets NQF's evaluation criteria.

1a. Evidence to Support the Measure Focus

The measure focus is evidence-based, demonstrated as follows:

- Health outcome: [3] a rationale supports the relationship of the health outcome to processes or structures of care. Applies to patient-reported outcomes (PRO), including health-related quality of life/functional status, symptom/symptom burden, experience with care, health-related behavior.
- Intermediate clinical outcome: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured intermediate clinical outcome leads to a desired health outcome.
- Process: [5] a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured process leads to a desired health outcome.
- Structure: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured structure leads to a desired health outcome.
- Efficiency: [6] evidence not required for the resource use component.

Notes

3. Generally, rare event outcomes do not provide adequate information for improvement or discrimination; however, serious reportable events that are compared to zero are appropriate outcomes for public reporting and quality improvement.

4. The preferred systems for grading the evidence are the U.S. Preventive Services Task Force (USPSTF) grading definitions and methods, or Grading of Recommendations, Assessment, Development and Evaluation (GRADE) guidelines.

5. Clinical care processes typically include multiple steps: assess → identify problem/potential problem → choose/plan intervention (with patient input) → provide intervention → evaluate impact on health status. If the measure focus is one step in such a multistep process, the step with the strongest evidence for the link to the desired outcome should be selected as the focus of measurement. Note: A measure focused only on collecting PROM data is not a PRO-PM.

6. Measures of efficiency combine the concepts of resource use and quality (see NQF's Measurement Framework: Evaluating Efficiency Across Episodes of Care; AQA Principles of Efficiency Measures).

1a.1.This is a measure of: (*should be consistent with type of measure entered in De.1*)

Outcome

☒ Health outcome: Potentially Avoidable Complications

☐Patient-reported outcome (PRO): Click here to name the PRO

PROs include HRQoL/functional status, symptom/symptom burden, experience with care, health-related behaviors

☐ Intermediate clinical outcome (*e.g., lab value*): Click here to name the intermediate outcome

☐ Process: Click here to name the process

☐ Structure: Click here to name the structure

☐ Other: Click here to name what is being measured

HEALTH OUTCOME/PRO PERFORMANCE MEASURE *If not a health outcome or PRO, skip to 1a.3*

1a.2. Briefly state or diagram the path between the health outcome (or PRO) and the healthcare structures, processes, interventions, or services that influence it.

CAD is a chronic condition with a high prevalence rate that can be controlled by primary and secondary prevention, the guidelines for which are well established (Weintraub 2011). Non-compliance to primary and secondary prevention is associated with potentially avoidable complications such as cardiovascular hospitalizations, the need for revascularization procedures and also an increase in all-cause cardiovascular mortality (Mozaffarian 2015). While there is a general understanding of the nature of care failures in chronically ill patients (e.g. ambulatory care sensitive hospitalizations) (Yuen 2004), there has been no attempt to measure the magnitude or the type of potentially avoidable complications, and the cost reductions that would ensue if a payment model encouraged care to be optimized at benchmarks achieved in studies.

There is enough evidence in the literature that highlights significant "gaps in care" in management of patients with chronic conditions (McGlynn 2003). Gaps in care, in turn lead to process failures that cause patients to incur unnecessary services and some harm (Jha 2013). For example, a report by the Agency of Health Care Research and Quality (AHRQ) highlighted the fact that in 2008, $4.4 million out of a total of 39 million (11 percent) hospital-stays that could have been prevented (Stranges 2008); and for Medicare beneficiaries one in five admissions were for a potentially preventable condition (Jiang 2006). To improve accountability in the delivery of medical care, AHRQ has developed a list of patient safety indicators (PSIs) to identify potential harms to patients and a list of ambulatory care sensitive conditions (ACSCs) to identify admissions that could have been potentially avoided with good outpatient care. AHRQ PQI 13 (Patient Quality Indicator) measures admission rates for angina without procedure (AHRQ 2008). Additionally, the Centers for Medicare and Medicaid Services (CMS) have taken a "Six Sigma" approach and defined Hospital Acquired Conditions (HACs) and "never events" that should almost never occur and are applying financial penalties when these events do occur (CMS 2012).

The Potentially avoidable complications (PAC) measure goes beyond the AHRQ PSIs, PQIs and the CMS HACs and creates a single comprehensive measure that measures all-cause harms for a patient with the index condition. Potentially avoidable complications (PACs) are the unwarranted health outcomes that this measure addresses (de Brantes 2010). Lack of patient education on self care techniques, poor care coordination, and poor arrangements of patient follow-up could lead to unnecessary ER visits, hospitalizations and gaps in care leading to increased morbidity and even repeat acute coronary syndrome including acute myocardial infarction (Weaver 2013) (Southern 2014). All these adverse events are aggregated together as a single comprehensive measure to study the overall rate of PACs in the CAD population.

Adult patient diagnosed with Coronary Artery Disease

↓

Physician practices fail to educate patients / Physician practices have poor access

↓

Patient visits ER / gets hospitalized (Ambulatory care sensitive hospitalization event)

↓

Patient discharged with management advise / remains in hospital for treatment of PAC

Well-managed patients with CAD should rarely incur a potentially avoidable complication such as an emergency room visit, and hospitalizations related to CAD should occur only in the rarest of circumstances.

The enclosed workbook entitled NQF_CAD_all_codes_risk_adjustment_06.30.15.xls lists the types of PACs and their frequency as calculated in a large regional database (see tab PAC overview). Over 42% of patients with CAD had a PAC, with about 17% of PACs directly related to CAD itself, such as hypotension, syncope or fluid and electrolyte disorders (see tab PAC Drill Down Graph). Although the preventable hospitalizations in the CAD population were low, at only 3.5% of all CAD episodes; approximately 34% of patients with CAD had PACs related to patient centered care failures such as poor control of diabetes, respiratory insufficiency and acute gastritis, many of them being managed in an outpatient setting in physician offices. As a result over 40% of episodes had a PAC indicator on the professional claims.

While PACs may not be eliminated completely, identifying the magnitude of PACs and knowledge of the cause for the most frequent or the most expensive PACs could place an emphasis in reducing them and as a consequence improving patient outcomes. The ability to clearly identify the type and frequency of each PAC creates a highly actionable measure for all providers that are managing or co-managing the patient; as well as for the health plan with whom the patient is a member (de Brantes 2009).

1a.2.1. State the rationale supporting the relationship between the health outcome (or PRO) to at least one healthcare structure, process, intervention, or service (*i.e., influence on outcome/PRO*).

Rationale: Better processes of care create an atmosphere of proactive management, consistency in care and standardized care patterns (Shekelle 2013) (Fenter 2006). Patient education and adopting safe practices significantly reduces occurrence of potentially avoidable complications (PACs) in all settings (Klein 2011) (Wachter 2013) (Berwick 2006) (Kovner 2011) (Farley 2013). It is known that by holding providers accountable for occurrence and costs of PACs, a built-in warranty is created around care of the index condition (de Brantes 2009).

Specifically, management of CAD using evidence-informed guidelines lead to significantly improved outcomes. A study evaluating the impact of prevention on reducing the burden of cardiovascular disease found that, for patients with established CAD, appropriate LDL cholesterol control could lead to an absolute reduction of MI risk of 40% (Kahn 2008).

Additionally, evidence-based pharmacological therapy such as proper use of angiotensin-converting enzyme inhibitors in coronary artery disease patients leads to reduction of cardiovascular endpoints such as death, MI and strokes (Danchin 2006). Adherence to primary and secondary guidelines for CAD management could lead to better outcomes, and reductions in PACs stemming from CAD (Smith 2011).

Like other chronic illnesses, coronary artery disease is marked by episodes of acute exacerbation requiring hospitalization, most commonly for acute coronary syndromes (ACS). Despite improvements in acute care and survival after ACS hospitalization, early readmissions remain common, and have significant clinical and financial impact (Southern 2014). Preventable readmissions have become a focus of national quality improvement effort.

Studies have demonstrated where care coordination exists, ambulatory care-sensitive hospitalizations decreased by 30% (Bodenheimer 2008). However, if patients do get hospitalized, discharge planning and good follow-up prevents unnecessary ER visits and readmissions (Weaver 2013) (Mittler 2013). Another study from the Boston Medical Center, demonstrated that although one in five hospitalizations are complicated by post-discharge adverse events, development of a strong discharge services program for patients admitted for medical conditions reduced hospital utilization within 30 days of discharge (Jack 2009). In addition, while in the hospital, safe practices reduce the burden of healthcare associated complications (Ranji 2007). Some of these are listed below:

1. Frequent hand-washing reduce hospital acquired infections (WHO 2007)
2. Carefully implemented protocols lead to reduced line sepsis (Pronovost 2010)
3. Aspirin on Discharge prevents repeat AMIs (Hall 2014)
4. Discharge planning and good follow-up prevents unnecessary ER visits and readmissions (Weaver 2013)
5. DVT prophylaxis in patients on bed rest avoids pulmonary embolism (Shekelle 2013)
6. Frequent change in position of CAD patients in the CCU avoids pressure sores (Shekelle 2013)
7. Adherence to primary and secondary prevention guidelines for CAD (Smith 2011)

PAC measures in the setting of CAD look at all-cause harms, such as the ones highlighted above, arising from poor management of a patient with CAD.

Note: For health outcome/PRO performance measures, no further information is required; however, you may provide evidence for any of the structures, processes, interventions, or service identified above.

INTERMEDIATE OUTCOME, PROCESS, OR STRUCTURE PERFORMANCE MEASURE

1a.3. Briefly state or diagram the path between structure, process, intermediate outcome, and health outcomes. Include all the steps between the measure focus and the health outcome.

1a.3.1. What is the source of the systematic review of the body of evidence that supports the performance measure?

☒ Clinical Practice Guideline recommendation – ***complete sections 1a.4, and 1a.7***

☐ US Preventive Services Task Force Recommendation – ***complete sections 1a.5 and 1a.7***

☐ Other systematic review and grading of the body of evidence (*e.g., Cochrane Collaboration, AHRQ Evidence Practice Center*) – ***complete sections 1a.6 and 1a.7***

☐ Other – ***complete section 1a.8***

Please complete the sections indicated above for the source of evidence. You may skip the sections that do not apply.

1a.4. CLINICAL PRACTICE GUIDELINE RECOMMENDATION

1a.4.1. Guideline citation (*including date*) and **URL for guideline** (*if available online*):

1a.4.2. Identify guideline recommendation number and/or page number and **quote verbatim, the specific guideline recommendation**.

1a.4.3. Grade assigned to the quoted recommendation with definition of the grade:

1a.4.4. Provide all other grades and associated definitions for recommendations in the grading system.
(*Note: If separate grades for the strength of the evidence, report them in section 1a.7.*)

1a.4.5. Citation and URL for methodology for grading recommendations (*if different from 1a.4.1*)**:**

1a.4.6. If guideline is evidence-based (rather than expert opinion), are the details of the quantity, quality, and consistency of the body of evidence available (e.g., evidence tables)?

☐ Yes → ***complete section 1a.7***

☐ No → ***report on another systematic review of the evidence in sections 1a.6 and 1a.7; if another review does not exist, provide what is known from the guideline review of evidence in 1a.7***

1a.5. UNITED STATES PREVENTIVE SERVICES TASK FORCE RECOMMENDATION

1a.5.1. Recommendation citation (*including date*) and **URL for recommendation** (*if available online*):

1a.5.2. Identify recommendation number and/or page number and **quote verbatim, the specific recommendation**.

1a.5.3. Grade assigned to the quoted recommendation with definition of the grade:

1a.5.4. Provide all other grades and associated definitions for recommendations in the grading system.
(*Note: the grading system for the evidence should be reported in section 1a.7.*)

1a.5.5. Citation and URL for methodology for grading recommendations (*if different from 1a.5.1*)**:**

Complete section 1a.7

1a.6. OTHER SYSTEMATIC REVIEW OF THE BODY OF EVIDENCE

1a.6.1. Citation (*including date*) and **URL** (*if available online*):

1a.6.2. Citation and URL for methodology for evidence review and grading (*if different from 1a.6.1*)**:**

Complete section 1a.7

1a.7. FINDINGS FROM SYSTEMATIC REVIEW OF BODY OF THE EVIDENCE SUPPORTING THE MEASURE

If more than one systematic review of the evidence is identified above, you may choose to summarize the one (or more) for which the best information is available to provide a summary of the quantity, quality, and consistency of the body of evidence. Be sure to identify which review is the basis of the responses in this section and if more than one, provide a separate response for each review.

1a.7.1. What was the specific structure, treatment, intervention, service, or intermediate outcome addressed in the evidence review?

1a.7.2. Grade assigned for the quality of the quoted evidence with definition of the grade:

1a.7.3. Provide all other grades and associated definitions for strength of the evidence in the grading system.

1a.7.4. What is the time period covered by the body of evidence? (*provide the date range, e.g., 1990-2010*).
Date range: Click here to enter date range

QUANTITY AND QUALITY OF BODY OF EVIDENCE

1a.7.5. How many and what type of study designs are included in the body of evidence? (*e.g., 3 randomized controlled trials and 1 observational study*)

1a.7.6. What is the overall quality of evidence <u>across studies</u> in the body of evidence? (*discuss the certainty or confidence in the estimates of effect particularly in relation to study factors such as design flaws, imprecision due to small numbers, indirectness of studies to the measure focus or target population*)

ESTIMATES OF BENEFIT AND CONSISTENCY ACROSS STUDIES IN BODY OF EVIDENCE

1a.7.7. What are the estimates of benefit—magnitude and direction of effect on outcome(s) <u>across studies</u> in the body of evidence? (*e.g., ranges of percentages or odds ratios for improvement/ decline across studies, results of meta-analysis, and statistical significance*)

1a.7.8. What harms were studied and how do they affect the net benefit (benefits over harms)?

N/A

UPDATE TO THE SYSTEMATIC REVIEW(S) OF THE BODY OF EVIDENCE

1a.7.9. If new studies have been conducted since the systematic review of the body of evidence, provide for <u>each</u> new study: 1) citation, 2) description, 3) results, 4) impact on conclusions of systematic review.

1a.8 OTHER SOURCE OF EVIDENCE

If source of evidence is NOT from a clinical practice guideline, USPSTF, or systematic review, please describe the evidence on which you are basing the performance measure.

1a.8.1 What process was used to identify the evidence?

Review of literature

1a.8.2. Provide the citation and summary for each piece of evidence.

1. Evidence, Performance Gap, Priority – Importance to Measure and Report

Extent to which the specific measure focus is evidence-based, important to making significant gains in healthcare quality, and improving health outcomes for a specific high-priority (high-impact) aspect of healthcare where there is variation in or overall less-than-optimal performance. ***Measures must be judged to meet all subcriteria to pass this criterion and be evaluated against the remaining criteria.***

1a. Evidence to Support the Measure Focus – See attached Evidence Submission Form

2740_CAD_Evidence_Attachment_HCI3-635717847016609999.docx

1b. Performance Gap

Demonstration of quality problems and opportunity for improvement, i.e., data demonstrating:

- considerable variation, or overall less-than-optimal performance, in the quality of care across providers; and/or
- disparities in care across population groups.

1b.1. **Briefly explain the rationale for this measure** *(e.g., the benefits or improvements in quality envisioned by use of this measure)*
Measures associated to potentially avoidable complication (PAC) have been used as comprehensive outcomes measures since 2007 for several conditions and procedures (de Brantes 2010) (Joynt 2013) (James 2013). In 2011, following the NQF endorsement of these measures for certain acute medical conditions (AMI, Pneumonia and Stroke), and for chronic conditions, they were adopted for various purposes, including the creation of related measures (NQF – Measure #1550). Some commercial payers have used them as a means for tracking outcomes (Yong 2010) and for tiering providers for pay for performance programs (BCBSNC). In addition, some provider organizations have used them in quality improvement efforts by homing in on the detailed specifications of the measures to reveal opportunities for care improvement (CALPERS – link below). Identification of PACs has spurred provider innovation (Bundled Payment Summit 2015) for practice re-engineering, to create proactive care pathways, and to focus on areas of high variability (McVary 2010). Some employers are also using measures of avoidable complications as public measures of quality (Colorado Business Group on Health) given the research that demonstrated the potential efficacy of these measures to differentiate provider quality and cost (Hibbard 2012). In fact in a series of focus groups led by Judy Hibbard and colleagues, the researchers found that the very framing of potentially avoidable complications as an indicator of potential harm, is an effective way of communicating the quality of care. And when measures of PACs were presented in conjunction with price, consumers intuitively accepted the logical relationship between low PACs – fewer "defects" – and lower price.

Accountability for and measurement of PACs occurs at the practice, medical group, provider system or purchaser/payer level. PAC rates are calculated as absolute values. For example, a health plan would report that 60% of its plan members with CAD incurred PACs in the study time window. The objective of the measure is to encourage the unit being measured to progressively reduce that amount over time. In addition, comparisons of PAC rates across plans or provider systems should be encouraged and publicly reported. An organization that uses the measure should be able to identify the leading causes of PACs and implement improvements to existing processes that will decrease PACs. There are several tools available for provider systems and health plans to impact PAC rates. These include care coordination across care settings; post-discharge planning and patient follow- up, active care management, sharing medical record data between care settings and providers, total quality management within hospitals and active reduction of patient safety failures. Reducing PACs has the potential to significantly improve the overall level of quality.

Creating a single measure of accountability for physicians and hospitals tied to gaps in quality is likely to yield much improved outcomes for patients. A measure of accountability for health plans helps them review trends over time and work with physicians and hospitals to improve the ways in which they engage patients using more optimal care management and care coordination (Cassel 2014). In addition, PAC measures could be used as a surrogate for quality in a consumer transparency tool to differentiate providers with regards to their performance.

Moreover, since these measures are claims based, there is minimal added burden for collecting the data, and it also avoids potential gaming that may occur for other measures that require reporting information to registries. Although use of administrative claims data in identifying conditions and measuring provider quality has been questioned, there are several studies in literature that acknowledge validity of its use (Normand 2007) (Quan 2009). Until more readily available data are at hand, use of administrative data to measure provider performance has steadily increased (Miller 2001), (NQF Quality Positioning System). Interestingly, in the current fee for service system, services for most PACs are rewarded by continued payment (except the CMS defined "never events") and hence to our advantage, adverse events surface in billing data. Claims based PAC measures; therefore serve as an alternative method to track adverse outcomes that do occur (Leibson 2008).

1b.2. Provide performance scores on the measure as specified (current and over time) at the specified level of analysis. *(This is required for endorsement maintenance. Include mean, std dev, min, max, interquartile range, scores by decile. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities included). This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*
The data included two years of administrative claims covering the period April 1, 2012 through December 17, 2014. There were a total 31,093 episodes of CAD.

Because providers with small volumes may provide unreliable estimates, we excluded any with fewer than 10 attributed episodes prior to the calculations. After this exclusion 468 (out of 5840) providers remained. Performance scores of these providers are summarized in the following table:

Unadjusted PAC Rates:

Median (IQR):	40.0% (29.9%, 54.8%)
Range:	0% -100%

Risk-Standardized PAC Rates (RSPR):

Median (IQR):	40.1% (32.6%, 47.5%)
Range:	0% - 84%

Please refer to the NQF_CAD_all_codes_risk_adjustment_06.30.15.xls workbook under the "ProviderAttribution Reliability" tab to see specific results for each provider.

1b.3. **If no or limited performance data on the measure as specified is reported in 1b2, then provide a summary of data from the literature that indicates opportunity for improvement or overall less than optimal performance on the specific focus of measurement.**

Despite the implementation of evidence-based programs such as the Care Transitions Intervention and Project BOOST at several hospitals, available evidence suggests that readmission rates in patients with CAD remain largely unchanged (Hansen 2011) (Axon 2013). Dartmouth Atlas Project analyzed 2008-2010 data and found that Medicare readmission rates from CAD remained unchanged in more than 90% of academic medical centers (Dartmouth Atlas Project 2013). A study by Brock et al. showed that though community interventions showed a modest reduction in hospital admissions of Medicare patients, readmissions as a percentage of hospital admissions did not change (Brock 2013).

At discharge, patients of CAD should undergo appropriate interventions including secondary prevention as per guidelines issued by the AHA in 2011 to prevent progression of disease leading to increased risk of readmissions (Smith 2011).

The PAC measures go beyond simple readmission rates and look for all-cause harms in patients with coronary artery disease. While PACs may not be eliminated completely, identifying the magnitude of PACs and knowledge of the cause for the most frequent or the most expensive PACs could place an emphasis in reducing them and as a consequence improving patient outcomes. The ability to clearly identify the type and frequency of each PAC creates a highly actionable measure for all providers that are managing or co-managing the patient; as well as for the health plan with whom the patient is a member (de Brantes 2010).

1c. High Priority (previously referred to as High Impact)

The measure addresses:

- a specific national health goal/priority identified by DHHS or the National Priorities Partnership convened by NQF;

OR

- a demonstrated high-priority (high-impact) aspect of healthcare (e.g., affects large numbers of patients and/or has a substantial impact for a smaller population; leading cause of morbidity/mortality; high resource use (current and/or future); severity of illness; and severity of patient/societal consequences of poor quality).

1c.1. Demonstrated high priority aspect of healthcare
Affects large numbers, A leading cause of morbidity/mortality, High resource use, Patient/societal consequences of poor quality, Severity of illness
1c.2. If Other:

1c.3. Provide epidemiologic or resource use data that demonstrates the measure addresses a high priority aspect of healthcare. List citations in 1c.4.
According to the National Center for Health Statistics 2011, cardiovascular disease represented the leading cause of mortality in the US across genders and ethnic groups. Cardiovascular disease accounts for more deaths than the next four leading diseases in the United States combined. Coronary artery disease (CAD), in particular, accounted for 405,209 deaths in 2008 in the US alone. Moreover in 2010, CAD was projected to cost the US upwards of $108.9 billion dollars (Rimmerman 2015).

CAD is a chronic condition with a high prevalence rate that can be controlled by primary and secondary prevention, the guidelines for which are well established (Weintraub 2011). Non-compliance to primary and secondary prevention is associated with potentially avoidable complications such as cardiovascular hospitalizations, the need for revascularization procedures and also an increase in all-cause cardiovascular mortality (Mozaffarian 2015). There is considerable positive economic impact that can be achieved by reducing the burden of hospital admissions attributable to CAD, by better adherence to care guidelines by both the provider and the patient. Strategies to promote population level health, targeting both individuals at all risk levels for CV disease as well as promoting healthy behavior amongst the people in the community as a whole are important to contain this global epidemic of cardiovascular disease (Mozaffarian 2015).

To improve accountability in the delivery of chronic care, AHRQ has developed a list of prevention quality indicators (PQIs) to identify ambulatory care sensitive conditions (ACSCs) and to measure rates of admissions that could have been potentially avoided with good outpatient care (AHRQ 2008). PQI 13 measures admission rates for angina without procedure. Even though hospitalizations for CAD should be potentially avoidable in their own right; once they do occur, the index stay itself may have a potentially avoidable complication (PAC) or patients may develop a PAC during the post-discharge period. PACs lead to significant variability in outcomes including prolonged hospitalizations, readmissions and emergency room visits, all indicating poor outcomes that harm the patient, cause payers to incur unnecessary costs; and could be improved by providers (deBrantes 2011) (Yong 2010). For coronary artery disease in particular, there is a variety of avoidable complications that could result in a readmission. These complications tend to have a high impact due to the subsequent care needed and associated costs (Smith 2011) (Southern 2014).

Therefore, there are many areas where improvement is possible in CAD, making it a high priority aspect of health care. The PAC measures go beyond simple readmission rates and look for all-cause harms in patients with coronary artery disease.

1d. Composite Quality Construct and Rationale

1d.1. **A composite performance measure is a combination of two or more component measures, each of which individually reflects quality of care, into a single performance measure with a single score.**

For purposes of NQF measure submission, evaluation, and endorsement, the following will be considered composites:

- Measures with two or more individual performance measure scores combined into one score for an accountable entity.
- Measures with two or more individual component measures assessed separately for each patient and then aggregated into one score for an accountable entity:
  - all-or-none measures (e.g., all essential care processes received, or outcomes experienced, by each patient); or
  - any-or-none measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient).

1d.1. Please identify the composite measure construction: any-or-none measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient)any-or-none measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient)

1d.2. **Describe the quality construct, including:**

- the overall area of quality
- included component measures and
- the relationship of the component measures to the overall composite and to each other.

The PAC measures, as we define them, look at many "care defects" comprehensively. They are composed of several cross-cutting measures and together they paint a global picture of the provider's overall performance.

We classify PACs into two types: Type 1 PACs are directly related to the index condition and are often controlled by the servicing provider; Type 2 PACs, on the other hand result from patient safety failures and could be reduced by better systems and better processes in care. Both types of PACs could occur in any setting and so could be identified through any type of claims coming in the administrative dataset, including in-patient, out-patient, or professional claims. PACs may occur any time during the episode time window. PACs are counted as a dichotomous (yes/no) outcome. If a patient had one or more PACs, they get counted as a "yes" or a 1.

The PAC measure definitions encompass several other measures that are accepted as being valid complications of care and are widely used throughout the country. These include CMS defined Hospital Acquired Conditions (HACs), Hospital Inpatient Quality Reporting measures, Avoidable Readmissions, AHRQ defined patient safety indicators (PSIs), NQF endorsed patient safety measures such as patient fall rates, pressure ulcer rates, and peri-operative pulmonary embolism or deep vein thrombosis rates.

All defined PACs, irrespective of their type, or site of occurrence, are aggregated to create an overall comprehensive, composite measure. They all have equal weighting, since they are measured simply by the frequency of their occurrence.

1d.3. **Describe the rationale for constructing a composite measure, including how the composite provides a distinctive or additive value over the component measures individually.**
Each individual PAC, when measured in isolation, provides a very limited picture of the performance of the provider(s) who are managing or co-managing the care of the patient. However, looking at all the PACs that may occur individually or concurrently in a patient with a given episode provides a comprehensive picture of the care received by the patient for that particular condition or illness.

Additionally, the frequency of occurrence of individual PACs may be so low that it may require very high sample sizes from individual

providers to achieve any meaningful and reliable comparisons. But aggregating all the PACs into a single quality metric creates meaningful scores that can be compared across providers even with relatively smaller sample sizes.

Additionally, a comprehensive measure is easier to explain to the average consumer. From a patient's point of view, any bad outcome has an impact on their health with respect to return to work, functional limitations and need for additional support. If a provider has a high PAC rate with regards to one component PAC but not the other PACs, the impact on the patient is still adverse. In selecting providers, individual component PAC scores would mean nothing to a patient, but aggregating it to a comprehensive quality score could be a measure of "all-cause" harms and easier to interpret and act on.

1d.4. **Describe how the aggregation and weighting of the component measures are consistent with the stated quality construct and rationale.**
In constructing the comprehensive composite PAC measure, each component PAC, as clinically defined by the subject matter experts, was given the same weight so that arbitrary weights may not bias the results. Furthermore, the measure is constructed so that the occurrence of any number of PACs during a defined episode would only count as one occurrence. As such, the patient is the ultimate unit of measurement and if the patient incurred any PAC during the episode, then that counts against the numerator.

Since the emphasis of the PAC measure was to simply identify the occurrence of PACs in any setting, aggregation of the PAC counts to create a comprehensive quality score with equal weights has been met with overall support from the clinical working groups as well as from the implementation sites.

2. Reliability and Validity—Scientific Acceptability of Measure Properties

Extent to which the measure, as specified, produces consistent (reliable) and credible (valid) results about the quality of care when implemented. ***Measures must be judged to meet the subcriteria for both reliability and validity to pass this criterion and be evaluated against the remaining criteria.***

2a.1. Specifications The measure is well defined and precisely specified so it can be implemented consistently within and across organizations and allows for comparability. eMeasures should be specified in the Health Quality Measures Format (HQMF) and the Quality Data Model (QDM).

De.5. **Subject/Topic Area** *(check all the areas that apply):*
Cardiovascular, Cardiovascular : Ischemic Heart Disease, Coronary Artery Disease

S.2a. **If this is an eMeasure**, HQMF specifications must be attached. Attach the zipped output from the eMeasure authoring tool (MAT) - if the MAT was not used, contact staff. (Use the specification fields in this online form for the plain-language description of the specifications)
This is not an eMeasure **Attachment:**

S.2b. **Data Dictionary, Code Table, or Value Sets** *(and risk model codes and coefficients when applicable) must be attached. (Excel or csv file in the suggested format preferred - if not, contact staff)*
Attachment **Attachment:** NQF_CAD_all_codes_risk_adjustment_06.30.15-635719625915810933.xlsx

S.3. **For endorsement maintenance**, please briefly describe any changes to the measure specifications since last endorsement date and explain the reasons.
Not applicable

S.4. **Numerator Statement** *(Brief, narrative description of the measure focus or what is being measured about the target population, i.e., cases from the target population with the target process, condition, event, or outcome)*
IF an OUTCOME MEASURE, state the outcome being measured. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
Outcome: Number of patients who triggered an episode of coronary artery disease (CAD), are followed for at least one-year, and had one or more potentially avoidable complications (PACs) during the episode time window.

S.5. **Time Period for Data** *(What is the time period in which data will be aggregated for the measure, e.g., 12 mo, 3 years, look back to August for flu vaccination? Note if there are different time periods for the numerator and denominator.)*
The time window is the most recent 12 months of the episode, once a patient has triggered a CAD episode.

S.6. **Numerator Details** *(All information required to identify and calculate the cases from the target population with the target process, condition, event, or outcome such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
IF an OUTCOME MEASURE, describe how the observed outcome is identified/counted. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
Patients that have triggered a CAD episode, and are identified as having services for potentially avoidable complications (PACs), during the most recent 12 months of the episode. The enclosed excel workbook entitled NQF_CAD_all_codes_risk_adjustment_06.30.15 gives the detailed codes for PACs in the tabs entitled PACs I-9 and PACs I-10. PACs are identified only based on diagnosis codes.

Services for PACs are identified as follows:
a.Any service (professional, outpatient facility, ancillary) that is relevant to CAD and has a PAC code in any position on the claim
b.Any admission to an acute care facility, that is relevant to CAD
c.Any admission to a post-acute care facility that is relevant to CAD and has a PAC code in any position on the claim

S.7. **Denominator Statement** *(Brief, narrative description of the target population being measured)*
Adult patients aged 18 years and above who triggered an episode of coronary artery disease (CAD) and are followed for at least one-year.

S.8. **Target Population Category** *(Check all the populations for which the measure is specified and tested if any):*
Populations at Risk, Populations at Risk : Dual eligible beneficiaries, Populations at Risk : Individuals with multiple chronic conditions, Populations at Risk : Veterans, Senior Care

S.9. **Denominator Details** *(All information required to identify and calculate the target population/denominator such as definitions, specific data collection items/responses , code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
Please refer to the enclosed excel workbook entitled
NQF_CAD_all_codes_risk_adjustment 06.30.15

The target population is identified using the following criteria:
1.Using administrative claims database, patients with CAD are identified using one of two of the following criteria:
a.Patients having an office visit with a trigger code of CAD in any position, followed by a second confirmatory office visit (with a trigger code of CAD in any position), at least 30 days apart.
b.Patients with a Principal Dx of a CAD trigger code on an in-hospital stay claim.
The trigger codes for CAD are provided in the tab called “Triggers I-9” or “Triggers I-10”.
2. The patient should have continuous enrollment for the entire time window with no more than 30 days as an enrollment gap, with the entity providing the data (so we can ensure that the database has captured most of the claims for the patient during the episode time window).
3. The patient should have a complete episode time window in the claims data – so there are at least 12 months of claims in the database for the patient.
4. Patient should be at least 18 years of age

Once the episode is triggered all relevant claims are assigned to the episode. Relevant claims could be inpatient facility claims, outpatient facility claims, professional services, laboratory services, imaging services, ancillary claims, home health, durable medical equipment as well as pharmacy claims across the entire continuum of care centered around the patient’s episode of care.

Relevant claims are identified as those that have a diagnosis code that matches the codes in the typical Dx codes tabs (Typical Dx I-9 or Typical Dx I-10), or in the PAC Dx codes tab (PACs I-9 or PACs I-10) AND a procedure code as identified in the Relevant Procedures I-9 & I-10 tab in the enclosed workbook. Relevant admissions to acute and post-acute care facilities are also included in the denominator.

S.10. **Denominator Exclusions** *(Brief narrative description of exclusions from the target population)*
Denominator exclusions include exclusions of either "patients" or "claims" based on the following criteria:
1. "Patients" excluded are those that do not meet the enrollment criteria. If patient has an enrollment gap for more than 30 days during the episode time window, it is considered as an enrollment gap
2. "Patients" are also excluded if the cost of the episode is an outlier at greater than 99th percentile or less than 1st percentile value for all episodes. This is another way to ensure that episodes are complete as well as they do not bring in random noise into the analysis due to inappropriate codes or services.
3. "Claims" are excluded from the CAD measure if they are considered not relevant to CAD care.

S.11. **Denominator Exclusion Details** *(All information required to identify and calculate exclusions from the denominator such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
Denominator exclusions include exclusions of "patients" as well as "claims" not relevant to CAD care. Please refer to the enclosed excel workbook entitled (NQF_CAD_all_codes_risk_adjustment 06.30.15.xls)

1. "Patients" are excluded from the measure if they meet one of the following criteria:
a. If age is < 18 years
b. If gender is missing
c. If they do not have continuous enrollment for the entire time window with a maximum of 30 day enrollment gap with the entity providing the data (this helps determine if the database has captured most of the claims for the patient in the time window).
d. If the patient does not have at least 12 months of claims in the database (this helps eliminate incomplete episodes).
e. The episode cost is an outlier (less than 1st percentile or greater than 99th percentile value for all episodes of the same type). This eliminates extreme variation that may result from random outlier events.

2. "Claims" are excluded from the measure if they meet one of the following criteria:
a. If none of the diagnosis codes on the claim are on the list of "triggers" or relevant diagnosis codes (either typical Dx or PAC Dx) for CAD.
b. If none of the procedure / CPT codes on the claim are on the list of relevant procedure codes for CAD.
c. If the CAD trigger hospitalization also triggers a major surgical procedure such as coronary bypass procedure or angioplasty, suggesting that CAD may be a comorbidity or an indication for the surgery.
d. The "principal" diagnosis on an inpatient stay claim during the episode time window triggers its own episode
e. The procedure code on a claim during the episode time window triggers its own episode

S.12. **Stratification Details/Variables** *(All information required to stratify the measure results including the stratification variables, definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format with at S.2b)*
None

S.13. **Risk Adjustment Type** (Select type. Provide specifications for risk stratification in S.12 and for statistical model in S.14-15)
Statistical risk model
If other:

S.14. **Identify the statistical risk model method and variables** *(Name the statistical method - e.g., logistic regression and list all the risk factor variables. Note - risk model development and testing should be addressed with measure testing under Scientific Acceptability)*
Conceptual Model
Variations in outcomes across populations may be due to patient-related factors or due to provider-controlled factors. When we adjust for patient-related factors, the remaining variance in PACs are due to factors that could be controlled by all providers that are managing or co-managing the patient, both during and after hospitalization.

Statistical Method:
Logistic Regression model to determine the probability of a patient incurring a PAC

Demographic variables, comorbid conditions, as well as clinical severity indicators are fed as independent risk factors into the model. Risk Factors are collected historically. Subtype information is collected from the index claim and any look-back period, if relevant. Subtypes are clinical severity indicators suggesting severity of the episode itself, for example, diagnosis of unstable angina in a CAD patient. For each patient the "predicted" coefficients from the risk adjustment models are summed to give the predicted probabilities of the occurrence of a PAC.

Risk Factors :(Please refer to the enclosed excel workbook entitled (NQF_CAD_all_codes_risk_adjustment 06.30.15.xls). The risk factors along with their codes are listed in the tabs called "All Risk Factors I-9" and "All Risk Factors I-10" and also listed below:

AGE CONTINUOUS VARIABLE
GENDER FEMALE = 1 (MALE IS REFERENCE = 0)

Risk Factor #	Risk Factor Name
RF0101	Anoxic Brain Damage, persistent vegetative state

S.15. **Detailed risk model specifications** *(must be in attached data dictionary/code list Excel or csv file. Also indicate if available at measure-specific URL identified in S.1.)*
Note: Risk model details (including coefficients, equations, codes with descriptors, definitions), should be provided on a separate worksheet in the suggested format in the Excel or csv file with data dictionary/code lists at S.2b.
Available in attached Excel or csv file at S.2b

S.15a. **Detailed risk model specifications** (*if not provided in excel or csv file at S.2b*)

S.16. **Type of score:**
Rate/proportion
If other:

S.17. **Interpretation of Score** *(Classifies interpretation of score according to whether better quality is associated with a higher score, a lower score, a score falling within a defined interval, or a passing score)*
Better quality = Lower score

S.18. **Calculation Algorithm/Measure Logic** *(Describe the calculation of the measure score as an ordered sequence of steps including identifying the target population; exclusions; cases meeting the target process, condition, event, or outcome; aggregating data; risk adjustment; etc.)*
Please refer to the enclosed excel workbook entitled (NQF_CAD_all_codes_risk_adjustment 06.30.15.xls).

Assembling the Denominator:

Using administrative claims database, patients with CAD are identified using one of two criteria: 1) Patients having an office visit with a trigger code of CAD in any position, followed by a second confirmatory office visit (with a trigger code of CAD in any position), at least 30 days apart, 2) Patients a Principal Dx of a CAD trigger code on an in-hospital stay claim. The trigger codes for CAD are provided in the tab called “Triggers I-9” or “Triggers I-10”.

Patients are retained if they are 18 years of age or more, do not have a missing gender, have at least 12 month of claims in the database, have a maximum of 30-day enrollment gap for the entire episode time window, and have no outlier episode costs. All relevant professional, laboratory, imaging, ancillary and other claims that are incurred during the episode time window are included as part of the episode. Claims are considered relevant to CAD care if they have one of the diagnosis codes, as listed on the tab entitled Triggers I-9, Triggers 1-10, PACs I-9, PACs I-10, Typical Dx I-9, or Typical Dx I-10 in any position on the claim AND a procedure code as identified in the Relevant Procedures I-9 & I-10 tab in the enclosed workbook. Relevant admissions to acute and post-acute care facilities are also included in the denominator. All relevant pharmacy claims carrying codes that match the ingredients listed in the Pharmacy tab of the enclosed workbook are also included as part of the episode. Services are pulled as part of the CAD episode based on the diagnosis codes as defined above or if they have a service code that is marked as “sufficient”

for that episode.

If a patient has more than one concurrent episode, and the claim is relevant to both episodes, the claim could get multi-assigned, except in the case of procedural episodes that get carved out with respect to the index stay. So if an inpatient stay claim carried a principal Dx code that matched the trigger diagnosis code for CAD but they also had a procedure code for CABG (coronary artery bypass surgery), the stay claim would get uniquely assigned to CABG and not be counted with CAD.

Once all the episodes are assembled, episodes that match the exclusion criteria, such as those with outlier costs, are flagged (those with total episode costs less than 1st percentile or greater than 99th percentile), and excluded from the final analysis.

Assembling the Numerator:

For every episode included in the denominator, services are flagged as having a PAC (potentially avoidable complication) based on the criteria listed below:

Any service (professional, outpatient facility, ancillary) with a PAC code in any position on the claim

Any admission to an acute care facility, that is relevant to CAD

Relevant claims that do not have any PAC codes, and do not qualify as a PAC based on the criteria outlined above, are listed as typical claims. All included relevant pharmacy services are flagged as typical. Patients that have even a single PAC claim are counted as part of the numerator.

Calculating the measure:

Proportion of CAD patients that have PACs is simply the ratio of patients with PACs within the HTN population and is called the PAC rate as shown in the equation below:

PAC rate = Patients with CAD that have at least one PAC claim / Total number of CAD patients

A flow chart demonstrating the series of steps and the counts of patients at each step is shown in tab entitled Decision Tree of the enclosed workbook called NQF_CAD_all_codes_risk_adjustment 06.30.15.xls

Drill Down Calculations:

Further analysis from this construct helps create actionable reports.

For example as shown in the tab labeled PAC overview, not only do we have the PAC rate for a population, we can break them down by the PAC type – type 1 being directly related to CAD and so actionable by the servicing physician, while type 2 PACs are related to patient safety failures and can be improved by process improvement. Additionally, analyzing potentially avoidable admissions helps focus strategies in reducing them.

Risk Adjustment:

Once we have the observed PAC rates, we risk-adjust them for patient factors such as patient demographics, comorbidities collected historically, and for severity of illness or procedure using subtypes collected from the index stay and / or look-back period. This helps adjust for factors outside the providers control and levels the playing field for provider performance comparisons.

Unit of Analysis:
The unit of analysis is the individual episode.

Dependent Variable:
The dependent variable is a dichotomous variable indicating whether an episode had one or more claims assigned as a PAC (=1) or not (=0).

Independent Variables:
A number of patient-related “risk factors” or covariates are included in the models:

Patient demographics: age, gender, and an indicator of whether a member has enrolled within the previous 6 months.

This latter risk factor is intended to account for the patient's lack of claims history, which limits the number of potential comorbidities that can be identified.

Comorbidities: These are conditions or events that occurred prior to the start of the episode that can have a potential impact on the patient's risk of having a PAC. The risk factors are 170 disease indicators (0/1) identified through the presence of ICD diagnosis codes on individual medical claims and collected from the historical claims data before the start of an episode. These are universally applied across all episodes. Please see the tab labeled "All Risk Factors I-9" and "All Risk Factors I-10" for a list of risk factors and their corresponding codes in the enclosed workbook called NQF_CAD_all_codes_risk_adjustment 06.30.15.xls

Episode Subtypes or Severity Markers: These are markers that distinguish an episode as being more severe than another. They indicate either specific patient comorbidities that are known to make the procedure or condition more difficult to treat (e.g., obesity) or severity of the illness itself (e.g., unstable angina). Please see the tab labeled "Subtypes I-9" and "Subtypes I-10" for a list of subtypes and their corresponding codes in the enclosed workbook called NQF_CAD_all_codes_risk_adjustment 06.30.15.xls

As mentioned previously, to avoid creating perverse incentives all comorbidities and subtypes are identified prior to or at the very start of the episode. None are identified during the episode period.

Statistical Methods

We use logistic regression to model the probability of at least one PAC occurring during the episode. Only comorbidities and subtypes are included in the models as covariates if they are present in at least 10 episodes to prevent unstable coefficients. No further model building is conducted after the initial models are built. This reflects a desire to explain as much variation in the probability of having a PAC as possible, but it does not make it a priority that all covariates in the model be individually significant or even uncorrelated with each other. Accordingly, the model uses a very large group of covariates. This modeling approach allows for fewer potentially artificial constraints around the definitions of what constitutes severity of a episode condition, and lets each regression model determine for itself which of the factors are more significant for a specific episode. Non-significant covariates in episode models can not overly influence predicted outcomes, nor is much harm realized, if a group of correlated covariates work together to explain variation rather than having the variation explained by a single best factor.

When more than one line of business is included in the data, separate models are calculated for each sample (i.e., commercial, Medicaid etc.).

Provider Attribution and calculating PAC rates by provider:

Once episodes are constructed they are attributed to providers based on one of the various attribution rules. For CAD, episodes are attributed to the primary care physician, internist or cardiologist with the highest count of office visits.

Using the logistic regression technique described above, a model is developed that gives estimates for each risk factor and subtype for the patients in the population analyzed. These estimates are used to develop patient-level probabilities for the occurrence of PACs. The patient-level probability estimates are summed to construct aggregated measures (e.g., facility/provider-level). This method is similar to the methods employed by the Centers for Medicare and Medicaid Services (CMS) and endorsed by the National Quality Forum (NQF) to construct similar facility- and practice-level measures (i.e., mortality, readmissions, etc.):

For each provider, the number of actual observed occurrences of the outcome is summed across all attributed patients with that episode, to give the observed PAC rates for the provider.

Similarly adjusted probabilities from the risk adjustment models are summed across all attributed patients to give expected PACs for the provider.

The observed sum is then divided by the summed probabilities (O/E). This number yields whether the provider or facility had more PACs than expected (ratio>1), as expected (ratio=1), or less than expected (ratio<1). This calculation yields a practice-level unstandardized performance ratio.

To facilitate accurate comparisons of rates across units of analysis, this ratio is then standardized to the community rate using the indirect method. Specifically, the provider-level rate is multiplied by the expected community rate, calculated as the sum of adjusted probabilities for every individual in the sample across all providers in the analysis. This measure, known as the standardized rate, represents what the unit's risk-adjusted rate would be for the outcome of interest if its patient population was reflective of the of the overall community.

The formula for this calculation is as follows:

Adj Outcome_j={(SUM Observed_ij)/(SUM Prob_ij)} × {(SUM Prob_i) / (# of episodes)}
Where individual is attributed to unit of analysis j (e.g., practice, provider, etc.)

Minimum sample size requirements for PAC measures are a function of the reliability testing of the measures on every dataset on which the measures are applied. Our research suggests that minimum sample sizes to achieve high degrees of reliability in the measures are a function of the dataset analyzed, and as such may vary from dataset to dataset. One should not infer that a minimum sample size achieved in one dataset will apply to another.

S.19. **Calculation Algorithm/Measure Logic Diagram URL or Attachment** *(You also may provide a diagram of the Calculation Algorithm/Measure Logic described above at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
Available in attached appendix at A.1

S.20. **Sampling** *(If measure is based on a sample, provide instructions for obtaining the sample and guidance on minimum sample size.)*
IF a PRO-PM, identify whether (and how) proxy responses are allowed.
Not applicable

S.21. **Survey/Patient-reported data** *(If measure is based on a survey, provide instructions for conducting the survey and guidance on minimum response rate.)*
IF a PRO-PM, specify calculation of response rates to be reported with performance measure results.
Not applicable

S.22. **Missing data** (specify how missing data are handled, e.g., imputation, delete case.)
Required for Composites and PRO-PMs.
If patient related data is missing, the case is deleted from both the numerator and the denominator

S.23. **Data Source** *(Check ONLY the sources for which the measure is SPECIFIED AND TESTED).*
If other, please describe in S.24.
Administrative claims

S.24. **Data Source or Collection Instrument** *(Identify the specific data source/data collection instrument e.g. name of database, clinical registry, collection instrument, etc.)*
IF a PRO-PM, identify the specific PROM(s); and standard methods, modes, and languages of administration.
The information is based on a two-year claims database from a large regional commercial insurer. The database has over 3.2 million covered lives and $25.9 billion in "allowed amounts" for claims costs. The database is an administrative claims database with medical as well as pharmacy claims.

The methodology can be used on any claims database with at least two years of data and a minimum of 150 patients with the index condition or hospitalization. Having pharmacy data adds to the richness of the risk-adjustment models.
The calculations of rates of potentially avoidable complications can be replicated by anyone that uses the measure specifications along with the metadata file that is available for free on our web site at http://www.hci3.org/ecre/xml-agreement.html.
We also plan on providing a limited automated analysis, at no cost, on our website.
The methodology has been tested on databases of several health plans as well as on a few employer databases.

No data collection instrument was used.

S.25. **Data Source or Collection Instrument** *(available at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
No data collection instrument provided

S.26. **Level of Analysis** *(Check ONLY the levels of analysis for which the measure is SPECIFIED AND TESTED)*
Clinician : Group/Practice, Clinician : Team

S.27. **Care Setting** *(Check ONLY the settings for which the measure is SPECIFIED AND TESTED)*
Ambulatory Care : Ambulatory Surgery Center (ASC), Ambulatory Care : Clinician Office/Clinic, Hospital/Acute Care Facility, Other
If other: Across the care continuum

S.28. **COMPOSITE Performance Measure** - Additional Specifications *(Use this section as needed for aggregation and weighting*

rules, or calculation of individual performance measures if not individually endorsed.) The individual complications are considered measurable components. Separate specifications are not required for this measure.

2a. Reliability – See attached Measure Testing Submission Form
2b. Validity – See attached Measure Testing Submission Form
2740_CAD_Testing_Reliability_Validity_HCI3-635719664690615149.docx

NATIONAL QUALITY FORUM—Composite Measure Testing (subcriteria 2a2, 2b2-2b7, 2d)

Composite Measure Title: 2740
Measure Title: Proportion of Patients with coronary artery disease (CAD) that have a Potentially Avoidable Complication (during the episode time window)
Date of Submission: 06/30/15
Composite Construction:
☐Two or more individual performance measure scores combined into one score
☐ All-or-none measures (e.g., all essential care processes received or outcomes experienced by each patient)
☐ Any-or-none measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient)

Instructions

- Measures must be tested for all the data sources and levels of analyses that are specified. ***If there is more than one set of data specifications or more than one level of analysis, contact NQF staff*** about how to present all the testing information in one form.
- **For all measures, sections 1, 2a2, 2b2, 2b3, and 2b5 must be completed.**
- **For outcome and resource use measures**, section **2b4** also must be completed.
- If specified for **multiple data sources/sets of specificaitons** (e.g., claims and EHRs), section **2b6** also must be completed.
- Respond to all questions as instructed with answers immediately following the question. All information on testing to demonstrate meeting the subcriteria for reliability (2a2) and validity (2b2-2b6) must be in this form. An appendix for *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 20 pages (*incuding questions/instructions;* minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the testing results for this measure meet NQF's evaluation criteria for testing.

2a2. Reliability testing [10] demonstrates the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise. For **PRO-PMs and composite performance measures**, reliability should be demonstrated for the computed performance score.

2b2. Validity testing [11] demonstrates that the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality. For **PRO-PMs and composite performance measures**, validity should be demonstrated for the computed performance score.

2b3. Exclusions are supported by the clinical evidence; otherwise, they are supported by evidence of sufficient frequency of occurrence so that results are distorted without the exclusion; [12]
AND
If patient preference (e.g., informed decisionmaking) is a basis for exclusion, there must be evidence that the exclusion impacts performance on the measure; in such cases, the measure must be specified so that the information about patient preference and the effect on the measure is transparent (e.g., numerator category computed separately, denominator exclusion category computed separately). [13]

2b4. For outcome measures and other measures when indicated (e.g., resource use):

- **an evidence-based risk-adjustment strategy** (e.g., risk models, risk stratification) is specified; is based on patient factors that influence the measured outcome (but not factors related to disparities in care or the quality of care) and are present at start of care; [14,15] and has demonstrated adequate discrimination and calibration

OR

- rationale/data support no risk adjustment/ stratification.

2b5. Data analysis of computed measure scores demonstrates that methods for scoring and analysis of the specified measure allow for **identification of statistically significant and practically/clinically meaningful** [16] **differences in performance**;
OR
there is evidence of overall less-than-optimal performance.

2b6. If multiple data sources/methods are specified, there is demonstration they produce comparable results.

2b7. For **eMeasures, composites, and PRO-PMs** (or other measures susceptible to missing data), analyses identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias.

Notes
10. Reliability testing applies to both the data elements and computed measure score. Examples of reliability testing for data elements include, but are not limited to: inter-rater/abstractor or intra-rater/abstractor studies; internal consistency for multi-item scales; test-retest for survey items. Reliability testing of the measure score addresses precision of measurement (e.g., signal-to-noise).
11. Validity testing applies to both the data elements and computed measure score. Validity testing of data elements typically analyzes agreement with another authoritative source of the same information. Examples of validity testing of the measure score include, but are not limited to: testing hypotheses that the measures scores indicate quality of care, e.g., measure scores are different for groups known to have differences in quality assessed by another valid quality measure or method; correlation of measure scores with another valid indicator of quality for the specific topic; or relationship to conceptually related measures (e.g., scores on process measures to scores on outcome measures). Face validity of the measure score as a quality indicator may be adequate if accomplished through a systematic and transparent process, by identified experts, and explicitly addresses whether performance scores resulting from the measure as specified can be used to distinguish good from poor quality.
12. Examples of evidence that an exclusion distorts measure results include, but are not limited to: frequency of occurrence, variability of exclusions across providers, and sensitivity analyses with and without the exclusion.
13. Patient preference is not a clinical exception to eligibility and can be influenced by provider interventions.
14. Risk factors that influence outcomes should not be specified as exclusions.

15. Risk models should not obscure disparities in care for populations by including factors that are associated with differences/inequalities in care, such as race, socioeconomic status, or gender (e.g., poorer treatment outcomes of African American men with prostate cancer or inequalities in treatment for CVD risk factors between men and women). It is preferable to stratify measures by race and socioeconomic status rather than to adjust out the differences.
16. With large enough sample sizes, small differences that are statistically significant may or may not be practically or clinically meaningful. The substantive question may be, for example, whether a statistically significant difference of one percentage point in the percentage of patients who received smoking cessation counseling (e.g., 74 percent v. 75 percent) is clinically meaningful; or whether a statistically significant difference of $25 in cost for an episode of care (e.g., $5,000 v. $5,025) is practically meaningful. Measures with overall less-than-optimal performance may not demonstrate much variability across providers.

1. DATA/SAMPLE USED FOR ALL TESTING OF THIS MEASURE
Often the same data are used for all aspects of measure testing. In an effort to eliminate duplication, the first five questions apply to all measure testing. If there are differences by aspect of testing,(e.g., reliability vs. validity) be sure to indicate the specific differences in question 1.7.

1.1. What type of data was used for testing? (*Check all the sources of data identified in the measure specifications and data used for testing the measure. Testing must be provided for all the sources of data specified and intended for measure implementation.* ***If different data sources are used for the numerator and denominator, indicate N [numerator] or D [denominator] after the checkbox.***)

Measure Specified to Use Data From: (*must be consistent with data sources entered in S.23*)	**Measure Tested with Data From:**
☐ abstracted from paper record	☐ abstracted from paper record
☐ administrative claims	☐ administrative claims
☐ clinical database/registry	☐ clinical database/registry
☐ abstracted from electronic health record	☐ abstracted from electronic health record
☐ eMeasure (HQMF) implemented in EHRs	☐ eMeasure (HQMF) implemented in EHRs
☐ other: Click here to describe	☐ other: Click here to describe

1.2. If an existing dataset was used, identify the specific dataset (*the dataset used for testing must be consistent with the measure specifications for target population and healthcare entities being measured; e.g., Medicare Part A claims, Medicaid claims, other commercial insurance, nursing home MDS, home health OASIS, clinical registry*).

The information is based on a two-year administrative claims database from a large regional commercial insurer. The database contains medical and pharmacy claims on over 3.2 million covered lives and more than $25.9 billion in "allowed amounts" for costs.

1.3. What are the dates of the data used in testing? April 1, 2012 – December 17, 2014

1.4. What levels of analysis were tested? (*testing must be provided for all the levels specified and intended for measure implementation, e.g., individual clinician, hospital, health plan*)

Measure Specified to Measure Performance of: (*must be consistent with levels entered in item S.26*)	**Measure Tested at Level of:**
☐ individual clinician	☐ individual clinician
☐ group/practice	☐ group/practice
☐ hospital/facility/agency	☐ hospital/facility/agency

☐ health plan	☐ health plan
☐ other: Integrated Delivery System	☐ other:

1.5. How many and which measured entities were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of measured entities included in the analysis (e.g., size, location, type); if a sample was used, describe how entities were selected for inclusion in the sample*)

There were a total of 5,840 providers in the data set. Because providers with small volumes may provide unreliable estimates, we excluded any with fewer than 10 attributed episodes prior to the reliability calculations. After this exclusion, there were 468 providers left.

1.6. How many and which patients were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of patients included in the analysis (e.g., age, sex, race, diagnosis); if a sample was used, describe how patients were selected for inclusion in the sample*)

After exclusions (see 2b.3.1 below), there were a total of 31,093 episodes of CAD were included in the testing and analysis. Patients in these episodes were, on average, 56.4 years of age (range 18-64) and 27% were female. We did not have race information on these patients. All patients for this analysis had a trigger inpatient claim of CAD as identified in our code tables.

1.7. If there are differences in the data or sample used for different aspects of testing (e.g., reliability, validity, exclusions, risk adjustment), identify how the data or sample are different for each aspect of testing reported below.

For the reliability analysis, we restricted the data to only providers with at least 10 attributed episodes. For risk adjustment, all episodes were used in the analysis, regardless of the provider to which they were attributed.

1.8 What were the patient-level sociodemographic (SDS) variables that were available and analyzed in the data or sample used? For example, patient-reported data (e.g., income, education, language), proxy variables when SDS data are not collected from each patient (e.g. census tract), or patient community characteristics (e.g. percent vacant housing, crime rate).
None of the analyses included SDS variables.

2a2. RELIABILITY TESTING
Note: *If accuracy/correctness (validity) of data elements was empirically tested, separate reliability testing of data elements is not required – in 2a2.1 check critical data elements; in 2a2.2 enter "see section 2b2 for validity testing of data elements"; and skip 2a2.3 and 2a2.4.*

2a2.1. What level of reliability testing was conducted? (*may be one or both levels*)
☐ **Critical data elements used in the measure** (*e.g., inter-abstractor reliability; data element reliability must address ALL critical data elements*)
☐ **Performance measure score** (e.g., *signal-to-noise analysis*)

2a2.2. For each level checked above, describe the method of reliability testing and what it tests (*describe the steps—do not just name a method; what type of error does it test; what statistical analysis was used*)

We assessed the reliability of the measure to demonstrate that it sufficiently differentiates performance between providers using the beta-binomial method, which is applicable to measures of this type. Reliability is a measure that distinguishes the signal (the extent of performance variation between entities that is due to true differences

in performance) from statistical noise. Our approach follows directly from the methods outlined in the technical report "The Reliability of Provider Profiling: A Tutorial" by J.L. Adams.

Reference:

Adams JL. The Reliability of Provider Profiling: A Tutorial. Rand Corporation. http://www.rand.org/pubs/technical_reports/TR653.html.

2a2.3. For each level of testing checked above, what were the statistical results from reliability testing? (e.g., *percent agreement and kappa for the critical data elements; distribution of reliability statistics from a signal-to-noise analysis*)

The table below provides a summary of the reliability score for different minimum sample size thresholds. For complete results, refer to the workbook entitled, NQF_CAD_all_codes_risk_adjustment_06.30.15.xls, under the "ProviderAttribution Reliability" tab to see provider-specific results.

Reliability Scores	**Minimum # Episodes Per Provider**		
	>=10	**>=25**	**>=50**
# of Providers (%)	468 (100)	171 (37)	80 (17)
Median (IQR)	0.73 (0.61,0.83)	0.85 (0.79,0.91)	0.92 (0.88,0.95)
Range	0.50-1.00	0.72-0.99	0.84-0.99

2a2.4 What is your interpretation of the results in terms of demonstrating reliability? (i.e., *what do the results mean and what are the norms for the test conducted?*)

Reliability scores can vary from 0.0 to 1.0, with a score of zero indicating that all variation is attributable to measurement error (noise, or variation across patients within providers) whereas a reliability of 1.0 implies that all variation is caused by real difference in performance across accountable entities.

There is not a clear cut-off for minimum reliability level. Values above 0.7, however, are considered sufficient to see differences between some physicians and the mean, and values above 0.9 are considered sufficient to see differences between pairs of physicians (see Adams, 2009 cited above).

Although scores among providers with at least 10 episodes were low, many had scores that met or exceeded the minimum acceptable level for reliability. Moreover, limiting providers to those with at least 25 or 50 episodes, scores were consistently good. These results demonstrate that the measure sufficiently differentiates providers' performance.

Minimum sample size requirements for PAC measures are a function of the reliability testing of the measures on every dataset on which the measures are applied. Our research suggests that minimum sample sizes to achieve high degrees of reliability in the measures are a function of the dataset analyzed, and as such may vary from dataset to dataset. One should not infer that a minimum sample size achieved in one dataset would apply to another.

2b2. VALIDITY TESTING

Note: *Current guidance for composite measure evaluation states that validity should be demonstrated for the composite performance measure score. If not feasible for initial endorsement, acceptable alternatives include*

assessment of content or face validity of the composite OR demonstration of validity for each component. Empirical validity testing of the composite measure score is expected by the time of endorsement maintenance.

2b2.1. What level of validity testing was conducted?

☐ **Composite performance measure score**

☐ **Empirical validity testing**

☐ **Systematic assessment of face validity of performance measure score as an indicator** of quality or resource use (*i.e., is an accurate reflection of performance on quality or resource use and can distinguish good from poor performance*)

☐ **Systematic assessment of content validity**

☐ **Validity testing for component measures** *(check all that apply)*

***Note**: applies to ALL component measures, unless already endorsed or are being submitted for individual endorsement.*

☐ **Endorsed (or submitted) as individual performance measures**

☐ **Critical data elements** (*data element validity must address ALL critical data elements*)

☐ **Empirical validity testing of the component measure score(s)**

☐ **Systematic assessment of face validity of component measure score(s) as an indicator** of quality or resource use (*i.e., is an accurate reflection of performance on quality or resource use and can distinguish good from poor performance*)

2b2.2. For each level of testing checked above, describe the method of validity testing and what it tests (*describe the steps—do not just name a method; what was tested, e.g., accuracy of data elements compared to authoritative source, relationship to another measure as expected; what statistical analysis was used)*

Content validity was built into the development of the definitions of potentially avoidable complications (PACs). This involved working with clinicians who are experts in their respective fields and specific to the episodes for which PACs are being measured. In particular, the clinical experts focused on whether or not a potentially avoidable complication can be deemed as such for a specific episode of care, and help defined and review all of the diagnosis and procedure codes for each PAC. The enclosed link lists clinicians who have participated in the various Clinical Working Groups (http://www.hci3.org/content/clinical-working-group-contributors). Some of the clinical experts have also participated in monthly webinars that highlight the clinical aspects of these measures (http://www.hci3.org/content/using-ecrs-providers).

In addition, we illustrate that our measure has face validity in several ways.

Beyond the up front work performed by clinical experts, the validity of the measure has also been tested in various real world settings. For example, we have presented results of claims data analyses that reveal the frequency and costs of PACs to physicians in several different healthcare systems involved in our pilot site implementations, as well as to medical directors from the employer coalitions and the health plans that provided the dataset to run the analyses. Some of these implementations include the Pennsylvania Employee Benefits Trust Fund and local provider groups and hospital, Horizon Blue Cross Blue Shield of NJ and many physicians and health systems.

In addition, we have performed dozens of analyses of very large claims data sets and reported results of rates and costs of PACs to policy makers, health plan leaders and physician leaders from different states. These include:

- Vermont Payment Reform Commission
- Maine Health Management Coalition
- WellPoint / Anthem CT

- NY State Medicaid
- CT Medicaid
- CO All-payer Claims Database, Center for Improving Value in Health Care

These analyses and their results have influenced, and continue to influence, the development of various public reporting, payment reform and delivery system reform efforts. To-date, we have never experienced either wholesale or partial rejection of the results of analyses showing rates of PACs, which demonstrates the level of acceptability – face validity – of the measures from the payer, policymaker, employer and payer communities.

As importantly, measures of potentially avoidable complications have face-validity with consumers. In a series of focus groups, Judy Hibbard and colleagues[1] examined the impact of presenting information about price and quality of certain providers in influencing the decisions of consumers. They tested the validity of PACs as a discriminator of quality, as well as other measures of quality, and used the dollar symbol to illustrate the level of price, much like is done for restaurant reviews. When the PAC measure was used, respondents selected the providers with the lowest PAC rates with a high level of confidence in choice, and used it as a surrogate for a strong quality signal. To the contrary, when more standard measures of quality were used, consumers tended to ignore them and use price as a surrogate for quality. As such, what the researchers found is that the very framing of potentially avoidable complications as an indicator of potential harm, is an effective way of communicating the quality of care. And when measures of PACs were presented in conjunction with price, consumers intuitively accepted the logical relationship between low PACs – fewer "defects" – and lower price.

Finally, our measure definitions encompass several other measures that are accepted as being valid complications of care and are widely used throughout the country. These include CMS defined Hospital Acquired Conditions (HACs)[2], Hospital Inpatient Quality Reporting measures [3], Avoidable Readmissions [4,5], AHRQ defined patient safety indicators (PSIs) [6], NQF endorsed patient safety measures such as patient fall rates, pressure ulcer rates, and peri-operative pulmonary embolism or deep vein thrombosis rates [7].

2b2.3. What were the statistical results from validity testing? (*e.g., correlation; t-test*)
Not applicable.

2b2.4. What is your interpretation of the results in terms of demonstrating validity? (i.*e., what do the results mean and what are the norms for the test conducted?*)

Given the significant clinical input that went into developing the measure, the widespread use and acceptance the measure has gained among a wide variety of individuals and organizations across the health system (public and private payers, clinicians, consultants, patients, etc.) [1-13], and the parallels between this measure and other measures that are in widespread use, this demonstrates that the measure has strong face validity.

2b3. EXCLUSIONS ANALYSIS

NA ☐ no exclusions — *skip to section 2b4*

2b3.1. Describe the method of testing exclusions and what it tests (*describe the steps—do not just name a method; what was tested, e.g., whether exclusions affect overall performance scores; what statistical analysis was used*)

No formal exclusion testing was done since no real exclusions were done. The only patients excluded were the ones that had incomplete or missing data and those that would not have given a homogenous population such as outliers.

Exclusions include exclusions of "patients" as well as "claims" not relevant to CAD care. Please refer to the enclosed excel workbook entitled (NQF_CAD_all_codes_risk_adjustment_06.30.15.xls)

1. "Patients" are excluded from the measure if they meet one of the following criteria:
a. If age is < 18 years
b. If gender is missing
c. If they do not have continuous enrollment for the entire time window with a maximum of 30 day enrollment gap with the entity providing the data (this helps determine if the database has captured most of the claims for the patient in the time window).
d. If the patient does not have at least 12 months of claims in the database (this helps eliminate incomplete episodes).
e. The episode cost is an outlier (less than 1st percentile or greater than 99th percentile value for all episodes of the same type). This eliminates extreme variation that may result from random outlier events.

2. "Claims" are excluded from the measure if they meet one of the following criteria:
a. If none of the diagnosis codes on the claim are on the list of "triggers" or relevant diagnosis codes (either typical Dx or PAC Dx) for CAD.
b. If none of the procedure / CPT codes on the claim are on the list of relevant procedure codes for CAD.
c. If the CAD trigger hospitalization also triggers a major surgical procedure such as coronary bypass procedure or angioplasty, suggesting that CAD may be a comorbidity or an indication for the surgery.
d. The "principal" diagnosis on an inpatient stay claim during the episode time window triggers its own episode
e. The procedure code on a claim during the episode time window triggers its own episode

2b3.2. What were the statistical results from testing exclusions? (*include overall number and percentage of individuals excluded, frequency distribution of exclusions across measured entities, and impact on performance measure scores*)

We started with a total CAD population of 63,972 episodes. After all the exclusions were applied, the remaining CAD population included in the analysis consisted of 34,016 episodes. As mentioned above, no real exclusions were done. The only patients excluded were the ones that had incomplete or missing data and those that would not have given a homogenous population such as outliers. As such, no formal exclusion testing was done.

2b3.3. What is your interpretation of the results in terms of demonstrating that exclusions are needed to prevent unfair distortion of performance results? (*i.e., the value outweighs the burden of increased data collection and analysis. Note: **If patient preference is an exclusion**, the measure must be specified so that the effect on the performance score is transparent, e.g., scores with and without exclusion*)

No formal analysis was done on the impact of exclusions on performance scores.

Descriptive Explanation:

Exclusions of patients were for the following reasons. Some are for comparative purposes and some for medical reasons.

(a) Comparative Purposes:
We excluded patients that did not have complete enrollment for the entire episode time window. This was done to ensure that the database had complete information on patients to be able to create the entire episode. Including patients with only a partial episode window could distort the measure by artificially reducing the actual count of patients with PACs.

(b) Medical Reasons:
Patients with outlier costs (less than 1st percentile value or greater than 99th percentile) were considered to be different from the general pool, and excluded from both the numerator and the denominator. This is another way to ensure that episodes are complete (because incomplete episodes may have very low costs), and do not bring in random noise into the analysis due to inappropriate codes or services (high outliers).

2b4. RISK ADJUSTMENT/STRATIFICATION FOR OUTCOME OR RESOURCE USE MEASURES
If not an intermediate or health outcome, or PRO-PM, or resource use measure, skip to section 2b5.

2b4.1./S13 What method of controlling for differences in case mix is used?
☐ **No risk adjustment or stratification**
☐ **Statistical risk model** with 170 potential risk factors and episode specific subtypes
☐ **Stratification by** Click here to enter number of categories **risk categories**
☐ **Other,** Click here to enter description

2b4.1.2. If an outcome or resource use measure is not risk adjusted or stratified, provide rationale and analyses to demonstrate that controlling for differences in patient characteristics (case mix) is not needed to achieve fair comparisons across measured entities.

2b4.2/S14. Identify the statistical risk model variables (Name the statistical method – e.g., logistic regression and list all the risk factor variables.
A number of patient-related "risk factors" or covariates are included in the models:

Patient demographics: age, gender, and an indicator of whether a member has enrolled within the previous 6 months. This latter risk factor is intended to account for the patient's lack of claims history, which limits the number of potential comorbidities that can be identified.

Comorbidities: These are conditions or events that occurred prior to the start of the episode that can have a potential impact on the patient's risk of having a PAC. The risk factors are 170 disease indicators (0/1) identified through the presence of ICD diagnosis codes on individual medical claims and collected from the historical claims data before the start of an episode. These are universally applied across all episodes. Please see the tab labeled "All Risk Factors I-9" and "All Risk Factors I-10" for a list of risk factors and their corresponding codes in the enclosed workbook called NQF_CAD_all_codes_risk_adjustment_06.30.15.xls. This list was selected based on input from clinical experts in clinical working groups.

Episode Subtypes or Severity Markers: These are markers that distinguish an episode as being more severe than another. They indicate either specific patient comorbidities that are known to make the procedure or condition more difficult to treat (e.g., obesity) or severity of the illness itself (e.g., Previous CABG, PCI). Subtypes are specific to each unique episode and are included in the models only if they are present at the start of the episode. Please see the tab labeled "Subtypes I-9" and "Subtypes I-10" for a list of subtypes and their corresponding codes in the enclosed workbook called NQF_CAD_all_codes_risk_adjustment_06.30.15.xls. This list was selected based on input from clinical experts in clinical working groups.

Candidate comorbidities and subtypes were included in the models as covariates if they were present in at least 10 episodes to prevent unstable coefficients.

The detailed list of all possible risk factors and subtypes is provided in the tables below.

2b4.2.1/S15. Detailed risk model specifications including coefficients, equations, codes with descriptors, definitions(may be attached in an Excel or cvs file)
All Risk Factors with their coefficients are detailed in the enclosed workbook called NQF_CAD_all_codes_risk_adjustment_06.30.15.xls – Please reference the tabs titled Risk Factor Prevalence and Risk Model.

2b4.3. Describe the conceptual/clinical <u>and</u> statistical methods and criteria used to select patient factors (clinical factors or sociodemographic factors) used in the statistical risk model or for stratification by risk(*e.g., potential factors identified in the literature and/or expert panel; regression analysis; statistical significance of p<0.10; correlation of x or higher; patient factors should be present at the start of care*)

Risk factors are comorbidity indicators collected from historical claims before the start of an episode. These are universally applied across all episodes. This list was selected based on input from clinical experts in clinical working groups. In addition, the Clinical Working Groups identified episode specific severity markers that were called episode subtypes and they help distinguish an episode as being more severe than another.

All risk factors and subtypes must be present prior to, or at the start of the episode and are identified using diagnosis codes in the patient's historical claims.

To be included in the risk adjustment models, any risk factor or subtype must be present in at least 10 episodes. Beyond this no further model building was conducted to add or remove risk factors or subtypes from the model after it was initially run. This reflects a desire to explain as much variation in the probability of having a PAC

as possible, but does not make it a priority that all covariates be individually significant or even uncorrelated with each other. Accordingly, the model uses a very large group of covariates. This modeling approach allows for fewer potentially artificial constraints around the definitions of what constitutes severity, and lets the model determine for itself which of the factors are more significant. Non-significant covariates cannot overly influence the predicted outcomes, nor is much harm realized, if a group of correlated covariates work together to explain variation rather than having the variation explained by a single best factor.

2b4.4a. What were the statistical results of the analyses used to select risk factors?

As explained above, no formal analysis was conducted to select risk factors. In fact, all potential risk factors and subtypes with a count of at least 10 episodes were retained to serve as predictors. The goal was to achieve a more complete explanatory model rather than achieve parsimony.

Please reference the tabs titled Risk Model in the NQF_CAD_all_codes_risk_adjustment_06.30.15.xls workbook to see the list of risk factors that met the selection criteria.

2b4.4b. Describe the analyses and interpretation resulting in the decision to select SDS factors (e.g. prevalence of the factor across measured entities, empirical association with the outcome, contribution of unique variation in the outcome, assessment of between-unit effects and within-unit effects)

Not Applicable since our analysis did include SDS variables

2b4.5. Describe the method of testing/analysis used to develop and validate the adequacy of the statistical model or stratification approach (*describe the steps—do not just name a method; what statistical analysis was used*)

Model Development Approach

We used logistic regression to model the probability of at least one PAC occurring during the episode. The model included all covariates that were identified through the process above. No further model building was conducted after the initial model was run. This reflects a desire to explain as much variation in the probability of having a PAC as possible, but does not make it a priority that all covariates be individually significant or even uncorrelated with each other. Accordingly, the model uses a very large group of covariates. This modeling approach allows for fewer potentially artificial constraints around the definitions of what constitutes severity, and lets the model determine for itself which of the factors are more significant. Non-significant covariates can not overly influence the predicted outcomes, nor is much harm realized, if a group of correlated covariates work together to explain variation rather than having the variation explained by a single best factor.

For a more complete description of the risk adjustment approach, please see the document entitled, "PACs and Severity Adjustment Fact Sheet" that accompanies this submission.

Approach to Model Testing and Validation

To determine the validity and performance of the model, we used the split sample method to divide the patient sample randomly into: 1) the model building data set (80% of the sample) and 2) the test data set (20% of sample. The model was built using logistic regression on the first data set and then the coefficients from the development model were tested in the second dataset. Area under the curve (AUC) and the c-statistic were used to compare the predictive ability of the model in each of the data sets. Hosmer-Lemeshow Goodness-of-Fit tests and comparisons of observed to expected probabilities across risk deciles were further examined to assess the model's overall predictive accuracy.

Provide the statistical results from testing the approach to controlling for differences in patient characteristics (case mix) below.
If stratified, skip to 2b4.9

2b4.6. Statistical Risk Model Discrimination Statistics (*e.g., c-statistic, R-squared*)**:**

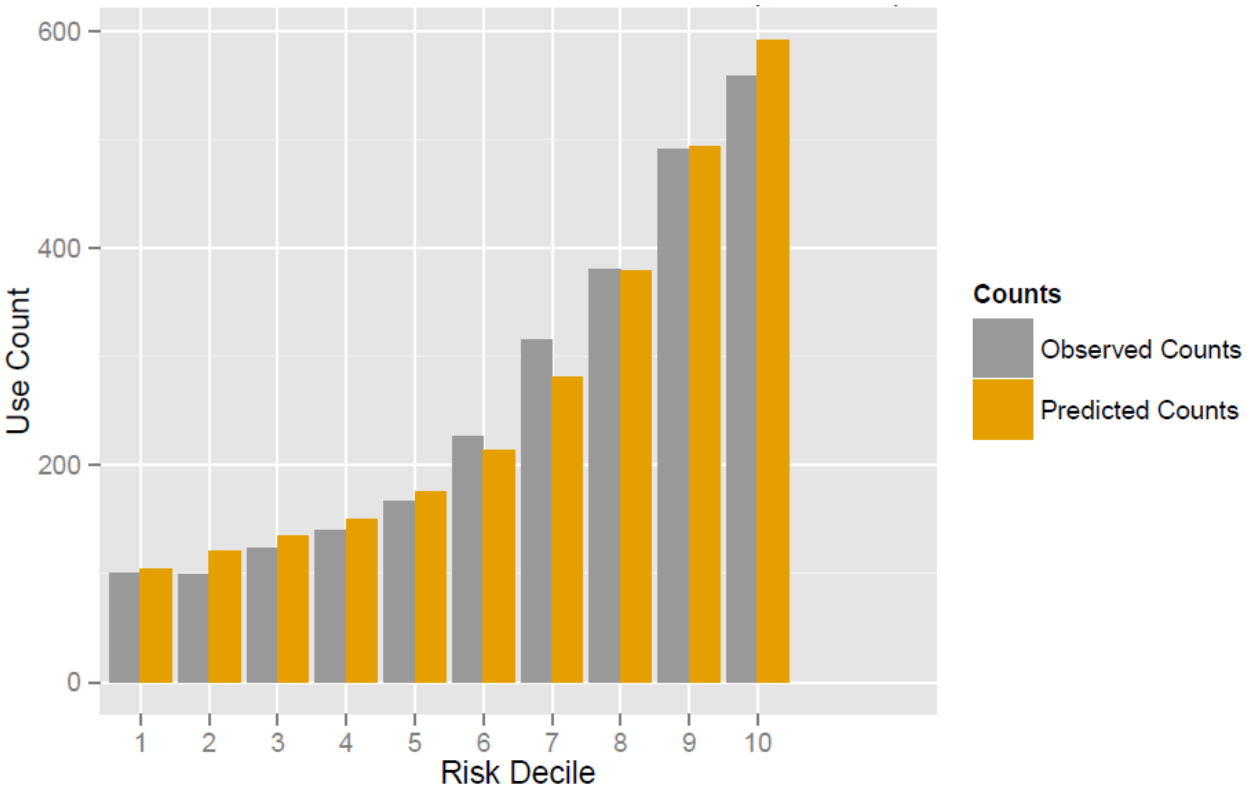
Sample	Accuracy (%)*	AUC
Test	75.4%	0.803
Validation	74.5%	0.792

*Episodes with predicted probabilities <50% were classified as having a predicted 0 (not having a PAC). Episodes with predicted probabilities >50% were classified as having a predicted 1 (having a PAC)

2b4.7. Statistical Risk Model Calibration Statistics (*e.g., Hosmer-Lemeshow statistic*):

Sample	Chi Square	Degrees of Freedom	p-value
Test	199.5	8	<0.0001
Validation	51.8	8	<0.0001

2b4.8. Statistical Risk Model Calibration – Risk decile plots or calibration curves:



2b4.9. Results of Risk Stratification Analysis:
Not applicable

2b4.10. What is your interpretation of the results in terms of demonstrating adequacy of controlling for differences in patient characteristics (case mix)? (i.*e., what do the results mean and what are the norms for the test conducted*)

The C statistic is a measure of the extent to which a statistical model is able to discriminate between a patient with and without an outcome. The c-statistic ranges from 0.5 to 1.0. A c-statistic of 0.50 indicates the model is no better than random prediction, implying that the patient risk factors do not predict variation in the outcome; conversely, a c-statistic of 1.0 indicates perfect prediction, implying patients' outcomes can be predicted completely by their risk factors, and physicians and hospitals play little role in patients' outcomes. Models with c-statistic values of at least 0.7 are considered good and those above 0.8 are considered strong [1]. The purpose of the model is to adjust for patient-related factors. The remaining unexplained differences in PAC rates are due to factors that could be controlled by all providers that are managing or co-managing the patient, during the entire episode time window.

The c-statistics of the testing and validation samples (0.803 and 0.792, respectively) indicate that the risk models have strong discriminatory power. Indeed, the accuracy values show that the model correctly predicts whether an episode had or did not have a PAC about 75% of the time, well above what would be expected if the predictions were made at random (i.e., 50%). Although the H-L test was significant for the testing sample, meaning that the model is not a good fit, this test is generally known to be sensitive to the number of groupings used and sample sizes. Additionally, the risk decile plot shows that the model predicts PACs similarly to the observed PACs across all deciles.

Overall, the results strongly suggest that the models have strong predictive power.

2b4.11. Optional Additional Testing for Risk Adjustment (*not required, but would provide additional support of adequacy of risk model, e.g., testing of risk model in another data set; sensitivity analysis for missing data; other methods that were assessed*)

NA

2b5. IDENTIFICATION OF STATISTICALLY SIGNIFICANT & MEANINGFUL DIFFERENCES IN PERFORMANCE

2b5.1. Describe the method for determining if statistically significant and clinically/practically meaningful differences in performance measure scores among the measured entities can be identified (*describe the steps—do not just name a method; what statistical analysis was used? Do not just repeat the information provided related to performance gap in 1b)*

To directly compare PAC rates across providers or providers while also appropriately accounting for differences in patient severity, we calculated a risk-standardized PAC rate for each provider. This method is similar to calculations used by others for reporting outcomes measures [1]. For each provider, the ratio of observed attributed episodes with PACs to the expected number of attributed episodes with PACs given the patient's risk factor and estimated from the risk-adjustment model was calculated. This number yielded whether the provider had more PACs than expected (ratio>1), as expected (ratio=1), or less than expected (ratio<1). We then multiplied this ratio by the overall expected PAC rate across all providers to obtain the risk-standardized PAC rate for the provider. This measure represents what a provider's PAC rate would be if its patient population was reflective of the overall population.

Because providers with small volumes may provide unreliable estimates, we excluded any with fewer than 10 attributed episodes prior to the calculations. Comparison of risk-adjusted PAC rates gives a measure of the provider's relative performance. Our analysis compared risk-standardized PAC rates across providers. We analyzed various descriptive statistics including the range in PAC rates, medians, interquartile range, etc.

Reference:

[1] See, for example: NQF#1550: Hospital-level risk-standardized complication rate (RSCR) following elective primary total hip arthroplasty (THA) and / or total knee arthroplasty (TKA). Online version: http://bit.ly/1BWQTRt

2b5.2. What were the statistical results from testing the ability to identify statistically significant and/or clinically/practically meaningful differences in performance measure scores across measured entities? (e.g., *number and percentage of entities with scores that were statistically significantly different from mean or some benchmark, different from expected; how was meaningful difference defined*)

Summary of Unadjusted and Adjusted Performance Scores Across Providers:

PAC Rates	Minimum # Episodes Per Provider	
	>=10	>=25
Unadjusted		
Median (IQR)	40% (30%, 55%)	39% (32%, 51%)

Range	0%-100%	8%-94%
Adjusted (RSPR)*		
Median (IQR)	40% (33%, 47%)	41% (34%, 46%)
Range	0%-84%	11%-71%

***RSPR = Risk Standardized PAC Rate**

Please refer to the NQF_CAD_all_codes_risk_adjustment_06.30.15.xls workbook under the "ProviderAttribution Reliability" tab to see specific results for each provider.

2b5.3. What is your interpretation of the results in terms of demonstrating the ability to identify statistically significant and/or clinically/practically meaningful differences in performance across measured entities? (i.*e., what do the results mean in terms of statistical and meaningful differences?*)
The variation in risk-adjusted rates suggests there are meaningful differences in performance between providers in risk-standardized PAC rates for patients with an episode of CAD.

Minimum sample size requirements for PAC measures are a function of the reliability testing of the measures on every dataset on which the measures are applied. Our research suggests that minimum sample sizes to achieve high degrees of reliability in the measures are a function of the dataset analyzed, and as such may vary from dataset to dataset. One should not infer that a minimum sample size achieved in one dataset would apply to another.

2b6. COMPARABILITY OF PERFORMANCE SCORES WHEN MORE THAN ONE SET OF SPECIFICATIONS
If only one set of specifications, this section can be skipped.

Note: *This criterion is directed to measures with more than one set of specifications/instructions (e.g., one set of specifications for how to identify and compute the measure from medical record abstraction and a different set of specifications for claims or eMeasures). It does not apply to measures that use more than one source of data in one set of specifications/instructions (e.g., claims data to identify the denominator and medical record abstraction for the numerator).* ***Comparability is not required when comparing performance scores with and without SDS factors in the risk adjustment model. However, if comparability is not demonstrated for measures with more than one set of specifications/instructions, the different specifications (e.g., for medical records vs. claims) should be submitted as separate measures.***

2b6.1. Describe the method of testing conducted to demonstrate comparability of performance scores for the same entities across the different data sources/specifications (*describe the steps—do not just name a method; what statistical analysis was used*)

Not applicable

2b6.2. What were the statistical results from testing comparability of performance scores for the same entities when using different data sources/specifications? (*e.g., correlation, rank order*)

Not performed

2b6.3. What is your interpretation of the results in terms of demonstrating comparability of performance measure scores for the same entities across the different data sources/specifications? (i.*e., what do the results mean and what are the norms for the test conducted*)

Not applicable

2b7. MISSING DATA ANALYSIS AND MINIMIZING BIAS

2b7.1. Describe the method of testing conducted to identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias (*describe the steps—do not just name a method; what statistical analysis was used*)

If patient related data is missing, the entire patient is excluded from the numerator as well as the denominator.

Within our measure constructs, presence of potentially avoidable complications are identified from administrative claims data. Furthermore, the measure is constructed so that the occurrence of any number of PACs during a defined episode would only count as one occurrence.

According to our measure definition, in constructing the measure it is possible for a provider to have only one or some types of PACs and not others. Alternatively, the provider may have all PAC types occur for their patients. The measure only considers whether any PAC occurred regardless of the type, and all PAC types are weighted equally, therefore there is no potential for the absence of specific PAC types to bias performance scores for individual providers.

For these reasons, no formal analyses were done on missing data.

2b7.2. What is the overall frequency of missing data, the distribution of missing data across providers, and the results from testing related to missing data? (*e.g., results of sensitivity analysis of the effect of various rules for missing data/nonresponse; if no empirical sensitivity analysis, identify the approaches for handling missing data that were considered and pros and cons of each*)

Not applicable

2b7.3. What is your interpretation of the results in terms of demonstrating that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias**?** (i.*e., what do the results mean in terms of supporting the selected approach for missing data and what are the norms for the test conducted; if no empirical analysis, provide rationale for the selected approach for missing data*)

Not applicable

2d. EMPIRICAL ANALYSIS TO SUPPORT COMPOSITE CONSTRUCTION APPROACH

Note: *If empirical analyses do not provide adequate results—or are not conducted—justification must be provided and accepted in order to meet the must-pass criterion of Scientific Acceptability of Measure Properties. Each of the following questions has instructions if there is no empirical analysis.*

2d1. Empirical analysis demonstrating that the component measures fit the quality construct, add value to the overall composite, and achieve the object of parsimony to the extent possible.

The PAC measures, as we define them, look at many "care defects" comprehensively. They are composed of several cross-cutting measures and together they paint a global picture of the provider's overall performance.

PACs may occur any time during the episode time window. PACs are counted as a dichotomous (yes/no) outcome. If a patient had one or more PACs, they get counted as a "yes" or a 1. The enclosed workbook entitled NQF_CAD_all_codes_risk_adjustment_06.30.15.xls provides outputs from empirical analysis. The tab labeled "PAC overview" demonstrates percentage of episodes that had at least one PAC, and provides the breakdown of PACs: 1) by the type of PAC whether directly related to index condition or due to patient safety failures; 2) the setting of the PAC, whether seen in the in-patient setting, out-patient facility or during professional visits; and 3) preventable hospitalizations.

The "PAC Drill Down Graph" provides further detail on each component of the PAC and their frequency. As can be seen by the individual counts and the graph, while each individual PAC may have such small occurrences that no meaningful comparisons in provider performances could be made; together, they add value to provide a comprehensive picture that result in meaningful numbers. The aggregation of PACs to a comprehensive, composite measure, in itself provides the parsimony that is so desirable.

2d1.1 Describe the method used (*describe the steps—do not just name a method; what statistical analysis was used; if no empirical analysis, provide justification)*

All PACs, as clinically defined by the subject matter experts were used with equal weighting. Since the emphasis of the PAC measure is to identify the occurrence of PACs in any setting, a simple and straightforward approach was adopted.

2d1.2. What were the statistical results obtained from the analysis of the components? (e.g., *correlations, contribution of each component to the composite score, etc.*; *if no empirical analysis, identify the components that were considered and the pros and cons of each*)

No formal analysis was performed.

2d1.3. What is your interpretation of the results in terms of demonstrating that the components included in the composite are consistent with the described quality construct and add value to the overall composite? (i.*e., what do the results mean in terms of supporting inclusion of the components; if no empirical analysis, provide rationale for the components that were selected)*

Since our premise is that all PACs are potentially avoidable, we adopted the approach to count all PACs and give them equal weights. The overall composite score results in the quality construct that could be measured and interpreted.

2d2. Empirical analysis demonstrating that the aggregations and weighting rules are consistent with the quality construct and achieve the objective of simplicity to the extent possible

2d2.1 Describe the method used (*describe the steps—do not just name a method; what statistical analysis was used; if no empirical analysis, provide justification)*

Within our measure constructs, presence of potentially avoidable complications are identified from administrative claims data. Additionally, if a patient had one or more PACs, it is simply counted as a 1, i.e., flagged as having a PAC. The measure only considers whether any PAC occurred regardless of the type, or the site, and all PAC types are weighted equally. Therefore, no formal analysis of individual components was performed.

2d2.2. What were the statistical results obtained from the analysis of the aggregation and weighting rules? (e.g., *results of sensitivity analysis of effect of different aggregations and/or weighting rules; if no empirical analysis, identify the aggregation and weighting rules that were considered and the pros and cons of each*)

We chose not to weight the components of the measure.

Considerations were given to the fact that preventable hospitalizations may be given more weight, than PACs identified in a doctor's office. Similarly PACs in an in-patient setting may have more serious implications on a patient's ultimate outcome, than PACs occurring in an outpatient setting. Additionally, preventable hospitalizations as well as index hospitalizations, each with longer lengths of stay, may have serious PACs. But how do we weigh these effects? An alternative model was considered, where cost could be considered as a surrogate for the weights. Higher cost PACs could imply more serious PACs. However, differences in costs could be driven by many issues other than the PAC itself, such as unit price of the service, method of reimbursements, contracting arrangements etc.

Furthermore, in-patient facility billing does not allow for the distinction of PAC related costs from other costs within the stay. We would fail to capture PAC related costs within the stay and potentially underweight those. As a result, the decision was made to avoid weighting and keep the measure as a straightforward count.

2d2.3. What is your interpretation of the results in terms of demonstrating the aggregation and weighting rules are consistent with the described quality construct? (i.*e., what do the results mean in terms of supporting the selected rules for aggregation and weighting; if no empirical analysis, provide rationale for the selected rules for aggregation and weighting*)

Measuring all providers with the same yardstick will provide consistent results and reasonable comparisons over time. If the goal is to reduce PACs, then the PAC measure as was constructed with the help of various experts in the field would provide reasonable comparisons. A word of caution however pertains to the sample size of the provider panel before making any reasonable conclusions.

Minimum sample size requirements for PAC measures are a function of the reliability testing of the measures on every dataset on which the measures are applied. Our research suggests that minimum sample sizes to achieve high degrees of reliability in the measures are a function of the dataset analyzed, and as such may vary from dataset to dataset. One should not infer that a minimum sample size achieved for high reliability in one dataset would apply to another.

2d3. Empirical analysis demonstrating that the approach for handling missing data minimizes bias (*i.e., achieves scores that are an accurate reflection of quality*)**.**

Note: *Applies to the overall composite measure; the focus is on missing data rather than exclusions, which are considered in 2b3.*

Please refer to section 2b7

2d3.1. What is the overall frequency of missing data and the distribution of missing data across providers?

2d3.2. Describe the method used to compare approaches for handling missing data (*describe the steps—do not just name a method; what statistical analysis was used; if no empirical analysis, provide justification)*

2d3.3. What were the statistical results obtained from the analysis of missing data? (e.g., *results of sensitivity analysis of effect of various rules for missing data; if no empirical analysis, identify the approaches for handling missing data that were considered and pros and cons of each*)

2d3.4. What is your interpretation of the results in terms of demonstrating that the approach used for missing data minimizes bias? (i.*e., what do the results mean in terms of supporting the selected approach for missing data; if no empirical analysis, provide rationale for the selected approach for missing data*)

3. Feasibility

Extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

3a. Byproduct of Care Processes

For clinical measures, the required data elements are routinely generated and used during care delivery (e.g., blood pressure, lab test, diagnosis, medication order).

3a.1. **Data Elements Generated as Byproduct of Care Processes.**

Coded by someone other than person obtaining original information (e.g., DRG, ICD-9 codes on claims)

If other:

3b. Electronic Sources

The required data elements are available in electronic health records or other electronic sources. If the required data are not in electronic health records or existing electronic sources, a credible, near-term path to electronic collection is specified.

3b.1. **To what extent are the specified data elements available electronically in defined fields?** *(i.e., data elements that are needed to compute the performance measure score are in defined, computer-readable fields)*

ALL data elements are in defined fields in electronic claims

3b.2. **If ALL the data elements needed to compute the performance measure score are not from electronic sources, specify a credible, near-term path to electronic capture, OR provide a rationale for using other than electronic sources.**

3b.3. **If this is an eMeasure, provide a summary of the feasibility assessment in an attached file or make available at a measure-specific URL.**

Attachment:

3c. Data Collection Strategy

Demonstration that the data collection strategy (e.g., source, timing, frequency, sampling, patient confidentiality, costs associated with fees/licensing of proprietary measures) can be implemented (e.g., already in operational use, or testing demonstrates that it is ready to put into operational use). For eMeasures, a feasibility assessment addresses the data elements and measure logic and demonstrates the eMeasure can be implemented or feasibility concerns can be adequately addressed.

3c.1. **Describe what you have learned/modified as a result of testing and/or operational use of the measure regarding data collection, availability of data, missing data, timing and frequency of data collection, sampling, patient confidentiality, time and cost of data collection, other feasibility/implementation issues.**

IF a PRO-PM, consider implications for both individuals providing PROM data (patients, service recipients, respondents) and those whose performance is being measured.

As part of our general implementation of these measures and related analyses, we have worked through dozens of different and sometimes very large datasets. From Medicare to Medicaid to regional and national commercial carriers, as well as individual employers, the principal lesson learned is the heterogeneity of the data sets and the significant variability in fill rate of critical data elements. As a result, we have created highly specific recommendations for which data elements are required to ensure measure validity, the accuracy of those data elements, and their completeness in the dataset. When claims datasets are organized in the way we specify in the measure analysis, and contain the coding information required, the analysis of the measure and its results are highly reliable.

3c.2. **Describe any fees, licensing, or other requirements to use any aspect of the measure as specified** *(e.g., value/code set, risk model, programming code, algorithm)*.

The calculations of rates of potentially avoidable complications can be replicated by anyone that uses the measure specifications along with the metadata file that is available for free on our web site at http://www.hci3.org/ecre/xml-agreement.html.

We also plan on providing a limited automated analysis, at no cost, on our website.

4. Usability and Use

Extent to which potential audiences (e.g., consumers, purchasers, providers, policy makers) are using or could use performance results for both accountability and performance improvement to achieve the goal of high-quality, efficient healthcare for individuals or populations.

4a. Accountability and Transparency

Performance results are used in at least one accountability application within three years after initial endorsement and are publicly reported within six years after initial endorsement (or the data on performance results are available). If not in use at the time of initial endorsement, then a credible plan for implementation within the specified timeframes is provided.

4.1. Current and Planned Use

NQF-endorsed measures are expected to be used in at least one accountability application within 3 years and publicly reported within 6 years of initial endorsement in addition to performance improvement.

Planned	Current Use (for current use provide URL)
Public Reporting Professional Certification or Recognition Program Quality Improvement with Benchmarking (external benchmarking to multiple organizations)	Payment Program Blue Cross Blue Shield of North Carolina https://www.bcbsnc.com/ Blue Cross Blue Shield of New Jersey http://www.horizonblue.com/ Pennsylvania Employee Benefits Trust Fund https://www.pebtf.org/ Quality Improvement (Internal to the specific organization) Blue Cross Blue Shield of North Carolina https://www.bcbsnc.com/assets/providers/public/pdfs/specialty_methodology.pdf

4a.1. For each CURRENT use, checked above, provide:

- Name of program and sponsor
- Purpose
- Geographic area and number and percentage of accountable entities and patients included

Measures associated to potentially avoidable complications (PACs) are in use today with some private sector payers and gaining further acceptance among a wide variety of organizations across the health system (public and private payers, clinicians, consultants, all-payer claims database stewards, etc.) [1-8]. They are being used in various capacities in different pilot site implementations. To name a few:

•BCBSA (Blue Cross Blue Shield Association) – uses them for their Centers of Excellence (COE) programs: Blue Distinction
•BCBSNC (Blue Cross Blue Shield of North Carolina) – is using them for tiering providers

In addition, the PAC measures are incorporated by the following organizations in their bundled payment programs:

•BCBSSC – for CABG and PCI programs
•Horizon BCBSNJ– for CHF and CABG programs
•BCBSNC
•PEBTF in PA

http://www.ajmc.com/interviews/Lili-Brillstein-on-How-Bundled-Payments-Are-Tranforming-Healthcare

In these programs they look at PACs related to the measure for process improvement activities and for practice re-engineering.

We have created reports for rates of PACs for the following organizations:
-Vermont Payment Reform
-Maine Health Management Coalition

-WellPoint / Anthem CT
-NY State Medicaid
-CT Medicaid
-CO All-payer Claims Database, Center for Improving Value in Health Care

There are several companies that are leveraging these measures to create analytics and software for customers – these include HealthQx, Aver Informatics, McKesson, and TriZetto.

Below are some references that highlight our work with Potentially Avoidable Complications (PACs).

4a.2. If not currently publicly reported OR used in at least one other accountability application (e.g., payment program, certification, licensing) what are the reasons? (*e.g., Do policies or actions of the developer/steward or accountable entities restrict access to performance results or impede implementation?*)
N/A

4a.3. If not currently publicly reported OR used in at least one other accountability application, provide a credible plan for implementation within the expected timeframes -- any accountability application within 3 years and publicly reported within 6 years of initial endorsement. (*Credible plan includes the specific program, purpose, intended audience, and timeline for implementing the measure within the specified timeframes. A plan for accountability applications addresses mechanisms for data aggregation and reporting.*)
Measures associated with PACs are currently in use as described in the prior section. In addition, we are working with several not-for-profit and for-profit organizations to provide them with the algorithms needed to calculate rates of potentially avoidable complications. Some of these organizations include:

Fair Health – based in NY and whose mission is to increase transparency of provider cost and quality,

CastLight – based in CA and serving large employers. We currently provide CastLight with Bridges To Excellence recognitions and will work with them to augment provider transparency by using PAC measures,

MA APCD (Massachusetts All Payers Claims Database) Council – we currently have an agreement in place with the MA APCD Council to produce PAC measures on hospitals and physicians and report back to the council with tests of reliability and validity of the measures. The purpose is to authorize the publication of these measures,
Maryland Health Care Cost Commission – we have a two year agreement to produce measures of cost and quality for public dissemination.

4b. Improvement

Progress toward achieving the goal of high-quality, efficient healthcare for individuals or populations is demonstrated. If not in

use for performance improvement at the time of initial endorsement, then a credible rationale describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.

4b.1. **Progress on Improvement. (Not required for initial endorsement unless available.)**
Performance results on this measure (current and over time) should be provided in 1b.2 and 1b.4. Discuss:

- **Progress (trends in performance results, number and percentage of people receiving high-quality healthcare)**
- **Geographic area and number and percentage of accountable entities and patients included**

We do not have any public information to share about the improvements in rates of potentially avoidable complications, as the implementation of these measures is too recent to provide valid comparisons. Further, some of the definitions of PACs have changed since the measures were initially endorsed, making comparisons even more difficult and unreliable.

Nevertheless, the variation in performance scores presented in Section 1b.2 indicates that there are differences between providers in their risk-adjusted PAC rates (higher scores equal worse performance). This suggests that real opportunities exist to identify lower performing providers and reduce the overall occurrence of PACs.

4b.2. **If no improvement was demonstrated, what are the reasons? If not in use for performance improvement at the time of initial endorsement, provide a credible rationale that describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.**
Performance results provide summary PACs rates by provider, which can be used by payers and providers in a number of ways to improve the quality of care.

From the payer perspective, payers can use this information to 1) create a high-value provider networks, 2) work with high-value providers to share best practices, 3) incentivize low-value providers to improve, 4) modify their insurance design to activate consumers to select the right care from the right providers at the right time.

From the provider perspective, providers can 1) view services and activity for their patients longitudinally across the entire care continuum, such as frequency of readmissions and ED visits and drill down on patients with high PAC rates, 2) review actionable drill down reports to identify the most frequent PACs across all patients to create care pathways and process improvement plans to impact the most frequent PACs.

4c. Unintended Consequences

The benefits of the performance measure in facilitating progress toward achieving high-quality, efficient healthcare for individuals or populations outweigh evidence of unintended negative consequences to individuals or populations (if such evidence exists).

4c.1. **Were any unintended negative consequences to individuals or populations identified during testing; OR has evidence of unintended negative consequences to individuals or populations been reported since implementation? If so, identify the negative unintended consequences and describe how benefits outweigh them or actions taken to mitigate them.**
No unintended consequences were reported, but there is the potential for:
1. Under-coding of PACs in the claim stream resulting in under-reporting the actual rate and/or providers gaming the measures
2. Payers calculating the measures even with inadequate sample sizes and using the results to penalize providers

The measure is designed for transparency efforts and to spur quality improvement. Detailed PAC reports can help providers identify areas of quality improvement. Even detailed reports of small samples of patients can be helpful for quality improvement purposes, but not for public reporting. To mitigate the potential for invalid provider comparisons, we specify in this submission the minimum sample size needed to ensure the reliability of a provider's score. Ultimately, there isn't any good way to prevent provider gaming of the measure by under-coding claims, however, under the current DRG payment methodology, many providers would be penalized by under-coding PACs since these codes often result in the assignment of more complicated DRGs.

5. Comparison to Related or Competing Measures

If a measure meets the above criteria and there are endorsed or new related measures (either the same measure focus or the same target population) or competing measures (both the same measure focus and the same target population), the measures are compared to address harmonization and/or selection of the best measure.

5. Relation to Other NQF-endorsed Measures

Are there related measures (conceptually, either same measure focus or target population) or competing measures (conceptually both the same measure focus and same target population)? If yes, list the NQF # and title of all related and/or competing measures.

Yes

5.1a. **List of related or competing measures (selected from NQF-endorsed measures)**

0337 : Pressure Ulcer Rate (PDI 2)
0450 : Perioperative Pulmonary Embolism or Deep Vein Thrombosis Rate (PSI 12)
0705 : Proportion of Patients Hospitalized with Stroke that have a Potentially Avoidable Complication (during the Index Stay or in the 30-day Post-Discharge Period)
0708 : Proportion of Patients Hospitalized with Pneumonia that have a Potentially Avoidable Complication (during the Index Stay or in the 30-day Post-Discharge Period)
0709 : Proportion of patients with a chronic condition that have a potentially avoidable complication during a calendar year.
1789 : Hospital-Wide All-Cause Unplanned Readmission Measure (HWR)

5.1b. **If related or competing measures are not NQF endorsed please indicate measure title and steward.**

-0531 Patient Safety for Selected Indicators (Composite Measure, endorsed) (AHRQ)
-CMS defined hospital acquired conditions (HACs) are a subset of our PACs. We have pain-stakingly matched the definitions to provide as much consistency as possible. http://www.cms.

5a. Harmonization

The measure specifications are harmonized with related measures;
OR
The differences in specifications are justified

5a.1. **If this measure conceptually addresses EITHER the same measure focus OR the same target population as NQF-endorsed measure(s):**
Are the measure specifications completely harmonized?

No

5a.2. **If the measure specifications are not completely harmonized, identify the differences, rationale, and impact on interpretability and data collection burden.**

Some of the measures listed in the prior section are, fully harmonized with the submitted measure, in particular, 0705, 0708, and 0709. Other measures such as 0337 and 0450 are in fact, subsets of our measure. However, there are some measures that are not harmonized, in particular the 30-day all-cause readmission measures and the Hospital wide all-cause readmission measure. While the submitted PAC measure include hospitalizations and readmissions that occur during the episode time window, the hospitalizations, by definition, have to be relevant to the underlying condition. For chronic conditions, most relevant hospitalizations within the entire episode time window are considered potentially avoidable. PACs include readmissions and are designed to enable accountability at the locus of provider control as well as some shared accountability between settings, centered around a patient, and for a specific medical episode of care. In that sense, they are consistent with the all-cause 30-day readmission rates, but represent a subset of those admissions. However, they do extend to the entire episode time window. As such, the PAC measures, as submitted, don't create added burden of reporting because the readmissions reported are simply a part of the broader 30-day all-cause readmission measures already endorsed by NQF. Because PAC measures are comprehensive, they include patient safety events as well as other adverse events, including hospitalizations and ED visits during the entire continuum of care. As a result, they are a comprehensive measure of avoidable complications for a specific medical episode. The data collection for all of the HCI3 measures is automated by a software package and is fully harmonized with all other PAC measures. A single download automates creation of all reports related to each of the PAC measures.

5b. Competing Measures

The measure is superior to competing measures (e.g., is a more valid or efficient way to measure);
OR
Multiple measures are justified.

5b.1. **If this measure conceptually addresses both the same measure focus and the same target population as NQF-endorsed measure(s):**
Describe why this measure is superior to competing measures (e.g., a more valid or efficient way to measure quality); OR provide

a rationale for the additive value of endorsing an additional measure. (Provide analyses when possible.)

PAC measures are composite measures representing "all-cause harms". They look at many "care defects" comprehensively. They are composed of several cross-cutting measures and together they paint a global picture of the provider's overall performance.

PACs may occur any time during the episode time window. . Furthermore, the measure is constructed so that the occurrence of any number of PACs during a defined episode would only count as one occurrence. PACs look at readmissions, emergency room visits, adverse events due to errors of omission or commission. They look at complications that are due to patient safety failures, and also those directly related to the index condition. These are all a cause of significant waste and quality concerns. As such, the measure can provide clinicians with an overall and comprehensive view, in one measure, of all potentially avoidable complications for a patient and drive quality improvement efforts.

For clinicians and facilities increasingly engaged in value-based payment efforts and/or driving quality improvement for population health, the value of a PAC measure over a series of related, but more discrete measures, is that one can better determine if the sources of complications primarily stem from activities within the facility or outside the facility, and the specific nature of the complications that have a higher frequency of occurrence. While individual components of the PAC measure may have small frequencies and may be difficult to interpret with regards to provider performance or actionability, aggregating all the PACs into a comprehensive, composite measure provides the parsimony that is so desirable. For providers, it's far easier to construct a quality dashboard from a parsimonious set of measures, and that's what PAC measures offer.

Further, as a comprehensive outcome measure, PACs are also useful for public transparency of quality, as substantiated by the research from Judy Hibbard and colleagues previously cited in the "testing" section of this submission. As a comprehensive outcome measure, they are easier to explain to the average consumer. From a patient's point of view, any bad outcome has an impact on their health with respect to return to work, functional limitations and need for additional support. If a provider has a high PAC rate with regards to one component PAC but not the other PACs, the impact on the patient is still adverse. In selecting providers, individual component PAC scores would mean nothing to a patient, but aggregating it to a comprehensive quality score could be a measure of "all-cause" harms and easier to interpret and act on.

Appendix

A.1 Supplemental materials may be provided in an appendix. All supplemental materials (such as data collection instrument or methodology reports) should be organized in one file with a table of contents or bookmarks. If material pertains to a specific submission form number, that should be indicated. Requested information should be provided in the submission form and required attachments. There is no guarantee that supplemental materials will be reviewed.

Additional Information

Ad.1 **Workgroup/Expert Panel involved in measure development**
Provide a list of sponsoring organizations and workgroup/panel members' names and organizations. Describe the members' role in measure development.
From 2006 onwards, and under the auspices of various funding organizations, HCI3 has convened and managed, or helped to convene and manage, Clinical Working Groups to inform the development and refinement of the measures. For example, in 2011, 2012 and 2013, HCI3 worked collaboratively with the American Board of Medical Specialties and the American Medical Association's Physicians Consortium for Performance Improvement, under a federal contract, to convene and get input from various clinical experts on definitions of episodes of care and their sequelae, including avoidable complications.

Some of the clinical experts that have contributed to our work include:
-Dr. John Allen, American Gastroenterology Association (AGA)
-Dr. Morton Arnsdorf, Cardiologist, University of Chicago, IL

-Dr. Peter Bach, Memorial Sloan Kettering Cancer Center (MSKCC)
-Dr. Peter Basch, Primary Care, Medstar Health, DC
-Dr. Justin Beckelman, Radiation Oncology, University of Pennsylvania, PA
-Dr. Debra Bingham, Executive Director, California Maternal Quality Care Collaborative (CMQCC) at Stanford University, CA
-Dr. John Birkmeyer, American Society of Metabolic and Bariatric Surgery (ASMBS)
-Dr. Linda Bosserman, Wilshire Oncology Medical Group, CA
-Dr. Matthew Brengman, American Society of Metabolic and Bariatric Surgery (ASBMS)
-Dr. Joel Brill, American Gastroenterology Association (AGA)
-Dr. George Cautilli, Cautilli Orthopedic Surgical Specialists PC, Yardley, PA
-Dr. Ashwini Davison, Internist, Johns Hopkins Hospital, MD
-Dr. James Denneny, III, American Academy of Otolaryngology – Head and Neck Surgery (AAO-HNS)
-Dr. Chris Gallagher, American Society of Metabolic and Bariatric Surgery (ASMBS)
-Dr. Robert Haralson, III, American Academy of Orthopedic Surgeons (AAOS)
-Ms. Dawn Holcombe, Executive Director, Connecticut Oncology Association, CT
-Dr. Colin Howden, American Gastroenterology Association (AGA)
-Dr. John Knightly, American Association of Neurological Surgeons (AANS)
-Dr. Larry Kosinski, American Gastroenterology Association (AGA)
-Dr. Nalini Krishnan, Obstetrics & Gynecology, MN
-Dr. Kelly Kyanko, Internist, NYU School of Medicine, NY
-Dr. Tara Lagu, Internist & Infectious Disease, Baystate Medical Center, MA
-Dr. Robert Lee, Society of Thoracic Surgeons (STS)
-Dr. Alex Little, Society of Thoracic Surgeons (STS)
-Dr. Michael London, Orthopedic Surgeon, OMNI Orthopedics, OH
-Dr. Elliott Main, Obstetrics & Gynecology, California Pacific Medical Center, CA
-Dr. Constantine Mantz, 21st Century Oncology, FL
-Dr. Joseph Messer, Cardiologist, Rush University Medical Center, IL
-Dr. David Metz, American Gastroenterology Association (AGA)
-Dr. Ronald Nahass, Infectious Disease Care, NJ
-Dr. Ajay Nehra, Urologist, Rush University Medical Center, IL
-Dr. Francis Nichols, Society of Thoracic Surgeons (STS)
-Dr. Patrick O'Connor, Primary Care, HealthPartners, MN
-Dr. Sara Perkel, National Comprehensive Cancer Network, PA
-Dr. David Peura, American Gastroenterology Association (AGA)
-Dr. John Ratliff, American Association of Neurological Surgeons (AANS)
-Dr. Steven Schutzer, Connecticut Joint Replacement Institute, CT

#2747 Proportion of Patients with Heart Failure (HF) that have a Potentially Avoidable Complication (during the episode time window), Last Updated: Aug 18, 2015

NATIONAL QUALITY FORUM

Measure Information - Composite

This document contains the information submitted by measure developers/stewards, but is organized according to NQF's measure evaluation criteria and process. The item numbers refer to those in the submission form but may be in a slightly different order here. In general, the item numbers also reference the related criteria (e.g., item 1b.1 relates to subcriterion 1b).

Brief Measure Information

NQF #: 2747
Measure Title: Proportion of Patients with Heart Failure (HF) that have a Potentially Avoidable Complication (during the episode time window)
Measure Steward: Health Care Incentives Improvement Institute Inc. (HCI3)
Brief Description of Measure: Percent of adult population aged 18 + years who triggered an episode of heart failure (HF), are followed for at least one-year, and have one or more potentially avoidable complications (PACs). PACs may occur any time during the episode time window. Please reference attached document labeled NQF_HF_all_codes_risk_adjustment_06.30.15.xls, in the tabs labeled PACs I-9 and PAC I-10 for a list of code definitions of PACs relevant to HF.
We define PACs as one of two types:
(1) Type 1 PACs - PACs directly related to the index condition: Patients are considered to have a PAC, if they receive services during the episode time window for any of the complications directly related to HF, such as for hypotension, acute heart failure, fluid and electrolyte disturbances etc.
(2) Type 2 PACs - PACs suggesting Patient Safety Failures: Patients are also considered to have a PAC, if they receive services during the episode time window for any of the complications related to patient safety failures such as for sepsis, infections, phlebitis, deep vein thrombosis, pressure sores etc.
All relevant admissions in a patient with HF are considered potentially avoidable and flagged as PACs.
PACs are counted as a dichotomous (yes/no) outcome. If a patient had one or more PACs, they get counted as a "yes" or a 1. The enclosed workbook labeled NQF_HF_all_codes_risk_adjustment_06.30.15.xls serves as an example. The tab labeled PAC overview gives the percent of HF episodes that have a PAC and the tab labeled "PAC drill down" gives the types of PACs and their frequencies in HF episodes within this dataset.
The information is based on a two-year claims database from a large regional commercial insurer. The database had over 3.2 million covered lives and over $25.9 billion in "allowed amounts" for claims costs. The database is an administrative claims database with medical as well as pharmacy claims.
Developer Rationale: Each individual PAC, when measured in isolation, provides a very limited picture of the performance of the provider(s) who are managing or co-managing the care of the patient. However, looking at all the PACs that may occur individually or concurrently in a patient with a given episode provides a comprehensive picture of the care received by the patient for that particular condition or illness.

Additionally, the frequency of occurrence of individual PACs may be so low that it may require very high sample sizes from individual providers to achieve any meaningful and reliable comparisons. But aggregating all the PACs into a single quality metric creates meaningful scores that can be compared across providers even with relatively smaller sample sizes.

Additionally, a comprehensive measure is easier to explain to the average consumer. From a patient's point of view, any bad outcome has an impact on their health with respect to return to work, functional limitations and need for additional support. If a provider has a high PAC rate with regards to one component PAC but not the other PACs, the impact on the patient is still adverse. In selecting providers, individual component PAC scores would mean nothing to a patient, but aggregating it to a comprehensive quality score could be a measure of "all-cause" harms and easier to interpret and act on.

Numerator Statement: Outcome: Number of patients who triggered an episode of heart failure (HF), are followed for at least one-year, and had one or more potentially avoidable complications (PACs) during the episode time window.

Denominator Statement: Adult patients aged 18 years and above who triggered an episode of heart failure (HF) and are followed for at least one-year.
Denominator Exclusions: Denominator exclusions include exclusions of either "patients" or "claims" based on the following criteria:
1. "Patients" excluded are those that do not meet the enrollment criteria. If patient has an enrollment gap for more than 30 days during the episode time window, it is considered as an enrollment gap
2. "Patients" are also excluded if the cost of the episode is an outlier at greater than 99th percentile or less than 1st percentile value for all episodes. This is another way to ensure that episodes are complete as well as they do not bring in random noise into the analysis due to inappropriate codes or services.
3. "Claims" are excluded from the HF measure if they are considered not relevant to HF care.

Measure Type: Outcome
Data Source: Administrative claims
Level of Analysis: Clinician : Group/Practice, Clinician : Team
Is this an eMeasure? ☐ **Yes** ☒ **No** **If Yes, was it re-specified from a previously endorsed measure?** ☐ **Yes** ☐ **No**

1d.1. **Composite Measure Construction:** any-or-none measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient)any-or-none measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient)
Component Measures (if endorsed or submitted for endorsement):

Is this a MAINTENANCE measure submission? ☐ **Yes** ☒ **No, this is a NEW measure submission.**
For MAINTENANCE, state the Original Endorsement Date: n/a **Most Recent Endorsement Date:** n/a

Preliminary Analysis

The preliminary analysis was developed in response to recommendations from NQF's Consensus Task Force and measurement stakeholders as a way to enhance and streamline the measures evaluation and voting processes. The preliminary analysis will help to guide the Standing Committee evaluation of each measure by summarizing the measure developer submission, guide measure evaluation discussion, and identify topic areas for additional input. **NQF staff would like to stress that the preliminary analysis is intended to be used as a guide to facilitate the Committee's discussion and evaluation.**

Criteria 1: Importance to Measure and Report

1a. Evidence

1a. Evidence. The evidence requirements for a health *outcomes* measure include providing rationale that supports the relationship of the health outcome to processes or structures of care. The guidance for evaluating the clinical evidence asks if health outcomes measures agree the relationship between the measured health outcome and at least one clinical action is identified and supported by the stated rationale.

The developer provides the following evidence for this outcome measure:

- This new risk-adjusted (by age, gender and clinical co-morbidities) outcomes measure that assesses the proportion of adult patients with claims triggered Heart Failure (HF) with at least one Potentially Avoidable Complications (PAC) within 12 months of HF triggered claims data. Based on NQF's criteria, this measure is considered an "any or none" composite measure that assesses if 1 or more PACs or "care defects" have occurred for the index episode. For this composite measure, the individual complications considered the measurable components. PACs are classified in two types: 1) related to CAD, and 2) related to Patient Safety Failures.
- PACs are classified in two types: 1) related to HF, and 2) related to Patient Safety Failures, combining the 2 types into a single PAC rate to calculate the proportion of patients with 1 or more PAC. PACs are considered unwarranted health outcomes that combine concepts from AHRQ PSIs, PQIs and the CMS HACs, and episode-specific PACs into all-cause patient harms that are measured during an index condition for use at the practice, medical group, provider system or purchaser/payer levels to identify quality of care gaps between practices and hospitals.
- The developer links primary & secondary prevention care gaps, poor patient education, poor care coordination and

poor follow-up increase unnecessary ER visits, hospitalizations, readmissions, and mortalities to increased PACs, and state that PACs for HF patients should occur rarely in well-managed patients.

- The evidence for Patient Safety Failure PACs is described to be within the influence of the measured entity, and does not describe the influence of non-healthcare-related impacts on PAC rates. The progression of the episode condition, illness or disease is also not mentioned as a contributor to PAC rates in the evidence.
- In addition to linking processes of care to outcomes, the developer provides an extensive PAC literature review in sections 1a.2. and 1a.2.1. for HF, Patient Safety Failures & processes of care, as well as background information on the process for PAC development.

Questions for the Committee:

- *Does sufficient evidence exist connecting Patient Safety Failures to the HF index episode?*
- *For possible exception to the evidence criteria:*
  - *Are there, or could there be, performance measures of a related health outcome, OR evidence-based intermediate clinical outcomes, intervention/treatment?*
  - *Is there evidence of a systematic assessment of expert opinion beyond those involved in developing the measure?*

1b. Gap in Care/Opportunity for Improvement and 1b. Disparities

1b. Performance Gap. The performance gap requirements include demonstrating quality problems and opportunity for improvement.

- The developer provides CAD prevalence & impacts data, rationales and general information on PAC measure utility and applicable setting use.
- HF PAC performance gap data are calculated from PROMETHEUS administrative claims data from April 1, 2012 through December 17, 2014, for providers with ≥ 10 attributable index episodes. The data includes 81 of 2110 (3.8%) providers from 6,025 of 25,284 (23.8%) index episodes in 3,258,706 unique beneficiaries.

Unadjusted PAC Rates:		**Risk-Standardized PAC Rates (RSPR):**	
Median (IQR):	40.6% (30.8%, 57.1%)	Median (IQR):	39.9% (32.4%, 46.2%)
Range:	9.1% - 80%	Range:	14.5% - 67.9%

- Limited descriptive data on the patient, provider and payer are provided. The developer provides "Overview" and "Drill Down" PAC rates in the spreadsheet demonstrating gap, though PAC rates for individual complications are not provided.
- The developer does not provide data on disparities.

Questions for the Committee:

- *Is there a gap in care that warrants a national performance measure?*
- *If no disparities information is provided, are you aware of evidence that disparities exist in this area of healthcare?*
- *Should this measure be indicated as disparities sensitive?*

1c. Priority

1c. High Priority (previously "High Impact") requires measures to address national health goal/priority or a demonstrated high-impact aspect of care.

- *Beginning in 2015, priority is no longer an NQF measure evaluation criterion.*

Committee pre-evaluation comments

Criteria 1: Importance to Measure and Report (including 1a, 1b, 1c)

1. ***Committee's Overview Comments***:
   - This is an outcome measure - Potentially Avoidable Complication
   - Measure does include items from the AHRQ Patient Safety Indicators, PQIs and CMS Hospital Acquired

Conditions but also includes a myriad of other events/conditions that are claimed to be PACs related to HF. No distinction is made regarding the severity of a PAC (only HF-related or Patient Safety Failure). No distinction is made regarding the number of PACs that occur in a single patient. It is any or none.

- The developers define a very broad composite measure of potential avoidable complications (PACs) that lumps any heart-failure related events (hypotension, respiratory insufficiency, acute heart failure, pulmonary edema, fluid and electrolyte disturbances, etc) with any patient safety failures (sepsis, infections, phlebitis, deep vein thrombosis, pressure sores, etc).
- The assertion that well-managed patients with heart failure should rarely incur a potentially avoidable complication such as an emergency room visit or hospitalization related to heart failure is ludicrous.
- The developer cites data that support the efficacy of multi-pronged interventions for improving primary and secondary prevention care (patient education, care coordination and follow-up) with a reduction in ER visits, and all-cause hospitalizations, but not mortality.
- They cite no data to support the composite measure of PACs as a quality metric, but argue for it on face validity grounds.
- The developers cite a 42.5% rate of PACs in a large regional database, but an actual preventable hospitalization rate of only 5% of all HF episodes.

1a. ***Committee's Comments on Evidence to Support Measure Focus:***

- There is a lengthy explanation of how failures in care can lead to PACs and readmissions. There is no direct cause and effect data evidence (for the myriad of PACs listed) -- just associations. There are approximately 846 different diagnosis codes identified as HF-related PACs. The PACs are derived from two years of claims data from a large regional commercial insurer. One PAC is listed as ""adverse effect of drug - correct use"" How is this avoidable?
- Also for the data to be reliable more than 10 attributable episodes per provider were required. Only 81 of 2110 (3.8%) met this criteria.
- The evidence connecting Patient Safety Failures to the HF index episode is lacking.
- I do not see a compelling argument for making an exception to the evidence criteria, nor do the developers cite any systematic assessment of expert opinion beyond the developers.

1b. ***Committee's Comments on Performance Gap:***

- Developer provides adjusted and unadjusted PAC occurance rates. There is no optimum rate/lowest rate provided. There is an assumption that PACs should never/rarely occur. That may be true for some, but not all of the PACs listed.
- Unadjusted PACs 40.6% (range 9.1-80%) Risk adjusted PACs 39.9 (range 14.5-67.9%)
- The developers cite data showing wide variance in current performance on this proposed measure (14.5-67.9% risk-standardized PAC rate). They cite no quality improvement metrics or goals for ""acceptable performance.""
- No data was provided on disparities in care for population subgroups. I seem to remember seeing data on racial disparities for HF care.
- I do not think this measure should be indicated as disparities sensitive.

1c. ***Committee's Comments on Composite Performance Measure:***

- This is a composite measure. If a patient as 1 or 20 PACs within "at least one year from the index encounter" it is counted at 1 (yes). I am not sure that this is reasonable. The PACs are also not weighted by severity.
- The composite performance measure appears to be overly broad, including numerous elements having little or no demonstrable connection with heart failure or the healthcare provided for patients with heart failure. Even if I were a lumper, instead of a splitter, I would not feel comfortable with this measure.

Criteria 2: Scientific Acceptability of Measure Properties
2a. Reliability
2a1. Reliability Specifications
2a1. Specifications requires the measure, as specified, to produce consistent (reliable) and credible (valid) results about

the quality of care when implemented.

- The measure assesses the rate of patients with 1 or more PAC(s) during index episodes. This new risk adjusted outcomes measure is specified for use at the clinician group and team levels of analyses.
- The measure exclusively uses electronically available administrative claims data to calculation the measure score, and for this measure, better care equals lower scores.
- The developer describes non-patient-related PACs as controllable by provider processes without further analysis as other influencers that may contribute to PAC rates beyond the patient and provider (e.g., payer, access, suppliers, etc.).
- Patient- and claims- based exclusions are provided to promote the availability and consistency of claims data capture, including payer enrollment requirements, cost outliers of < 1% or > 99%, and claims not relevant to HF.
- Developers provide administrative claims data for HF & PAC (HF- & Patient Safety Failure-related) triggers, describe a complete 12-month episode time window. A calculation algorithm is provided.
- ICD-9 & ICD-10 codes are provided, though ICD-10 descriptions & an ICD-9 to ICD-10 crosswalk methodology are not provided.
- A conceptual risk model and statistical method using logistic regression model for determining the probability of a patient incurring a PAC are provided. After adjusting for patient-related factors, the developers state the remaining PAC variance is due to factors potentially controlled by the provider during and after hospitalization. "Predicted" coefficients from the risk adjustment models are summed to give predicted probabilities of PAC occurrence.

Questions for the Committee:

- *Are all the data elements clearly defined? Are all appropriate codes included?*
- *Is the logic or calculation algorithm clear?*
- *Is this measure specified to pertain only to providers with at least 10 episodes (per the reliability testing described below)?*
- *Is it likely this measure can be consistently implemented?*
- *Is additional evidence required to determine whether group/practice/team level of analysis is appropriate?*

2a2. Reliability Testing Testing attachment

2a2. Reliability testing demonstrates if the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise enough to distinguish differences in performance across providers.

- The developer tested reliability at the performance measure score, and used a beta-binomial model and a signal-to-noise analysis, which is appropriate for this type of measure, to differentiate the true difference between measured entities (the signal) to random measurement error (the noise). A value of 0 indicates that all variation is due to measurement error and a value of 1 indicates that all variation is due to real differences in between hospital performance. A value of 0.7 is often regarded as a minimum acceptable reliability value.
- The measure is specified for HF patients ≥ 18 years, though the testing sample includes patients 18 through 64 years
- Providers with < 10 HF episodes were excluded from reliability testing, though the measure is specified for patient without episode restrictions. A sample 6,025 HF episodes from 81 providers were included after less than 10 HF episodes were excluded. The mean age of 53.4 (18-64 years) and 38% female in the testing analysis exclusively using administrative claims data.
- The developer states, "Minimum sample size requirements for PAC measures are a function of the reliability testing of the measures on every dataset on which the measures are applied. Our research suggests that

minimum sample sizes to achieve high degrees of reliability in the measures are a function of the dataset analyzed, and as such may vary from dataset to dataset. One should not infer that a minimum sample size achieved in one dataset will apply to another." The developer also states that very high sample sizes are to achieve any meaningful and reliable comparisons.

- A patient may have more than one condition-specific concurrent episode with claims applied to both episodes. If an inpatient claim corresponds to a procedure index episode and to a condition index episode, the claim would be assigned to the procedure index episode, rather than the condition index episode (e.g., for a claim that corresponds to both index episodes of HF & CABG, the claim would be assigned to CABG).
- Patient with missing gender were excluded from the denominator, and no other missing data was identified.
- Reliability results are provided in the table below, as well as in great detail in the accompanied spreadsheet with median (IQR) results demonstrating reliability of 0.61(0.52,0.75) for ≥ 10 providers, increasing with the number of providers, demonstrating the measure is able to demonstrate differences in performance. For reliability analysis, providers were restricted to the minimum of 10 HF episodes, though all episodes were included in the risk model.

Reliability Scores	Minimum # Episodes Per Provider		
	>=10	>=25	>=50
# of Providers (%)	81 (100)	27 (33)	13 (16)
Median (IQR)	0.61 (0.52,0.75)	0.80 (0.75,0.85)	0.85 (0.83,0.87)
Range	0.43-0.94	0.69-0.94	0.80-0.94

The table provides a summary reliability scores minimum sample size thresholds. Complete results are provided in the workbook entitled, NQF_HF_all_codes_risk_adjustment_06.30.15.xls, under the "ProviderAttribution Reliability" tab.

Questions for the Committee:

- *Reliability testing was conducted only for those providers with at least 10 episodes. Can differences in performance be identified for providers with fewer than 10 episodes? Should the measure be specified to include only those providers with at least 10 episodes? Is the test sample adequate to generalize for widespread implementation?*
- *Do the results demonstrate sufficient reliability so that differences in performance can be identified?*

2b. Validity

2b1. Validity: Specifications

2b1. Validity Specifications. This section should determine if the measure specifications are consistent with the evidence.

- Because this is an outcome measure, the rationale that is presented for subcriterion 1a does not necessarily have to address all of the variables used to calculate the measure.
- The measure uses a statistical risk model with 170 risk factors and episode-specific subtypes/severity markers including age, gender and clinical comorbidities, on at least 10 claims to determine "stable" covariates and assess comorbidity or procedure impact on the PAC. All covariates must be present prior to an episode trigger. No formal covariate analysis was conducted to select risk factors beyond the present on a minimum of 10 claims threshold. The developer describes the heterogeneity of the provided data sets as crucial to ensure measure validity, and the accuracy and completeness of the data sets.
- The developers did not provide disparities data, an exploration of a conceptual relation to SDS, or SDS factors in the risk model.

Question for the Committee:

- *Are the specifications consistent with the evidence?*

○ *Are these variables available and generally accessible for the measured patient population?*

2b2. Validity testing

2b2. Validity Testing should demonstrate the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality.

- The developer conducted systematic assessment of face validity for the performance measure score for validity testing in numerous ways, including the use of monthly multi-specialty clinical working groups, and other tests of face validity, along with focus groups, face validity comparisons of the measure to other national accountability measures, as well as additional literature for the measure & PAC development process.
- No empiric results are provided for the face validity tests described above.

Questions for the Committee:

○ *Is the test sample adequate to generalize for widespread implementation?*

○ *Do the results demonstrate sufficient validity so that conclusions about quality can be made?*

○ *Do you agree that the score from this measure as specified is an indicator of quality?*

2b3-2b7. Threats to Validity

2b3. Exclusions:

- The developer describes patient- (demographic, enrollment or low/high claims cost) and claims-based (due to missing or non-relevant data) exclusions for the measure. They further state nearly half of the original population of HF patients was removed from the denominator with applied exclusions.
- A significant number of patients were eliminated from the measure due to exclusion criteria, including 6,025 of 25,284 (23.8%) HF episodes (in 3,258,706 unique beneficiaries) and 81 of 2110 (3.8%) providers.

Questions for the Committee:

○ *Are high cost outliers (> 99%) exclusions an opportunity to identify PACs?*

○ *Does the high number of exclusions restrict the measure use?*

○ *Are the exclusions consistent with the evidence?*

○ *Are any patients or patient groups inappropriately excluded from the measure?*

○ *Are the exclusions/exceptions of sufficient frequency and variation across providers to be needed (and outweigh the data collection burden)?*

2b4. Risk adjustment:

- The risk model (detailed in the accompanied spreadsheet) includes 170 factors and episode-specific subtypes including age, gender, 12-month enrollment marker, co-morbidities, and episode severity markers.
- No SDS factors beyond age and gender was included in the risk-adjustment approach. Beyond noting that race was not available for analysis, no description of the of the conceptual relationships between patient sociodemographic factors, patient clinical factors, quality of care, and the outcomes (PAC rates) was provided., nor do they discuss the availability of SDS variables, beyond stating that "race" as an SDS variable was not available for analysis. The developer briefly discus general psychosocial and socioecononmic barriers that found in decreased HF care processes.
- Logistic regression was used to model the probability of at least one PAC during an episode. The reasoning for no additional modeling performed is described.
- The performance of the model was determined with a split sample method by estimating the model coefficients using a development dataset (80% of the sample) and applying those coefficients to a validation dataset (20% of the sample). C-statistics for the development and validation samples were 0.807 and 0.754, respectively. C-statistics measures the extent of a statistical model to discriminate between a patient with and without PAC, with an ability to predict if a PAC is or is not present about 69% to 74% of the time. A c-statistic of 0.50 indicates the model is no better than random prediction, implying that the patient risk factors do not predict variation in the outcome; conversely, a c-statistic of 1.0 indicates perfect prediction, implying patients' outcomes can be predicted completely by their risk

factors, and physicians and hospitals play little role in patients' outcomes. Models with c-statistic values of at least 0.7 are considered good and those above 0.8 are considered strong.

- Both Hosmer-Lemeshow Goodness-of-Fit statistics and risk-decide plots were provided to indicate model fit. Results from the Hosmer-Lemeshow test suggest that the fit is not good; however, this test is sensitive to the number of groupings and sample sizes. Results from the risk decile plot indicate that the predicted PAC rates are similar to the observed PAC rates across all deciles of risk. The developer states the model demonstrates sufficient predictive power.

Questions for the Committee:

- *Is the Committee aware of conceptual relationship(s) between additional patient-level SDS factors, patient clinical factors, quality of care, and PACs (other than gender and age)? If so, what data might be available to allow an empirical analysis of these relationships?*
- *Is an appropriate risk-adjustment strategy included in the measure?*
- *Are the candidate and final variables included in the risk adjustment model adequately described for the measure to be implemented?*
- *Are all of the risk adjustment variables present at the start of care? If not, describe the rationale provided.*

2b5. Meaningful difference:

- The developer presents PAC rates across providers and also providers adjusting for differences in patient severity in a ratio of observed to expected attributable episodes to PACS accounting for patient severity, and calculates estimates from the risk model, for risk-standardized PAC rates for the provider.

Summary of Unadjusted and Adjusted Performance Scores Across Providers:

PAC Rates	Minimum # Episodes Per Provider	
	>=10	>=25
Unadjusted		
Median (IQR)	41% (31%, 57%)	36% (23%, 42%)
Range	9%-80%	10%-79%
Adjusted (RSPR)*		
Median (IQR)	40% (32%, 46%)	37% (30%, 44%)
Range	14%-68%	14%-50%

***RSPR = Risk Standardized PAC Rate**

Please refer to the NQF_HF_all_codes_risk_adjustment_06.30.15.xls workbook under the "ProviderAttribution Reliability" tab to see specific results for each provider.

Question for the Committee:

- *Does this measure identify meaningful differences about quality?*

2b6. Comparability of data sources/methods:

- As there is only one data source used for measure calculation (administrative claims), comparability of data sources or methods is not applicable.

Question for the Committee:

- *Are the candidate and final variables included in the risk adjustment model adequately described for the measure to be implemented?*

2b7. Missing Data

- No formal analysis of missing data is provided. As the measure assesses the rate of patients with PACs, rather

than the rate of PACs per index episode, the total number of PACs is not included in the PAC rate.
- Patient with missing gender were excluded from the denominator, and no other missing data was identified.
- The developers state the under-coding of claims is unavoidable in the current DRG payment structure which could lead to under capture or missing PACs.

2d. Empirical Analysis to Support Composite Construction
- As an "any or none" composite, the individual complications are considered measurable components of the composite. Frequency and distribution statistics are provided in the PAC Overview and PAC Drill Down tabs in the measure spreadsheet, which detail PAC types and subtypes. The identification of individual PACs are not provided (e.g., sepsis, unattended falls, DVT).
- PACs are counted as a dichotomous (yes/no) outcome. If a patient had one or more PACs, they get counted as a "yes" or a 1. Since our premise is that all PACs are potentially avoidable, we adopted the approach to count all PACs and give them equal weights. The overall composite score results in the quality construct that could be measured and interpreted.
- The developer states that no formal analysis was performed on missing data. For details, see 2b7 above.

Committee pre-evaluation comments

Criteria 2: Scientific Acceptability of Measure Properties (including all 2a, 2b, and 2d)

2a1. &2b1.: ***Committee's Comments on Reliability-Specifications:***
- Numerator -patients who triggered an episode of heart failure followed for AT LEAST ONE YEAR (vague) and had one or more PACs during the episode time window (not really defined)
- There are so many codes used for triggering and for PACs it would be nearly impossible to say that all the appropriate ones are included and inappropriate ones excluded.
- There are very complex decision tree and risk adjustment calculations made and based on claims data.
- The data elements are clearly defined individually, with appropriate codes included.
- The logic is clear, though I disagree with the inclusion of numerous elements.
- The beta-binomial method data for signal-to-noise ratio showed a wide range of scores across all providers. Among those with at least 10 episodes, the mean was 0.61, and scores for many were low. Scores among providers with 25 or more episodes were consistently good (mean = 0.80) and continued to improve as provider sample size increased to >50 (mean = 0.85). The developers assert that this demonstrates that for providers with a minimum number of episodes, the measure sufficiently differentiates performance.

2a2.: ***Committee's Comments on Reliability-Testing:***
- When testing for reliability, the developers included only providers with 10 or more episodes with PACs. Out of more than 2000 providers, the analysis only included 81. The reliability was still only 0.67 (average) for providers with >=10 episodes it was 0.61. There were only 27 providers with more than 25 episodes (Reliability 0.80).
- The good news is that not very many providers had a large number of episode that involved PACs. Just how well it differentiates between the >10 and more than 25 is hard to say.
- Differences in quality could be expected to be even larger in providers with <10 episodes, and should be measurable.
- The quality data is bound to be more valid for providers of >=10 episodes, so the measure should perhaps be specified for such providers.

2b1.: ***Committee's Comments on Validity-Specifications***:
- For many of the PACs, the evidence is only their own claims data that demonstrates at best an association between the PAC and heart failure.
- The specifications appear to be reasonably consistent with the evidence, though the validity as a composite measure is still troubling.

2b2.: ***Committee's Comments on Validity-Testing:***
- There are 170 risk factors used to adjust the risk any particular patient would have for a PAC.
- There is no disparities data but clearly disparities such as availability of care can be involved.
- The calculations for this measure are very complex and related to administrative claims data. The coding for the

claims is readily available to insurance carriers but the program for calculating the measure performance is not readily available.

- I am not convinced that the score for this measure is an indicator of quality. For example, electrolyte disturbance is a PAC but a conscientious provider would at least be looking for this problem by ordering blood work and then treating any abnormality -- which they would code for the visit and therefore be penalized for it.
- Content validity of the definitions of potentially avoidable complications (PACs) was established by working monthly with clinicians who are experts in their respective fields and specific to the episodes for which PACs are being measured. The clinical experts focused on whether or not a potentially avoidable complication can be deemed as such for a specific episode of care, and they helped to define and review all of the diagnosis and procedure codes for each PAC.
- Face validity was established in several ways. The developers presented results of claims data analyses that reveal the frequency and costs of PACs to physicians in several different healthcare systems involved in their pilot site implementations, as well as to medical directors from the employer coalitions and the health plans that provided the dataset to run the analyses. Some of these implementations include the Pennsylvania Employee Benefits Trust Fund and local provider groups and hospital, Horizon Blue Cross Blue Shield of NJ and many physicians and health systems.
- In addition, they performed dozens of analyses of very large claims data sets and reported results of rates and costs of PACs to policy makers, health plan leaders and physician leaders from different states. They state that "To-date, we have never experienced either wholesale or partial rejection of the results of analyses showing rates of PACs, which demonstrates the level of acceptability – face validity – of the measures from the payer, policymaker, employer and payer communities."
- The developers assert that measures of potentially avoidable complications have face-validity with consumers. In a series of focus groups, information presented about price and quality of certain providers was seen to influence the decisions of consumers. When the PAC measure was used, respondents selected the providers with the lowest PAC rates with a high level of confidence in choice, and used it as a surrogate for a strong quality signal.
- The test sample is adequate to generalize for widespread implementation.
- The results demonstrate sufficient internal validity for conclusions about quality to be made, though the external validity is still questionable.
- I do not agree that the score from this measure is a valid indicator of healthcare quality, because it incorporates too many PACs that cannot be influenced by improving healthcare quality in the real world.

2b3-7.: ***Committee's Comments on Threats to Validity:***

- Half or more of the denominator being removed based on exclusions seems like an awful lot.
- I do think that outliers are reasonable to exclude.
- The goodness of fit test revealed that there was not goodness of fit.
- I do not agree with the exclusion of high-cost outliers. They are especially likely to have PACs.
- The high number of exclusions definitely limits the usefulness of the measure.
- I am not clear whether the exclusions are consistent with the evidence or on why there were so many exclusions.
- No formal analysis was done on the impact of exclusions on performance scores.
- Risk adjustment for race and socioeconomic status probably would be appropriate, but the developers note that race was unavailable and they do not mention SES.
- The risk adjustment model variables are adequately described for measure implementation.
- No formal analysis of missing data was provided. Only missing gender was identified, with no other specific data types missing.
- No empirical data was provided to support the inclusion of individual elements into the composite measure, nor to demonstrate their added value. Although the aggregation is supported by the developer's rationale, I disagree with their rationale and consider it to be overly inclusive."

2d.: ***Committee's Comments on Composite Performance Measure:***

- I do not think that an all or none composite is a good measure of quality in this situation. Clearly some PACs have more impact than others. Serious PACs should be addressed before getting to the level of "any".
- This is no empirical analysis of the composite measure's performance beyond construct and face validity demonstrations.

Criterion 3. Feasibility

3. Feasibility is the extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

- All measure elements are readily available in electronic sources via administrative claims data, and coded by someone other than the person obtaining the original information (e.g., DRG, ICD-9 codes on claims).
- The developer provides an excel spreadsheet attachment including diagnoses, visits, hospitalizations, post-acute facility stays, procedures, laboratory tests and procedures/surgeries, for HF & PAC triggers, and describe the time window for measuring PACs as 12 months following a HF episode triggers, as well as a decision tree for measure calculation and implementation.
- The measure specifications, metadata and calculation algorithms are available free of charge on the developer's website. Limited analytics are planned at no cost to the end user.
- This is not an eMeasure.

Questions for the Committee:

- *Are the required data elements routinely generated and used during care delivery?*
- *Are the required data elements available in electronic form, e.g., EHR or other electronic sources?*
- *Is the data collection strategy ready to be put into operational use?*

Committee pre-evaluation comments

Criteria 3: Feasibility

3.: ***Committee's Comments on Feasibility:***

- The data elements are available to claims analysts but not to other groups. The computer program with all of the risk adjustments is specific to this data set and may not apply to others.
- The developer does offer their calculation algorithm free of charge
- The required data elements are routinely generated and used during care delivery, and are available in electronic form.
- The data collection strategy is ready to be put into operational use.

Criterion 4: Usability and Use

4. Usability and Use evaluate the extent to which audiences (e.g., consumers, purchasers, providers, policymakers) use or could use performance results for both accountability and performance improvement activities.

- This is a newly developed claims measure is currently used in accountability programs for payers, states, and planned uses for public reporting, professional certification or recognition programs, and external quality improvement for benchmarking purposes.
- The developer states that PAC measures provide a foundation for the relationship between healthcare quality and cost and assist in the exploration of practice reengineering and alternative payment models, act as indicators of potential harm, and is spurring the development of private-based analytics software for further outcomes exploration.
- No public improvement rates are available due to recent implementation and variation in PAC definitions have also modified, though the provided PROMETHEUS data suggest wide variation in performance and improvement opportunities. Payer and Provider improvement use perspectives are outlined.
- The developer found no noted unintended consequences, though they state the measure is intended for transparency and QI activities only. They also state the under-coding of claims is unavoidable in the current DRG payment structure could be an unintended consequences of the measure, and payers calculating the measures even with inadequate

sample sizes and using the results to penalize providers could lead to invalid provider comparisons.

- If the measure was theoretically to be used for accountability purposes to "ding" the measured entity as defined in the level of analysis, further exploration of PAC antecedents and the measured entity is warranted, especially with small group practices and very small PAC rates. In the original testing sample of 2110 providers, when providers with fewer than 10 HF episodes were eliminated from analysis due to less reliability estimates with small numbers, 81 remained for analysis.

Questions for the Committee *:*

- *Is the measure publicly reported?*
- *How can the performance results be used to further the goal of high-quality, efficient healthcare?*
- *Should PAC measures also include the clinician: group in the analysis or include population-level only entities?*
- *Do the benefits of the measure outweigh any potential unintended consequences?*

Committee pre-evaluation comments

Criteria 4: Usability and Use

4.: ***Committee's Comments on Usability and Use:***

- The measure does not appear to be publically reported although it is in use and public reporting is "planned"
- The measure is publicly reported.
- The performance result could possibly be used to further the goal of high-quality, efficient healthcare.
- The PAC measures should include the clinician: group in the analysis and include population-level only entities.
- The potential benefits of the measure probably outweigh any potential unintended consequences (none of which were anticipated/specified), although the magnitude of potential benefit is quite unclear.

Criterion 5: Related and Competing Measures

5.1a. List of related or competing measures (selected from NQF-endorsed measures)

0330 : Hospital 30-day, all-cause, risk-standardized readmission rate (RSRR) following heart failure (HF) hospitalization
0337 : Pressure Ulcer Rate (PDI 2)
0450 : Perioperative Pulmonary Embolism or Deep Vein Thrombosis Rate (PSI 12)
0705 : Proportion of Patients Hospitalized with Stroke that have a Potentially Avoidable Complication (during the Index Stay or in the 30-day Post-Discharge Period)
0708 : Proportion of Patients Hospitalized with Pneumonia that have a Potentially Avoidable Complication (during the Index Stay or in the 30-day Post-Discharge Period)
0709 : Proportion of patients with a chronic condition that have a potentially avoidable complication during a calendar year.
1789 : Hospital-Wide All-Cause Unplanned Readmission Measure (HWR)

5.1b. If related or competing measures are not NQF endorsed please indicate measure title and steward.

-0531 Patient Safety for Selected Indicators (Composite Measure, AHRQ) (endorsed)

- -CMS defined hospital acquired conditions (HACs) are a subset of our PACs. We have pain-stakingly matched the definitions to provide as much consistency as possible. http://www.cms.gov/Medicare/Quality-Initiatives-Patient-Assessment-Instruments/HospitalQualityInits/HospitalRHQDAPU.html Summarize any harmonization efforts, i.e., responses from the developers regarding harmonization.
- Briefly summarize next steps according to protocol

Pre-meeting public and member comments

•

NATIONAL QUALITY FORUM—Evidence (subcriterion 1a)

Measure Number (*if previously endorsed*)**:** 2747

Measure Title: Proportion of Patients Hospitalized with Heart Failure (HF) that have a Potentially Avoidable Complication (during the Index Stay or in the 30-day Post-Discharge Period)

IF the measure is a component in a composite performance measure, provide the title of the Composite Measure here: Click here to enter composite measure #/ title

Date of Submission: 6/30/2015

Instructions

- *For composite performance measures:*
  - *A separate evidence form is required for each component measure unless several components were studied together.*
  - *If a component measure is submitted as an individual performance measure, attach the evidence form to the individual measure submission.*
- Respond to all questions as instructed with answers immediately following the question. All information needed to demonstrate meeting the evidence subcriterion (1a) must be in this form. An appendix of *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 10 pages (*incudes questions/instructions*; minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the evidence for this measure meets NQF's evaluation criteria.

1a. Evidence to Support the Measure Focus

The measure focus is evidence-based, demonstrated as follows:

- Health outcome: [3] a rationale supports the relationship of the health outcome to processes or structures of care. Applies to patient-reported outcomes (PRO), including health-related quality of life/functional status, symptom/symptom burden, experience with care, health-related behavior.
- Intermediate clinical outcome: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured intermediate clinical outcome leads to a desired health outcome.
- Process: [5] a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured process leads to a desired health outcome.
- Structure: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured structure leads to a desired health outcome.

- Efficiency: [6] evidence not required for the resource use component.

Notes

3. Generally, rare event outcomes do not provide adequate information for improvement or discrimination; however, serious reportable events that are compared to zero are appropriate outcomes for public reporting and quality improvement.

4. The preferred systems for grading the evidence are the U.S. Preventive Services Task Force (USPSTF) grading definitions and methods, or Grading of Recommendations, Assessment, Development and Evaluation (GRADE) guidelines.

5. Clinical care processes typically include multiple steps: assess → identify problem/potential problem → choose/plan intervention (with patient input) → provide intervention → evaluate impact on health status. If the measure focus is one step in such a multistep process, the step with the strongest evidence for the link to the desired outcome should be selected as the focus of measurement. Note: A measure focused only on collecting PROM data is not a PRO-PM.

6. Measures of efficiency combine the concepts of resource use and quality (see NQF's Measurement Framework: Evaluating Efficiency Across Episodes of Care; AQA Principles of Efficiency Measures).

1a.1.This is a measure of: (*should be consistent with type of measure entered in De.1*)

Outcome

☒ Health outcome: Potentially Avoidable Complications

☐ Patient-reported outcome (PRO): Click here to name the PRO

PROs include HRQoL/functional status, symptom/symptom burden, experience with care, health-related behaviors

☐ Intermediate clinical outcome (*e.g., lab value*): Click here to name the intermediate outcome

☐ Process: Click here to name the process

☐ Structure: Click here to name the structure

☐ Other: Click here to name what is being measured

HEALTH OUTCOME/PRO PERFORMANCE MEASURE *If not a health outcome or PRO, skip to 1a.3*

1a.2. Briefly state or diagram the path between the health outcome (or PRO) and the healthcare structures, processes, interventions, or services that influence it.

The combination of the aging of the population and improved survival after acute myocardial infarction (AMI) has created a rapid growth in the number of patients currently living with chronic heart failure (CHF), with a concomitant increase in the number of hospitalizations for decompensated heart failure (McCoullough 2002). Despite advances in medical therapy, admission rates following heart failure hospitalization remain high (Stevenson 2011) (Cubbon 2011). Discharge from a heart failure hospitalization is followed by a readmission within 30 days in approximately 24% of cases (Desai 2012) with more than 50% patients readmitted to hospital within 6 months of discharge (Ross 2010). This is despite well-established guidelines like the, "Get With The Guidelines®- Heart Failure" the American Heart Association's collaborative quality improvement program of evidence-based care of patients hospitalized with heart failure (AHA 2013).

Causes of readmissions may be various. These may include local practice patterns, for example, hospitals with higher overall admissions tend to have higher readmission rates after HF hospitalization (Epstein 2011). Readmissions are also influenced by psychosocial and socioeconomic barriers that limit compliance with medications, life style changes, self-monitoring and appropriate follow up (Fonarow 2008). There is also a tendency for higher readmissions in centers with resource limitations such as lower nurse staffing levels and limited cardiac capabilities (Joynt 2011).

The need for consistently high quality, efficient care for heart failure is urgent. To improve accountability in the delivery of medical care, AHRQ has developed a list of patient safety indicators (PSIs) to identify potential harms to patients and a list of ambulatory care sensitive conditions (ACSCs) to identify admissions that could have been potentially avoided with good outpatient care (AHRQ 2008). Additionally, the Centers for Medicare and Medicaid Services (CMS) have taken a "Six Sigma" approach and defined Hospital Acquired Conditions (HACs) and "never events" that should almost never occur and are applying financial penalties when these events do occur (CMS 2012).

The Potentially avoidable complications (PAC) measure goes beyond the AHRQ PSIs, PQIs and the CMS HACs and creates a single comprehensive measure that measures all-cause harms for a patient with the index condition. Potentially avoidable complications (PACs) are the unwarranted health outcomes that this measure addresses (deBrantes 2010). Lack of patient education on self care techniques, diet and weight management; poor discharge instructions, poor care coordination, and poor arrangements of patient follow-up lead to unnecessary ER visits and hospitalizations due to acute exacerbations of heart failure and other complications (Bonow 2012). All these adverse events are aggregated together as a single comprehensive measure to study the overall rate of PACs in the HF population.

Adult patient diagnosed with Heart Failure

↓

Physician practices fail to educate patients / Physician practices have poor access

↓

Patient visits ER / gets hospitalized (Ambulatory care sensitive hospitalization event)

↓

Patient discharged with management advise / remains in hospital for treatment of PAC

Well-managed patients with HF should rarely incur a potentially avoidable complication such as an emergency room visit, and hospitalizations related to HF should be avoidable by proactive care and good management.

The enclosed workbook entitled NQF_HF_all_codes_risk_adjustment 06.30.15.xls lists the types of PACs and their frequency as calculated in a large regional database (see tab PAC overview). 42.5% of patients with HF had a PAC, with about 28% of PACs directly related to HF itself, such as respiratory insufficiency, acute CHF, pulmonary edema or fluid and electrolyte disorders (see tab PAC Drill Down Graph). Although the preventable hospitalizations in this dataset for the HF population were low, at only 5% of all HF episodes; approximately 26.5% of patients with HF had PACs related to patient centered care failures such as poor control of diabetes, urinary tract infections, and acute gastritis, many of them being managed in an outpatient setting in physician offices. As a result, about 41% of episodes had a PAC indicator on professional claims.

While PACs may not be eliminated completely, identifying the magnitude of PACs and knowledge of the cause for the most frequent or the most expensive PACs could place an emphasis in reducing them and as a consequence improving patient outcomes. The ability to clearly identify the type and frequency of each PAC creates a highly actionable measure for all providers that are managing or co-managing the patient; as well as for the health plan with whom the patient is a member (de Brantes 2009).

1a.2.1. State the rationale supporting the relationship between the health outcome (or PRO) to at least one healthcare structure, process, intervention, or service (*i.e., influence on outcome/PRO*).

Note: For health outcome/PRO performance measures, no further information is required; however, you may provide evidence for any of the structures, processes, interventions, or service identified above.

Rationale: Better processes of care create an atmosphere of proactive management, consistency in care and standardized care patterns (Shekelle 2013) (Fenter 2006). Patient education and adopting safe practices significantly reduces occurrence of potentially avoidable complications (PACs) in all settings (Klein 2011) (Wachter 2013) (Berwick 2006) (Kovner 2011) (Farley 2013). It is known that by holding providers accountable for occurrence and costs of PACs, an built-in warranty is created around care of the index condition (de Brantes 2009).

While CHF has been noted as the most common indication for hospitalization for adults 65 and older, a prospective randomized trial showed a 56.2% reduction in the number of readmissions for heart failure due to intensive nurse-directed education, care coordination, and follow up (Rich 1995). This study also showed that the reduction of hospital admissions led to a savings on $460 per patient. Moreover, improved hospital and post-discharge care, including pre-discharge planning, home-based follow-up, and patient education, have all demonstrated decrease in heart failure related readmission rates suggesting that healthcare services / care processes influence outcomes in heart failure patients (Krumholz 2002).

AHRQ performed a meta-analysis of 53 published randomized control trials and reported on 47 studies. They found that home-visiting programs and heart failure clinic interventions, both of which are multicomponent complex interventions, reduced all-cause readmissions. However no single component intervention reduced all cause readmission. They also showed that interventions that focused on reducing readmissions did not impact mortality rates adversely (AHRQ 2014). Therefore if interventions are chosen according to the available body of evidence it is possible to reduce PAC's.

According to the Joint Commission (JC) heart failure performance measure, at discharge patients with HF must receive comprehensive discharge instructions that address activity level, diet, discharge medications, follow-up appointment, weight monitoring, and actions to take in case of worsening symptoms (Joint Commission 2010). These JC measures are publicly reported by hospitals. In 2011, the ACC/AHA/AMA (American Medical Association) Performance Consortium added a documented post-discharge appointment to the list of recommended HF performance measures (AHRQ 2014) (Bonow 2012).

Guideline directed medical therapy (GDMT) is a comprehensive combination of lifestyle modifications and medications and is tailored to care for a spectrum of HF patients ranging from outpatient care to hospitalized patients with a view to improving outcomes. GDMT if followed optimally should reduce hospitalizations in the former and reduce readmission rates in the latter. Various factors influence readmission rates and identifying these issues could give a window of opportunity to correct the trend. These may include local practice patterns, for eg. Hospitals with higher overall admissions tend to have higher readmission rates after HF hospitalization (Epstein 2011). Readmissions are also influenced by

psychosocial and socioeconomic barriers that limit compliance with medications, life style changes, self-monitoring and appropriate follow up (Fonarow 2008). There is also a tendency for higher readmissions in centers with resource limitations such as lower nurse staffing levels and limited cardiac capabilities (Joynt 2011).

Studies have demonstrated where care coordination exists, ambulatory care-sensitive hospitalizations decreased by 30% (Bodenheimer 2008). However, if patients do get hospitalized, discharge planning and good follow-up prevents unnecessary ER visits and readmissions (Weaver 2013) (Mittler 2013). Another study from the Boston Medical Center, demonstrated that although one in five hospitalizations are complicated by post-discharge adverse events, development of a strong discharge services program for patients admitted for medical conditions reduced hospital utilization within 30 days of discharge (Jack 2009). In addition, while in the hospital, safe practices reduce the burden of healthcare associated complications (Ranji 2007). Some of these are listed below:

1. Frequent hand-washing reduce hospital acquired infections (WHO 2007)
2. Carefully implemented protocols lead to reduced line sepsis (Pronovost 2010)
3. Discharge planning and good follow-up prevents unnecessary ER visits and readmissions (Weaver 2013)
4. DVT prophylaxis in patients on bed rest avoids pulmonary embolism (Shekelle 2013)
5. Frequent change in position of HF patients in the CCU avoids pressure sores (Shekelle 2013)

PAC measures in the setting of heart failure look at all-cause harms, such as the ones highlighted above, arising from poor management of a patient with heart failure.

Note: For health outcome/PRO performance measures, no further information is required; however, you may provide evidence for any of the structures, processes, interventions, or service identified above.

INTERMEDIATE OUTCOME, PROCESS, OR STRUCTURE PERFORMANCE MEASURE

1a.3. Briefly state or diagram the path between structure, process, intermediate outcome, and health outcomes. Include all the steps between the measure focus and the health outcome.

1a.3.1. What is the source of the systematic review of the body of evidence that supports the performance measure?

☒ Clinical Practice Guideline recommendation – ***complete sections 1a.4, and 1a.7***

☐ US Preventive Services Task Force Recommendation – ***complete sections 1a.5 and 1a.7***

☐ Other systematic review and grading of the body of evidence (*e.g., Cochrane Collaboration, AHRQ Evidence Practice Center*) – ***complete sections 1a.6 and 1a.7***

☐ Other – ***complete section 1a.8***

Please complete the sections indicated above for the source of evidence. You may skip the sections that do not apply.

1a.4. CLINICAL PRACTICE GUIDELINE RECOMMENDATION

1a.4.1. Guideline citation (*including date*) and **URL for guideline** (*if available online*):

1a.4.2. Identify guideline recommendation number and/or page number and **quote verbatim, the specific guideline recommendation**.

1a.4.3. Grade assigned to the quoted recommendation with definition of the grade:

1a.4.4. Provide all other grades and associated definitions for recommendations in the grading system. (*Note: If separate grades for the strength of the evidence, report them in section 1a.7.*)

1a.4.5. Citation and URL for methodology for grading recommendations (*if different from 1a.4.1*)**:**

1a.4.6. If guideline is evidence-based (rather than expert opinion), are the details of the quantity, quality, and consistency of the body of evidence available (e.g., evidence tables)?

☐ Yes → ***complete section 1a.7***

☐ No → ***report on another systematic review of the evidence in sections 1a.6 and 1a.7; if another review does not exist, provide what is known from the guideline review of evidence in 1a.7***

1a.5. UNITED STATES PREVENTIVE SERVICES TASK FORCE RECOMMENDATION

1a.5.1. Recommendation citation (*including date*) and **URL for recommendation** (*if available online*):

1a.5.2. Identify recommendation number and/or page number and **quote verbatim, the specific recommendation**.

1a.5.3. Grade assigned to the quoted recommendation with definition of the grade:

1a.5.4. Provide all other grades and associated definitions for recommendations in the grading system. (*Note: the grading system for the evidence should be reported in section 1a.7.*)

1a.7. FINDINGS FROM SYSTEMATIC REVIEW OF BODY OF THE EVIDENCE SUPPORTING THE MEASURE

If more than one systematic review of the evidence is identified above, you may choose to summarize the one (or more) for which the best information is available to provide a summary of the quantity, quality, and consistency of the body of evidence. Be sure to identify which review is the basis of the responses in this section and if more than one, provide a separate response for each review.

1a.7.1. What was the specific structure, treatment, intervention, service, or intermediate outcome addressed in the evidence review?

1a.7.2. Grade assigned for the quality of the quoted evidence with definition of the grade:

1a.7.3. Provide all other grades and associated definitions for strength of the evidence in the grading system.

1a.7.4. What is the time period covered by the body of evidence? (*provide the date range, e.g., 1990-2010*).
Date range: Click here to enter date range

QUANTITY AND QUALITY OF BODY OF EVIDENCE

1a.7.5. How many and what type of study designs are included in the body of evidence? (*e.g., 3 randomized controlled trials and 1 observational study*)

1a.7.6. What is the overall quality of evidence <u>across studies</u> in the body of evidence? (*discuss the certainty or confidence in the estimates of effect particularly in relation to study factors such as design flaws, imprecision due to small numbers, indirectness of studies to the measure focus or target population*)

ESTIMATES OF BENEFIT AND CONSISTENCY ACROSS STUDIES IN BODY OF EVIDENCE

1a.7.7. What are the estimates of benefit—magnitude and direction of effect on outcome(s) <u>across studies</u> in the body of evidence? (*e.g., ranges of percentages or odds ratios for improvement/ decline across studies, results of meta-analysis, and statistical significance*)

1a.7.8. What harms were studied and how do they affect the net benefit (benefits over harms)?

N/A

UPDATE TO THE SYSTEMATIC REVIEW(S) OF THE BODY OF EVIDENCE

1a.7.9. If new studies have been conducted since the systematic review of the body of evidence, provide for <u>each</u> new study: 1) citation, 2) description, 3) results, 4) impact on conclusions of systematic review.

1a.8 OTHER SOURCE OF EVIDENCE

If source of evidence is NOT from a clinical practice guideline, USPSTF, or systematic review, please describe the evidence on which you are basing the performance measure.

1a.8.1 What process was used to identify the evidence?

1a.8.2. Provide the citation and summary for each piece of evidence.

1. Evidence, Performance Gap, Priority – Importance to Measure and Report

Extent to which the specific measure focus is evidence-based, important to making significant gains in healthcare quality, and improving health outcomes for a specific high-priority (high-impact) aspect of healthcare where there is variation in or overall less-than-optimal performance. ***Measures must be judged to meet all subcriteria to pass this criterion and be evaluated against the remaining criteria.***

1a. Evidence to Support the Measure Focus – See attached Evidence Submission Form
2747_HF_Evidence_Attachment_HCI3-635717853216006588.docx

1b. Performance Gap

Demonstration of quality problems and opportunity for improvement, i.e., data demonstrating:

- considerable variation, or overall less-than-optimal performance, in the quality of care across providers; and/or
- disparities in care across population groups.

1b.1. **Briefly explain the rationale for this measure** *(e.g., the benefits or improvements in quality envisioned by use of this measure)*
Measures associated to potentially avoidable complication (PAC) have been used as comprehensive outcomes measures since 2007 for several conditions and procedures (de Brantes 2010) (Joynt 2013) (James 2013). In 2011, following the NQF endorsement of these measures for certain acute medical conditions (AMI, Pneumonia and Stroke), and for chronic conditions, they were adopted for various purposes, including the creation of related measures (NQF – Measure #1550). Some commercial payers have used them as a means for tracking outcomes (Yong 2010) and for tiering providers for pay for performance programs (BCBSNC). In addition, some provider organizations have used them in quality improvement efforts by homing in on the detailed specifications of the measures to reveal opportunities for care improvement (CALPERS – link below). Identification of PACs has spurred provider innovation (Bundled Payment Summit 2015) for practice re-engineering, to create proactive care pathways, and to focus on areas of high variability (McVary 2010). Some employers are also using measures of avoidable complications as public measures of quality (Colorado Business Group on Health) given the research that demonstrated the potential efficacy of these measures to differentiate provider quality and cost (Hibbard 2012). In fact in a series of focus groups led by Judy Hibbard and colleagues, the researchers found that the very framing of potentially avoidable complications as an indicator of potential harm, is an effective way of communicating the quality of care. And when measures of PACs were presented in conjunction with price, consumers intuitively accepted the logical relationship between low PACs – fewer "defects" – and lower price.

Accountability for and measurement of PACs occurs at the practice, medical group, provider system or purchaser/payer level. PAC rates are calculated as absolute values. For example, a health plan would report that 40% of its plan members with hypertension incurred PACs in the study time window. The objective of the measure is to encourage the unit being measured to progressively reduce that amount over time. In addition, comparisons of PAC rates across plans or provider systems should be encouraged and publicly reported. An organization that uses the measure should be able to identify the leading causes of PACs and implement improvements to existing processes that will decrease PACs. There are several tools available for provider systems and health plans to impact PAC rates. These include care coordination across care settings; post-discharge planning and patient follow- up, active care management, sharing medical record data between care settings and providers, total quality management within hospitals and active reduction of patient safety failures. Reducing PACs has the potential to significantly improve the overall level of quality.

Creating a single measure of accountability for physicians and hospitals tied to gaps in quality is likely to yield much improved outcomes for patients. A measure of accountability for health plans helps them review trends over time and work with physicians and hospitals to improve the ways in which they engage patients using more optimal care management and care coordination (Cassel 2014). In addition, PAC measures could be used as a surrogate for quality in a consumer transparency tool to differentiate providers with regards to their performance.

Moreover, since these measures are claims based, there is minimal added burden for collecting the data, and it also avoids potential gaming that may occur for other measures that require reporting information to registries. Although use of administrative claims data in identifying conditions and measuring provider quality has been questioned, there are several studies in literature that acknowledge validity of its use (Normand 2007) (Quan 2009). Until more readily available data are at hand, use of administrative data to measure provider performance has steadily increased (Miller 2001) (NQF Quality Positioning System). Interestingly, in the

current fee for service system, services for most PACs are rewarded by continued payment (except the CMS defined "never events") and hence to our advantage, adverse events surface in billing data. Claims based PAC measures; therefore serve as an alternative method to track adverse outcomes that do occur (Leibson 2008).

1b.2. Provide performance scores on the measure as specified (current and over time) at the specified level of analysis. *(This is required for endorsement maintenance. Include mean, std dev, min, max, interquartile range, scores by decile. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities included). This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*
The data included two years of administrative claims covering the period April 1, 2012 through December 17, 2014. There were a total 6,025 episodes of HF.

Because providers with small volumes may provide unreliable estimates, we excluded any with fewer than 10 attributed episodes prior to the calculations. After this exclusion 81 (out of 2110) providers remained. Performance scores of these providers are summarized in the following table:

Unadjusted PAC Rates:
- Median (IQR): 40.6% (30.8%, 57.1%)
- Range: 9.1% - 80%

Risk-Standardized PAC Rates (RSPR):
- Median (IQR): 39.9% (32.4%, 46.2%)
- Range: 14.5% - 67.9%

Please refer to the NQF_HF_all_codes_risk_adjustment 06.30.15.xls workbook under the "Provider Attribution" tab to see specific results for each provider.

1b.3. If no or limited performance data on the measure as specified is reported in 1b2, then provide a summary of data from the literature that indicates opportunity for improvement or overall less than optimal performance on the specific focus of measurement.
While CHF has been noted as the most common indication for hospitalization for adults 65 and older, a prospective randomized trial showed a 56.2% reduction in the number of readmissions for heart failure due to intensive nurse-directed education, care coordination, and follow up (Rich 1995). This study also showed that the reduction of hospital admissions led to a savings on $460 per patient. Moreover, improved hospital and post-discharge care, including pre-discharge planning, home-based follow-up, and patient education, have all demonstrated decrease in heart failure related readmission rates suggesting that healthcare services / care processes influence outcomes in heart failure patients (Krumholz 2002).

Many congestive heart failure (CHF) hospitalizations are considered potentially preventable and can be attributed to the failure of the outpatient health care system to properly manage and treat CHF (Will 2012). The American College of Cardiology Foundation (ACCF) and the American Heart Association (AHA) have jointly produced and updated guidelines for management of cardiovascular disease since 1980. The latest Heart Failure guideline released in 2013 states, "Adherence to the clinical practice guidelines herein reproduced should lead to improved patient outcomes" (Yancy 2013). These outcomes include reduction in PAC's due to HF including morbidity associated with progress of HF and a reduction in hospitalizations for HF.

The PAC measures go beyond simple readmission rates and look for all-cause harms in patients with heart failure. As our own analysis demonstrates, the readmission rates in heart failure patients are currently much lower (13.7%) than just a few years ago, as compared to published literature (Discharge from a heart failure hospitalization is followed by a readmission within 30 days in approximately 24% of cases (Desai 2012) with more than 50% patients readmitted to hospital within 6 months of discharge (Ross 2010)). Although this definitely suggests a positive trend in improvements over time, we do not have documented proof since our analysis is not on the same study population over time. On the other hand, we do notice that the overall PAC rates for the heart failure episode continue to be high (over 62%) and they are being reflected in high PAC counts in the professional claims (over 59%) suggesting that they have not completely been eliminated.

While PACs may not be completely eliminated, identifying their magnitude and understanding their causality, in particular for the most frequent or the most expensive, could lead to improving patient outcomes (de Brantes 2008) (de Brantes 2010).

1b.5. **If no or limited data on disparities from the measure as specified is reported in 1b4, then provide a summary of data from the literature that addresses disparities in care on the specific focus of measurement. Include citations.**
Not applicable

1c. High Priority (previously referred to as High Impact)

The measure addresses:

- a specific national health goal/priority identified by DHHS or the National Priorities Partnership convened by NQF; OR
- a demonstrated high-priority (high-impact) aspect of healthcare (e.g., affects large numbers of patients and/or has a substantial impact for a smaller population; leading cause of morbidity/mortality; high resource use (current and/or future); severity of illness; and severity of patient/societal consequences of poor quality).

1c.1. **Demonstrated high priority aspect of healthcare**
Affects large numbers, A leading cause of morbidity/mortality, High resource use, Patient/societal consequences of poor quality, Severity of illness
1c.2. **If Other:**

1c.3. **Provide epidemiologic or resource use data that demonstrates the measure addresses a high priority aspect of healthcare. List citations in 1c.4.**
Heart failure (HF) is a chronic progressive resource intensive condition with a high economic and social burden. Approximately 5.1 million persons in the United States have clinically manifest HF, and the prevalence continues to rise (Go 2013). In the Medicare-eligible population, HF prevalence increased from 90 to 121 per 1000 beneficiaries from 1994 to 2003 (Curtis 2008). Heart Failure is one of the leading causes for hospitalization in Americans 65 and over and is the primary diagnosis in >1 million hospitalizations annually (Yancy 2013), accounting for a total Medicare expenditure exceeding $17 billion (Desai 2012). The total cost of HF care in the United States exceeds $30 billion annually, with over half of these costs spent on hospitalizations (Yancy 2013)(Go 2013). Patients hospitalized for HF are at high risk for readmissions, with a 25% rate of readmission within one month (Krumholz 2009).

In 2007, the Medicare Payment Advisory Commission called for hospital-specific public reporting of readmission rates, identifying HF as a priority condition. The Commission stated that readmissions for HF were common, costly, and often preventable (MedPac 2007). An estimated 12.5 percent of readmissions for HF were potentially preventable (AHRQ 2014). AHRQ has identified HF to be an ambulatory-care–sensitive conditions (ACSC) with a Prevention Quality Indicator (PQI) to track outcomes (Will 2012) (Ranji 2007).

The 2013 American Heart Association/American College of Cardiology (AHA/ACC) published guidelines for post discharge HF interventions (Yancy 2013). Despite advances in medical therapy across the spectrum of cardiovascular diseases, and the availability of guideline-directed medical therapy (GDMT) to represent optimal medical therapy as defined by ACCF/AHA guideline, hospitalizations due to poor management of HF continue to rise (Yancy 2013).

Many congestive heart failure (CHF) hospitalizations are considered potentially preventable and can be attributed to the failure of the outpatient health care system to properly manage and treat CHF (Will 2012). In 2012, CDC published a study analyzing data from National Hospital Discharge Survey between 1995 through 2009. There were 121,741 records with preventable hospitalizations for CHF among adults translating to a weighted number of 15,208,518 hospitalizations for adults in the United States during the 15-year study period, an average of 1,013,901 each year. Approximately 75% of preventable hospitalizations for CHF occurred in people aged 65 or older (Will 2012).

Therefore, there are many areas where improvement is possible in HF, making it a high priority aspect of health care. The PAC measures go beyond simple readmission rates and look for all-cause harms in patients with heart failure.

1d. Composite Quality Construct and Rationale

1d.1. A composite performance measure is a combination of two or more component measures, each of which individually reflects quality of care, into a single performance measure with a single score.

For purposes of NQF measure submission, evaluation, and endorsement, the following will be considered composites:

- Measures with two or more individual performance measure scores combined into one score for an accountable entity.
- Measures with two or more individual component measures assessed separately for each patient and then aggregated into one score for an accountable entity:
    - all-or-none measures (e.g., all essential care processes received, or outcomes experienced, by each patient); or
    - any-or-none measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient).

1d.1. Please identify the composite measure construction: any-or-none measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient)any-or-none measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient)

1d.2. Describe the quality construct, including:

- the overall area of quality
- included component measures and
- the relationship of the component measures to the overall composite and to each other.

The PAC measures, as we define them, look at many "care defects" comprehensively. They are composed of several cross-cutting measures and together they paint a global picture of the provider's overall performance.

We classify PACs into two types: Type 1 PACs are directly related to the index condition and are often controlled by the servicing provider; Type 2 PACs, on the other hand result from patient safety failures and could be reduced by better systems and better processes in care. Both types of PACs could occur in any setting and so could be identified through any type of claims coming in the administrative dataset, including in-patient, out-patient, or professional claims. PACs may occur any time during the episode time window. PACs are counted as a dichotomous (yes/no) outcome. If a patient had one or more PACs, they get counted as a "yes" or a 1.

The PAC measure definitions encompass several other measures that are accepted as being valid complications of care and are widely used throughout the country. These include CMS defined Hospital Acquired Conditions (HACs), Hospital Inpatient Quality Reporting measures, Avoidable Readmissions, AHRQ defined patient safety indicators (PSIs), NQF endorsed patient safety measures such as patient fall rates, pressure ulcer rates, and peri-operative pulmonary embolism or deep vein thrombosis rates.

All defined PACs, irrespective of their type, or site of occurrence, are aggregated to create an overall comprehensive, composite measure. They all have equal weighting, since they are measured simply by the frequency of their occurrence.

1d.3. Describe the rationale for constructing a composite measure, including how the composite provides a distinctive or additive value over the component measures individually.

Each individual PAC, when measured in isolation, provides a very limited picture of the performance of the provider(s) who are managing or co-managing the care of the patient. However, looking at all the PACs that may occur individually or concurrently in a patient with a given episode provides a comprehensive picture of the care received by the patient for that particular condition or illness.

Additionally, the frequency of occurrence of individual PACs may be so low that it may require very high sample sizes from individual providers to achieve any meaningful and reliable comparisons. But aggregating all the PACs into a single quality metric creates meaningful scores that can be compared across providers even with relatively smaller sample sizes.

Additionally, a comprehensive measure is easier to explain to the average consumer. From a patient's point of view, any bad outcome has an impact on their health with respect to return to work, functional limitations and need for additional support. If a provider has a high PAC rate with regards to one component PAC but not the other PACs, the impact on the patient is still adverse. In selecting providers, individual component PAC scores would mean nothing to a patient, but aggregating it to a comprehensive quality score could be a measure of "all-cause" harms and easier to interpret and act on.

1d.4. **Describe how the aggregation and weighting of the component measures are consistent with the stated quality construct and rationale.**

In constructing the comprehensive composite PAC measure, each component PAC, as clinically defined by the subject matter experts, was given the same weight so that arbitrary weights may not bias the results. Furthermore, the measure is constructed so that the occurrence of any number of PACs during a defined episode would only count as one occurrence. As such, the patient is the ultimate unit of measurement and if the patient incurred any PAC during the episode, then that counts against the numerator.

Since the emphasis of the PAC measure was to simply identify the occurrence of PACs in any setting, aggregation of the PAC counts to create a comprehensive quality score with equal weights has been met with overall support from the clinical working groups as well as from the implementation sites.

2. Reliability and Validity—Scientific Acceptability of Measure Properties

Extent to which the measure, as specified, produces consistent (reliable) and credible (valid) results about the quality of care when implemented. ***Measures must be judged to meet the subcriteria for both reliability and validity to pass this criterion and be evaluated against the remaining criteria.***

2a.1. Specifications The measure is well defined and precisely specified so it can be implemented consistently within and across organizations and allows for comparability. eMeasures should be specified in the Health Quality Measures Format (HQMF) and the Quality Data Model (QDM).

S.3. **For endorsement maintenance**, please briefly describe any changes to the measure specifications since last endorsement date and explain the reasons.

Not applicable

S.4. **Numerator Statement** *(Brief, narrative description of the measure focus or what is being measured about the target population, i.e., cases from the target population with the target process, condition, event, or outcome)*

IF an OUTCOME MEASURE, state the outcome being measured. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.

Outcome: Number of patients who triggered an episode of heart failure (HF), are followed for at least one-year, and had one or more potentially avoidable complications (PACs) during the episode time window.

S.5. **Time Period for Data** *(What is the time period in which data will be aggregated for the measure, e.g., 12 mo, 3 years, look back*

to August for flu vaccination? Note if there are different time periods for the numerator and denominator.)
The time window is the most recent 12 months of the episode, once a patient has triggered a HF episode.

S.6. **Numerator Details** *(All information required to identify and calculate the cases from the target population with the target process, condition, event, or outcome such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
IF an OUTCOME MEASURE, describe how the observed outcome is identified/counted. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
Patients that have triggered a HF episode, and are identified as having services for potentially avoidable complications (PACs), during the most recent 12 months of the episode. The enclosed excel workbook entitled NQF_HF_all_codes_risk_adjustment_06.30.15 gives the detailed codes for PACs in the tabs entitled PACs I-9 and PACs I-10. PACs are identified only based on diagnosis codes.

Services for PACs are identified as follows:
a. Any service (professional, outpatient facility, ancillary) that is relevant to HF and has a PAC code in any position on the claim
b. Any admission to an acute care facility, that is relevant to HF
c. Any admission to a post-acute care facility that is relevant to HF and has a PAC code in any position on the claim

S.7. **Denominator Statement** *(Brief, narrative description of the target population being measured)*
Adult patients aged 18 years and above who triggered an episode of heart failure (HF) and are followed for at least one-year.

S.8. **Target Population Category** *(Check all the populations for which the measure is specified and tested if any):*
Populations at Risk, Populations at Risk : Dual eligible beneficiaries, Populations at Risk : Individuals with multiple chronic conditions, Populations at Risk : Veterans, Senior Care

S.9. **Denominator Details** *(All information required to identify and calculate the target population/denominator such as definitions, specific data collection items/responses , code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
Please refer to the enclosed excel workbook entitled
NQF_HF_all_codes_risk_adjustment 06.30.15

The target population is identified using the following criteria:
1. Using administrative claims database, patients with HF are identified using one of the following criteria:
a. Patients having an office visit with a trigger code of HF in any position, followed by a second confirmatory office visit (with a trigger code of HF in any position), at least 30 days apart.
b. Patients with a Principal Dx of a HF trigger code on an in-hospital stay claim.
The trigger codes for HF are provided in the tab called "Triggers I-9" or "Triggers I-10".
2. The patient should have continuous enrollment for the entire time window with no more than 30 days as an enrollment gap, with the entity providing the data (so we can ensure that the database has captured most of the claims for the patient during the episode time window).
3. The patient should have a complete episode time window in the claims data – so there are at least 12 months of claims in the database for the patient.
4. Patient should be at least 18 years of age

Once the episode is triggered all relevant claims are assigned to the episode. Relevant claims could be inpatient facility claims, outpatient facility claims, professional services, laboratory services, imaging services, ancillary claims, home health, durable medical equipment as well as pharmacy claims across the entire continuum of care centered around the patient's episode of care. Relevant claims are identified as those that have a diagnosis code that matches the codes in the typical Dx codes tabs (Typical Dx I-9 or Typical Dx I-10), or in the PAC Dx codes tab (PACs I-9 or PACs I-10) AND a procedure code as identified in the Relevant Procedures I-9 & I-10 tab in the enclosed workbook. Relevant admissions to acute and post-acute care facilities are also included in the denominator.

S.10. **Denominator Exclusions** *(Brief narrative description of exclusions from the target population)*
Denominator exclusions include exclusions of either "patients" or "claims" based on the following criteria:
1. "Patients" excluded are those that do not meet the enrollment criteria. If patient has an enrollment gap for more than 30 days

during the episode time window, it is considered as an enrollment gap
2. "Patients" are also excluded if the cost of the episode is an outlier at greater than 99th percentile or less than 1st percentile value for all episodes. This is another way to ensure that episodes are complete as well as they do not bring in random noise into the analysis due to inappropriate codes or services.
3. "Claims" are excluded from the HF measure if they are considered not relevant to HF care.

S.11. **Denominator Exclusion Details** *(All information required to identify and calculate exclusions from the denominator such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
Denominator exclusions include exclusions of "patients" as well as "claims" not relevant to HF care. Please refer to the enclosed excel workbook entitled (NQF_HF_all_codes_risk_adjustment 06.30.15.xls)

1. "Patients" are excluded from the measure if they meet one of the following criteria:
a. If age is < 18 years
b. If gender is missing
c. If they do not have continuous enrollment for the entire time window with a maximum of 30 day enrollment gap with the entity providing the data (this helps determine if the database has captured most of the claims for the patient in the time window).
d. If the patient does not have at least 12 months of claims in the database (this helps eliminate incomplete episodes).
e. The episode cost is an outlier (less than 1st percentile or greater than 99th percentile value for all episodes of the same type). This eliminates extreme variation that may result from random outlier events.

2. "Claims" are excluded from the measure if they meet one of the following criteria:
a. If none of the diagnosis codes on the claim are on the list of "triggers" or relevant diagnosis codes (either typical Dx or PAC Dx) for HF.
b. If none of the procedure / CPT codes on the claim are on the list of relevant procedure codes for HF.
c. If the HF trigger hospitalization also triggers a major surgical procedure such as coronary bypass procedure or angioplasty, suggesting that HF may be a comorbidity or an indication for the surgery.
d. The "principal" diagnosis on an inpatient stay claim during the episode time window triggers its own episode
e. The procedure code on a claim during the episode time window triggers its own episode

S.12. **Stratification Details/Variables** *(All information required to stratify the measure results including the stratification variables, definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format with at S.2b)*
None

S.13. **Risk Adjustment Type** (Select type. Provide specifications for risk stratification in S.12 and for statistical model in S.14-15)
Statistical risk model
If other:

S.14. **Identify the statistical risk model method and variables** *(Name the statistical method - e.g., logistic regression and list all the risk factor variables. Note - risk model development and testing should be addressed with measure testing under Scientific Acceptability)*
Conceptual Model
Variations in outcomes across populations may be due to patient-related factors or due to provider-controlled factors. When we adjust for patient-related factors, the remaining variance in PACs are due to factors that could be controlled by all providers that are managing or co-managing the patient, both during and after hospitalization.

Statistical Method:
Logistic Regression model to determine the probability of a patient incurring a PAC
Demographic variables, comorbid conditions, as well as clinical severity indicators are fed as independent risk factors into the model. Risk Factors are collected historically. Subtype information is collected from the index claim and any look-back period, if relevant. Subtypes are clinical severity indicators suggesting severity of the episode itself, for example, diagnosis of diastolic heart failure in a HF patient. For each patient the "predicted" coefficients from the risk adjustment models are summed to give the predicted probabilities of the occurrence of a PAC.

Risk Factors :(Please refer to the enclosed excel workbook entitled (NQF_HF_all_codes_risk_adjustment 06.30.15.xls). The risk factors along with their codes are listed in the tabs called “All Risk Factors I-9” and “All Risk Factors I-10” and also listed below:

AGE CONTINUOUS VARIABLE
GENDER FEMALE = 1 (MALE IS REFERENCE = 0)

Risk Factor #	Risk Factor Name
RF0101	Anoxic Brain Damage, persistent vegetative state
RF0102	Delirium, Meningitis, Encephalitis
RF0103	Previous Stroke, Paralysis
RF0104	Cerebral Palsy and Other Paralytic Syndromes
RF0105	Spinal Cord Disorders/Injuries
RF0106	Polyneuropathy
RF0107	Multiple Sclerosis
RF0108	Convulsions, Epilepsy
RF0109	Dementia
RF0110	Parkinson´s and Huntington´s Diseases
RF0111	Cerebrovascular Disease
RF0115	after care, rehabilitation
RF0201	visual loss, blindness, retinal tear, detachment
RF0301	ENT, Upper Respiratory Problems
RF0401	Respiratory Failure, O2, ventilator dependence
RF0402	Advanced COPD, Asthma
RF0403	Empyema, bronchiectasis, Pneumonias
RF0404	Aspiration Pneumonia, Laryngeal Problems
RF0406	TB, Pneumoconiosis, Aspergillosis
RF0407	Tobacco use, Lung disease due to External Fumes
RF0408	Other Lung Disease
RF0501	Previous Shock, Syncope, Vent Fibrillation
RF0503	Advanced CHF
RF0504	Cardiomyopathy, valve disorders
RF0505	Cardiac Arrhythmias, Heart Block
RF0506	Pacemaker, AICD
RF0507	Endocarditis, Other post surgical cardiac problems
RF0508	Other Cardiovascular Disease
RF0511	DVT, Pulm Embolism, Pulm Heart Disease
RF0512	Unstable Angina
RF0513	Hypotension, chronic, orthostatic
RF0514	Hyperlipidemia
RF0515	Intraaortic Balloon Pump
RF0516	ventricular assist device, ecmo, prolonged bypass
RF0517	Previous electrophysiology studies, cryoablation
RF0518	Recent AMI
RF0519	Previous PCI

RF1702 Lung and Intrathoracic Cancers
RF1703 Neuroendocrine, Myeloproliferative Cancers
RF1704 Poorly differentiated, Secondary, Metastatic Cancers
RF1705 Other Tumors
RF1706 Acute Leukemia
RF1707 Cancer uterus, localized female organs
RF1708 Colorectal, Hepatobiliary and other GI cancers
RF1709 Breast, Prostate, Thyroid cancers
RF1710 Testicular Cancer and localized of male organs
RF1711 Cancer of Bladder and Urinary Tract
RF1712 Musculoskeletal Cancers
RF1801 Sepsis, MRSA, Opportunitistic infections
RF1901 Schizophrenia
RF1902 Major Depressive, Bipolar, and Paranoid Disorders
RF2001 Drug/Alcohol Psychosis
RF2002 Drug/Alcohol Dependence
RF2101 Drug Reactions, long term use of drugs
RF2102 Intra-abdominal injury
RF2201 Extensive Third-Degree Burns

RF2301 Major Organ Transplant Status
RF2302 Artificial Openings for Feeding or Elimination
RF2303 Complications of Medical & Surgical Care and Trauma
RF2304 severe morbid obesity
RF2305 morbid obesity
RF2306 obesity
RF2307 mild sleep apnea, hypoventilation
RF2308 moderate sleep apnea, hypoventilation
RF2309 obstructive sleep apnea
RF2310 Severe Protein-Calorie Malnutrition
RF2311 Mild-mod malnutrition
RF2401 Severe Head Injury
RF2402 Major Head Injury
RF2403 Vertebral Fractures without Spinal Cord Injury
RF2404 Falls, Fractures
RF2405 Amputation
RF2501 HIV/AIDS

Subtypes for HF
Diastolic Heart Failure
Cardiomyopathy
Hypertensive Heart Disease w Heart Failure
Hypertensive Heart Disease w Heart Failure & CKD
Heart Aneurysm and other Sequelae of AMI
Heart Valve Disorders
Previous heart valve replacement
Acute pericarditis
Chronic, adhesive, constrictive pericarditis
Other pericarditis
Myocarditis
Pulmonary heart disease
Other heart disease
Pacemaker, Defibrillator in place
Transplanted Heart
Protein Calorie Malnutrition
Tobacco Use

The prevalence of the risk factors in our reference dataset are listed in the enclosed workbook entitled NQF_HF_all_codes_risk_adjustment 06.30.15.xls – see tab "Risk Factor Prevalence". The output of the regression model are given in the same workbook in the tab 'Risk Model'.

S.15. **Detailed risk model specifications** *(must be in attached data dictionary/code list Excel or csv file. Also indicate if available at measure-specific URL identified in S.1.)*
Note: Risk model details (including coefficients, equations, codes with descriptors, definitions), should be provided on a separate worksheet in the suggested format in the Excel or csv file with data dictionary/code lists at S.2b.
Available in attached Excel or csv file at S.2b

S.15a. **Detailed risk model specifications** (*if not provided in excel or csv file at S.2b*)
Please see tab entitled Risk Model in the enclosed excel workbook entitled (NQF_HF_all_codes_risk_adjustment 06.30.15.xls).

S.16. **Type of score:**
Rate/proportion
If other:

S.17. Interpretation of Score *(Classifies interpretation of score according to whether better quality is associated with a higher score, a lower score, a score falling within a defined interval, or a passing score)*
Better quality = Lower score

S.18. Calculation Algorithm/Measure Logic *(Describe the calculation of the measure score as an ordered sequence of steps including identifying the target population; exclusions; cases meeting the target process, condition, event, or outcome; aggregating data; risk adjustment; etc.)*
Please refer to the enclosed excel workbook entitled (NQF_HF_all_codes_risk_adjustment 06.30.15.xls).

Assembling the Denominator:

Using administrative claims database, patients with HF are identified using one of two criteria: 1) Patients having an office visit with a trigger code of HF in any position, followed by a second confirmatory office visit (with a trigger code of HF in any position), at least 30 days apart, 2) Patients a Principal Dx of a HF trigger code on an in-hospital stay claim. The trigger codes for HF are provided in the tab called “Triggers I-9” or “Triggers I-10”.

Patients are retained if they are 18 years of age or more, do not have a missing gender, have at least 12 month of claims in the database, have a maximum of 30-day enrollment gap for the entire episode time window, and have no outlier episode costs. All relevant professional, laboratory, imaging, ancillary and other claims that are incurred during the episode time window are included as part of the episode. Claims are considered relevant to HF care if they have one of the diagnosis codes, as listed on the tab entitled Triggers I-9, Triggers 1-10, PACs I-9, PACs I-10, Typical Dx I-9, or Typical Dx I-10 in any position on the claim AND a procedure code as identified in the Relevant Procedures I-9 & I-10 tab in the enclosed workbook. Relevant admissions to acute and post-acute care facilities are also included in the denominator. All relevant pharmacy claims carrying codes that match the ingredients listed in the Pharmacy tab of the enclosed workbook are also included as part of the episode. Services are pulled as part of the HF episode based on the diagnosis codes as defined above or if they have a service code that is marked as “sufficient” for that episode.

If a patient has more than one concurrent episode, and the claim is relevant to both episodes, the claim could get multi-assigned, except in the case of procedural episodes that get carved out with respect to the index stay. So if an inpatient stay claim carried a principal Dx code that matched the trigger diagnosis code for HF but they also had a procedure code for CABG (coronary artery bypass surgery), the stay claim would get uniquely assigned to CABG and not be counted with HF.

Once all the episodes are assembled, episodes that match the exclusion criteria, such as those with outlier costs, are flagged (those with total episode costs less than 1st percentile or greater than 99th percentile), and excluded from the final analysis.

Assembling the Numerator:

For every episode included in the denominator, services are flagged as having a PAC (potentially avoidable complication) based on the criteria listed below:

- Any service (professional, outpatient facility, ancillary) with a PAC code in any position on the claim
- Any admission to an acute care facility, that is relevant to HF

Relevant claims that do not have any PAC codes, and do not qualify as a PAC based on the criteria outlined above, are listed as typical claims. All included relevant pharmacy services are flagged as typical. Patients that have even a single PAC claim are counted as part of the numerator.

Calculating the measure:

Proportion of HF patients that have PACs is simply the ratio of patients with PACs within the HTN population and is called the PAC rate as shown in the equation below:

PAC rate = Patients with HF that have at least one PAC claim / Total number of HF patients

A flow chart demonstrating the series of steps and the counts of patients at each step is shown in tab entitled Decision Tree of the enclosed workbook called NQF_HF_all_codes_risk_adjustment 06.30.15.xls

Drill Down Calculations:

Further analysis from this construct helps create actionable reports.

For example as shown in the tab labeled PAC overview, not only do we have the PAC rate for a population, we can break them down by the PAC type – type 1 being directly related to HF and so actionable by the servicing physician, while type 2 PACs are related to patient safety failures and can be improved by process improvement. Additionally, analyzing potentially avoidable admissions helps focus strategies in reducing them.

Risk Adjustment:

Once we have the observed PAC rates, we risk-adjust them for patient factors such as patient demographics, comorbidities collected historically, and for severity of illness or procedure using subtypes collected from the index stay and / or look-back period. This helps adjust for factors outside the providers control and levels the playing field for provider performance comparisons.

Unit of Analysis:
The unit of analysis is the individual episode.

Dependent Variable:
The dependent variable is a dichotomous variable indicating whether an episode had one or more claims assigned as a PAC (=1) or not (=0).

Independent Variables:
A number of patient-related "risk factors" or covariates are included in the models:

Patient demographics: age, gender, and an indicator of whether a member has enrolled within the previous 6 months. This latter risk factor is intended to account for the patient's lack of claims history, which limits the number of potential comorbidities that can be identified.

Comorbidities: These are conditions or events that occurred prior to the start of the episode that can have a potential impact on the patient's risk of having a PAC. The risk factors are 170 disease indicators (0/1) identified through the presence of ICD diagnosis codes on individual medical claims and collected from the historical claims data before the start of an episode. These are universally applied across all episodes. Please see the tab labeled "All Risk Factors I-9" and "All Risk Factors I-10" for a list of risk factors and their corresponding codes in the enclosed workbook called NQF_HF_all_codes_risk_adjustment 06.30.15.xls

Episode Subtypes or Severity Markers: These are markers that distinguish an episode as being more severe than another. They indicate either specific patient comorbidities that are known to make the procedure or condition more difficult to treat (e.g., obesity) or severity of the illness itself (e.g., unstable anginadiastolic heart failure). Please see the tab labeled "Subtypes I-9" and "Subtypes I-10" for a list of subtypes and their corresponding codes in the enclosed workbook called NQF_HF_all_codes_risk_adjustment 06.30.15.xls

As mentioned previously, to avoid creating perverse incentives all comorbidities and subtypes are identified prior to or at the very start of the episode. None are identified during the episode period.

Statistical Methods
We use logistic regression to model the probability of at least one PAC occurring during the episode. Only comorbidities and subtypes are included in the models as covariates if they are present in at least 10 episodes to prevent unstable coefficients. No further model building is conducted after the initial models are built. This reflects a desire to explain as much variation in the probability of having a PAC as possible, but it does not make it a priority that all covariates in the model be individually significant or even uncorrelated with each other. Accordingly, the model uses a very large group of covariates. This modeling approach allows for fewer potentially artificial constraints around the definitions of what constitutes severity of a episode condition, and lets each regression model determine for itself which of the factors are more significant for a specific episode. Non-significant covariates in episode models can not overly influence predicted outcomes, nor is much harm realized, if a group of correlated covariates work together to explain variation rather than having the variation explained by a single best factor.

When more than one line of business is included in the data, separate models are calculated for each sample (i.e., commercial, Medicaid etc.).

Provider Attribution and calculating PAC rates by provider:

Once episodes are constructed they are attributed to providers based on one of the various attribution rules. For HF, episodes are attributed to the primary care physician, internist, or cardiologist with the highest count of office visits.

Using the logistic regression technique described above, a model is developed that gives estimates for each risk factor and subtype for the patients in the population analyzed. These estimates are used to develop patient-level probabilities for the occurrence of PACs. The patient-level probability estimates are summed to construct aggregated measures (e.g., facility/provider-level). This method is similar to the methods employed by the Centers for Medicare and Medicaid Services (CMS) and endorsed by the National Quality Forum (NQF) to construct similar facility- and practice-level measures (i.e., mortality, readmissions, etc.):

For each provider, the number of actual observed occurrences of the outcome is summed across all attributed patients with that episode, to give the observed PAC rates for the provider.

Similarly adjusted probabilities from the risk adjustment models are summed across all attributed patients to give expected PACs for the provider.

The observed sum is then divided by the summed probabilities (O/E). This number yields whether the provider or facility had more PACs than expected (ratio>1), as expected (ratio=1), or less than expected (ratio<1). This calculation yields a practice-level unstandardized performance ratio.

To facilitate accurate comparisons of rates across units of analysis, this ratio is then standardized to the community rate using the indirect method. Specifically, the provider-level rate is multiplied by the expected community rate, calculated as the sum of adjusted probabilities for every individual in the sample across all providers in the analysis. This measure, known as the standardized rate, represents what the unit's risk-adjusted rate would be for the outcome of interest if its patient population was reflective of the of the overall community.

The formula for this calculation is as follows:

Adj Outcome_j={(SUM Observed_ij)/(SUM Prob_ij)} × {(SUM Prob_i) / (# of episodes)}
Where individual is attributed to unit of analysis j (e.g., practice, provider, etc.)

Minimum sample size requirements for PAC measures are a function of the reliability testing of the measures on every dataset on which the measures are applied. Our research suggests that minimum sample sizes to achieve high degrees of reliability in the measures are a function of the dataset analyzed, and as such may vary from dataset to dataset. One should not infer that a minimum sample size achieved in one dataset will apply to another.

S.19. **Calculation Algorithm/Measure Logic Diagram URL or Attachment** *(You also may provide a diagram of the Calculation Algorithm/Measure Logic described above at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
Available in attached appendix at A.1

S.20. **Sampling** *(If measure is based on a sample, provide instructions for obtaining the sample and guidance on minimum sample size.)*
IF a PRO-PM, identify whether (and how) proxy responses are allowed.
Not applicable

S.21. **Survey/Patient-reported data** *(If measure is based on a survey, provide instructions for conducting the survey and guidance on minimum response rate.)*
IF a PRO-PM, specify calculation of response rates to be reported with performance measure results.
Not applicable

S.22. **Missing data** (specify how missing data are handled, e.g., imputation, delete case.)
Required for Composites and PRO-PMs.
If patient related data is missing, the case is deleted from both the numerator and the denominator

S.23. **Data Source** *(Check ONLY the sources for which the measure is SPECIFIED AND TESTED).*
If other, please describe in S.24.
Administrative claims

S.24. **Data Source or Collection Instrument** *(Identify the specific data source/data collection instrument e.g. name of database, clinical registry, collection instrument, etc.)*
IF a PRO-PM, identify the specific PROM(s); and standard methods, modes, and languages of administration.
The information is based on a two-year claims database from a large regional commercial insurer. The database has over 3.2 million covered lives and $25.9 billion in "allowed amounts" for claims costs. The database is an administrative claims database with medical as well as pharmacy claims.

The methodology can be used on any claims database with at least two years of data and a minimum of 150 patients with the index condition or hospitalization. Having pharmacy data adds to the richness of the risk-adjustment models.
The calculations of rates of potentially avoidable complications can be replicated by anyone that uses the measure specifications along with the metadata file that is available for free on our web site at http://www.hci3.org/ecre/xml-agreement.html.
We also plan on providing a limited automated analysis, at no cost, on our website.
The methodology has been tested on databases of several health plans as well as on a few employer databases.

No data collection instrument was used.

S.25. **Data Source or Collection Instrument** *(available at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
No data collection instrument provided

S.26. **Level of Analysis** *(Check ONLY the levels of analysis for which the measure is SPECIFIED AND TESTED)*
Clinician : Group/Practice, Clinician : Individual, Clinician : Team

S.27. **Care Setting** *(Check ONLY the settings for which the measure is SPECIFIED AND TESTED)*
Ambulatory Care : Ambulatory Surgery Center (ASC), Ambulatory Care : Clinician Office/Clinic, Other
If other: Across the care continuum

S.28. **COMPOSITE Performance Measure** - Additional Specifications *(Use this section as needed for aggregation and weighting rules, or calculation of individual performance measures if not individually endorsed.)*

2747_HF_Testing_Reliability_Validity_HCI3-635719668856800768.docx

NATIONAL QUALITY FORUM—Measure Testing (subcriteria 2a2, 2b2-2b7)

Measure Number (*if previously endorsed*)**:** 2747
Measure Title: Proportion of Patients with Heart Failure (HF) that have a Potentially Avoidable Complication (during the episode time window)
Date of Submission: 06/30/15
Type of Measure:
Composite Construction:
☐Two or more individual performance measure scores combined into one score
☐ All-or-none measures (e.g., all essential care processes received or outcomes experienced by each patient)
☐ Any-or-none measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient)

Instructions
- Measures must be tested for all the data sources and levels of analyses that are specified. ***If there is more***

than one set of data specifications or more than one level of analysis, contact NQF staff about how to present all the testing information in one form.

- **For <u>all</u> measures, sections 1, 2a2, 2b2, 2b3, and 2b5 must be completed.**
- **For <u>outcome and resource use</u> measures**, section **2b4** also must be completed.
- If specified for **<u>multiple data sources/sets of specificaitons</u>** (e.g., claims and EHRs), section **2b6** also must be completed.
- Respond to <u>all</u> questions as instructed with answers immediately following the question. All information on testing to demonstrate meeting the subcriteria for reliability (2a2) and validity (2b2-2b6) must be in this form. An appendix for *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 20 pages (*incuding questions/instructions;* minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

<u>Note</u>: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the testing results for this measure meet NQF's evaluation criteria for testing.

2a2. Reliability testing [10] demonstrates the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise. For **PRO-PMs and composite performance measures**, reliability should be demonstrated for the computed performance score.

2b2. Validity testing [11] demonstrates that the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality. For **PRO-PMs and composite performance measures**, validity should be demonstrated for the computed performance score.

2b3. Exclusions are supported by the clinical evidence; otherwise, they are supported by evidence of sufficient frequency of occurrence so that results are distorted without the exclusion; [12]

AND

If patient preference (e.g., informed decisionmaking) is a basis for exclusion, there must be evidence that the exclusion impacts performance on the measure; in such cases, the measure must be specified so that the information about patient preference and the effect on the measure is transparent (e.g., numerator category computed separately, denominator exclusion category computed separately). [13]

2b4. For outcome measures and other measures when indicated (e.g., resource use):

- **an evidence-based risk-adjustment strategy** (e.g., risk models, risk stratification) is specified; is based on patient factors that influence the measured outcome (but not factors related to disparities in care or the quality of care) and are present at start of care; [14,15] and has demonstrated adequate discrimination and calibration

OR

- rationale/data support no risk adjustment/ stratification.

2b5. Data analysis of computed measure scores demonstrates that methods for scoring and analysis of the specified measure allow for **identification of statistically significant and practically/clinically meaningful** [16] **differences in performance**;
OR
there is evidence of overall less-than-optimal performance.

2b6. If multiple data sources/methods are specified, there is demonstration they produce comparable results.

2b7. For **eMeasures, composites, and PRO-PMs** (or other measures susceptible to missing data), analyses identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias.

Notes
10. Reliability testing applies to both the data elements and computed measure score. Examples of reliability testing for data elements include, but are not limited to: inter-rater/abstractor or intra-rater/abstractor studies; internal consistency for multi-item scales; test-retest for survey items. Reliability testing of the measure score addresses precision of measurement (e.g., signal-to-noise).
11. Validity testing applies to both the data elements and computed measure score. Validity testing of data elements typically analyzes agreement with another authoritative source of the same information. Examples of validity testing of the measure score include, but are not limited to: testing hypotheses that the measures scores indicate quality of care, e.g., measure scores are different for groups known to have differences in quality assessed by another valid quality measure or method; correlation of measure scores with another valid indicator of quality for the specific topic; or relationship to conceptually related measures (e.g., scores on process measures to scores on outcome measures). Face validity of the measure score as a quality indicator may be adequate if accomplished through a systematic and transparent process, by identified experts, and explicitly addresses whether performance scores resulting from the measure as specified can be used to distinguish good from poor quality.
12. Examples of evidence that an exclusion distorts measure results include, but are not limited to: frequency of occurrence, variability of exclusions across providers, and sensitivity analyses with and without the exclusion.
13. Patient preference is not a clinical exception to eligibility and can be influenced by provider interventions.
14. Risk factors that influence outcomes should not be specified as exclusions.
15. Risk models should not obscure disparities in care for populations by including factors that are associated with differences/inequalities in care, such as race, socioeconomic status, or gender (e.g., poorer treatment outcomes of African American men with prostate cancer or inequalities in treatment for CVD risk factors between men and women). It is preferable to stratify measures by race and socioeconomic status rather than to adjust out the differences.
16. With large enough sample sizes, small differences that are statistically significant may or may not be practically or clinically meaningful. The substantive question may be, for example, whether a statistically significant difference of one percentage point in the percentage of patients who received smoking cessation counseling (e.g., 74 percent v. 75 percent) is clinically meaningful; or whether a statistically significant difference of $25 in cost for an episode of care (e.g., $5,000 v. $5,025) is practically meaningful. Measures with overall less-than-optimal performance may not demonstrate much variability across providers.

1. DATA/SAMPLE USED FOR ALL TESTING OF THIS MEASURE

Often the same data are used for all aspects of measure testing. In an effort to eliminate duplication, the first five questions apply to all measure testing. If there are differences by aspect of testing,(e.g., reliability vs. validity) be sure to indicate the specific differences in question 1.7.

1.1. What type of data was used for testing? (*Check all the sources of data identified in the measure specifications and data used for testing the measure. Testing must be provided for all the sources of data specified and intended for measure implementation.* ***If different data sources are used for the numerator and denominator, indicate N [numerator] or D [denominator] after the checkbox.***)

Measure Specified to Use Data From: (*must be consistent with data sources entered in S.23*)	**Measure Tested with Data From:**
☐ abstracted from paper record	☐ abstracted from paper record
☐ administrative claims	☐ administrative claims
☐ clinical database/registry	☐ clinical database/registry
☐ abstracted from electronic health record	☐ abstracted from electronic health record
☐ eMeasure (HQMF) implemented in EHRs	☐ eMeasure (HQMF) implemented in EHRs
☐ other: Click here to describe	☐ other: Click here to describe

1.2. If an existing dataset was used, identify the specific dataset (*the dataset used for testing must be consistent with the measure specifications for target population and healthcare entities being measured; e.g., Medicare Part A claims, Medicaid claims, other commercial insurance, nursing home MDS, home health OASIS, clinical registry*).

The information is based on a two-year administrative claims database from a large regional commercial insurer. The database contains medical and pharmacy claims on over 3.2 million covered lives and more than $25.9 billion in "allowed amounts" for costs.

1.3. What are the dates of the data used in testing? April 1, 2012 – December 17, 2014

1.4. What levels of analysis were tested? (*testing must be provided for all the levels specified and intended for measure implementation, e.g., individual clinician, hospital, health plan*)

Measure Specified to Measure Performance of: (*must be consistent with levels entered in item S.26*)	**Measure Tested at Level of:**
☐ individual clinician	☐ individual clinician
☐ group/practice	☐ group/practice
☐ hospital/facility/agency	☐ hospital/facility/agency
☐ health plan	☐ health plan
☐ other: Integrated Delivery System	☐ other:

1.5. How many and which measured entities were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of measured entities included in the analysis (e.g., size, location, type); if a sample was used, describe how entities were selected for inclusion in the sample*)

There were a total of 2,110 providers in the data set. Because providers with small volumes may provide unreliable estimates, we excluded any with fewer than 10 attributed episodes prior to the reliability calculations. After this exclusion, there were 81 providers left.

1.6. How many and which patients were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of patients included in the analysis (e.g., age, sex, race, diagnosis); if a sample was used, describe how patients were selected for inclusion in the sample*)

After exclusions (see 2b.3.1 below), there were a total of 6,025 episodes of HF were included in the testing and analysis. Patients in these episodes were, on average, 53.4 years of age (range 18-64) and 38% were female. We did not have race information on these patients. All patients for this analysis had a trigger inpatient claim of HF as identified in our code tables.

1.7. If there are differences in the data or sample used for different aspects of testing (e.g., reliability, validity, exclusions, risk adjustment), identify how the data or sample are different for each aspect of testing reported below.

For the reliability analysis, we restricted the data to only providers with at least 10 attributed episodes. For risk adjustment, all episodes were used in the analysis, regardless of the provider to which they were attributed.

1.8 What were the patient-level sociodemographic (SDS) variables that were available and analyzed in the data or sample used? For example, patient-reported data (e.g., income, education, language), proxy variables when SDS data are not collected from each patient (e.g. census tract), or patient community characteristics (e.g. percent vacant housing, crime rate).
None of the analyses included SDS variables.

2a2. RELIABILITY TESTING
***Note**: If accuracy/correctness (validity) of data elements was empirically tested, separate reliability testing of data elements is not required – in 2a2.1 check critical data elements; in 2a2.2 enter "see section 2b2 for validity testing of data elements"; and skip 2a2.3 and 2a2.4.*

2a2.1. What level of reliability testing was conducted? (*may be one or both levels*)
☐ **Critical data elements used in the measure** (*e.g., inter-abstractor reliability; data element reliability must address ALL critical data elements*)
☐ **Performance measure score** (e.g., *signal-to-noise analysis*)

2a2.2. For each level checked above, describe the method of reliability testing and what it tests (*describe the steps—do not just name a method; what type of error does it test; what statistical analysis was used*)

We assessed the reliability of the measure to demonstrate that it sufficiently differentiates performance between providers using the beta-binomial method, which is applicable to measures of this type. Reliability is a measure that distinguishes the signal (the extent of performance variation between entities that is due to true differences in performance) from statistical noise. Our approach follows directly from the methods outlined in the technical report "The Reliability of Provider Profiling: A Tutorial" by J.L. Adams.

Reference:

Adams JL. The Reliability of Provider Profiling: A Tutorial. Rand Corporation. http://www.rand.org/pubs/technical_reports/TR653.html.

2a2.3. For each level of testing checked above, what were the statistical results from reliability testing? (e.*g., percent agreement and kappa for the critical data elements; distribution of reliability statistics from a signal-to-noise analysis*)

The table below provides a summary of the reliability score for different minimum sample size thresholds. For complete results, refer to the workbook entitled, NQF_HF_all_codes_risk_adjustment_06.30.15.xls, under the "ProviderAttribution Reliability" tab to see provider-specific results.

Reliability Scores	Minimum # Episodes Per Provider		
	>=10	>=25	>=50
# of Providers (%)	81 (100)	27 (33)	13 (16)
Median (IQR)	0.61 (0.52,0.75)	0.80 (0.75,0.85)	0.85 (0.83,0.87)
Range	0.43-0.94	0.69-0.94	0.80-0.94

2a2.4 What is your interpretation of the results in terms of demonstrating reliability? (i.*e., what do the results mean and what are the norms for the test conducted?*)

Reliability scores can vary from 0.0 to 1.0, with a score of zero indicating that all variation is attributable to measurement error (noise, or variation across patients within providers) whereas a reliability of 1.0 implies that all variation is caused by real difference in performance across accountable entities.

There is not a clear cut-off for minimum reliability level. Values above 0.7, however, are considered sufficient to see differences between some physicians and the mean, and values above 0.9 are considered sufficient to see differences between pairs of physicians (see Adams, 2009 cited above).

Although there was a wide range of scores across all providers with at least 10 episodes and scores for many were generally low, those among providers with 25 or more episodes were consistently good and continued to improve as provider sample size increased. This demonstrates that for providers with a minimum number of episodes the measure sufficiently differentiates performance.

Minimum sample size requirements for PAC measures are a function of the reliability testing of the measures on every dataset on which the measures are applied. Our research suggests that minimum sample sizes to achieve high degrees of reliability in the measures are a function of the dataset analyzed, and as such may vary from dataset to dataset. One should not infer that a minimum sample size achieved in one dataset would apply to another.

2b2. VALIDITY TESTING

2b2.1. What level of validity testing was conducted? (*may be one or both levels*)

☐ **Composite performance measure score**

☐ **Empirical validity testing**

☐ **Systematic assessment of face validity of performance measure score as an indicator** of quality or resource use (*i.e., is an accurate reflection of performance on quality or resource use and can distinguish good from poor performance*)

☐ **Systematic assessment of content validity**

☐ **Validity testing for component measures** *(check all that apply)*

***Note**: applies to ALL component measures, unless already endorsed or are being submitted for individual endorsement.*

☐ **Endorsed (or submitted) as individual performance measures**

☐ **Critical data elements** (*data element validity must address ALL critical data elements*)

☐ **Empirical validity testing of the component measure score(s)**

☐ **Systematic assessment of face validity of component measure score(s) as an indicator** of quality or resource use (*i.e., is an accurate reflection of performance on quality or resource use and can distinguish good from poor performance*)

2b2.2. For each level of testing checked above, describe the method of validity testing and what it tests (*describe the steps—do not just name a method; what was tested, e.g., accuracy of data elements compared to authoritative source, relationship to another measure as expected; what statistical analysis was used)*

Content validity was built into the development of the definitions of potentially avoidable complications (PACs). This involved working with clinicians who are experts in their respective fields and specific to the episodes for which PACs are being measured. In particular, the clinical experts focused on whether or not a potentially avoidable complication can be deemed as such for a specific episode of care, and help defined and review all of the diagnosis and procedure codes for each PAC. The enclosed link lists clinicians who have participated in the various Clinical Working Groups (http://www.hci3.org/content/clinical-working-group-contributors). Some of the clinical experts have also participated in monthly webinars that highlight the clinical aspects of these measures (http://www.hci3.org/content/using-ecrs-providers).

In addition, we illustrate that our measure has face validity in several ways.

Beyond the up front work performed by clinical experts, the validity of the measure has also been tested in various real world settings. For example, we have presented results of claims data analyses that reveal the frequency and costs of PACs to physicians in several different healthcare systems involved in our pilot site implementations, as well as to medical directors from the employer coalitions and the health plans that provided the dataset to run the analyses. Some of these implementations include the Pennsylvania Employee Benefits Trust Fund and local provider groups and hospital, Horizon Blue Cross Blue Shield of NJ and many physicians and health systems.

In addition, we have performed dozens of analyses of very large claims data sets and reported results of rates and costs of PACs to policy makers, health plan leaders and physician leaders from different states. These include:

- Vermont Payment Reform Commission
- Maine Health Management Coalition
- WellPoint / Anthem CT
- NY State Medicaid
- CT Medicaid

- CO All-payer Claims Database, Center for Improving Value in Health Care

These analyses and their results have influenced, and continue to influence, the development of various public reporting, payment reform and delivery system reform efforts. To-date, we have never experienced either wholesale or partial rejection of the results of analyses showing rates of PACs, which demonstrates the level of acceptability – face validity – of the measures from the payer, policymaker, employer and payer communities.

As importantly, measures of potentially avoidable complications have face-validity with consumers. In a series of focus groups, Judy Hibbard and colleagues[1] examined the impact of presenting information about price and quality of certain providers in influencing the decisions of consumers. They tested the validity of PACs as a discriminator of quality, as well as other measures of quality, and used the dollar symbol to illustrate the level of price, much like is done for restaurant reviews. When the PAC measure was used, respondents selected the providers with the lowest PAC rates with a high level of confidence in choice, and used it as a surrogate for a strong quality signal. To the contrary, when more standard measures of quality were used, consumers tended to ignore them and use price as a surrogate for quality. As such, what the researchers found is that the very framing of potentially avoidable complications as an indicator of potential harm, is an effective way of communicating the quality of care. And when measures of PACs were presented in conjunction with price, consumers intuitively accepted the logical relationship between low PACs – fewer "defects" – and lower price.

Finally, our measure definitions encompass several other measures that are accepted as being valid complications of care and are widely used throughout the country. These include CMS defined Hospital Acquired Conditions (HACs)[2], Hospital Inpatient Quality Reporting measures [3], Avoidable Readmissions [4,5], AHRQ defined patient safety indicators (PSIs) [6], NQF endorsed patient safety measures such as patient fall rates, pressure ulcer rates, and peri-operative pulmonary embolism or deep vein thrombosis rates [7].

2b2.3. What were the statistical results from validity testing? (*e.g., correlation; t-test*)
Not applicable.

2b2.4. What is your interpretation of the results in terms of demonstrating validity? (i.*e., what do the results mean and what are the norms for the test conducted?*)

Given the significant clinical input that went into developing the measure, the widespread use and acceptance the measure has gained among a wide variety of individuals and organizations across the health system (public and private payers, clinicians, consultants, patients, etc.) [1-13], and the parallels between this measure and other measures that are in widespread use, this demonstrates that the measure has strong face validity.

_____

2b3. EXCLUSIONS ANALYSIS

NA ☐ no exclusions — *skip to section 2b4*

2b3.1. Describe the method of testing exclusions and what it tests (*describe the steps—do not just name a method; what was tested, e.g., whether exclusions affect overall performance scores; what statistical analysis was used*)

Exclusions included exclusions of "patients" as well as "claims" not relevant to HF care. Please refer to the enclosed excel workbook entitled (NQF_HF_all_codes_risk_adjustment_06.30.15.xls)

1. "Patients" are excluded from the measure if they meet one of the following criteria:
a. If age is < 18 years
b. If gender is missing
c. If they do not have continuous enrollment for the entire time window with a maximum of 30 day enrollment gap with the entity providing the data (this helps determine if the database has captured most of the claims for the patient in the time window).
d. If the patient does not have at least 12 months of claims in the database (this helps eliminate incomplete episodes).
e. The episode cost is an outlier (less than 1st percentile or greater than 99th percentile value for all episodes of the same type). This eliminates extreme variation that may result from random outlier events.

2. "Claims" are excluded from the measure if they meet one of the following criteria:
a. If none of the diagnosis codes on the claim are on the list of "triggers" or relevant diagnosis codes (either typical Dx or PAC Dx) for HF.
b. If none of the procedure / CPT codes on the claim are on the list of relevant procedure codes for HF.
c. If the HF trigger hospitalization also triggers a major surgical procedure such as coronary bypass procedure or angioplasty, suggesting that HF may be a comorbidity or an indication for the surgery.
d. The "principal" diagnosis on an inpatient stay claim during the episode time window triggers its own episode
e. The procedure code on a claim during the episode time window triggers its own episode

2b3.2. What were the statistical results from testing exclusions? (*include overall number and percentage of individuals excluded, frequency distribution of exclusions across measured entities, and impact on performance measure scores*)

We started with a total HF population of 25,284 episodes. After all the exclusions were applied, the remaining HF population included in the analysis consisted of 6,025 episodes. As mentioned above, no real exclusions were done. The only patients excluded were the ones that had incomplete or missing data and those that would not have given a homogenous population such as outliers. As such, no formal exclusion testing was done.

2b3.3. What is your interpretation of the results in terms of demonstrating that exclusions are needed to prevent unfair distortion of performance results? (*i.e., the value outweighs the burden of increased data collection and analysis. Note: **If patient preference is an exclusion**, the measure must be specified so that the effect on the performance score is transparent, e.g., scores with and without exclusion*)

No formal analysis was done on the impact of exclusions on performance scores.

Descriptive Explanation:

Exclusions of patients were for the following reasons. Some are for comparative purposes and some for medical reasons.

(a) Comparative Purposes:
We excluded patients that did not have complete enrollment for the entire episode time window. This was done to ensure that the database had complete information on patients to be able to create the entire episode. Including patients with only a partial episode window could distort the measure by artificially reducing the actual count of patients with PACs.

(b) Medical Reasons:
Patients with outlier costs (less than 1st percentile value or greater than 99th percentile) were considered to be different from the general pool, and excluded from both the numerator and the denominator. This is another way to ensure that episodes are complete (because incomplete episodes may have very low costs), and do not bring in random noise into the analysis due to inappropriate codes or services (high outliers).

2b4. RISK ADJUSTMENT/STRATIFICATION FOR OUTCOME OR RESOURCE USE MEASURES
If not an intermediate or health outcome, or PRO-PM, or resource use measure, skip to section 2b5.

2b4.1./S13 What method of controlling for differences in case mix is used?

☐ **No risk adjustment or stratification**
☐ **Statistical risk model with 170 potential risk factors** and episode specific subtypes
☐ **Stratification by** Click here to enter number of categories **risk categories**
☐ **Other,** Click here to enter description

2b4.1.2. If an outcome or resource use measure is not risk adjusted or stratified, provide rationale and analyses to demonstrate that controlling for differences in patient characteristics (case mix) is not needed to achieve fair comparisons across measured entities.

2b4.2/S14. Identify the statistical risk model variables (Name the statistical method – e.g., logistic regression and list all the risk factor variables.
A number of patient-related "risk factors" or covariates are included in the models:

Patient demographics: age, gender, and an indicator of whether a member has enrolled within the previous 6 months. This latter risk factor is intended to account for the patient's lack of claims history, which limits the number of potential comorbidities that can be identified.

Comorbidities: These are conditions or events that occurred prior to the start of the episode that can have a potential impact on the patient's risk of having a PAC. The risk factors are 170 disease indicators (0/1) identified through the presence of ICD diagnosis codes on individual medical claims and collected from the historical claims data before the start of an episode. These are universally applied across all episodes. Please see the tab labeled "All Risk Factors I-9" and "All Risk Factors I-10" for a list of risk factors and their corresponding codes in the enclosed workbook called NQF_HF_all_codes_risk_adjustment_06.30.15.xls. This list was selected based on input from clinical experts in clinical working groups.

Episode Subtypes or Severity Markers: These are markers that distinguish an episode as being more severe than another. They indicate either specific patient comorbidities that are known to make the procedure or condition more difficult to treat (e.g., obesity) or severity of the illness itself (e.g., Cardiomyopathy). Subtypes are specific to each unique episode and are included in the models only if they are present at the start of the episode. Please see the tab labeled "Subtypes I-9" and "Subtypes I-10" for a list of subtypes and their corresponding codes in the enclosed workbook called NQF_HF_all_codes_risk_adjustment_06.30.15.xls. This list was selected based on input from clinical experts in clinical working groups.

Candidate comorbidities and subtypes were included in the models as covariates if they were present in at least 10 episodes to prevent unstable coefficients.

2b4.2.1/S15. Detailed risk model specifications including coefficients, equations, codes with descriptors, definitions(may be attached in an Excel or cvs file)
All Risk Factors with their coefficients are detailed in the enclosed workbook called NQF_HF_all_codes_risk_adjustment_06.30.15.xls – Please reference the tabs titled Risk Factor Prevalence and Risk Model.

2b4.3. Describe the conceptual/clinical and statistical methods and criteria used to select patient factors (clinical factors or sociodemographic factors) used in the statistical risk model or for stratification by risk(*e.g., potential factors identified in the literature and/or expert panel; regression analysis; statistical significance of p<0.10; correlation of x or higher; patient factors should be present at the start of care*)

Risk factors are comorbidity indicators collected from historical claims before the start of an episode. These are universally applied across all episodes. This list was selected based on input from clinical experts in clinical working groups. In addition, the Clinical Working Groups identified episode specific severity markers that were called episode subtypes and they help distinguish an episode as being more severe than another.

All risk factors and subtypes must be present prior to, or at the start of the episode and are identified using diagnosis codes in the patient's historical claims.

To be included in the risk adjustment models, any risk factor or subtype must be present in at least 10 episodes. Beyond this no further model building was conducted to add or remove risk factors or subtypes from the model after it was initially run. This reflects a desire to explain as much variation in the probability of having a PAC as possible, but does not make it a priority that all covariates be individually significant or even uncorrelated with each other. Accordingly, the model uses a very large group of covariates. This modeling approach allows for fewer potentially artificial constraints around the definitions of what constitutes severity, and lets the model determine for itself which of the factors are more significant. Non-significant covariates cannot overly influence the predicted outcomes, nor is much harm realized, if a group of correlated covariates work together to explain variation rather than having the variation explained by a single best factor.

2b4.4a. What were the statistical results of the analyses used to select risk factors?
As explained above, no formal analysis was conducted to select risk factors. In fact, all potential risk factors and subtypes with a count of at least 10 episodes were retained to serve as predictors. The goal was to achieve a more complete explanatory model rather than achieve parsimony.

Please reference the tabs titled Risk Model in the NQF_HF_all_codes_risk_adjustment_06.30.15.xls workbook to see the list of risk factors that met the selection criteria.

2b4.4b. Describe the analyses and interpretation resulting in the decision to select SDS factors (e.g. prevalence of the factor across measured entities, empirical association with the outcome, contribution of unique variation in the outcome, assessment of between-unit effects and within-unit effects)
Not Applicable since our analysis did include SDS variables

2b4.5. Describe the method of testing/analysis used to develop and validate the adequacy of the statistical model or stratification approach (*describe the steps—do not just name a method; what statistical analysis was used*)

Model Development Approach

We used logistic regression to model the probability of at least one PAC occurring during the episode. The model included all covariates that were identified through the process above. No further model building was conducted after the initial model was run. This reflects a desire to explain as much variation in the probability of having a PAC as possible, but does not make it a priority that all covariates be individually significant or even uncorrelated with each other. Accordingly, the model uses a very large group of covariates. This modeling approach allows for fewer potentially artificial constraints around the definitions of what constitutes severity, and lets the model determine for itself which of the factors are more significant. Non-significant covariates can not overly influence the predicted outcomes, nor is much harm realized, if a group of correlated covariates work together to explain variation rather than having the variation explained by a single best factor.

For a more complete description of the risk adjustment approach, please see the document entitled, "PACs and Severity Adjustment Fact Sheet" that accompanies this submission.

Approach to Model Testing and Validation

To determine the validity and performance of the model, we used the split sample method to divide the patient sample randomly into: 1) the model building data set (80% of the sample) and 2) the test data set (20% of sample. The model was built using logistic regression on the first data set and then the coefficients from the development model were tested in the second dataset. Area under the curve (AUC) and the c-statistic were used to compare the predictive ability of the model in each of the data sets. Hosmer-Lemeshow Goodness-of-Fit tests and comparisons of observed to expected probabilities across risk deciles were further examined to assess the model's overall predictive accuracy.

Provide the statistical results from testing the approach to controlling for differences in patient characteristics (case mix) below.

If stratified, skip to 2b4.9

2b4.6. Statistical Risk Model Discrimination Statistics (*e.g., c-statistic, R-squared*)**:**

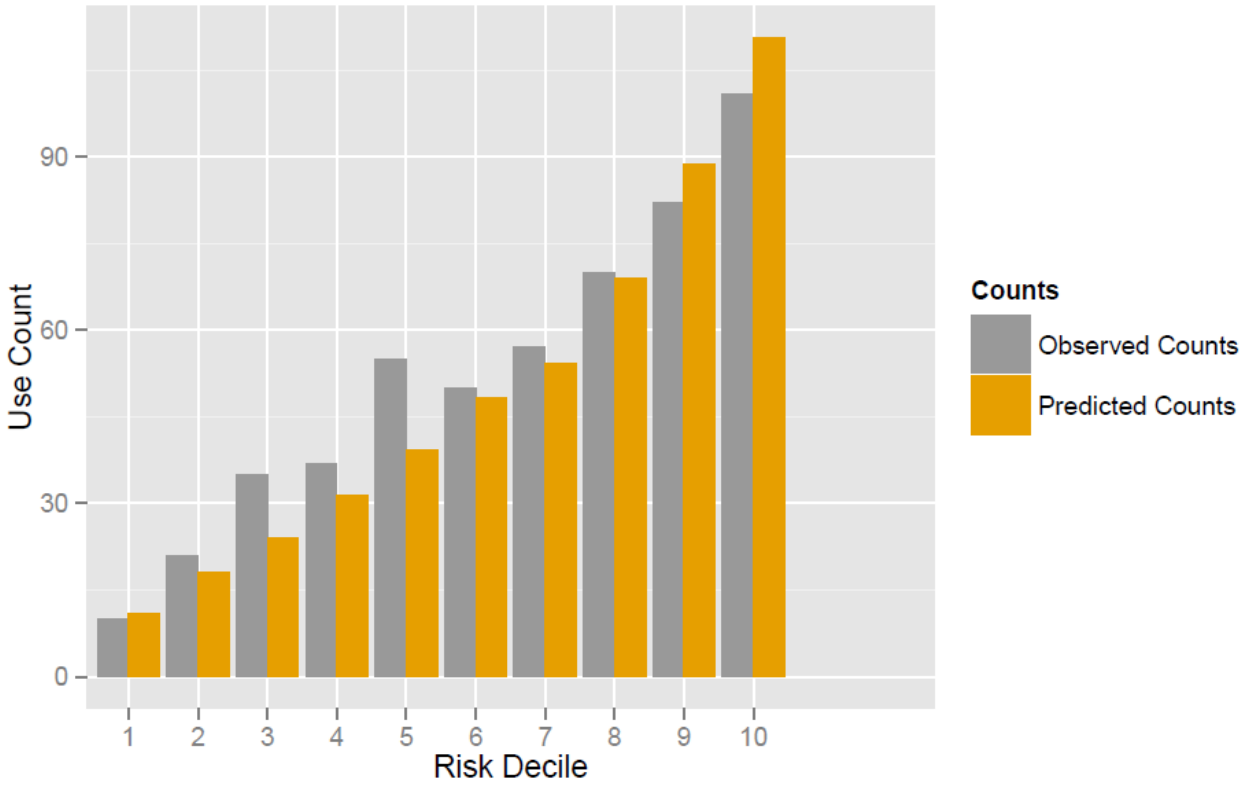
Sample	Accuracy (%)*	AUC
Test	73.5%	0.807
Validation	68.8%	0.754

*Episodes with predicted probabilities <50% were classified as having a predicted 0 (not having a PAC). Episodes with predicted probabilities >50% were classified as having a predicted 1 (having a PAC)

2b4.7. Statistical Risk Model Calibration Statistics (*e.g., Hosmer-Lemeshow statistic*):

Sample	Chi Square	Degrees of Freedom	p-value
Test	31.6	8	<0.0001
Validation	30.6	8	<0.0001

2b4.8. Statistical Risk Model Calibration – Risk decile plots or calibration curves:



2b4.9. Results of Risk Stratification Analysis:
Not applicable

2b4.10. What is your interpretation of the results in terms of demonstrating adequacy of controlling for differences in patient characteristics (case mix)? (i*.e., what do the results mean and what are the norms for the test conducted*)

The C statistic is a measure of the extent to which a statistical model is able to discriminate between a patient with and without an outcome. The c-statistic ranges from 0.5 to 1.0. A c-statistic of 0.50 indicates the model is no better than random prediction, implying that the patient risk factors do not predict variation in the outcome; conversely, a c-statistic of 1.0 indicates perfect prediction, implying patients' outcomes can be predicted completely by their risk factors, and physicians and hospitals play little role in patients' outcomes. Models with c-statistic values of at least 0.7 are considered good and those above 0.8 are considered strong [1]. The purpose of the model is to adjust for patient-related factors. The remaining unexplained differences in PAC rates are due to factors that could be controlled by all providers that are managing or co-managing the patient, during the entire episode time window.

The c-statistics of the testing and validation samples (0.807 and 0.754, respectively) indicate that the risk models have good discriminatory power. Indeed, the accuracy values show that the model correctly predicts whether an episode had or did not have a PAC 69% to 74% of the time, well above what would be expected if the predictions were made at random (i.e., 50%). Although the H-L test was significant for the testing sample, meaning that the model is not a good fit, this test is generally known to be sensitive to the number of groupings used and sample sizes. Nevertheless, the risk decile plot indicates, that, other than decile 5, the models predict PACs similarly to observed PACs across the risk deciles.

Overall, the results indicate the models have sufficient predictive power.

2b4.11. Optional Additional Testing for Risk Adjustment (*not required, but would provide additional support of adequacy of risk model, e.g., testing of risk model in another data set; sensitivity analysis for missing data; other methods that were assessed*)
Not applicable

_____

2b5. IDENTIFICATION OF STATISTICALLY SIGNIFICANT & MEANINGFUL DIFFERENCES IN PERFORMANCE
2b5.1. Describe the method for determining if statistically significant and clinically/practically meaningful differences in performance measure scores among the measured entities can be identified (*describe the steps—do not just name a method; what statistical analysis was used? Do not just repeat the information provided related to performance gap in 1b)*

To directly compare PAC rates across providers while also appropriately accounting for differences in patient severity, we calculated a risk-standardized PAC rate for each provider. This method is similar to calculations used by others for reporting outcomes measures [1]. For each provider, the ratio of observed attributed episodes with PACs to the expected number of attributed episodes with PACs given the patient's risk factor and estimated from the risk-adjustment model was calculated. This number yielded whether the provider had more PACs than expected (ratio>1), as expected (ratio=1), or less than expected (ratio<1). We then multiplied this ratio by the overall expected PAC rate across all providers to obtain the risk-standardized PAC rate for the provider. This measure represents what a provider's PAC rate would be if its patient population was reflective of the overall population.

Because providers with small volumes may provide unreliable estimates, we excluded any with fewer than 10 attributed episodes prior to the calculations. Comparison of risk-adjusted PAC rates gives a measure of the provider's relative performance. Our analysis compared risk-standardized PAC rates across providers. We analyzed various descriptive statistics including the range in PAC rates, medians, interquartile range, etc.

References:

[1] See, for example: NQF#1550: Hospital-level risk-standardized complication rate (RSCR) following elective primary total hip arthroplasty (THA) and / or total knee arthroplasty (TKA). Online version: http://bit.ly/1BWQTRt

2b5.2. What were the statistical results from testing the ability to identify statistically significant and/or clinically/practically meaningful differences in performance measure scores across measured entities? (e.g., *number and percentage of entities with scores that were statistically significantly different from mean or some benchmark, different from expected; how was meaningful difference defined*)

Summary of Unadjusted and Adjusted Performance Scores Across Providers:

PAC Rates	Minimum # Episodes Per Provider	
	>=10	>=25
Unadjusted		
Median (IQR)	41% (31%, 57%)	36% (23%, 42%)
Range	9%-80%	10%-79%
Adjusted (RSPR)*		
Median (IQR)	40% (32%, 46%)	37% (30%, 44%)
Range	14%-68%	14%-50%

***RSPR = Risk Standardized PAC Rate**

Please refer to the NQF_HF_all_codes_risk_adjustment_06.30.15.xls workbook under the "ProviderAttribution Reliability" tab to see specific results for each provider.

2b5.3. What is your interpretation of the results in terms of demonstrating the ability to identify statistically significant and/or clinically/practically meaningful differences in performance across measured entities? (i*.e., what do the results mean in terms of statistical and meaningful differences?*)
Even after right-adjustment, the variation in risk-adjusted rates suggests there are meaningful differences in performance between providers in risk-standardized PAC rates for patients with an episode of HF.

Minimum sample size requirements for PAC measures are a function of the reliability testing of the measures on every dataset on which the measures are applied. Our research suggests that minimum sample sizes to achieve high degrees of reliability in the measures are a function of the dataset analyzed, and as such may vary from dataset to dataset. One should not infer that a minimum sample size achieved in one dataset would apply to another.

2b6. COMPARABILITY OF PERFORMANCE SCORES WHEN MORE THAN ONE SET OF SPECIFICATIONS
If only one set of specifications, this section can be skipped.

Note*: This criterion is directed to measures with more than one set of specifications/instructions (e.g., one set of specifications for how to identify and compute the measure from medical record abstraction and a different set of specifications for claims or eMeasures). It does not apply to measures that use more than one source of data in one set of specifications/instructions (e.g., claims data to identify the denominator and medical record abstraction for the numerator).* ***Comparability is not required when comparing performance scores with and without SDS factors in the risk adjustment model. However, if comparability is not demonstrated for measures with more than one set of specifications/instructions, the different specifications (e.g., for medical records vs. claims) should be submitted as separate measures.***

2b6.1. Describe the method of testing conducted to demonstrate comparability of performance scores for the same entities across the different data sources/specifications (*describe the steps—do not just name a method; what statistical analysis was used*)

2b6.2. What were the statistical results from testing comparability of performance scores for the same entities when using different data sources/specifications? (*e.g., correlation, rank order*)

2b6.3. What is your interpretation of the results in terms of demonstrating comparability of performance measure scores for the same entities across the different data sources/specifications? (i.*e., what do the results mean and what are the norms for the test conducted*)

2b7. MISSING DATA ANALYSIS AND MINIMIZING BIAS

2b7.1. Describe the method of testing conducted to identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias (*describe the steps—do not just name a method; what statistical analysis was used*)

If patient related data is missing, the entire patient is excluded from the numerator as well as the denominator.

Within our measure constructs, presence of potentially avoidable complications are identified from administrative claims data. Furthermore, the measure is constructed so that the occurrence of any number of PACs during a defined episode would only count as one occurrence.

According to our measure definition, in constructing the measure it is possible for a provider to have only one or some types of PACs and not others. Alternatively, the provider may have all PAC types occur for their patients. The measure only considers whether any PAC occurred regardless of the type, and all PAC types are weighted equally, therefore we believe, there is no potential for the absence of specific PAC types to bias performance scores for individual providers.

For these reasons, no formal analyses were done on missing data

2b7.2. What is the overall frequency of missing data, the distribution of missing data across providers, and the results from testing related to missing data? (*e.g., results of sensitivity analysis of the effect of various rules for missing data/nonresponse; if no empirical sensitivity analysis, identify the approaches for handling missing data that were considered and pros and cons of each*)
Not applicable

2b7.3. What is your interpretation of the results in terms of demonstrating that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias**?** (i.*e., what do the results mean in terms of supporting the selected approach for missing data and what are the norms for the test conducted; if no empirical analysis, provide rationale for the selected approach for missing data*)

Not applicable

2d. EMPIRICAL ANALYSIS TO SUPPORT COMPOSITE CONSTRUCTION APPROACH

Note: *If empirical analyses do not provide adequate results—or are not conducted—justification must be provided and accepted in order to meet the must-pass criterion of Scientific Acceptability of Measure Properties. Each of the following questions has instructions if there is no empirical analysis.*

2d1. Empirical analysis demonstrating that the component measures fit the quality construct, add value to the overall composite, and achieve the object of parsimony to the extent possible.

The PAC measures, as we define them, look at many "care defects" comprehensively. They are composed of several cross-cutting measures and together they paint a global picture of the provider's overall performance.

PACs may occur any time during the episode time window. PACs are counted as a dichotomous (yes/no) outcome. If a patient had one or more PACs, they get counted as a "yes" or a 1. The enclosed workbook entitled NQF_HF_all_codes_risk_adjustment_06.30.15.xls provides outputs from empirical analysis. The tab labeled "PAC overview" demonstrates percentage of episodes that had at least one PAC, and provides the breakdown of PACs: 1) by the type of PAC whether directly related to index condition or due to patient safety failures; 2) the setting of the PAC, whether seen in the in-patient setting, out-patient facility or during professional visits; and 3) preventable hospitalizations.

The "PAC Drill Down Graph" provides further detail on each component of the PAC and their frequency. As can be seen by the individual counts and the graph, while each individual PAC may have such small occurrences that no meaningful comparisons in provider performances could be made; together, they add value to provide a comprehensive picture that result in meaningful numbers. The aggregation of PACs to a comprehensive, composite measure, in itself provides the parsimony that is so desirable.

2d1.1 Describe the method used (*describe the steps—do not just name a method; what statistical analysis was used; if no empirical analysis, provide justification)*

All PACs, as clinically defined by the subject matter experts were used with equal weighting. Since the emphasis of the PAC measure is to identify the occurrence of PACs in any setting, a simple and straightforward approach was adopted.

2d1.2. What were the statistical results obtained from the analysis of the components? (e.g., *correlations, contribution of each component to the composite score, etc.*; *if no empirical analysis, identify the components that were considered and the pros and cons of each*)

No formal analysis was performed.

2d1.3. What is your interpretation of the results in terms of demonstrating that the components included in the composite are consistent with the described quality construct and add value to the overall composite? (i.*e., what do the results mean in terms of supporting inclusion of the components; if no empirical analysis, provide rationale for the components that were selected)*

Since our premise is that all PACs are potentially avoidable, we adopted the approach to count all PACs and give them equal weights. The overall composite score results in the quality construct that could be measured and interpreted.

2d2. Empirical analysis demonstrating that the aggregations and weighting rules are consistent with the quality construct and achieve the objective of simplicity to the extent possible

2d2.1 Describe the method used (*describe the steps—do not just name a method; what statistical analysis was used; if no empirical analysis, provide justification)*

Within our measure constructs, presence of potentially avoidable complications are identified from administrative claims data. Additionally, if a patient had one or more PACs, it is simply counted as a 1, i.e., flagged as having a PAC. The measure only considers whether any PAC occurred regardless of the type, or the site, and all PAC types are weighted equally. Therefore, no formal analysis of individual components was performed.

2d2.2. What were the statistical results obtained from the analysis of the aggregation and weighting rules? (e.g., *results of sensitivity analysis of effect of different aggregations and/or weighting rules; if no empirical analysis, identify the aggregation and weighting rules that were considered and the pros and cons of each*)

We chose not to weight the components of the measure.

Considerations were given to the fact that preventable hospitalizations may be given more weight, than PACs identified in a doctor's office. Similarly PACs in an in-patient setting may have more serious implications on a patient's ultimate outcome, than PACs occurring in an outpatient setting. Additionally, preventable hospitalizations as well as index hospitalizations, each with longer lengths of stay, may have serious PACs. But how do we weigh these effects? An alternative model was considered, where cost could be considered as a surrogate for the weights. Higher cost PACs could imply more serious PACs. However, differences in costs could be driven by many issues other than the PAC itself, such as unit price of the service, method of reimbursements, contracting arrangements etc.

Furthermore, in-patient facility billing does not allow for the distinction of PAC related costs from other costs within the stay. We would fail to capture PAC related costs within the stay and potentially underweight those. As a result, the decision was made to avoid weighting and keep the measure as a straightforward count.

2d2.3. What is your interpretation of the results in terms of demonstrating the aggregation and weighting rules are consistent with the described quality construct? (i.*e., what do the results mean in terms of supporting the selected rules for aggregation and weighting; if no empirical analysis, provide rationale for the selected rules for aggregation and weighting*)

Measuring all providers with the same yardstick will provide consistent results and reasonable comparisons over time. If the goal is to reduce PACs, then the PAC measure as was constructed with the help of various

experts in the field would provide reasonable comparisons. A word of caution however pertains to the sample size of the provider panel before making any reasonable conclusions.

Minimum sample size requirements for PAC measures are a function of the reliability testing of the measures on every dataset on which the measures are applied. Our research suggests that minimum sample sizes to achieve high degrees of reliability in the measures are a function of the dataset analyzed, and as such may vary from dataset to dataset. One should not infer that a minimum sample size achieved for high reliability in one dataset would apply to another.

2d3. Empirical analysis demonstrating that the approach for handling missing data minimizes bias (*i.e., achieves scores that are an accurate reflection of quality*)**.**

Note: *Applies to the overall composite measure; the focus is on missing data rather than exclusions, which are considered in 2b3.*

Please refer to section 2b7

2d3.1. What is the overall frequency of missing data and the distribution of missing data across providers?

2d3.2. Describe the method used to compare approaches for handling missing data (*describe the steps—do not just name a method; what statistical analysis was used; if no empirical analysis, provide justification)*

2d3.3. What were the statistical results obtained from the analysis of missing data? (e.g., *results of sensitivity analysis of effect of various rules for missing data; if no empirical analysis, identify the approaches for handling missing data that were considered and pros and cons of each*)

2d3.4. What is your interpretation of the results in terms of demonstrating that the approach used for missing data minimizes bias? (i.*e., what do the results mean in terms of supporting the selected approach for missing data; if no empirical analysis, provide rationale for the selected approach for missing data*)

3. Feasibility

Extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

3a. Byproduct of Care Processes

For clinical measures, the required data elements are routinely generated and used during care delivery (e.g., blood pressure, lab test, diagnosis, medication order).

3a.1. **Data Elements Generated as Byproduct of Care Processes.**

Coded by someone other than person obtaining original information (e.g., DRG, ICD-9 codes on claims)

If other:

3b. Electronic Sources

The required data elements are available in electronic health records or other electronic sources. If the required data are not in

electronic health records or existing electronic sources, a credible, near-term path to electronic collection is specified.

3b.1. **To what extent are the specified data elements available electronically in defined fields?** *(i.e., data elements that are needed to compute the performance measure score are in defined, computer-readable fields)*
ALL data elements are in defined fields in electronic claims

3b.2. **If ALL the data elements needed to compute the performance measure score are not from electronic sources, specify a credible, near-term path to electronic capture, OR provide a rationale for using other than electronic sources.**

3b.3. **If this is an eMeasure, provide a summary of the feasibility assessment in an attached file or make available at a measure-specific URL.**
Attachment:

3c. Data Collection Strategy

Demonstration that the data collection strategy (e.g., source, timing, frequency, sampling, patient confidentiality, costs associated with fees/licensing of proprietary measures) can be implemented (e.g., already in operational use, or testing demonstrates that it is ready to put into operational use). For eMeasures, a feasibility assessment addresses the data elements and measure logic and demonstrates the eMeasure can be implemented or feasibility concerns can be adequately addressed.

3c.1. **Describe what you have learned/modified as a result of testing and/or operational use of the measure regarding data collection, availability of data, missing data, timing and frequency of data collection, sampling, patient confidentiality, time and cost of data collection, other feasibility/implementation issues.**
IF a PRO-PM, consider implications for both individuals providing PROM data (patients, service recipients, respondents) and those whose performance is being measured.
As part of our general implementation of these measures and related analyses, we have worked through dozens of different and sometimes very large datasets. From Medicare to Medicaid to regional and national commercial carriers, as well as individual employers, the principal lesson learned is the heterogeneity of the data sets and the significant variability in fill rate of critical data elements. As a result, we have created highly specific recommendations for which data elements are required to ensure measure validity, the accuracy of those data elements, and their completeness in the dataset. When claims datasets are organized in the way we specify in the measure analysis, and contain the coding information required, the analysis of the measure and its results are highly reliable.

3c.2. **Describe any fees, licensing, or other requirements to use any aspect of the measure as specified** *(e.g., value/code set, risk model, programming code, algorithm)*.
The calculations of rates of potentially avoidable complications can be replicated by anyone that uses the measure specifications along with the metadata file that is available for free on our web site at http://www.hci3.org/ecre/xml-agreement.html.
We also plan on providing a limited automated analysis, at no cost, on our website.

4. Usability and Use

Extent to which potential audiences (e.g., consumers, purchasers, providers, policy makers) are using or could use performance results for both accountability and performance improvement to achieve the goal of high-quality, efficient healthcare for individuals or populations.

4a. Accountability and Transparency

Performance results are used in at least one accountability application within three years after initial endorsement and are publicly reported within six years after initial endorsement (or the data on performance results are available). If not in use at the time of initial endorsement, then a credible plan for implementation within the specified timeframes is provided.

4.1. **Current and Planned Use**
NQF-endorsed measures are expected to be used in at least one accountability application within 3 years and publicly reported within 6 years of initial endorsement in addition to performance improvement.

Planned	Current Use (for current use provide URL)
Public Reporting Professional Certification or Recognition Program Quality Improvement with Benchmarking (external benchmarking to multiple organizations)	Payment Program Blue Cross Blue Shield of North Carolina Blue Cross Blue Shield of New Jersey), Pennsylvania Employee Benefits Trust Fund https://www.bcbsnc.com/ http://www.horizonblue.com/ https://www.pebtf.org/ Quality Improvement (Internal to the specific organization) Blue Cross Blue Shield of North Carolina https://www.bcbsnc.com/

4a.1. **For each CURRENT use, checked above, provide:**

- Name of program and sponsor
- Purpose
- Geographic area and number and percentage of accountable entities and patients included

Measures associated to potentially avoidable complications (PACs) are in use today with some private sector payers and gaining further acceptance among a wide variety of organizations across the health system (public and private payers, clinicians, consultants, all-payer claims database stewards, etc.) [1-8]. They are being used in various capacities in different pilot site implementations. To name a few:

•BCBSA (Blue Cross Blue Shield Association) – uses them for their Centers of Excellence (COE) programs: Blue Distinction
•BCBSNC (Blue Cross Blue Shield of North Carolina) – is using them for tiering providers

In addition, the PAC measures are incorporated by the following organizations in their bundled payment programs:

•BCBSSC – for CABG and PCI programs
•Horizon BCBSNJ– for CHF and CABG programs
•BCBSNC
•PEBTF in PA

http://www.ajmc.com/interviews/Lili-Brillstein-on-How-Bundled-Payments-Are-Tranforming-Healthcare

In these programs they look at PACs related to the measure for process improvement activities and for practice re-engineering.

We have created reports for rates of PACs for the following organizations:
-Vermont Payment Reform
-Maine Health Management Coalition
-WellPoint / Anthem CT
-NY State Medicaid
-CT Medicaid
-CO All-payer Claims Database, Center for Improving Value in Health Care

There are several companies that are leveraging these measures to create analytics and software for customers – these include HealthQx, Aver Informatics, McKesson, and TriZetto.

Below are some references that highlight our work with Potentially Avoidable Complications (PACs).

4a.2. If not currently publicly reported OR used in at least one other accountability application (e.g., payment program, certification, licensing) what are the reasons? (*e.g., Do policies or actions of the developer/steward or accountable entities restrict access to performance results or impede implementation?*)
N/A

4a.3. If not currently publicly reported OR used in at least one other accountability application, provide a credible plan for implementation within the expected timeframes -- any accountability application within 3 years and publicly reported within 6 years of initial endorsement. (*Credible plan includes the specific program, purpose, intended audience, and timeline for implementing the measure within the specified timeframes. A plan for accountability applications addresses mechanisms for data aggregation and reporting.*)
Measures associated with PACs are currently in use as described in the prior section. In addition, we are working with several not-for-profit and for-profit organizations to provide them with the algorithms needed to calculate rates of potentially avoidable complications. Some of these organizations include:

Fair Health – based in NY and whose mission is to increase transparency of provider cost and quality,

CastLight – based in CA and serving large employers. We currently provide CastLight with Bridges To Excellence recognitions and will work with them to augment provider transparency by using PAC measures,

MA APCD (Massachusetts All Payers Claims Database) Council – we currently have an agreement in place with the MA APCD Council to produce PAC measures on hospitals and physicians and report back to the council with tests of reliability and validity of the measures. The purpose is to authorize the publication of these measures,
Maryland Health Care Cost Commission – we have a two year agreement to produce measures of cost and quality for public dissemination.

4b. Improvement

Progress toward achieving the goal of high-quality, efficient healthcare for individuals or populations is demonstrated. If not in use for performance improvement at the time of initial endorsement, then a credible rationale describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.

4b.1. Progress on Improvement. (Not required for initial endorsement unless available.)
Performance results on this measure (current and over time) should be provided in 1b.2 and 1b.4. Discuss:

- **Progress (trends in performance results, number and percentage of people receiving high-quality healthcare)**
- **Geographic area and number and percentage of accountable entities and patients included**

We do not have any public information to share about the improvements in rates of potentially avoidable complications, as the implementation of these measures is too recent to provide valid comparisons. Further, some of the definitions of PACs have changed since the measures were initially endorsed, making comparisons even more difficult and unreliable.

Nevertheless, the variation in performance scores presented in Section 1b.2 indicates that there are differences between providers in their risk-adjusted PAC rates (higher scores equal worse performance). This suggests that real opportunities exist to identify lower performing providers and reduce the overall occurrence of PACs.

4b.2. **If no improvement was demonstrated, what are the reasons? If not in use for performance improvement at the time of initial endorsement, provide a credible rationale that describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.**
Performance results provide summary PACs rates by provider, which can be used by payers and providers in a number of ways to improve the quality of care.

From the payer perspective, payers can use this information to 1) create a high-value provider networks, 2) work with high-value providers to share best practices, 3) incentivize low-value providers to improve, 4) modify their insurance design to activate consumers to select the right care from the right providers at the right time.

From the provider perspective, providers can 1) view services and activity for their patients longitudinally across the entire care continuum, such as frequency of readmissions and ED visits and drill down on patients with high PAC rates, 2) review actionable drill down reports to identify the most frequent PACs across all patients to create care pathways and process improvement plans to impact the most frequent PACs.

4c. Unintended Consequences

The benefits of the performance measure in facilitating progress toward achieving high-quality, efficient healthcare for individuals or populations outweigh evidence of unintended negative consequences to individuals or populations (if such evidence exists).

4c.1. **Were any unintended negative consequences to individuals or populations identified during testing; OR has evidence of unintended negative consequences to individuals or populations been reported since implementation? If so, identify the negative unintended consequences and describe how benefits outweigh them or actions taken to mitigate them.**
No unintended consequences were reported, but there is the potential for:
1. Under-coding of PACs in the claim stream resulting in under-reporting the actual rate and/or providers gaming the measures
2. Payers calculating the measures even with inadequate sample sizes and using the results to penalize providers

The measure is designed for transparency efforts and to spur quality improvement. Detailed PAC reports can help providers identify areas of quality improvement. Even detailed reports of small samples of patients can be helpful for quality improvement purposes, but not for public reporting. To mitigate the potential for invalid provider comparisons, we specify in this submission the minimum sample size needed to ensure the reliability of a provider's score. Ultimately, there isn't any good way to prevent provider gaming of the measure by under-coding claims, however, under the current DRG payment methodology, many providers would be penalized by under-coding PACs since these codes often result in the assignment of more complicated DRGs.

5. Comparison to Related or Competing Measures

If a measure meets the above criteria and there are endorsed or new related measures (either the same measure focus or the same target population) or competing measures (both the same measure focus and the same target population), the measures are compared to address harmonization and/or selection of the best measure.

5. Relation to Other NQF-endorsed Measures
Are there related measures (conceptually, either same measure focus or target population) or competing measures (conceptually both the same measure focus and same target population)? If yes, list the NQF # and title of all related and/or competing measures.
Yes

5.1a. **List of related or competing measures (selected from NQF-endorsed measures)**
0330 : Hospital 30-day, all-cause, risk-standardized readmission rate (RSRR) following heart failure (HF) hospitalization
0337 : Pressure Ulcer Rate (PDI 2)
0450 : Perioperative Pulmonary Embolism or Deep Vein Thrombosis Rate (PSI 12)
0705 : Proportion of Patients Hospitalized with Stroke that have a Potentially Avoidable Complication (during the Index Stay or in the

30-day Post-Discharge Period)
0708 : Proportion of Patients Hospitalized with Pneumonia that have a Potentially Avoidable Complication (during the Index Stay or in the 30-day Post-Discharge Period)
0709 : Proportion of patients with a chronic condition that have a potentially avoidable complication during a calendar year.
1789 : Hospital-Wide All-Cause Unplanned Readmission Measure (HWR)

5.1b. **If related or competing measures are not NQF endorsed please indicate measure title and steward.**
-0531 Patient Safety for Selected Indicators (Composite Measure, AHRQ) (endorsed)
-CMS defined hospital acquired conditions (HACs) are a subset of our PACs. We have pain-stakingly matched the definitions to provide as much consistency as possible. http://www.cms.gov/Medicare/Quality-Initiatives-Patient-Assessment-Instruments/HospitalQualityInits/HospitalRHQDAPU.html

5a. Harmonization

The measure specifications are harmonized with related measures;
OR
The differences in specifications are justified

5a.1. **If this measure conceptually addresses EITHER the same measure focus OR the same target population as NQF-endorsed measure(s):**
Are the measure specifications completely harmonized?
No

5a.2. **If the measure specifications are not completely harmonized, identify the differences, rationale, and impact on interpretability and data collection burden.**
Some of the measures listed in the prior section are, fully harmonized with the submitted measure, in particular, 0705, 0708, and 0709. Other measures such as 0337 and 0450 are in fact, subsets of our measure. However, there are some measures that are not harmonized, in particular the 30-day all-cause readmission measures and the Hospital wide all-cause readmission measure. While the submitted PAC measure include hospitalizations and readmissions that occur during the episode time window, the hospitalizations, by definition, have to be relevant to the underlying condition. For chronic conditions, most relevant hospitalizations within the entire episode time window are considered potentially avoidable. PACs include readmissions and are designed to enable accountability at the locus of provider control as well as some shared accountability between settings, centered around a patient, and for a specific medical episode of care. In that sense, they are consistent with the all-cause 30-day readmission rates, but represent a subset of those admissions. However, they do extend to the entire episode time window. As such, the PAC measures, as submitted, don't create added burden of reporting because the readmissions reported are simply a part of the broader 30-day all-cause readmission measures already endorsed by NQF. Because PAC measures are comprehensive, they include patient safety events as well as other adverse events, including hospitalizations and ED visits during the entire continuum of care. As a result, they are a comprehensive measure of avoidable complications for a specific medical episode. The data collection for all of the HCI3 measures is automated by a software package and is fully harmonized with all other PAC measures. A single download automates creation of all reports related to each of the PAC measures.

5b. Competing Measures

The measure is superior to competing measures (e.g., is a more valid or efficient way to measure);
OR
Multiple measures are justified.

5b.1. **If this measure conceptually addresses both the same measure focus and the same target population as NQF-endorsed measure(s):**
Describe why this measure is superior to competing measures (e.g., a more valid or efficient way to measure quality); OR provide a rationale for the additive value of endorsing an additional measure. (Provide analyses when possible.)
PAC measures are composite measures representing "all-cause harms". They look at many "care defects" comprehensively. They are composed of several cross-cutting measures and together they paint a global picture of the provider's overall performance.

PACs may occur any time during the episode time window. Furthermore, the measure is constructed so that the occurrence of any number of PACs during a defined episode would only count as one occurrence. PACs look at readmissions, emergency room visits, adverse events due to errors of omission or commission. They look at complications that are due to patient safety failures, and also

those directly related to the index condition. These are all a cause of significant waste and quality concerns. As such, the measure can provide clinicians with an overall and comprehensive view, in one measure, of all potentially avoidable complications for a patient and drive quality improvement efforts.

For clinicians and facilities increasingly engaged in value-based payment efforts and/or driving quality improvement for population health, the value of a PAC measure over a series of related, but more discrete measures, is that one can better determine if the sources of complications primarily stem from activities within the facility or outside the facility, and the specific nature of the complications that have a higher frequency of occurrence. While individual components of the PAC measure may have small frequencies and may be difficult to interpret with regards to provider performance or actionability, aggregating all the PACs into a comprehensive, composite measure provides the parsimony that is so desirable. For providers, it's far easier to construct a quality dashboard from a parsimonious set of measures, and that's what PAC measures offer.

Further, as a comprehensive outcome measure, PACs are also useful for public transparency of quality, as substantiated by the research from Judy Hibbard and colleagues previously cited in the "testing" section of this submission. As a comprehensive outcome measure, they are easier to explain to the average consumer. From a patient's point of view, any bad outcome has an impact on their health with respect to return to work, functional limitations and need for additional support. If a provider has a high PAC rate with regards to one component PAC but not the other PACs, the impact on the patient is still adverse. In selecting providers, individual component PAC scores would mean nothing to a patient, but aggregating it to a comprehensive quality score could be a measure of "all-cause" harms and easier to interpret and act on.

Appendix

A.1 Supplemental materials may be provided in an appendix. All supplemental materials (such as data collection instrument or methodology reports) should be organized in one file with a table of contents or bookmarks. If material pertains to a specific submission form number, that should be indicated. Requested information should be provided in the submission form and required attachments. There is no guarantee that supplemental materials will be reviewed.

Additional Information

Ad.1 **Workgroup/Expert Panel involved in measure development**
Provide a list of sponsoring organizations and workgroup/panel members' names and organizations. Describe the members' role in measure development.
From 2006 onwards, and under the auspices of various funding organizations, HCI3 has convened and managed, or helped to convene and manage, Clinical Working Groups to inform the development and refinement of the measures. For example, in 2011, 2012 and 2013, HCI3 worked collaboratively with the American Board of Medical Specialties and the American Medical Association's Physicians Consortium for Performance Improvement, under a federal contract, to convene and get input from various clinical experts on definitions of episodes of care and their sequelae, including avoidable complications.

Some of the clinical experts that have contributed to our work include:
-Dr. John Allen, American Gastroenterology Association (AGA)
-Dr. Morton Arnsdorf, Cardiologist, University of Chicago, IL
-Dr. Peter Bach, Memorial Sloan Kettering Cancer Center (MSKCC)
-Dr. Peter Basch, Primary Care, Medstar Health, DC
-Dr. Justin Beckelman, Radiation Oncology, University of Pennsylvania, PA
-Dr. Debra Bingham, Executive Director, California Maternal Quality Care Collaborative (CMQCC) at Stanford University, CA
-Dr. John Birkmeyer, American Society of Metabolic and Bariatric Surgery (ASMBS)
-Dr. Linda Bosserman, Wilshire Oncology Medical Group, CA

-Dr. Matthew Brengman, American Society of Metabolic and Bariatric Surgery (ASBMS)
-Dr. Joel Brill, American Gastroenterology Association (AGA)
-Dr. George Cautilli, Cautilli Orthopedic Surgical Specialists PC, Yardley, PA
-Dr. Ashwini Davison, Internist, Johns Hopkins Hospital, MD
-Dr. James Denneny, III, American Academy of Otolaryngology – Head and Neck Surgery (AAO-HNS)
-Dr. Chris Gallagher, American Society of Metabolic and Bariatric Surgery (ASMBS)
-Dr. Robert Haralson, III, American Academy of Orthopedic Surgeons (AAOS)
-Ms. Dawn Holcombe, Executive Director, Connecticut Oncology Association, CT
-Dr. Colin Howden, American Gastroenterology Association (AGA)
-Dr. John Knightly, American Association of Neurological Surgeons (AANS)
-Dr. Larry Kosinski, American Gastroenterology Association (AGA)
-Dr. Nalini Krishnan, Obstetrics & Gynecology, MN
-Dr. Kelly Kyanko, Internist, NYU School of Medicine, NY
-Dr. Tara Lagu, Internist & Infectious Disease, Baystate Medical Center, MA
-Dr. Robert Lee, Society of Thoracic Surgeons (STS)
-Dr. Alex Little, Society of Thoracic Surgeons (STS)
-Dr. Michael London, Orthopedic Surgeon, OMNI Orthopedics, OH
-Dr. Elliott Main, Obstetrics & Gynecology, California Pacific Medical Center, CA
-Dr. Constantine Mantz, 21st Century Oncology, FL
-Dr. Joseph Messer, Cardiologist, Rush University Medical Center, IL
-Dr. David Metz, American Gastroenterology Association (AGA)
-Dr. Ronald Nahass, Infectious Disease Care, NJ
-Dr. Ajay Nehra, Urologist, Rush University Medical Center, IL
-Dr. Francis Nichols, Society of Thoracic Surgeons (STS)
-Dr. Patrick O'Connor, Primary Care, HealthPartners, MN
-Dr. Sara Perkel, National Comprehensive Cancer Network, PA
-Dr. David Peura, American Gastroenterology Association (AGA)
-Dr. John Ratliff, American Association of Neurological Surgeons (AANS)
-Dr. Steven Schutzer, Connecticut Joint Replacement Institute, CT
-Dr. Leif Solberg, Primary Care, HealthPartners, MN
-Dr. Scott Sporer, Midwest Orthopedics at Rush, Chicago IL
-Dr. Bonnie Weiner, Cardiologist, Worcester Medical Center, MA
-Dr. Jonathan Weiner, Bariatric Surgery codes, Prof of Health Policy and Management, Johns Hopkins University, MD
-Dr. Janet Wright, Cardiologist, Northstate Cardiology Consultants, CA

MEASURE WORKSHEET

Measure Information - Composite

This document contains the information submitted by measure developers/stewards, but is organized according to NQF's measure evaluation criteria and process. The item numbers refer to those in the submission form but may be in a slightly different order here. In general, the item numbers also reference the related criteria (e.g., item 1b.1 relates to subcriterion 1b).

Brief Measure Information

NQF #: 2748

De.2. **Measure Title:** Proportion of Patients with Hypertension (HTN) that have a Potentially Avoidable Complication (during the episode time window)

Co.1.1. **Measure Steward:** Health Care Incentives Improvement Institute Inc. (HCI3)

De.3. **Brief Description of Measure:** Percent of adult population aged 18 + years who triggered an episode of hypertension (HTN), are followed for at least one-year, and have one or more potentially avoidable complications (PACs). PACs may occur any time during the episode time window. Please reference attached document labeled NQF_HTN_all_codes_risk_adjustment_06.30.15.xls, in the tabs labeled PACs I-9 and PAC I-10 for a list of code definitions of PACs relevant to HTN.

We define PACs as one of two types:

(1) Type 1 PACs - PACs directly related to the index condition: Patients are considered to have a PAC, if they receive services during the episode time window for any of the complications directly related to HTN, such as for malignant hypertension, blurred vision, acute CHF etc.

(2) Type 2 PACs - PACs suggesting Patient Safety Failures: Patients are also considered to have a PAC, if they receive services during the episode time window for any of the complications related to patient safety failures such as for sepsis, infections, phlebitis, deep vein thrombosis, pressure sores etc..

All relevant admissions in a patient with HTN are considered potentially avoidable and flagged as PACs.

PACs are counted as a dichotomous (yes/no) outcome. If a patient had one or more PACs, they get counted as a "yes" or a 1. The enclosed workbook labeled NQF_HTN_all_codes_risk_adjustment_06.30.15.xls serves as an example. The tab labeled PAC overview gives the percent of HTN episodes that have a PAC and the tab labeled "PAC drill down" gives the types of PACs and their frequencies in HTN episodes within this dataset.

The information is based on a two-year claims database from a large regional commercial insurer. The database had over 3.2 million covered lives and over $25.9 billion in "allowed amounts" for claims costs. The database is an administrative claims database with medical as well as pharmacy claims.

1b.1. **Developer Rationale:** Each individual PAC, when measured in isolation, provides a very limited picture of the performance of the provider(s) who are managing or co-managing the care of the patient. However, looking at all the PACs that may occur individually or concurrently in a patient with a given episode provides a comprehensive picture of the care received by the patient for that particular condition or illness.

Additionally, the frequency of occurrence of individual PACs may be so low that it may require very high sample sizes from individual providers to achieve any meaningful and reliable comparisons. But aggregating all the PACs into a single quality metric creates meaningful scores that can be compared across providers even with relatively smaller sample sizes.

Additionally, a comprehensive measure is easier to explain to the average consumer. From a patient's point of view, any bad outcome has an impact on their health with respect to return to work, functional limitations and need for additional support. If a provider has a high PAC rate with regards to one component PAC but not the other PACs, the impact on the patient is still adverse. In selecting providers, individual component PAC scores would mean nothing to a patient, but aggregating it to a comprehensive quality score could be a measure of "all-cause" harms and easier to interpret and act on.

S.4. **Numerator Statement:** Outcome: Number of patients who triggered an episode of hypertension (HTN), are followed for at least

one-year, and had one or more potentially avoidable complications (PACs) during the episode time window.
S.7. **Denominator Statement:** Adult patients aged 18 years and above who triggered an episode of hypertension (HTN) and are followed for at least one-year.
S.10. **Denominator Exclusions:** Denominator exclusions include exclusions of either "patients" or "claims" based on the following criteria:
1. "Patients" excluded are those that do not meet the enrollment criteria. If patient has an enrollment gap for more than 30 days during the episode time window, it is considered as an enrollment gap
2. "Patients" are also excluded if the cost of the episode is an outlier at greater than 99th percentile or less than 1st percentile value for all episodes. This is another way to ensure that episodes are complete as well as they do not bring in random noise into the analysis due to inappropriate codes or services.
3. "Claims" are excluded from the HTN measure if they are considered not relevant to HTN care.

De.1. **Measure Type:** Outcome
S.23. **Data Source:** Administrative claims
S.26. **Level of Analysis:** Clinician : Group/Practice, Clinician : Individual, Clinician : Team

Preliminary Analysis

The preliminary analysis was developed in response to recommendations from NQF's Consensus Task Force and measurement stakeholders as a way to enhance and streamline the measures evaluation and voting processes. The preliminary analysis will help to guide the Standing Committee evaluation of each measure by summarizing the measure developer submission, guide measure evaluation discussion, and identify topic areas for additional input. **NQF staff would like to stress that the preliminary analysis is intended to be used as a guide to facilitate the Committee's discussion and evaluation.**

Criteria 1: Importance to Measure and Report

1a. Evidence

1a. Evidence. The evidence requirements for this *health outcomes* measure include providing rationale that supports the relationship of the health outcome to processes or structures of care. The guidance for evaluating the clinical evidence asks if health outcomes measures agree the relationship between the measured health outcome and at least one clinical action is identified and supported by the stated rationale.

- This new risk-adjusted (by age, gender and clinical co-morbidities) outcomes measure that assesses the proportion of adult patients with claims triggered Hypertension (HTN) with at least one Potentially Avoidable Complications (PAC) within 12 months of CAD triggered claims data. Based on NQF's criteria, this measure is considered an "any or none" composite measure that assesses if 1 or more PACs or "care defects" have occurred for the index episode. For this composite measure, the individual complications considered the measurable components.
- PACs are classified in two types: 1) related to HTN, and 2) related to Patient Safety Failures, combining the 2 types into a single PAC rate to calculate the proportion of patient with 1 or more PAC. PACs are considered unwarranted health outcomes that combine concepts from AHRQ PSIs, PQIs and the CMS HACs and episode-specific PACs into all-cause patient harms that is measured during an index condition for use at the practice, medical group, provider system or purchaser/payer levels to identify quality of care gaps between practices and hospitals.
- The developer links primary & secondary prevention care gaps, poor patient education, poor care coordination and poor follow-up increase unnecessary ER visits, hospitalizations, readmissions, and mortalities to increased PACs, and state that PACs for HTN patients should occur rarely in well-managed patients.
- The evidence for Patient Safety Failure PACs is described to be within the influence of the measured entity, and does not describe the influence of non-healthcare-related impacts on PAC rates. The progression of the episode condition, illness or disease is also not mentioned as a contributor to PAC rates in the evidence.
- In addition to linking processes of care to outcomes, the developer provides an extensive PAC literature review in

sections 1a.2. and 1a.2.1. for HTN, Patient Safety Failures & processes of care, as well as background information on the process for PAC development.

Questions for the Committee:

- *Does sufficient evidence exist connecting Patient Safety Failures to the HTN index episode?*
- *For possible exception to the evidence criteria:*
  - *Are there, or could there be, performance measures of a related health outcome, OR evidence-based intermediate clinical outcomes, intervention/treatment?*
  - *Is there evidence of a systematic assessment of expert opinion beyond those involved in developing the measure?*

1b. Gap in Care/Opportunity for Improvement and 1b. Disparities

1b. Performance Gap. The performance gap requirements include demonstrating quality problems and opportunity for improvement.

- The developer provides HTN prevalence & impacts data, rationales and general information on PAC measure utility and applicable setting use.
- HTN PAC performance gap data are calculated from PROMETHEUS administrative claims data from April 1, 2012 through December 17, 2014, for providers with ≥ 10 attributable index episodes. The data includes 3,702 of 23,125 (16%) providers from 262,273 of 409,442 index episodes in 3,258,706 unique beneficiaries.

Unadjusted PAC Rates:		**Risk-Standardized PAC Rates (RSPR):**	
Median (IQR):	29.7% (20.0%, 42.9%)	Median (IQR):	31.1% (24.2%, 37.8%)
Range:	0% -100%	Range:	0% -173%

- Limited descriptive data on the patient, provider and payer are provided. The developer provides "Overview" and "Drill Down" PAC rates in the spreadsheet demonstrating gap, though PAC rates for individual complications are not provided.
- The developer cites 2013 CDC National Health Statistics data on the prevalence & treatment of HTN, remaining constant at ~ 30% over the last decade, with Mexican-Americans born outside the US, persons without health insurance had lower BP control, with Black adults have higher HTN rates and lower BP control to Caucasians.

Questions for the Committee:

- *Is there a gap in care that warrants a national performance measure?*
- *If no disparities information is provided, are you aware of evidence that disparities exist in this area of healthcare?*
- *Should this measure be indicated as disparities sensitive?*

1c. Priority

1c. High Priority (previously "High Impact") requires measures to address national health goal/priority or a demonstrated high-impact aspect of care.

- *Beginning in 2015, priority is no longer an NQF measure evaluation criterion.*

Committee pre-evaluation comments

Criteria 1: Importance to Measure and Report (including 1a, 1b, 1c)

1. ***Committee's Overview Comments***:
   - Somewhat weak and unconventional for traditional CV measures

1a. ***Committee's Comments on Evidence to Support Measure Focus:***

- Somewhat weak and unconventional for traditional CV measures

1b. ***Committee's Comments on Performance Gap:***

- Very difficult to understand the performance gap as it captures one very common condition and relation of that condition to numerous, likely quite unrelated "adverse" outcomes

1c. ***Committee's Comments on Composite Performance Measure:***

- Not Applicable

Criteria 2: Scientific Acceptability of Measure Properties

2a. Reliability

2a1. Reliability Specifications

2a1. Specifications requires the measure, as specified, to produce consistent (reliable) and credible (valid) results about the quality of care when implemented.

- The measure assesses the rate of patients with 1 or more PAC(s) during index episodes. This new risk adjusted outcomes measure is specified for use at the clinician group and team levels of analyses.
- The measure exclusively uses electronically available administrative claims data to calculation the measure score, and for this measure, better care equals lower scores.
- The developer describes non-patient-related PACs as controllable by provider processes without further analysis as other influencers that may contribute to PAC rates beyond the patient and provider (e.g., payer, access, suppliers, etc.).
- Patient- and claims-based exclusions are provided to promote the availability and consistency of claims data capture, including payer enrollment requirements, cost outliers of < 1% or > 99%, and claims not relevant to HTN.
- Developers provide a robust data set of administrative claims codes for HTN & PAC (HTN- & Patient Safety Failure-related) triggers, describe a complete 12-month episode time window. A calculation algorithm is provided.
- ICD-9 & ICD-10 codes are provided, though ICD-10 descriptions & an ICD-9 to ICD-10 crosswalk methodology are not provided.
- A conceptual risk model and statistical method using logistic regression model for determining the probability of a patient incurring a PAC are provided. After adjusting for patient-related factors, the developers state the remaining PAC variance is due to factors potentially controlled by the provider during and after hospitalization. "Predicted" coefficients from the risk adjustment models are summed to give predicted probabilities of PAC occurrence.

Questions for the Committee:

- *Are all the data elements clearly defined? Are all appropriate codes included?*
- *Is the logic or calculation algorithm clear?*
- *Is this measure specified to pertain only to providers with at least 10 episodes (per the reliability testing described below)?*
- *Is it likely this measure can be consistently implemented?*
- *Is additional evidence required to determine whether group/practice/team level of analysis is appropriate?*

2a2. Reliability Testing Testing attachment

2a2. Reliability testing demonstrates if the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise enough to distinguish differences in performance across providers.

- The measure is specified for HTN patients ≥ 18 years, though the testing sample includes patients 18 through 64 years
- The developer tested reliability at the performance measure score, and used a beta-binomial model and a signal-to-noise analysis, which is appropriate for this type of measure, to differentiate the true difference between measured entities (the signal) to random measurement error (the noise). A value of 0 indicates that all variation is due to

measurement error and a value of 1 indicates that all variation is due to real differences in between hospital performance. A value of 0.7 is often regarded as a minimum acceptable reliability value.

- A sample of 262,273 providers was initially included in the data set, though providers with less than 10 HTN episodes were excluded, allowing for 3,702 (1.4%) remaining providers. There were 147,169 HTN episodes with a mean age of 53.0 (18-64 years) and 46% female in the testing analysis exclusively using administrative claims data.
- A patient may have more than one condition-specific concurrent episode with claims applied to both episodes. If an inpatient claim corresponds to a procedure index episode and to a condition index episode, the claim would be assigned to the procedure index episode, rather than the condition index episode (e.g., for a claim that corresponds to both index episodes of HF & CABG, the claim would be assigned to CABG).
- Patient with missing gender were excluded from the denominator, and no other missing data was identified.
- Reliability results are provided in the table below, as well as in great detail in the accompanied spreadsheet with median (IQR) results demonstrating reliability of 0.79 (0.67,0.89) for ≥ 10 providers, increasing with the number of providers, demonstrating the measure is able to demonstrate differences in performance. For reliability analysis, providers were restricted to the minimum of 10 HTN episodes, though all episodes were included in the risk model.

Reliability Scores	Minimum # Episodes Per Provider		
	>=10	>=25	>=50
# of Providers (%)	3,702 (100)	2,011 (54)	1,039 (28)
Median (IQR)	0.79 (0.67, 0.89)	0.87 (0.81, 0.92)	0.92 (0.89, 0.95)
Range	0.49-1.00	0.71-1.00	0.83-1.00

The table provides a summary reliability scores minimum sample size thresholds. Complete results are provided in the workbook entitled, NQF_HTN_all_codes_risk_adjustment_06.30.15.xls, under the "ProviderAttribution Reliability" tab.

Questions for the Committee:

- *Reliability testing was conducted only for those providers with at least 10 episodes. Can differences in performance be identified for providers with fewer than 10 episodes? Should the measure be specified to include only those providers with at least 10 episodes? Is the test sample adequate to generalize for widespread implementation?*
- *Do the results demonstrate sufficient reliability so that differences in performance can be identified?*

2b. Validity

2b1. Validity: Specifications

2b1. Validity Specifications. This section should determine if the measure specifications are consistent with the evidence.

- Because this is an outcome measure, the rationale that is presented for subcriterion 1a does not necessarily have to address all of the variables used to calculate the measure.
- The measure uses a statistical risk model with 170 risk factors and episode-specific subtypes/severity markers including age, gender and clinical comorbidities, on at least 10 claims to determine "stable" covariates and assess comorbidity or procedure impact on the PAC. All covariates must be present prior to an episode trigger. No formal covariate analysis was conducted to select risk factors beyond the present on a minimum of 10 claims threshold. The developer describes the heterogeneity of the provided data sets as crucial to ensure measure validity, and the accuracy and completeness of the data sets.
- The developers provide disparities data relation to age, race, and insurance status, though further exploration of a conceptual relation to SDS, or SDS factors in the risk model is not provided.

Question for the Committee:

- *Are the specifications consistent with the evidence?*
- *Are these variables available and generally accessible for the measured patient population?*
- *Does the Committee find a conceptual relation between the provided disparities data and potential SDS factors?*

2b2. Validity testing

2b2. Validity Testing should demonstrate the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality.

- The developer conducted systematic assessment of face validity for the performance measure score for validity testing in numerous ways, including the use of monthly multi-specialty clinical working groups, and other tests of face validity, along with focus groups, face validity comparisons of the measure to other national accountability measures, as well as additional literature for the measure & PAC development process.
- No empiric results are provided for the face validity tests described above.

Questions for the Committee:

- *Is the test sample adequate to generalize for widespread implementation?*
- *Do the results demonstrate sufficient validity so that conclusions about quality can be made?*
- *Do you agree that the score from this measure as specified is an indicator of quality?*

2b3-2b7. Threats to Validity

2b3. Exclusions:

- The developer describes patient- (demographic, enrollment or low/high claims cost) and claims-based (due to missing or non-relevant data) exclusions for the measure. They further state nearly half of the original population of HTN patients was removed from the denominator with applied exclusions.
- A significant number of patients were eliminated from the measure due to exclusion criteria, including 147,169 of 409,442 (35.9%) HTN (48.6%) episodes (in 3,258,706 unique beneficiaries) and 3,702 of 262,273 (1.4%) providers.

Questions for the Committee:

- *Are high cost outliers (> 99%) exclusions an opportunity to identify PACs?*
- *Does the high number of exclusions restrict the measure use?*
- *Are the exclusions consistent with the evidence?*
- *Are any patients or patient groups inappropriately excluded from the measure?*
- *Are the exclusions/exceptions of sufficient frequency and variation across providers to be needed (and outweigh the data collection burden)?*

2b4. Risk adjustment:

- The risk model (detailed in the accompanied spreadsheet) includes 170 factors and subtypes including age, gender, 12-month enrollment markers, co-morbidities, and episode severity markers.
- The developers provide disparities data relation to age, race, and insurance status, though further exploration of a conceptual relation to SDS, or SDS factors in the risk model is not provided.
- Logistic regression was used to model the probability of at least one PAC during an episode. The reasoning for no additional modeling performed is described.
- The performance of the model was determined with a split sample method by estimating the model coefficients using a development dataset (80% of the sample) and applying those coefficients to a validation dataset (20% of the sample). C-statistics for the development and validation samples with c-statistic results of 0.800 and 0.801, respectively. C-statistics measures the extent of a statistical model to discriminate between a patient with and without

PAC, with an ability to predict if a PAC is or is not present about 80% of the time. A c-statistic of 0.50 indicates the model is no better than random prediction, implying that the patient risk factors do not predict variation in the outcome; conversely, a c-statistic of 1.0 indicates perfect prediction, implying patients' outcomes can be predicted completely by their risk factors, and physicians and hospitals play little role in patients' outcomes. Models with c-statistic values of at least 0.7 are considered good and those above 0.8 are considered strong.

- Both Hosmer-Lemeshow Goodness-of-Fit statistics and risk-decide plots were provided to indicate model fit. Results from the Hosmer-Lemeshow test suggest that the fit is not good; however, this test is sensitive to the number of groupings and sample sizes. Results from the risk decile plot indicate that the predicted PAC rates are similar to the observed PAC rates across all deciles of risk. The developer states the model demonstrates sufficient predictive power.

Questions for the Committee:

- *Is the Committee aware of conceptual relationship(s) between additional patient-level SDS factors, patient clinical factors, quality of care, and PACs (other than gender and age)? If so, what data might be available to allow an empirical analysis of these relationships?*
- *Is an appropriate risk-adjustment strategy included in the measure?*
- *Are the candidate and final variables included in the risk adjustment model adequately described for the measure to be implemented?*
- *Are all of the risk adjustment variables present at the start of care? If not, describe the rationale provided.*

2b5. Meaningful differences:

- The developer presents PAC rates across providers and also providers adjusting for differences in patient severity in a ratio of observed to expected attributable episodes to PACS accounting for patient severity, and calculates estimates from the risk model, for risk-standardized PAC rates for the provider.

Summary of Unadjusted and Adjusted Performance Scores Across Providers:

PAC Rates	Minimum # Episodes Per Provider	
	>=10	>=25
Unadjusted		
Median (IQR)	30% (20%, 43%)	29% (20%, 41%)
Range	0%-100%	3%-100%
Adjusted (RSPR)*		
Median (IQR)	31% (24%, 38%)	31% (25%, 36%)
Range	0%-173%	4%-112%

***RSPR = Risk Standardized PAC Rate**

Please refer to the NQF_HTN_all_codes_risk_adjustment_06.30.15.xls workbook under the "ProviderAttribution Reliability" tab to see specific results for each provider.

Question for the Committee:

- *Does this measure identify meaningful differences about quality?*

2b6. Comparability of data sources/methods:

- As there is only one data source used for measure calculation (administrative claims), comparability of data sources or methods is not applicable.

Question for the Committee:

- *Are the candidate and final variables included in the risk adjustment model adequately described for the measure to be implemented?*

2b7. Missing Data

- No formal analysis of missing data is provided. As the measure assesses the rate of patients with PACs, rather than the rate of PACs per index episode, the total number of PACs is not included in the PAC rate.
- Patient with missing gender were excluded from the denominator, and no other missing data was identified.
- The developers state the under-coding of claims is unavoidable in the current DRG payment structure which could lead to under capture or missing PACs.

2d. Empirical Analysis to Support Composite Construction

- As an "any or none" composite, the individual complications are considered measurable components of the composite. Frequency and distribution statistics are provided in the PAC Overview and PAC Drill Down tabs in the measure spreadsheet, which detail PAC types and subtypes. The identification of individual PACs are not provided (e.g., sepsis, unattended falls, DVT).
- PACs are counted as a dichotomous (yes/no) outcome. If a patient had one or more PACs, they get counted as a "yes" or a 1. Since our premise is that all PACs are potentially avoidable, we adopted the approach to count all PACs and give them equal weights. The overall composite score results in the quality construct that could be measured and interpreted.
- The developer states that no formal analysis was performed on missing data. For details, see 2b7 above.

Committee pre-evaluation comments

Criteria 2: Scientific Acceptability of Measure Properties (including all 2a, 2b, and 2d)

2a1. &2b1.: ***Committee's Comments on Reliability-Specifications:***

- The elements are well defined
- The problem I have is that these are associations not causations
- The adverse outcomes are associated with HTN but unlikely to be caused by HTN

2a2.: ***Committee's Comments on Reliability-Testing:***

- Probably reliable if examined in very large populations

2b1.: ***Committee's Comments on Validity-Specifications***:

- Not valid, see above.

2b2.: ***Committee's Comments on Validity-Testing:***

- Not valid
- These are putative associations not causation

2b3-7.: ***Committee's Comments on Threats to Validity:***

- Not Applicable

2d.: ***Committee's Comments on Composite Performance Measure:***

- Not Applicable

Criterion 3. Feasibility

3. Feasibility is the extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

- All measure elements are readily available in electronic sources via administrative claims data, and coded by someone other than the person obtaining the original information (e.g., DRG, ICD-9 codes on claims).
- The developer provides an excel spreadsheet attachment including diagnoses, visits, hospitalizations, post-acute facility stays, procedures, laboratory tests and procedures/surgeries, for HTN & PAC triggers, and describe the time window for measuring PACs as 12 months following a HTN episode triggers, as well as a decision tree for measure calculation and implementation.
- The measure specifications, metadata and calculation algorithms are available free of charge on the developer's website. Limited analytics are planned at no cost to the end user.
- This is not an eMeasure.

Questions for the Committee:

- *Are the required data elements routinely generated and used during care delivery?*
- *Are the required data elements available in electronic form, e.g., EHR or other electronic sources?*
- *Is the data collection strategy ready to be put into operational use?*

Committee pre-evaluation comments

Criteria 3: Feasibility

3.: ***Committee's Comments on Feasibility:***

- Not feasible.

Criterion 4: Usability and Use

4. Usability and Use evaluate the extent to which audiences (e.g., consumers, purchasers, providers, policymakers) use or could use performance results for both accountability and performance improvement activities.

- This is a newly developed claims measure is currently used in accountability programs for payers, states, and is planned for public reporting, professional certification or recognition programs, and external quality improvement for benchmarking purposes.
- The developer states that PAC measures provide a foundation for the relationship between healthcare quality and cost and assist in the exploration of practice reengineering and alternative payment models, act as indicators of potential harm, and is spurring the development of private-based analytics software for further outcomes exploration. No public improvement rates are available due to recent implementation and variation in PAC definitions have also modified, though the provided PROMETHEUS data suggest wide variation in performance and improvement opportunities. Payer and Provider improvement use perspectives are also outlined.
- The developer found no noted unintended consequences, though they state the measure is intended for transparency and QI activities only. They also state the under-coding of claims is unavoidable in the current DRG payment structure could be an unintended consequences of the measure, and payers calculating the measures even with inadequate sample sizes and using the results to penalize providers could lead to invalid provider comparisons.
- If the measure was theoretically to be used for accountability purposes to "ding" the measured entity as defined in the level of analysis, further exploration of PAC antecedents and the measured entity is warranted, especially with small group practices and very small PAC rates. In the original testing sample of 262,273 providers, when providers with fewer than 10 HTN episodes were eliminated from analysis due to less reliability estimates with small numbers, 3,702 remained for analysis.

Questions for the Committee:

- *Is the measure publicly reported?*
- *How can the performance results be used to further the goal of high-quality, efficient healthcare?*
- *Should PAC measures also include the clinician: group in the analysis or include population-level only entities?*
- *Do the benefits of the measure outweigh any potential unintended consequences?*

Committee pre-evaluation comments

Criteria 4: Usability and Use

4.: ***Committee's Comments on Usability and Use:***

- I suspect this is one of the ""big data"" measures that can demonstrate association between almost any chronic condition and adverse outcome
- Whether there is causation and scientific validity should be proven first prior to implementing this type of measures

Criterion 5: Related and Competing Measures

.1a. List of related or competing measures (selected from NQF-endorsed measures)

0337 : Pressure Ulcer Rate (PDI 2)
0450 : Perioperative Pulmonary Embolism or Deep Vein Thrombosis Rate (PSI 12)
0705 : Proportion of Patients Hospitalized with Stroke that have a Potentially Avoidable Complication (during the Index Stay or in the 30-day Post-Discharge Period)
0708 : Proportion of Patients Hospitalized with Pneumonia that have a Potentially Avoidable Complication (during the Index Stay or in the 30-day Post-Discharge Period)
0709 : Proportion of patients with a chronic condition that have a potentially avoidable complication during a calendar year.
1789 : Hospital-Wide All-Cause Unplanned Readmission Measure (HWR)

5.1b. If related or competing measures are not NQF endorsed please indicate measure title and steward.

-0531 Patient Safety for Selected Indicators (Composite Measure, endorsed) (AHRQ)

- -CMS defined hospital acquired conditions (HACs) are a subset of our PACs. We have pain-stakingly matched the definitions to provide as much consistency as possible. http://www.cms.gov/Medicare/Quality-Initiatives-Patient-Assessment-Instruments/HospitalQualityInits/HospitalRHQDAPU.html

Pre-meeting public and member comments

-

NATIONAL QUALITY FORUM—Evidence (subcriterion 1a)

Measure Number (*if previously endorsed*)**:** 2748
Measure Title: Proportion of Patients with Hypertension (HTN) that have a Potentially Avoidable Complication (during the episode time window)
IF the measure is a component in a composite performance measure, provide the title of the Composite Measure here: Click here to enter composite measure #/ title

Date of Submission: 6/30/2015

Instructions

- *For composite performance measures:*
  - *A separate evidence form is required for each component measure unless several components were studied together.*
  - *If a component measure is submitted as an individual performance measure, attach the evidence form to the individual measure submission.*
- Respond to all questions as instructed with answers immediately following the question. All information needed to demonstrate meeting the evidence subcriterion (1a) must be in this form. An appendix of *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 10 pages (*incudes questions/instructions*; minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the evidence for this measure meets NQF's evaluation criteria.

1a. Evidence to Support the Measure Focus

The measure focus is evidence-based, demonstrated as follows:

- Health outcome: [3] a rationale supports the relationship of the health outcome to processes or structures of care. Applies to patient-reported outcomes (PRO), including health-related quality of life/functional status, symptom/symptom burden, experience with care, health-related behavior.
- Intermediate clinical outcome: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured intermediate clinical outcome leads to a desired health outcome.
- Process: [5] a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured process leads to a desired health outcome.
- Structure: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured structure leads to a desired health outcome.
- Efficiency: [6] evidence not required for the resource use component.

Notes

3. Generally, rare event outcomes do not provide adequate information for improvement or discrimination; however, serious reportable events that are compared to zero are appropriate outcomes for public reporting and quality improvement.

4. The preferred systems for grading the evidence are the U.S. Preventive Services Task Force (USPSTF) grading definitions and methods, or Grading of Recommendations, Assessment, Development and Evaluation (GRADE) guidelines.

5. Clinical care processes typically include multiple steps: assess → identify problem/potential problem → choose/plan intervention (with patient input) → provide intervention → evaluate impact on health status. If the measure focus is one step in such a multistep process, the step with the strongest evidence for the link to the desired outcome should be selected as the focus of measurement. Note: A measure focused only on collecting PROM data is not a PRO-PM.

6. Measures of efficiency combine the concepts of resource use and quality (see NQF's Measurement Framework: Evaluating Efficiency Across Episodes of Care; AQA Principles of Efficiency Measures).

1a.1.This is a measure of: (*should be consistent with type of measure entered in De.1*)

Outcome

☒ Health outcome: Potentially Avoidable Complications

☐ Patient-reported outcome (PRO): Click here to name the PRO

PROs include HRQoL/functional status, symptom/symptom burden, experience with care, health-related behaviors

☐ Intermediate clinical outcome (*e.g., lab value*): Click here to name the intermediate outcome

☐ Process: Click here to name the process

☐ Structure: Click here to name the structure

☐ Other: Click here to name what is being measured

HEALTH OUTCOME/PRO PERFORMANCE MEASURE *If not a health outcome or PRO, skip to 1a.3*

1a.2. Briefly state or diagram the path between the health outcome (or PRO) and the healthcare structures, processes, interventions, or services that influence it.

Given the ever-increasing number of patients with one or more chronic illness, the need for consistently high quality, efficient chronic illness care is urgent. While there is a general understanding of the nature of care failures in chronically ill patients (e.g. ambulatory care sensitive hospitalizations) (Yuen 2004), there has been no attempt to measure the magnitude or the type of potentially avoidable complications, and the cost reductions that would ensue if a payment model encouraged care to be optimized at benchmarks achieved in studies.

There is enough evidence in the literature that highlights significant "gaps in care" in management of patients with chronic conditions (McGlynn 2003). Gaps in care, in turn lead to process failures that cause patients to incur unnecessary services and some harm (Jha 2013). For example, a report by the Agency of Health Care Research and Quality (AHRQ) highlighted the fact that in 2008, $4.4 million out of a total of 39 million (11 percent) hospital-stays that could have been prevented (Stranges 2008); and for Medicare beneficiaries one in five admissions were for a potentially preventable condition (Jiang 2006). To improve accountability in the delivery of medical care, AHRQ has developed a list of patient safety indicators (PSIs) to identify potential harms to patients and a list of ambulatory care sensitive conditions (ACSCs) to identify admissions that could have been potentially avoided with good outpatient care (AHRQ 2008). Additionally, the Centers for Medicare and Medicaid Services (CMS) have taken a "Six Sigma" approach and defined Hospital Acquired Conditions (HACs) and "never events" that should almost never occur and are applying financial penalties when these events do occur (CMS 2012).

The Potentially avoidable complications (PAC) measure goes beyond the AHRQ PSIs, PQIs and the CMS HACs and creates a single comprehensive measure that measures all-cause harms for a patient with the index condition. Potentially avoidable complications (PACs) are the unwarranted health outcomes that this measure addresses (de Brantes 2010). Lack of patient education on self care techniques, poor care coordination, and poor arrangements of patient follow-up could lead to unnecessary ER visits, hospitalizations and gaps in care leading to increased morbidity. All these adverse events are aggregated together as a single comprehensive measure to study the overall rate of PACs in the HTN population.

Adult patient diagnosed with Hypertension
↓
Physician practices fail to educate patients / Physician practices have poor access
↓
Patient visits ER / gets hospitalized (Ambulatory care sensitive hospitalization event)
↓
Patient discharged with management advise / remains in hospital for treatment of PAC

Well-managed patients with HTN should rarely incur a potentially avoidable complication such as an emergency room visit, and hospitalizations related to HTN should occur only in the rarest of circumstances.

The enclosed workbook entitled NQF_HTN_all_codes_risk_adjustment_06.30.15.xls lists the types of PACs and their frequency as calculated in a large regional database (see tab PAC overview). Over 31% of patients with HTN had a PAC, with about 13% of PACs directly related to HTN itself, such as malignant hypertension, syncope, or fluid and electrolyte disorders (see tab PAC Drill Down Graph). Although the preventable hospitalizations in the HTN population were low, at only 1.0% of all HTN episodes; approximately 24% of patients with HTN had PACs related to patient centered care failures such as poor control of diabetes, respiratory insufficiency and acute gastritis, many of them being managed in an outpatient setting in physician offices. As a result over 30% of episodes had a PAC indicator on their professional claims.

While PACs may not be eliminated completely, identifying the magnitude of PACs and knowledge of the cause for the most frequent or the most expensive PACs could place an emphasis in reducing them and as a consequence improving patient outcomes. The ability to clearly identify the type and frequency of each PAC, creates a highly actionable measure

for all providers that are managing or co-managing the patient; as well as for the health plan with whom the patient is a member (de Brantes 2009).

1a.2.1. State the rationale supporting the relationship between the health outcome (or PRO) to at least one healthcare structure, process, intervention, or service (*i.e., influence on outcome/PRO*).

Note: For health outcome/PRO performance measures, no further information is required; however, you may provide evidence for any of the structures, processes, interventions, or service identified above.

Rationale: Better processes of care create an atmosphere of proactive management, consistency in care and standardized care patterns (Shekelle 2013) (Fenter 2006). Patient education and adopting safe practices significantly reduces occurrence of potentially avoidable complications (PACs) in all settings (Klein 2011) (Wachter 2013) (Berwick 2006) (Kovner 2011) (Farley 2013). It is known that by holding providers accountable for occurrence and costs of PACs, an built-in warranty is created around care of the index condition (de Brantes 2009).

Specifically for Hypertension, Staessen et.al, showed that active treatment with antihypertensive medication reduced the risk for stroke by 42%, cardiovascular endpoints by 31% and sudden death by 26% (Staessen 1997). Beckett et.al., in a large randomized control trial comprising 3,845 patients showed a reduction in fatal and nonfatal stroke rates when appropriate antihypertensive treatment was instituted (Beckett 2008). In addition to pharmacological treatment, appropriate life style modifications also play an important role in reducing PAC’s

due to hypertension, particularly cardiovascular morbidity. The Life style Work Group published their guidelines in 2013, with recommendations on nutrition and physical activity to control hypertension and reduce cardiovascular risk (Eckel 2013).

Studies have demonstrated where care coordination exists, ambulatory care-sensitive hospitalizations decreased by 30% (Bodenheimer 2008). However, if patients do get hospitalized, discharge planning and good follow-up prevents unnecessary ER visits and readmissions (Weaver 2013) (Mittler 2013). Another study from the Boston Medical Center, demonstrated that although one in five hospitalizations are complicated by post-discharge adverse events, development of a strong discharge services program for patients admitted for medical conditions reduced hospital utilization within 30 days of discharge (Jack 2009). In addition, while in the hospital, safe practices reduce the burden of healthcare associated complications (Ranji 2007). Some of these are listed below:

1. Frequent hand-washing reduce hospital acquired infections (WHO 2007)
2. Carefully implemented protocols lead to reduced line sepsis (Pronovost 2010)
3. Discharge planning and good follow-up prevents unnecessary ER visits and readmissions (Weaver 2013)
4. DVT prophylaxis in patients on bed rest avoids pulmonary embolism (Shekelle 2013)
5. Frequent change in position of HTN patients in the CCU avoids pressure sores (Shekelle 2013)

PAC measures in the setting of hypertension look at all-cause harms, such as the ones highlighted above, arising from poor management of a patient with hypertension.

INTERMEDIATE OUTCOME, PROCESS, OR STRUCTURE PERFORMANCE MEASURE

1a.3. Briefly state or diagram the path between structure, process, intermediate outcome, and health outcomes. Include all the steps between the measure focus and the health outcome.

1a.3.1. What is the source of the systematic review of the body of evidence that supports the performance measure?

☒ Clinical Practice Guideline recommendation – ***complete sections 1a.4, and 1a.7***

☐ US Preventive Services Task Force Recommendation – ***complete sections 1a.5 and 1a.7***

☐ Other systematic review and grading of the body of evidence (*e.g., Cochrane Collaboration, AHRQ Evidence Practice Center*) – ***complete sections 1a.6 and 1a.7***

☐ Other – ***complete section 1a.8***

Please complete the sections indicated above for the source of evidence. You may skip the sections that do not apply.

1a.4. CLINICAL PRACTICE GUIDELINE RECOMMENDATION

1a.4.1. Guideline citation (*including date*) and **URL for guideline** (*if available online*):

1a.4.2. Identify guideline recommendation number and/or page number and **quote verbatim, the specific guideline recommendation**.

1a.4.3. Grade assigned to the quoted recommendation with definition of the grade:

1a.4.4. Provide all other grades and associated definitions for recommendations in the grading system. (*Note: If separate grades for the strength of the evidence, report them in section 1a.7.*)

1a.4.5. Citation and URL for methodology for grading recommendations (*if different from 1a.4.1*)**:**

1a.4.6. If guideline is evidence-based (rather than expert opinion), are the details of the quantity, quality, and consistency of the body of evidence available (e.g., evidence tables)?

☐ Yes → ***complete section 1a.7***

☐ No → ***report on another systematic review of the evidence in sections 1a.6 and 1a.7; if another review does not exist, provide what is known from the guideline review of evidence in 1a.7***

1a.5. UNITED STATES PREVENTIVE SERVICES TASK FORCE RECOMMENDATION

1a.5.1. Recommendation citation (*including date*) and **URL for recommendation** (*if available online*):

1a.5.2. Identify recommendation number and/or page number and **quote verbatim, the specific recommendation**.

1a.5.3. Grade assigned to the quoted recommendation with definition of the grade:

1a.5.4. Provide all other grades and associated definitions for recommendations in the grading system. (*Note: the grading system for the evidence should be reported in section 1a.7.*)

1a.5.5. Citation and URL for methodology for grading recommendations (*if different from 1a.5.1*)**:**

Complete section 1a.7

1a.6.2. Citation and URL for methodology for evidence review and grading (*if different from 1a.6.1*)**:**

Complete section 1a.7

1a.7. FINDINGS FROM SYSTEMATIC REVIEW OF BODY OF THE EVIDENCE SUPPORTING THE MEASURE

If more than one systematic review of the evidence is identified above, you may choose to summarize the one (or more) for which the best information is available to provide a summary of the quantity, quality, and consistency of the body of evidence. Be sure to identify which review is the basis of the responses in this section and if more than one, provide a separate response for each review.

1a.7.1. What was the specific structure, treatment, intervention, service, or intermediate outcome addressed in the evidence review?

1a.7.2. Grade assigned for the quality of the quoted evidence with definition of the grade:
1a.7.3. Provide all other grades and associated definitions for strength of the evidence in the grading system.

1a.7.4. What is the time period covered by the body of evidence? (*provide the date range, e.g., 1990-2010*). Date range: Click here to enter date range

QUANTITY AND QUALITY OF BODY OF EVIDENCE

1a.7.5. How many and what type of study designs are included in the body of evidence? (*e.g., 3 randomized controlled trials and 1 observational study*)

1a.7.6. What is the overall quality of evidence across studies in the body of evidence? (*discuss the certainty or confidence in the estimates of effect particularly in relation to study factors such as design flaws, imprecision due to small numbers, indirectness of studies to the measure focus or target population*)

ESTIMATES OF BENEFIT AND CONSISTENCY ACROSS STUDIES IN BODY OF EVIDENCE

1a.7.7. What are the estimates of benefit—magnitude and direction of effect on outcome(s) across studies in the body of evidence? (*e.g., ranges of percentages or odds ratios for improvement/ decline across studies, results of meta-analysis, and statistical significance*)

1a.7.8. What harms were studied and how do they affect the net benefit (benefits over harms)?
N/A

UPDATE TO THE SYSTEMATIC REVIEW(S) OF THE BODY OF EVIDENCE

1a.7.9. If new studies have been conducted since the systematic review of the body of evidence, provide for each new study: 1) citation, 2) description, 3) results, 4) impact on conclusions of systematic review.

1a.8 OTHER SOURCE OF EVIDENCE

If source of evidence is NOT from a clinical practice guideline, USPSTF, or systematic review, please describe the evidence on which you are basing the performance measure.

1a.8.1 What process was used to identify the evidence?

1a.8.2. Provide the citation and summary for each piece of evidence.

1. Evidence, Performance Gap, Priority – Importance to Measure and Report

Extent to which the specific measure focus is evidence-based, important to making significant gains in healthcare quality, and improving health outcomes for a specific high-priority (high-impact) aspect of healthcare where there is variation in or overall less-than-optimal performance. ***Measures must be judged to meet all subcriteria to pass this criterion and be evaluated against the remaining criteria.***

1a. Evidence to Support the Measure Focus – See attached Evidence Submission Form
2748_HTN_Evidence_Attachment_HCI3.docx

1b. Performance Gap

Demonstration of quality problems and opportunity for improvement, i.e., data demonstrating:

- considerable variation, or overall less-than-optimal performance, in the quality of care across providers; and/or
- disparities in care across population groups.

1b.1. Briefly explain the rationale for this measure *(e.g., the benefits or improvements in quality envisioned by use of this measure)*
Measures associated to potentially avoidable complication (PAC) have been used as comprehensive outcomes measures since 2007 for several conditions and procedures (de Brantes 2010) (Joynt 2013) (James 2013). In 2011, following the NQF endorsement of these measures for certain acute medical conditions (AMI, Pneumonia and Stroke), and for chronic conditions, they were adopted for various purposes, including the creation of related measures (NQF – Measure #1550). Some commercial payers have used them as a means for tracking outcomes (Yong 2010) and for tiering providers for pay for performance programs (BCBSNC). In addition, some provider organizations have used them in quality improvement efforts by homing in on the detailed specifications of the measures to reveal opportunities for care improvement (CALPERS – link below). Identification of PACs has spurred provider innovation (Bundled Payment Summit 2015) for practice re-engineering, to create proactive care pathways, and to focus on areas of high variability (McVary 2010). Some employers are also using measures of avoidable complications as public measures of quality (Colorado Business Group on Health) given the research that demonstrated the potential efficacy of these measures to differentiate provider quality and cost (Hibbard 2012). In fact in a series of focus groups led by Judy Hibbard and colleagues, the researchers found that the very framing of potentially avoidable complications as an indicator of potential harm, is an effective way of communicating the quality of care. And when measures of PACs were presented in conjunction with price, consumers intuitively accepted the logical relationship between low PACs – fewer "defects" – and lower price.

Accountability for and measurement of PACs occurs at the practice, medical group, provider system or purchaser/payer level. PAC rates are calculated as absolute values. For example, a health plan would report that 40% of its plan members with hypertension incurred PACs in the study time window. The objective of the measure is to encourage the unit being measured to progressively reduce that amount over time. In addition, comparisons of PAC rates across plans or provider systems should be encouraged and publicly reported. An organization that uses the measure should be able to identify the leading causes of PACs and implement improvements to existing processes that will decrease PACs. There are several tools available for provider systems and health plans to impact PAC rates. These include care coordination across care settings; post-discharge planning and patient follow- up, active care management, sharing medical record data between care settings and providers, total quality management within hospitals and active reduction of patient safety failures. Reducing PACs has the potential to significantly improve the overall level of quality.

Creating a single measure of accountability for physicians and hospitals tied to gaps in quality is likely to yield much improved outcomes for patients. A measure of accountability for health plans helps them review trends over time and work with physicians and hospitals to improve the ways in which they engage patients using more optimal care management and care coordination (Cassel 2014). In addition, PAC measures could be used as a surrogate for quality in a consumer transparency tool to differentiate providers with regards to their performance.

Moreover, since these measures are claims based, there is minimal added burden for collecting the data, and it also avoids potential gaming that may occur for other measures that require reporting information to registries. Although use of administrative claims data in identifying conditions and measuring provider quality has been questioned, there are several studies in literature that acknowledge validity of its use (Normand 2007) (Quan 2009). Until more readily available data are at hand, use of administrative data to measure provider performance has steadily increased (Miller 2001), (NQF Quality Positioning System). Interestingly, in the current fee for service system, services for most PACs are rewarded by continued payment (except the CMS defined "never events") and hence to our advantage, adverse events surface in billing data. Claims based PAC measures; therefore serve as an alternative method to track adverse outcomes that do occur (Leibson 2008).

1b.2. Provide performance scores on the measure as specified (current and over time) at the specified level of analysis. *(This is required for endorsement maintenance. Include mean, std dev, min, max, interquartile range, scores by decile. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities included). This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*

The data included two years of administrative claims covering the period April 1, 2012 through December 17, 2014. There were a total 262,273 episodes of HTN.

Because providers with small volumes may provide unreliable estimates, we excluded any with fewer than 10 attributed episodes prior to the calculations. After this exclusion 3,702 (out of 23,125) providers remained. Performance scores of these providers are

summarized in the following table:

Unadjusted PAC Rates:

Median (IQR):	29.7% (20.0%, 42.9%)
Range:	0% -100%

Risk-Standardized PAC Rates (RSPR):

Median (IQR):	31.1% (24.2%, 37.8%)
Range:	0% -173%

Please refer to the NQF_HTN_all_codes_risk_adjustment_06.30.15.xls workbook under the "ProviderAttribution Reliability" tab to see specific results for each provider.

1b.3. If no or limited performance data on the measure as specified is reported in 1b2, then provide a summary of data from the literature that indicates opportunity for improvement or overall less than optimal performance on the specific focus of measurement.

National Center for Chronic Disease Prevention and Health Promotion and the National Center for Health Statistics, CDC in 2013 published its statistics on the prevalence and treatment of hypertension in the US. According to the report, the prevalence of hypertension has remained consistent at about 30% in the last decade. Among adults with hypertension, Mexican-American persons born outside the United States, and persons without health insurance had lower rates of blood pressure control in 2005–2008. Black adults have higher rates of hypertension and lower rates of blood pressure control compared to Caucasians (Gillespie 2013). Another significant finding was that although the prevalence of hypertension was lowest among those aged 18–44 years (9.8%), the prevalence of blood pressure control was significantly lower among this group than their older counterparts. This is most likely because of lower rates of hypertension awareness and treatment with medication among younger adults. In order to address this gap, the United States Preventive Services Task Force (USPSTF) recommends blood pressure screening for all adults' aged =18 years (USPSTF 2007) .

1b.4. Provide disparities data from the measure as specified (current and over time) by population group, e.g., by race/ethnicity, gender, age, insurance status, socioeconomic status, and/or disability. *(This is required for endorsement maintenance. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities include.) This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*

Not applicable

1b.5. If no or limited data on disparities from the measure as specified is reported in 1b4, then provide a summary of data from the literature that addresses disparities in care on the specific focus of measurement. Include citations.

Not applicable

1c. High Priority (previously referred to as High Impact)

The measure addresses:

- a specific national health goal/priority identified by DHHS or the National Priorities Partnership convened by NQF; OR
- a demonstrated high-priority (high-impact) aspect of healthcare (e.g., affects large numbers of patients and/or has a substantial impact for a smaller population; leading cause of morbidity/mortality; high resource use (current and/or future); severity of illness; and severity of patient/societal consequences of poor quality).

1c.1. Demonstrated high priority aspect of healthcare

Affects large numbers, A leading cause of morbidity/mortality, High resource use, Patient/societal consequences of poor quality, Severity of illness

1c.2. If Other:

1c.3. Provide epidemiologic or resource use data that demonstrates the measure addresses a high priority aspect of healthcare. List citations in 1c.4.

Hypertension is a silent killer and affects 1 billion people worldwide. Globally about 9 million people are killed by the potentially avoidable consequences of hypertension (WHO 2013). One in 3 adults over the age of 18 suffer from hypertension in the US and almost half of them do not have adequate control of their blood pressure to less than 140/90mm Hg (Nwankwo 2013). Almost 2/3rd of the patients with hypertension are therefore at increased risk of cardiovascular events (Elliot 2003). The socioeconomic burden of preventable conditions such as stroke, coronary heart disease, heart failure, and end-stage renal disease can be reduced by adequate control of hypertension.

Preventing hypertension and its complications is less expensive than interventions like CABG or dialysis if hypertension is not controlled (Elliot 2003). The Eighth Joint National Committee (JNC 8) published in JAMA in 2014, issued evidence based guidelines stating that, "Hypertension remains one of the most important preventable contributors to disease and death. Abundant evidence from randomized controlled trials (RCTs) has shown benefit of antihypertensive drug treatment in reducing important health outcomes in persons with hypertension."(James 2014)

Despite advances in antihypertensive drug therapy and the availability of guidelines, hospitalizations for hypertension continue to be a drain on health care resources. Hospitalization for hypertension is a PAC and a preventable ambulatory care sensitive condition that represents a failure of outpatient care system. A study analyzing National Hospital Discharge Survey (NHDS) conducted by the National Center for Health Statistics (NCHS) showed that 35,503 preventable hospitalizations occurred for hypertension between 1995 and 2010 in people over the age of 18 years. Age and sex standardized rates showed that blacks were 3 times more likely than whites to be hospitalized for hypertension and women had higher rates then men (Will 2013).

To improve accountability in the delivery of chronic care, AHRQ has developed a list of prevention quality indicators (PQIs) to identify ambulatory care sensitive conditions (ACSCs) and to measure rates of admissions that could have been potentially avoided with good outpatient care (AHRQ 2008). Even though hospitalizations for hypertension should be potentially avoidable in their own right; once they do occur, the index stay itself may have a potentially avoidable complication (PAC) or patients may develop a PAC during the post-discharge period. PACs lead to significant variability in outcomes including prolonged hospitalizations, readmissions and emergency room visits, all indicating poor outcomes that harm the patient, cause payers to incur unnecessary costs; and could be improved by providers (de Brantes 2011) (Yong 2010).
Therefore, there are many areas where improvement is possible in hypertension, making it a high priority aspect of health care. The PAC measures go beyond simple readmission rates and look for all-cause harms in patients with hypertension.

1c.5. **If a PRO-PM (e.g. HRQoL/functional status, symptom/burden, experience with care, health-related behaviors), provide evidence that the target population values the measured PRO and finds it meaningful.** *(Describe how and from whom their input was obtained.)*
Not applicable

2. Reliability and Validity—Scientific Acceptability of Measure Properties

Extent to which the measure, as specified, produces consistent (reliable) and credible (valid) results about the quality of care when implemented. ***Measures must be judged to meet the subcriteria for both reliability and validity to pass this criterion and be evaluated against the remaining criteria.***

2a.1. Specifications The measure is well defined and precisely specified so it can be implemented consistently within and across organizations and allows for comparability. eMeasures should be specified in the Health Quality Measures Format (HQMF) and the Quality Data Model (QDM).

De.5. **Subject/Topic Area** *(check all the areas that apply):*
Cardiovascular, Cardiovascular : Hypertension

De.6. **Cross Cutting Areas** *(check all the areas that apply):*
Care Coordination, Care Coordination : Readmissions, Safety, Safety : Complications, Safety : Healthcare Associated Infections, Safety : Medication Safety, Safety : Readmissions, Safety : Venous Thromboembolism

S.1. **Measure-specific Web Page** *(Provide a URL link to a web page specific for this measure that contains current detailed specifications including code lists, risk model details, and supplemental materials. Do not enter a URL linking to a home page or to general information.)*
http://www.hci3.org/ecr_descriptions/ecr_description.php?version=5.2.006&name=HTN&submit=Submit

S.2a. **If this is an eMeasure**, HQMF specifications must be attached. Attach the zipped output from the eMeasure authoring tool (MAT) - if the MAT was not used, contact staff. (Use the specification fields in this online form for the plain-language description of the specifications)
This is not an eMeasure **Attachment:**

S.2b. **Data Dictionary, Code Table, or Value Sets** *(and risk model codes and coefficients when applicable) must be attached. (Excel or csv file in the suggested format preferred - if not, contact staff)*
Attachment **Attachment:** NQF_HTN_all_codes_risk_adjustment_06.30.15-635719646537139552.xlsx

S.3. **For endorsement maintenance**, please briefly describe any changes to the measure specifications since last endorsement date and explain the reasons.
Not applicable

S.4. **Numerator Statement** *(Brief, narrative description of the measure focus or what is being measured about the target population, i.e., cases from the target population with the target process, condition, event, or outcome)*
IF an OUTCOME MEASURE, state the outcome being measured. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
Outcome: Number of patients who triggered an episode of hypertension (HTN), are followed for at least one-year, and had one or more potentially avoidable complications (PACs) during the episode time window.

S.5. **Time Period for Data** *(What is the time period in which data will be aggregated for the measure, e.g., 12 mo, 3 years, look back to August for flu vaccination? Note if there are different time periods for the numerator and denominator.)*
The time window is the most recent 12 months of the episode, once a patient has triggered a HTN episode.

S.6. **Numerator Details** *(All information required to identify and calculate the cases from the target population with the target process, condition, event, or outcome such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
IF an OUTCOME MEASURE, describe how the observed outcome is identified/counted. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
Patients that have triggered a HTN episode, and are identified as having services for potentially avoidable complications (PACs), during the most recent 12 months of the episode. The enclosed excel workbook entitled NQF_HTN_all_codes_risk_adjustment_06.30.15 gives the detailed codes for PACs in the tabs entitled PACs I-9 and PACs I-10. PACs are identified only based on diagnosis codes.

Services for PACs are identified as follows:
a. Any service (professional, outpatient facility, ancillary) that is relevant to HTN and has a PAC code in any position on the claim
b. Any admission to an acute care facility, that is relevant to HTN
c. Any admission to a post-acute care facility that is relevant to HTN and has a PAC code in any position on the claim

S.7. **Denominator Statement** *(Brief, narrative description of the target population being measured)*
Adult patients aged 18 years and above who triggered an episode of hypertension (HTN) and are followed for at least one-year.

S.8. **Target Population Category** *(Check all the populations for which the measure is specified and tested if any):*
Populations at Risk, Populations at Risk : Dual eligible beneficiaries, Populations at Risk : Individuals with multiple chronic conditions, Populations at Risk : Veterans, Senior Care

S.9. **Denominator Details** *(All information required to identify and calculate the target population/denominator such as definitions, specific data collection items/responses , code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
Please refer to the enclosed excel workbook entitled
NQF_HTN_all_codes_risk_adjustment 06.30.15

The target population is identified using the following criteria:
1. Using administrative claims database, patients with HTN are identified using one of two of the following criteria:
a. Patients having an office visit with a trigger code of HTN in any position, followed by a second confirmatory office visit (with a trigger code of HTN in any position), at least 30 days apart.
b. Patients with a Principal Dx of a HTN trigger code on an in-hospital stay claim.
The trigger codes for HTN are provided in the tab called "Triggers I-9" or "Triggers I-10".
2. The patient should have continuous enrollment for the entire time window with no more than 30 days as an enrollment gap, with the entity providing the data (so we can ensure that the database has captured most of the claims for the patient during the episode time window).
3. The patient should have a complete episode time window in the claims data – so there are at least 12 months of claims in the database for the patient.
4. Patient should be at least 18 years of age

Once the episode is triggered all relevant claims are assigned to the episode. Relevant claims could be inpatient facility claims, outpatient facility claims, professional services, laboratory services, imaging services, ancillary claims, home health, durable medical equipment as well as pharmacy claims across the entire continuum of care centered around the patient's episode of care. Relevant claims are identified as those that have a diagnosis code that matches the codes in the typical Dx codes tabs (Typical Dx I-9 or Typical Dx I-10), or in the PAC Dx codes tab (PACs I-9 or PACs I-10) AND a procedure code as identified in the Relevant Procedures I-9 & I-10 tab in the enclosed workbook. Relevant admissions to acute and post-acute care facilities are also included in the denominator.

S.10. Denominator Exclusions *(Brief narrative description of exclusions from the target population)*
Denominator exclusions include exclusions of either "patients" or "claims" based on the following criteria:
1. "Patients" excluded are those that do not meet the enrollment criteria. If patient has an enrollment gap for more than 30 days during the episode time window, it is considered as an enrollment gap
2. "Patients" are also excluded if the cost of the episode is an outlier at greater than 99th percentile or less than 1st percentile value for all episodes. This is another way to ensure that episodes are complete as well as they do not bring in random noise into the analysis due to inappropriate codes or services.
3. "Claims" are excluded from the HTN measure if they are considered not relevant to HTN care.

S.11. Denominator Exclusion Details *(All information required to identify and calculate exclusions from the denominator such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
Denominator exclusions include exclusions of "patients" as well as "claims" not relevant to HTN care. Please refer to the enclosed excel workbook entitled (NQF_HTN_all_codes_risk_adjustment 06.30.15.xls)

1. "Patients" are excluded from the measure if they meet one of the following criteria:
a. If age is < 18 years
b. If gender is missing
c. If they do not have continuous enrollment for the entire time window with a maximum of 30 day enrollment gap with the entity providing the data (this helps determine if the database has captured most of the claims for the patient in the time window).
d. If the patient does not have at least 12 months of claims in the database (this helps eliminate incomplete episodes).
e. The episode cost is an outlier (less than 1st percentile or greater than 99th percentile value for all episodes of the same type). This eliminates extreme variation that may result from random outlier events.

2. "Claims" are excluded from the measure if they meet one of the following criteria:
a. If none of the diagnosis codes on the claim are on the list of "triggers" or relevant diagnosis codes (either typical Dx or PAC Dx) for HTN.
b. If none of the procedure / CPT codes on the claim are on the list of relevant procedure codes for HTN.
c. The "principal" diagnosis on an inpatient stay claim during the episode time window triggers its own episode
d. The procedure code on a claim during the episode time window triggers its own episode

S.12. Stratification Details/Variables *(All information required to stratify the measure results including the stratification variables, definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format with at S.2b)*
None

S.13. Risk Adjustment Type (Select type. Provide specifications for risk stratification in S.12 and for statistical model in S.14-15)
Statistical risk model
If other:

S.14. Identify the statistical risk model method and variables *(Name the statistical method - e.g., logistic regression and list all the risk factor variables. Note - risk model development and testing should be addressed with measure testing under Scientific Acceptability)*

Conceptual Model
Variations in outcomes across populations may be due to patient-related factors or due to provider-controlled factors. When we adjust for patient-related factors, the remaining variance in PACs are due to factors that could be controlled by all providers that are managing or co-managing the patient, both during and after hospitalization.

Statistical Method:
Logistic Regression model to determine the probability of a patient incurring a PAC
Demographic variables, comorbid conditions, as well as clinical severity indicators are fed as independent risk factors into the model. Risk Factors are collected historically. Subtype information is collected from the index claim and any look-back period, if relevant. Subtypes are clinical severity indicators suggesting severity of the episode itself, for example, hypertensive heart disease in a HTN patient. For each patient the "predicted" coefficients from the risk adjustment models are summed to give the predicted

probabilities of the occurrence of a PAC.

Risk Factors :(Please refer to the enclosed excel workbook entitled (NQF_HTN_all_codes_risk_adjustment 06.30.15.xls). The risk factors along with their codes are listed in the tabs called “All Risk Factors I-9” and “All Risk Factors I-10” and also listed below:

AGE CONTINUOUS VARIABLE
GENDER FEMALE = 1 (MALE IS REFERENCE = 0)

Risk Factor #	Risk Factor Name
RF0101	Anoxic Brain Damage, persistent vegetative state
RF0102	Delirium, Meningitis, Encephalitis
RF0103	Previous Stroke, Paralysis
RF0104	Cerebral Palsy and Other Paralytic Syndromes
RF0105	Spinal Cord Disorders/Injuries
RF0106	Polyneuropathy
RF0107	Multiple Sclerosis
RF0108	Convulsions, Epilepsy
RF0109	Dementia
RF0110	Parkinson´s and Huntington´s Diseases
RF0111	Cerebrovascular Disease
RF0115	after care, rehabilitation
RF0201	visual loss, blindness, retinal tear, detachment
RF0301	ENT, Upper Respiratory Problems
RF0401	Respiratory Failure, O2, ventilator dependence
RF0402	Advanced COPD, Asthma
RF0403	Empyema, bronchiectasis, Pneumonias
RF0404	Aspiration Pneumonia, Laryngeal Problems
RF0406	TB, Pneumoconiosis, Aspergillosis
RF0407	Tobacco use, Lung disease due to External Fumes
RF0408	Other Lung Disease
RF0501	Previous Shock, Syncope, Vent Fibrillation
RF0503	Advanced CHF
RF0504	Cardiomyopathy, valve disorders
RF0505	Cardiac Arrhythmias, Heart Block
RF0506	Pacemaker, AICD
RF0507	Endocarditis, Other post surgical cardiac problems
RF0508	Other Cardiovascular Disease
RF0511	DVT, Pulm Embolism, Pulm Heart Disease
RF0512	Unstable Angina
RF0513	Hypotension, chronic, orthostatic
RF0514	Hyperlipidemia
RF0515	Intraaortic Balloon Pump
RF0516	ventricular assist device, ecmo, prolonged bypass
RF0517	Previous electrophysiology studies, cryoablation
RF0518	Recent AMI
RF0519	Previous PCI
RF0520	Previous CABG
RF0521	Previous Heart & Valve Surgery
RF0522	Previous aortic reconstruction
RF0523	Previos carotid endarterectomy
RF0524	Aortic and peripheral vascular disease
RF0525	Advanced Aortic and Vascular Disease
RF0601	GI Bleed

RF0602 Intestinal Obstruction/Perforation
RF0603 Acute Gastritis, Duodenitis
RF0604 Gastroduodenal Ulcer
RF0606 Intestinal Uro-genital Fistula
RF0607 Abdominal hernia w complications
RF0608 Vascular insufficiency of intestine
RF0609 Inflammatory Bowel Disease
RF0610 Irritable Bowel
RF0611 Diverticulitis, Meckel´s
RF0612 Digestive congenital anomalies
RF0613 Intestinal infection
RF0614 Esophageal Perforation, Hmg, Barretts, Compl Hiatal Hernia
RF0615 Abnormal weight loss
RF0616 Achalasia, Esophageal spasm, Stricture, Dysphagia
RF0617 GERD, Hiatal Hernia, Other Upper GI Disorders
RF0618 Previous Bariatric Surgery
RF0619 Hx of colon polyps, family Hx of colon cancer
RF0620 Enterostomy, GI devices, lap band
RF0701 Pancreatic Disease
RF0702 Perforation, fistula GB, bile duct, pancreas
RF0703 Gall stones, cholecystitis
RF0704 End-Stage Liver Disease
RF0705 Hepatitis, Cirrhosis, Other Hepatbiliary Disorders
RF0706 Recent Gall Bladder, Hepatobilary Surgery
RF0707 Acute Pancreatitis, pseudo cyst
RF0801 Bone/Joint/Muscle Infections/Necrosis
RF0802 Muscular Dystrophy
RF0803 Osteoporosis, ostetits deformans, pathological fracture
RF0804 Rheumatoid Arthritis and Inflammatory Connective Tissue Disease
RF0805 Gout and other crystal arthropathies
RF0806 Other arthropathies
RF0807 Osteoarthritis
RF0808 Joint Deformities
RF0809 Knee derangements
RF0810 Traumatic Dislocation Knee
RF0811 Dislocation Hip
RF0812 Synovitis, Ruture Tendon
RF0813 Status Knee Replacement
RF0814 Status Total Hip Replacement
RF0901 Decubitus Ulcer
RF0902 Skin and wound problems
RF1001 Diabetes, poor control
RF1002 Advanced diabetes
RF1003 diabetes
RF1101 Acute renal failure
RF1102 Dialysis Dependent
RF1103 Nephritis
RF1104 Chronic renal failure
RF1105 Urinary Tract Infections
RF1301 Endometriosis
RF1302 Fibroid uterus, benign tumors of female organs
RF1303 Pelvic Inflammatory disease
RF1304 Uterine prolapse, cystocele, vaginocele
RF1305 Female Harmonal Disorders

RF1306 Ovarian, Broad Ligament Disorders
RF1308 Other disorders of uterus, cervix
RF1309 Menopausal Disorders
RF1310 Menstrual Disorders
RF1401 Multiparity, multigravida
RF1402 Elderly Primi, other
RF1403 Poor obstetric history
RF1406 Cervical incompetence
RF1407 Abnormalities of uterus, female genital tract
RF1408 Hypertension, pre-eclampsia in Pregnancy
RF1409 Severe pre-eclampsia w HTN, Eclampsia
RF1410 Maternal, gestational diabetes, large for date
RF1411 Genital Herpes
RF1412 Infections of genitourinary tract, venereal disease in pregnancy
RF1413 Infectious Diseases in Mother
RF1414 Cardiovascular disease in Mother
RF1415 Mental Disorders in Mother
RF1416 Epilepsy in Mother
RF1417 Liver and biliary tract disorders in mother
RF1418 Kidney Disease in Mother
RF1419 Other Maternal conditions
RF1421 Cephalopelvic Disproportion due to maternal causes
RF1436 Peripartum Cardiomyopathy
RF1441 Previous Cesarean section
RF1450 Maternal Obesity, previous Bariatric Surgery
RF1454 Previous Rupture Uterus, Obstetrical Trauma
RF1458 Complicated Pregnancy Delivery
RF1460 Thrombophlebitis, DVT during Pregnancy
RF1461 Puerperal Sepsis, other major puerperal complications
RF1462 Obstetrical Embolism, Air, Amniotic Fluid, Pulm, Pyemic
RF1467 Tobacco Use in Mother
RF1601 Bleeding Disorders
RF1602 Severe Hematological Disorders
RF1603 Disorders of Immunity
RF1604 Nutritional and other Anemias
RF1605 Long-term use of anticoag, Aspirin
RF1701 Head and Neck Cancers
RF1702 Lung and Intrathoracic Cancers
RF1703 Neuroendocrine, Myeloproliferative Cancers
RF1704 Poorly differentiated, Secondary, Metastatic Cancers
RF1705 Other Tumors
RF1706 Acute Leukemia
RF1707 Cancer uterus, localized female organs
RF1708 Colorectal, Hepatobiliary and other GI cancers
RF1709 Breast, Prostate, Thyroid cancers
RF1710 Testicular Cancer and localized of male organs
RF1711 Cancer of Bladder and Urinary Tract
RF1712 Musculoskeletal Cancers
RF1801 Sepsis, MRSA, Opportunitistic infections
RF1901 Schizophrenia
RF1902 Major Depressive, Bipolar, and Paranoid Disorders
RF2001 Drug/Alcohol Psychosis
RF2002 Drug/Alcohol Dependence
RF2101 Drug Reactions, long term use of drugs

RF2102 Intra-abdominal injury
RF2201 Extensive Third-Degree Burns
RF2301 Major Organ Transplant Status
RF2302 Artificial Openings for Feeding or Elimination
RF2303 Complications of Medical & Surgical Care and Trauma
RF2304 severe morbid obesity
RF2305 morbid obesity
RF2306 obesity
RF2307 mild sleep apnea, hypoventilation
RF2308 moderate sleep apnea, hypoventilation
RF2309 obstructive sleep apnea
RF2310 Severe Protein-Calorie Malnutrition
RF2311 Mild-mod malnutrition
RF2401 Severe Head Injury
RF2402 Major Head Injury
RF2403 Vertebral Fractures without Spinal Cord Injury
RF2404 Falls, Fractures
RF2405 Amputation
RF2501 HIV/AIDS

Subtypes for HTN
Hypertensive Heart Disease
Renovascular and other secondary hypertension

The prevalence of the risk factors in our reference dataset are listed in the enclosed workbook entitled NQF_HTN_all_codes_risk_adjustment 06.30.15.xls – see tab "Risk Factor Prevalence". The output of the regression model are given in the same workbook in the tab "Risk Model".

S.15. **Detailed risk model specifications** *(must be in attached data dictionary/code list Excel or csv file. Also indicate if available at measure-specific URL identified in S.1.)*
Note: Risk model details (including coefficients, equations, codes with descriptors, definitions), should be provided on a separate worksheet in the suggested format in the Excel or csv file with data dictionary/code lists at S.2b.
Available in attached Excel or csv file at S.2b

S.15a. **Detailed risk model specifications** (*if not provided in excel or csv file at S.2b*)

S.16. **Type of score:**
Rate/proportion
If other:

S.17. **Interpretation of Score** *(Classifies interpretation of score according to whether better quality is associated with a higher score, a lower score, a score falling within a defined interval, or a passing score)*
Better quality = Lower score

S.18. **Calculation Algorithm/Measure Logic** *(Describe the calculation of the measure score as an ordered sequence of steps including identifying the target population; exclusions; cases meeting the target process, condition, event, or outcome; aggregating data; risk adjustment; etc.)*
Please refer to the enclosed excel workbook entitled (NQF_HTN_all_codes_risk_adjustment 06.30.15.xls).

Assembling the Denominator:

Using administrative claims database, patients with HTN are identified using one of two criteria: 1) Patients having an office visit with a trigger code of HTN in any position, followed by a second confirmatory office visit (with a trigger code of HTN in any position),

at least 30 days apart, 2) Patients a Principal Dx of a HTN trigger code on an in-hospital stay claim. The trigger codes for HTN are provided in the tab called "Triggers I-9" or "Triggers I-10".

Patients are retained if they are 18 years of age or more, do not have a missing gender, have at least 12 month of claims in the database, have a maximum of 30-day enrollment gap for the entire episode time window, and have no outlier episode costs. All relevant professional, laboratory, imaging, ancillary and other claims that are incurred during the episode time window are included as part of the episode. Claims are considered relevant to HTN care if they have one of the diagnosis codes, as listed on the tab entitled Triggers I-9, Triggers 1-10, PACs I-9, PACs I-10, Typical Dx I-9, or Typical Dx I-10 in any position on the claim AND a procedure code as identified in the Relevant Procedures I-9 & I-10 tab in the enclosed workbook. Relevant admissions to acute and post-acute care facilities are also included in the denominator. All relevant pharmacy claims carrying codes that match the ingredients listed in the Pharmacy tab of the enclosed workbook are also included as part of the episode.

If a patient has more than one concurrent episode, and the claim is relevant to both episodes, the claim could get multi-assigned, except in the case of procedural episodes that get carved out with respect to the index stay. So if an inpatient stay claim carried a principal Dx code that matched the trigger diagnosis code for HTN but they also had a procedure code for CABG (coronary artery bypass surgery), the stay claim would get uniquely assigned to CABG and not be counted with HTN.

Once all the episodes are assembled, episodes that match the exclusion criteria, such as those with outlier costs, are flagged (those with total episode costs less than 1st percentile or greater than 99th percentile), and excluded from the final analysis.

Assembling the Numerator:

For every episode included in the denominator, services are flagged as having a PAC (potentially avoidable complication) based on the criteria listed below:

Any service (professional, outpatient facility, ancillary) with a PAC code in any position on the claim
Any admission to an acute care facility, that is relevant to HTN

Relevant claims that do not have any PAC codes, and do not qualify as a PAC based on the criteria outlined above, are listed as typical claims. All included relevant pharmacy services are flagged as typical. Patients that have even a single PAC claim are counted as part of the numerator.

Calculating the measure:

Proportion of HTN patients that have PACs is simply the ratio of patients with PACs within the HTN population and is called the PAC rate as shown in the equation below:

PAC rate = Patients with HTN that have at least one PAC claim / Total number of HTN patients

A flow chart demonstrating the series of steps and the counts of patients at each step is shown in tab entitled Decision Tree of the enclosed workbook called NQF_HTN_all_codes_risk_adjustment 06.30.15.xls

Drill Down Calculations:

Further analysis from this construct helps create actionable reports.

For example as shown in the tab labeled PAC overview, not only do we have the PAC rate for a population, we can break them down by the PAC type – type 1 being directly related to HTN and so actionable by the servicing physician, while type 2 PACs are related to patient safety failures and can be improved by process improvement. Additionally, analyzing potentially avoidable admissions helps focus strategies in reducing them.

Risk Adjustment:

Once we have the observed PAC rates, we risk-adjust them for patient factors such as patient demographics, comorbidities collected historically, and for severity of illness or procedure using subtypes collected from the index stay and / or look-back period. This helps adjust for factors outside the providers control and levels the playing field for provider performance comparisons.

Unit of Analysis:
The unit of analysis is the individual episode.

Dependent Variable:
The dependent variable is a dichotomous variable indicating whether an episode had one or more claims assigned as a PAC (=1) or not (=0).

Independent Variables:
A number of patient-related "risk factors" or covariates are included in the models:

Patient demographics: age, gender, and an indicator of whether a member has enrolled within the previous 6 months. This latter risk factor is intended to account for the patient's lack of claims history, which limits the number of potential comorbidities that can be identified.

Comorbidities: These are conditions or events that occurred prior to the start of the episode that can have a potential impact on the patient's risk of having a PAC. The risk factors are 170 disease indicators (0/1) identified through the presence of ICD diagnosis codes on individual medical claims and collected from the historical claims data before the start of an episode. These are universally applied across all episodes. Please see the tab labeled "All Risk Factors I-9" and "All Risk Factors I-10" for a list of risk factors and their corresponding codes in the enclosed workbook called NQF_HTN_all_codes_risk_adjustment 06.30.15.xls

Episode Subtypes or Severity Markers: These are markers that distinguish an episode as being more severe than another. They indicate either specific patient comorbidities that are known to make the procedure or condition more difficult to treat (e.g., obesity) or severity of the illness itself (e.g., unstable anginahypertensive heart disease). Please see the tab labeled "Subtypes I-9" and "Subtypes I-10" for a list of subtypes and their corresponding codes in the enclosed workbook called NQF_HTN_all_codes_risk_adjustment 06.30.15.xls

As mentioned previously, to avoid creating perverse incentives all comorbidities and subtypes are identified prior to or at the very start of the episode. None are identified during the episode period.

Statistical Methods
We use logistic regression to model the probability of at least one PAC occurring during the episode. Only comorbidities and subtypes are included in the models as covariates if they are present in at least 10 episodes to prevent unstable coefficients. No further model building is conducted after the initial models are built. This reflects a desire to explain as much variation in the probability of having a PAC as possible, but it does not make it a priority that all covariates in the model be individually significant or even uncorrelated with each other. Accordingly, the model uses a very large group of covariates. This modeling approach allows for fewer potentially artificial constraints around the definitions of what constitutes severity of a episode condition, and lets each regression model determine for itself which of the factors are more significant for a specific episode. Non-significant covariates in episode models can not overly influence predicted outcomes, nor is much harm realized, if a group of correlated covariates work together to explain variation rather than having the variation explained by a single best factor.

When more than one line of business is included in the data, separate models are calculated for each sample (i.e., commercial, Medicaid etc.).

Provider Attribution and calculating PAC rates by provider:

Once episodes are constructed they are attributed to providers based on one of the various attribution rules. For HTN, episodes are attributed to the primary care physician, internist or other physicians cardiologist with the highest count of office visits.

Using the logistic regression technique described above, a model is developed that gives estimates for each risk factor and subtype for the patients in the population analyzed. These estimates are used to develop patient-level probabilities for the occurrence of PACs. The patient-level probability estimates are summed to construct aggregated measures (e.g., facility/provider-level). This method is similar to the methods employed by the Centers for Medicare and Medicaid Services (CMS) and endorsed by the National Quality Forum (NQF) to construct similar facility- and practice-level measures (i.e., mortality, readmissions, etc.):

For each provider, the number of actual observed occurrences of the outcome is summed across all attributed patients with that episode, to give the observed PAC rates for the provider.

Similarly adjusted probabilities from the risk adjustment models are summed across all attributed patients to give expected

PACs for the provider.

The observed sum is then divided by the summed probabilities (O/E). This number yields whether the provider or facility had more PACs than expected (ratio>1), as expected (ratio=1), or less than expected (ratio<1). This calculation yields a practice-level unstandardized performance ratio.

To facilitate accurate comparisons of rates across units of analysis, this ratio is then standardized to the community rate using the indirect method. Specifically, the provider-level rate is multiplied by the expected community rate, calculated as the sum of adjusted probabilities for every individual in the sample across all providers in the analysis. This measure, known as the standardized rate, represents what the unit's risk-adjusted rate would be for the outcome of interest if its patient population was reflective of the of the overall community.

The formula for this calculation is as follows:

Adj Outcome_j={(SUM Observed_ij)/(SUM Prob_ij)} × {(SUM Prob_i) / (# of episodes)}
Where individual is attributed to unit of analysis j (e.g., practice, provider, etc.)

S.19. **Calculation Algorithm/Measure Logic Diagram URL or Attachment** *(You also may provide a diagram of the Calculation Algorithm/Measure Logic described above at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
Available in attached appendix at A.1

S.20. **Sampling** *(If measure is based on a sample, provide instructions for obtaining the sample and guidance on minimum sample size.)*
IF a PRO-PM, identify whether (and how) proxy responses are allowed.
Not applicable

S.21. **Survey/Patient-reported data** *(If measure is based on a survey, provide instructions for conducting the survey and guidance on minimum response rate.)*
IF a PRO-PM, specify calculation of response rates to be reported with performance measure results.
Not applicable

S.22. **Missing data** (specify how missing data are handled, e.g., imputation, delete case.)
Required for Composites and PRO-PMs.
If patient related data is missing, the case is deleted from both the numerator and the denominator.

S.23. **Data Source** *(Check ONLY the sources for which the measure is SPECIFIED AND TESTED).*
If other, please describe in S.24.
Administrative claims

S.24. **Data Source or Collection Instrument** *(Identify the specific data source/data collection instrument e.g. name of database, clinical registry, collection instrument, etc.)*
IF a PRO-PM, identify the specific PROM(s); and standard methods, modes, and languages of administration.
The information is based on a two-year claims database from a large regional commercial insurer. The database has over 3.2 million covered lives and $25.9 billion in "allowed amounts" for claims costs. The database is an administrative claims database with medical as well as pharmacy claims.

The methodology can be used on any claims database with at least two years of data and a minimum of 150 patients with the index condition or hospitalization. Having pharmacy data adds to the richness of the risk-adjustment models.
The calculations of rates of potentially avoidable complications can be replicated by anyone that uses the measure specifications along with the metadata file that is available for free on our web site at http://www.hci3.org/ecre/xml-agreement.html.
We also plan on providing a limited automated analysis, at no cost, on our website.
The methodology has been tested on databases of several health plans as well as on a few employer databases.

No data collection instrument was used.

S.25. **Data Source or Collection Instrument** *(available at measure-specific Web page URL identified in S.1 OR in attached appendix at*

A.1)
No data collection instrument provided

S.26. **Level of Analysis** *(Check ONLY the levels of analysis for which the measure is SPECIFIED AND TESTED)*
Clinician : Group/Practice, Clinician : Team, Health Plan, Population : National, Population : Regional, Population : State

S.27. **Care Setting** *(Check ONLY the settings for which the measure is SPECIFIED AND TESTED)*
Ambulatory Care : Ambulatory Surgery Center (ASC), Ambulatory Care : Clinician Office/Clinic, Other
If other: Across the care continuum

S.28. **COMPOSITE Performance Measure** - Additional Specifications *(Use this section as needed for aggregation and weighting rules, or calculation of individual performance measures if not individually endorsed.)*

2a. Reliability – See attached Measure Testing Submission Form
2b. Validity – See attached Measure Testing Submission Form
2748_HTN_Testing_Reliability_Validity_HCI3-635719660723458859.docx

NATIONAL QUALITY FORUM—Measure Testing (subcriteria 2a2, 2b2-2b7)

Measure Number (*if previously endorsed*)**:** 2748
Measure Title: Proportion of Patient with Hypertension (HTN) that have a Potentially Avoidable Complication (during the episode time window)
Date of Submission: 06/30/15
Composite Construction:

☐Two or more individual performance measure scores combined into one score
☐ All-or-none measures (e.g., all essential care processes received or outcomes experienced by each patient)
☐ Any-or-none measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient)

Instructions

- Measures must be tested for all the data sources and levels of analyses that are specified. ***If there is more than one set of data specifications or more than one level of analysis, contact NQF staff*** about how to present all the testing information in one form.
- **For all measures, sections 1, 2a2, 2b2, 2b3, and 2b5 must be completed.**
- **For outcome and resource use measures**, section **2b4** also must be completed.
- If specified for **multiple data sources/sets of specificaitons** (e.g., claims and EHRs), section **2b6** also must be completed.
- Respond to all questions as instructed with answers immediately following the question. All information on testing to demonstrate meeting the subcriteria for reliability (2a2) and validity (2b2-2b6) must be in this form. An appendix for *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 20 pages (*incuding questions/instructions;* minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other

stakeholders in understanding to what degree the testing results for this measure meet NQF's evaluation criteria for testing.

2a2. Reliability testing [10] demonstrates the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise. For **PRO-PMs and composite performance measures**, reliability should be demonstrated for the computed performance score.

2b2. Validity testing [11] demonstrates that the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality. For **PRO-PMs and composite performance measures**, validity should be demonstrated for the computed performance score.

2b3. Exclusions are supported by the clinical evidence; otherwise, they are supported by evidence of sufficient frequency of occurrence so that results are distorted without the exclusion; [12]
AND
If patient preference (e.g., informed decisionmaking) is a basis for exclusion, there must be evidence that the exclusion impacts performance on the measure; in such cases, the measure must be specified so that the information about patient preference and the effect on the measure is transparent (e.g., numerator category computed separately, denominator exclusion category computed separately). [13]

2b4. For outcome measures and other measures when indicated (e.g., resource use):

- **an evidence-based risk-adjustment strategy** (e.g., risk models, risk stratification) is specified; is based on patient factors that influence the measured outcome (but not factors related to disparities in care or the quality of care) and are present at start of care; [14,15] and has demonstrated adequate discrimination and calibration

OR

- rationale/data support no risk adjustment/ stratification.

2b5. Data analysis of computed measure scores demonstrates that methods for scoring and analysis of the specified measure allow for **identification of statistically significant and practically/clinically meaningful** [16] **differences in performance**;
OR
there is evidence of overall less-than-optimal performance.

2b6. If multiple data sources/methods are specified, there is demonstration they produce comparable results.

2b7. For **eMeasures, composites, and PRO-PMs** (or other measures susceptible to missing data), analyses identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias.

Notes
10. Reliability testing applies to both the data elements and computed measure score. Examples of reliability testing for data elements include, but are not limited to: inter-rater/abstractor or intra-rater/abstractor studies; internal consistency for multi-item scales; test-retest for survey items. Reliability testing of the measure score addresses precision of measurement (e.g., signal-to-noise).

11. Validity testing applies to both the data elements and computed measure score. Validity testing of data elements typically analyzes agreement with another authoritative source of the same information. Examples of validity testing of the measure score include, but are not limited to: testing hypotheses that the measures scores indicate quality of care, e.g., measure scores are different for groups known to have differences in quality assessed by another valid quality measure or method; correlation of measure scores with another valid indicator of quality for the specific topic; or relationship to conceptually related measures (e.g., scores on process measures to scores on outcome measures). Face validity of the measure score as a quality indicator may be adequate if accomplished through a systematic and transparent process, by identified experts, and explicitly addresses whether performance scores resulting from the measure as specified can be used to distinguish good from poor quality.
12. Examples of evidence that an exclusion distorts measure results include, but are not limited to: frequency of occurrence, variability of exclusions across providers, and sensitivity analyses with and without the exclusion.
13. Patient preference is not a clinical exception to eligibility and can be influenced by provider interventions.
14. Risk factors that influence outcomes should not be specified as exclusions.
15. Risk models should not obscure disparities in care for populations by including factors that are associated with differences/inequalities in care, such as race, socioeconomic status, or gender (e.g., poorer treatment outcomes of African American men with prostate cancer or inequalities in treatment for CVD risk factors between men and women). It is preferable to stratify measures by race and socioeconomic status rather than to adjust out the differences.
16. With large enough sample sizes, small differences that are statistically significant may or may not be practically or clinically meaningful. The substantive question may be, for example, whether a statistically significant difference of one percentage point in the percentage of patients who received smoking cessation counseling (e.g., 74 percent v. 75 percent) is clinically meaningful; or whether a statistically significant difference of $25 in cost for an episode of care (e.g., $5,000 v. $5,025) is practically meaningful. Measures with overall less-than-optimal performance may not demonstrate much variability across providers.

1. DATA/SAMPLE USED FOR ALL TESTING OF THIS MEASURE

Often the same data are used for all aspects of measure testing. In an effort to eliminate duplication, the first five questions apply to all measure testing. If there are differences by aspect of testing,(e.g., reliability vs. validity) be sure to indicate the specific differences in question 1.7.

1.1. What type of data was used for testing? (*Check all the sources of data identified in the measure specifications and data used for testing the measure. Testing must be provided for all the sources of data specified and intended for measure implementation.* ***If different data sources are used for the numerator and denominator, indicate N [numerator] or D [denominator] after the checkbox.***)

Measure Specified to Use Data From: (*must be consistent with data sources entered in S.23*)	**Measure Tested with Data From:**
☐ abstracted from paper record	☐ abstracted from paper record
☐ administrative claims	☐ administrative claims
☐ clinical database/registry	☐ clinical database/registry
☐ abstracted from electronic health record	☐ abstracted from electronic health record
☐ eMeasure (HQMF) implemented in EHRs	☐ eMeasure (HQMF) implemented in EHRs
☐ other: Click here to describe	☐ other: Click here to describe

1.2. If an existing dataset was used, identify the specific dataset (*the dataset used for testing must be consistent with the measure specifications for target population and healthcare entities being measured; e.g.,*

Medicare Part A claims, Medicaid claims, other commercial insurance, nursing home MDS, home health OASIS, clinical registry).

The information is based on a two-year administrative claims database from a large regional commercial insurer. The database contains medical and pharmacy claims on over 3.2 million covered lives and more than $25.9 billion in "allowed amounts" for costs.

1.3. What are the dates of the data used in testing? April 1, 2012 – December 17, 2014

1.4. What levels of analysis were tested? (*testing must be provided for all the levels specified and intended for measure implementation, e.g., individual clinician, hospital, health plan*)

Measure Specified to Measure Performance of: (*must be consistent with levels entered in item S.26*)	**Measure Tested at Level of:**
☐ individual clinician	☐ individual clinician
☐ group/practice	☐ group/practice
☐ hospital/facility/agency	☐ hospital/facility/agency
☐ health plan	☐ health plan
☐ other: Integrated Delivery System	☐ other:

1.5. How many and which measured entities were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of measured entities included in the analysis (e.g., size, location, type); if a sample was used, describe how entities were selected for inclusion in the sample*)

There were a total of 23,126 providers in the data set. Because providers with small volumes may provide unreliable estimates, we excluded any with fewer than 10 attributed episodes prior to the reliability calculations. After this exclusion, there were 3,702 providers left.

1.6. How many and which patients were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of patients included in the analysis (e.g., age, sex, race, diagnosis); if a sample was used, describe how patients were selected for inclusion in the sample*)

After exclusions (see 2b.3.1 below), there were a total of 262,273 episodes of HTN were included in the testing and analysis. Patients in these episodes were, on average, 53.0 years of age (range 18-64) and 46% were female. We did not have race information on these patients. All patients for this analysis had a trigger inpatient claim of HTN as identified in our code tables.

1.7. If there are differences in the data or sample used for different aspects of testing (e.g., reliability, validity, exclusions, risk adjustment), identify how the data or sample are different for each aspect of testing reported below.

For the reliability analysis, we restricted the data to only providers with at least 10 attributed episodes. For risk adjustment, all episodes were used in the analysis, regardless of the provider to which they were attributed.

1.8 What were the patient-level sociodemographic (SDS) variables that were available and analyzed in the data or sample used? For example, patient-reported data (e.g., income, education, language), proxy variables when SDS data are not collected from each patient (e.g. census tract), or patient community characteristics (e.g. percent vacant housing, crime rate).

None of the analyses included SDS variables.

2a2. RELIABILITY TESTING

***Note**: If accuracy/correctness (validity) of data elements was empirically tested, separate reliability testing of data elements is not required – in 2a2.1 check critical data elements; in 2a2.2 enter "see section 2b2 for validity testing of data elements"; and skip 2a2.3 and 2a2.4.*

2a2.1. What level of reliability testing was conducted? (*may be one or both levels*)

☐ **Critical data elements used in the measure** (*e.g., inter-abstractor reliability; data element reliability must address ALL critical data elements*)

☐ **Performance measure score** (e.g., *signal-to-noise analysis*)

2a2.2. For each level checked above, describe the method of reliability testing and what it tests (*describe the steps—do not just name a method; what type of error does it test; what statistical analysis was used*)

We assessed the reliability of the measure to demonstrate that it sufficiently differentiates performance between providers using the beta-binomial method, which is applicable to measures of this type. Reliability is a measure that distinguishes the signal (the extent of performance variation between entities that is due to true differences in performance) from statistical noise. Our approach follows directly from the methods outlined in the technical report "The Reliability of Provider Profiling: A Tutorial" by J.L. Adams.

Reference:

Adams JL. The Reliability of Provider Profiling: A Tutorial. Rand Corporation. http://www.rand.org/pubs/technical_reports/TR653.html.

2a2.3. For each level of testing checked above, what were the statistical results from reliability testing? (e.g., *percent agreement and kappa for the critical data elements; distribution of reliability statistics from a signal-to-noise analysis*)

The table below provides a summary of the reliability score for different minimum sample size thresholds. For complete results, refer to the workbook entitled, NQF_HTN_all_codes_risk_adjustment_06.30.15.xls, under the "ProviderAttribution Reliability" tab to see provider-specific results.

Reliability Scores	**Minimum # Episodes Per Provider**		
	>=10	**>=25**	**>=50**
# of Providers (%)	3,702 (100)	2,011 (54)	1,039 (28)
Median (IQR)	0.79 (0.67, 0.89)	0.87 (0.81, 0.92)	0.92 (0.89, 0.95)
Range	0.49-1.00	0.71-1.00	0.83-1.00

2a2.4 What is your interpretation of the results in terms of demonstrating reliability? (i.e., *what do the results mean and what are the norms for the test conducted?*)

Reliability scores can vary from 0.0 to 1.0, with a score of zero indicating that all variation is attributable to measurement error (noise, or variation across patients within providers) whereas a

reliability of 1.0 implies that all variation is caused by real difference in performance across accountable entities.

There is not a clear cut-off for minimum reliability level. Values above 0.7, however, are considered sufficient to see differences between some physicians and the mean, and values above 0.9 are considered sufficient to see differences between pairs of physicians (see Adams, 2009 cited above).

Although some scores among providers with at least 10 episodes were low, many had scores that met or exceeded the minimum acceptable level for reliability. Moreover, limiting providers to those with at least 25 or 50 episodes, scores were consistently good. These results demonstrate that the measure sufficiently differentiates providers' performance.

Minimum sample size requirements for PAC measures are a function of the reliability testing of the measures on every dataset on which the measures are applied. Our research suggests that minimum sample sizes to achieve high degrees of reliability in the measures are a function of the dataset analyzed, and as such may vary from dataset to dataset. One should not infer that a minimum sample size achieved in one dataset would apply to another.

2b2. VALIDITY TESTING

Note: *Current guidance for composite measure evaluation states that validity should be demonstrated for the composite performance measure score. If not feasible for initial endorsement, acceptable alternatives include assessment of content or face validity of the composite OR demonstration of validity for each component. Empirical validity testing of the composite measure score is expected by the time of endorsement maintenance.*

2b2.1. What level of validity testing was conducted?

☐ **Composite performance measure score**

- ☐ **Empirical validity testing**
- ☐ **Systematic assessment of face validity of performance measure score as an indicator** of quality or resource use (*i.e., is an accurate reflection of performance on quality or resource use and can distinguish good from poor performance*)
- ☐ **Systematic assessment of content validity**

☐ **Validity testing for component measures** *(check all that apply)*

Note: *applies to ALL component measures, unless already endorsed or are being submitted for individual endorsement.*

- ☐ **Endorsed (or submitted) as individual performance measures**
- ☐ **Critical data elements** (*data element validity must address ALL critical data elements*)
- ☐ **Empirical validity testing of the component measure score(s)**
- ☐ **Systematic assessment of face validity of component measure score(s) as an indicator** of quality or resource use (*i.e., is an accurate reflection of performance on quality or resource use and can distinguish good from poor performance*)

2b2.2. For each level of testing checked above, describe the method of validity testing and what it tests (*describe the steps—do not just name a method; what was tested, e.g., accuracy of data elements compared to authoritative source, relationship to another measure as expected; what statistical analysis was used)*

Content validity was built into the development of the definitions of potentially avoidable complications (PACs). This involved working with clinicians who are experts in their respective fields and specific to the episodes for which PACs are being measured. In particular, the clinical experts focused on whether or not a potentially avoidable complication can be deemed as such for a specific episode of care, and help defined and review all of the diagnosis and procedure codes for each PAC. The enclosed link lists clinicians who have participated in the various Clinical Working Groups (http://www.hci3.org/content/clinical-working-group-contributors). Some of the clinical experts have also participated in monthly webinars that highlight the clinical aspects of these measures (http://www.hci3.org/content/using-ecrs-providers).

In addition, we illustrate that our measure has face validity in several ways.

Beyond the up front work performed by clinical experts, the validity of the measure has also been tested in various real world settings. For example, we have presented results of claims data analyses that reveal the frequency and costs of PACs to physicians in several different healthcare systems involved in our pilot site implementations, as well as to medical directors from the employer coalitions and the health plans that provided the dataset to run the analyses. Some of these implementations include the Pennsylvania Employee Benefits Trust Fund and local provider groups and hospital, Horizon Blue Cross Blue Shield of NJ and many physicians and health systems.

In addition, we have performed dozens of analyses of very large claims data sets and reported results of rates and costs of PACs to policy makers, health plan leaders and physician leaders from different states. These include:

- Vermont Payment Reform Commission
- Maine Health Management Coalition
- WellPoint / Anthem CT
- NY State Medicaid
- CT Medicaid
- CO All-payer Claims Database, Center for Improving Value in Health Care

These analyses and their results have influenced, and continue to influence, the development of various public reporting, payment reform and delivery system reform efforts. To-date, we have never experienced either wholesale or partial rejection of the results of analyses showing rates of PACs, which demonstrates the level of acceptability – face validity – of the measures from the payer, policymaker, employer and payer communities.

As importantly, measures of potentially avoidable complications have face-validity with consumers. In a series of focus groups, Judy Hibbard and colleagues[1] examined the impact of presenting information about price and quality of certain providers in influencing the decisions of consumers. They tested the validity of PACs as a discriminator of quality, as well as other measures of quality, and used the dollar symbol to illustrate the level of price, much like is done for restaurant reviews. When the PAC measure was used, respondents selected the providers with the lowest PAC rates with a high level of confidence in choice, and used it as a surrogate for a

strong quality signal. To the contrary, when more standard measures of quality were used, consumers tended to ignore them and use price as a surrogate for quality. As such, what the researchers found is that the very framing of potentially avoidable complications as an indicator of potential harm, is an effective way of communicating the quality of care. And when measures of PACs were presented in conjunction with price, consumers intuitively accepted the logical relationship between low PACs – fewer "defects" – and lower price.

Finally, our measure definitions encompass several other measures that are accepted as being valid complications of care and are widely used throughout the country. These include CMS defined Hospital Acquired Conditions (HACs)[2], Hospital Inpatient Quality Reporting measures [3], Avoidable Readmissions [4,5], AHRQ defined patient safety indicators (PSIs) [6], NQF endorsed patient safety measures such as patient fall rates, pressure ulcer rates, and peri-operative pulmonary embolism or deep vein thrombosis rates [7].

2b2.3. What were the statistical results from validity testing? (*e.g., correlation; t-test*)
Not applicable.

2b2.4. What is your interpretation of the results in terms of demonstrating validity? (i.*e., what do the results mean and what are the norms for the test conducted?*)

Given the significant clinical input that went into developing the measure, the widespread use and acceptance the measure has gained among a wide variety of individuals and organizations across the health system (public and private payers, clinicians, consultants, patients, etc.) [1-13], and the parallels between this measure and other measures that are in widespread use, this demonstrates that the measure has strong face validity.

2b3. EXCLUSIONS ANALYSIS

NA ☐ no exclusions — *skip to section 2b4*

2b3.1. Describe the method of testing exclusions and what it tests (*describe the steps—do not just name a method; what was tested, e.g., whether exclusions affect overall performance scores; what statistical analysis was used*)

No formal exclusion testing was done since no real exclusions were done. The only patients excluded were the ones that had incomplete or missing data and those that would not have given a homogenous population such as outliers.

Exclusions included exclusions of "patients" as well as "claims" not relevant to HTN care. Please refer to the enclosed excel workbook entitled (NQF_HTN_all_codes_risk_adjustment_06.30.15.xls)

1. "Patients" are excluded from the measure if they meet one of the following criteria:
a. If age is < 18 years
b. If gender is missing
c. If they do not have continuous enrollment for the entire time window with a maximum of 30 day enrollment gap with the entity providing the data (this helps determine if the database has captured most of the claims for the patient in the time window).
d. If the patient does not have at least 12 months of claims in the database (this helps eliminate incomplete episodes).
e. The episode cost is an outlier (less than 1st percentile or greater than 99th percentile value for all episodes of the same type). This eliminates extreme variation that may result from random outlier events.

2. “Claims” are excluded from the measure if they meet one of the following criteria:
a. If none of the diagnosis codes on the claim are on the list of “triggers” or relevant diagnosis codes (either typical Dx or PAC Dx) for HTN.
b. If none of the procedure / CPT codes on the claim are on the list of relevant procedure codes for HTN.
c. The “principal” diagnosis on an inpatient stay claim during the episode time window triggers its own episode
d. The procedure code on a claim during the episode time window triggers its own episode.

2b3.2. What were the statistical results from testing exclusions? (*include overall number and percentage of individuals excluded, frequency distribution of exclusions across measured entities, and impact on performance measure scores*)

We started with a total HTN population of 409,442 episodes. After all the exclusions were applied, the remaining HTN population included in the analysis consisted of 262,273 episodes. As mentioned above, no real exclusions were done. The only patients excluded were the ones that had incomplete or missing data and those that would not have given a homogenous population such as outliers. As such, no formal exclusion testing was done.

2b3.3. What is your interpretation of the results in terms of demonstrating that exclusions are needed to prevent unfair distortion of performance results? (*i.e., the value outweighs the burden of increased data collection and analysis. Note: **If patient preference is an exclusion**, the measure must be specified so that the effect on the performance score is transparent, e.g., scores with and without exclusion*)

No formal analysis was done on the impact of exclusions on performance scores.

Descriptive Explanation:

Exclusions of patients were for the following reasons. Some are for comparative purposes and some for medical reasons.

(a) Comparative Purposes:
We excluded patients that did not have complete enrollment for the entire episode time window. This was done to ensure that the database had complete information on patients to be able to create the entire episode. Including patients with only a partial episode window could distort the measure by artificially reducing the actual count of patients with PACs.

(b) Medical Reasons:
Patients with outlier costs (less than 1st percentile value or greater than 99th percentile) were considered to be different from the general pool, and excluded from both the numerator and the denominator. This is another way to ensure that episodes are complete (because incomplete episodes may have very low costs), and do not bring in random noise into the analysis due to inappropriate codes or services (high outliers).

2b4. RISK ADJUSTMENT/STRATIFICATION FOR OUTCOME OR RESOURCE USE MEASURES
If not an intermediate or health outcome, or PRO-PM, or resource use measure, skip to section 2b5.

2b4.1./S13 What method of controlling for differences in case mix is used?
☐ **No risk adjustment or stratification**
☐ **Statistical risk model with 170 potential risk factors** and episode specific subtypes
☐ **Stratification by** Click here to enter number of categories **risk categories**
☐ **Other,** Click here to enter description

2b4.1.2. If an outcome or resource use measure is not risk adjusted or stratified, provide rationale and analyses to demonstrate that controlling for differences in patient characteristics (case mix) is not needed to achieve fair comparisons across measured entities.

2b4.2/S14. Identify the statistical risk model variables (Name the statistical method – e.g., logistic regression and list all the risk factor variables.
A number of patient-related "risk factors" or covariates are included in the models:

Patient demographics: age, gender, and an indicator of whether a member has enrolled within the previous 6 months. This latter risk factor is intended to account for the patient's lack of claims history, which limits the number of potential comorbidities that can be identified.

Comorbidities: These are conditions or events that occurred prior to the start of the episode that can have a potential impact on the patient's risk of having a PAC. The risk factors are 170 disease indicators (0/1)

identified through the presence of ICD diagnosis codes on individual medical claims and collected from the historical claims data before the start of an episode. These are universally applied across all episodes. Please see the tab labeled "All Risk Factors I-9" and "All Risk Factors I-10" for a list of risk factors and their corresponding codes in the enclosed workbook called NQF_HTN_all_codes_risk_adjustment 06.30.15.xls. This list was selected based on input from clinical experts in clinical working groups.

Episode Subtypes or Severity Markers: These are markers that distinguish an episode as being more severe than another. They indicate either specific patient comorbidities that are known to make the procedure or condition more difficult to treat (e.g., obesity) or severity of the illness itself (e.g., Hypertensive Heart Disease, Renovascular and other secondary hypertension). Subtypes are specific to each unique episode and are included in the models only if they are present at the start of the episode. Please see the tab labeled "Subtypes I-9" and "Subtypes I-10" for a list of subtypes and their corresponding codes in the enclosed workbook called NQF_HTN_all_codes_risk_adjustment_06.30.15.xls. This list was selected based on input from clinical experts in clinical working groups.

Candidate comorbidities and subtypes were included in the models as covariates if they were present in at least 10 episodes to prevent unstable coefficients.

2b4.2.1/S15. Detailed risk model specifications including coefficients, equations, codes with descriptors, definitions(may be attached in an Excel or cvs file)
All Risk Factors with their coefficients are detailed in the enclosed workbook called NQF_HTN_all_codes_risk_adjustment_06.30.15.xls – Please reference the tabs titled Risk Factor Prevalence and Risk Model.

2b4.3. Describe the conceptual/clinical and statistical methods and criteria used to select patient factors (clinical factors or sociodemographic factors) used in the statistical risk model or for stratification by risk(*e.g., potential factors identified in the literature and/or expert panel; regression analysis; statistical significance of p<0.10; correlation of x or higher; patient factors should be present at the start of care*)

Risk factors are comorbidity indicators collected from historical claims before the start of an episode. These are universally applied across all episodes. This list was selected based on input from clinical experts in clinical working groups. In addition, the Clinical Working Groups identified episode specific severity markers that were called episode subtypes and they help distinguish an episode as being more severe than another.

All risk factors and subtypes must be present prior to, or at the start of the episode and are identified using diagnosis codes in the patient's historical claims.

To be included in the risk adjustment models, any risk factor or subtype must be present in at least 10 episodes. Beyond this no further model building was conducted to add or remove risk factors or subtypes from the model after it was initially run. This reflects a desire to explain as much variation in the probability of having a PAC as possible, but does not make it a priority that all covariates be individually significant or even uncorrelated with each other. Accordingly, the model uses a very large group of covariates. This modeling approach allows for fewer potentially artificial constraints around the definitions of what constitutes severity, and lets the model determine for itself which of the factors are more significant. Non-significant covariates cannot overly influence the predicted outcomes, nor is much harm realized, if a group of correlated covariates work together to explain variation rather than having the variation explained by a single best factor.

2b4.4a. What were the statistical results of the analyses used to select risk factors?
As explained above, no formal analysis was conducted to select risk factors. In fact, all potential risk factors and subtypes with a count of at least 10 episodes were retained to serve as predictors. The goal was to achieve a more complete explanatory model rather than achieve parsimony.

Please reference the tabs titled Risk Model in the NQF_HTN_all_codes_risk_adjustment_06.30.15.xls workbook to see the list of risk factors that met the selection criteria.

2b4.4b. Describe the analyses and interpretation resulting in the decision to select SDS factors (e.g. prevalence of the factor across measured entities, empirical association with the outcome, contribution of unique variation in the outcome, assessment of between-unit effects and within-unit effects)

Not Applicable since our analysis did include SDS variables

2b4.5. Describe the method of testing/analysis used to develop and validate the adequacy of the statistical model or stratification approach (*describe the steps—do not just name a method; what statistical analysis was used*)

Model Development Approach

We used logistic regression to model the probability of at least one PAC occurring during the episode. The model included all covariates that were identified through the process above. No further model building was conducted after the initial model was run. This reflects a desire to explain as much variation in the probability of having a PAC as possible, but does not make it a priority that all covariates be individually significant or even uncorrelated with each other. Accordingly, the model uses a very large group of covariates. This modeling approach allows for fewer potentially artificial constraints around the definitions of what constitutes severity, and lets the model determine for itself which of the factors are more significant. Non-significant covariates can not overly influence the predicted outcomes, nor is much harm realized, if a group of correlated covariates work together to explain variation rather than having the variation explained by a single best factor.

For a more complete description of the risk adjustment approach, please see the document entitled, "PACs and Severity Adjustment Fact Sheet" that accompanies this submission.

Approach to Model Testing and Validation

To determine the validity and performance of the model, we used the split sample method to divide the patient sample randomly into: 1) the model building data set (80% of the sample) and 2) the test data set (20% of sample. The model was built using logistic regression on the first data set and then the coefficients from the development model were tested in the second dataset. Area under the curve (AUC) and the c-statistic were used to compare the predictive ability of the model in each of the data sets. Hosmer-Lemeshow Goodness-of-Fit tests and comparisons of observed to expected probabilities across risk deciles were further examined to assess the model's overall predictive accuracy.

Provide the statistical results from testing the approach to controlling for differences in patient characteristics (case mix) below.
If stratified, skip to 2b4.9

2b4.6. Statistical Risk Model Discrimination Statistics (*e.g., c-statistic, R-squared*)**:**

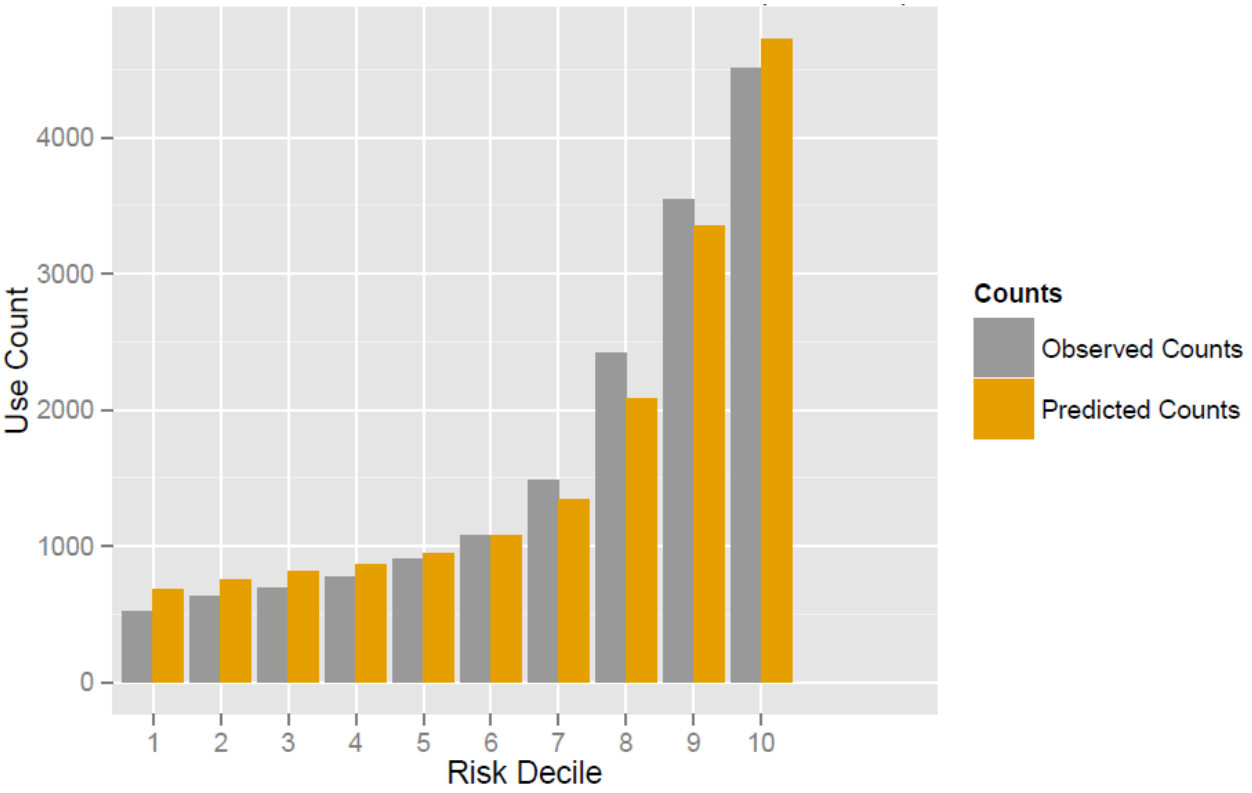
Sample	Accuracy (%)*	AUC
Test	79.0%	0.800
Validation	79.2%	0.801

*Episodes with predicted probabilities <50% were classified as having a predicted 0 (not having a PAC). Episodes with predicted probabilities >50% were classified as having a predicted 1 (having a PAC)

2b4.7. Statistical Risk Model Calibration Statistics (*e.g., Hosmer-Lemeshow statistic*):

Sample	Chi Square	Degrees of Freedom	p-value
Test	1500.1	8	<0.0001
Validation	337.7	8	<0.0001

2b4.8. Statistical Risk Model Calibration – Risk decile plots or calibration curves:



2b4.9. Results of Risk Stratification Analysis:
Not applicable

2b4.10. What is your interpretation of the results in terms of demonstrating adequacy of controlling for differences in patient characteristics (case mix)? (i.*e., what do the results mean and what are the norms for the test conducted*)

The C statistic is a measure of the extent to which a statistical model is able to discriminate between a patient with and without an outcome. The c-statistic ranges from 0.5 to 1.0. A c-statistic of 0.50 indicates the model is no better than random prediction, implying that the patient risk factors do not predict variation in the outcome; conversely, a c-statistic of 1.0 indicates perfect prediction, implying patients' outcomes can be predicted completely by their risk factors, and physicians and hospitals play little role in patients' outcomes. Models with c-statistic values of at least 0.7 are considered good and those above 0.8 are considered strong [1]. The purpose of the model is to adjust for patient-related factors. The remaining unexplained differences in PAC rates are due to factors that could be controlled by all providers that are managing or co-managing the patient, during the entire episode time window.

The c-statistics of the testing and validation samples (0.800 and 0.801, respectively) indicate that the risk models have strong discriminatory power. Indeed, the accuracy values show that the model correctly predicts whether an episode had or did not have a PAC just under 80% of the time, well above what would be expected if the predictions were made at random (i.e., 50%). Although the H-L tests were significant, meaning that the model is not a good fit, test is generally known to be sensitive to the number of groupings used and sample sizes. As shown by the risk decile plot, however, the model predicts PACs similar to the number of observed PACs across each of the deciles.

Overall, the results suggest that the model has sufficient predictive power.

2b4.11. Optional Additional Testing for Risk Adjustment (*not required, but would provide additional support of adequacy of risk model, e.g., testing of risk model in another data set; sensitivity analysis for missing data; other methods that were assessed*)

Not applicable

2b5. IDENTIFICATION OF STATISTICALLY SIGNIFICANT & MEANINGFUL DIFFERENCES IN PERFORMANCE

2b5.1. Describe the method for determining if statistically significant and clinically/practically meaningful differences in performance measure scores among the measured entities can be identified (*describe the steps—do not just name a method; what statistical analysis was used? Do not just repeat the information provided related to performance gap in 1b)*

To directly compare PAC rates across providers while also appropriately accounting for differences in patient severity, we calculated a risk-standardized PAC rate for each provider. This method is similar to calculations used by others for reporting outcomes measures [1]. For each provider, the ratio of observed attributed episodes with PACs to the expected number of attributed episodes with PACs given the patient's risk factor and estimated from the risk-adjustment model was calculated. This number yielded whether the provider had more PACs than expected (ratio>1), as expected (ratio=1), or less than expected (ratio<1). We then multiplied this ratio by the overall expected PAC rate across all providers to obtain the risk-standardized PAC rate for the provider. This measure represents what a provider's PAC rate would be if its patient population was reflective of the overall population.

Because providers with small volumes may provide unreliable estimates, we excluded any with fewer than 10 attributed episodes prior to the calculations. Comparison of risk-adjusted PAC rates gives a measure of the provider's relative performance. Our analysis compared risk-standardized PAC rates across providers. We analyzed various descriptive statistics including the range in PAC rates, medians, interquartile range, etc.

[1] See, for example: NQF#1550: Hospital-level risk-standardized complication rate (RSCR) following elective primary total hip arthroplasty (THA) and / or total knee arthroplasty (TKA). Online version: http://bit.ly/1BWQTRt

2b5.2. What were the statistical results from testing the ability to identify statistically significant and/or clinically/practically meaningful differences in performance measure scores across measured entities? (e.g., *number and percentage of entities with scores that were statistically significantly different from mean or some benchmark, different from expected; how was meaningful difference defined*)

Summary of Unadjusted and Adjusted Performance Scores Across Providers:

PAC Rates	Minimum # Episodes Per Provider	
	>=10	>=25

Unadjusted		
Median (IQR)	30% (20%, 43%)	29% (20%, 41%)
Range	0%-100%	3%-100%
Adjusted (RSPR)*		
Median (IQR)	31% (24%, 38%)	31% (25%, 36%)
Range	0%-173%	4%-112%

***RSPR = Risk Standardized PAC Rate**

Please refer to the NQF_HTN_all_codes_risk_adjustment_06.30.15.xls workbook under the "ProviderAttribution Reliability" tab to see specific results for each provider.

2b5.3. What is your interpretation of the results in terms of demonstrating the ability to identify statistically significant and/or clinically/practically meaningful differences in performance across measured entities? (i.*e., what do the results mean in terms of statistical and meaningful differences?*)
Even after right-adjustment, the variation in risk-adjusted rates suggests there are meaningful differences in performance between providers in risk-standardized PAC rates for patients with an episode of HTN.

Minimum sample size requirements for PAC measures are a function of the reliability testing of the measures on every dataset on which the measures are applied. Our research suggests that minimum sample sizes to achieve high degrees of reliability in the measures are a function of the dataset analyzed, and as such may vary from dataset to dataset. One should not infer that a minimum sample size achieved in one dataset would apply to another.

2b6. COMPARABILITY OF PERFORMANCE SCORES WHEN MORE THAN ONE SET OF SPECIFICATIONS
If only one set of specifications, this section can be skipped.

Note: *This criterion is directed to measures with more than one set of specifications/instructions (e.g., one set of specifications for how to identify and compute the measure from medical record abstraction and a different set of specifications for claims or eMeasures). It does not apply to measures that use more than one source of data in one set of specifications/instructions (e.g., claims data to identify the denominator and medical record abstraction for the numerator).* ***Comparability is not required when comparing performance scores with and without SDS factors in the risk adjustment model. However, if comparability is not demonstrated for measures with more than one set of specifications/instructions, the different specifications (e.g., for medical records vs. claims) should be submitted as separate measures.***

2b6.1. Describe the method of testing conducted to demonstrate comparability of performance scores for the same entities across the different data sources/specifications (*describe the steps—do not just name a method; what statistical analysis was used*)

2b6.2. What were the statistical results from testing comparability of performance scores for the same entities when using different data sources/specifications? (*e.g., correlation, rank order*)

2b6.3. What is your interpretation of the results in terms of demonstrating comparability of performance measure scores for the same entities across the different data sources/specifications? (i.*e., what do the*

results mean and what are the norms for the test conducted)

2b7. MISSING DATA ANALYSIS AND MINIMIZING BIAS

2b7.1. Describe the method of testing conducted to identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias (*describe the steps—do not just name a method; what statistical analysis was used*)

If patient related data is missing, the entire patient is excluded from the numerator as well as the denominator.

Within our measure constructs, presence of potentially avoidable complications are identified from administrative claims data. Furthermore, the measure is constructed so that the occurrence of any number of PACs during a defined episode would only count as one occurrence.

According to our measure definition, in constructing the measure it is possible for a provider to have only one or some types of PACs and not others. Alternatively, the provider may have all PAC types occur for their patients. The measure only considers whether any PAC occurred regardless of the type, and all PAC types are weighted equally, therefore we believe, there is no potential for the absence of specific PAC types to bias performance scores for individual providers.

For these reasons, no formal analyses were done on missing data.

2b7.2. What is the overall frequency of missing data, the distribution of missing data across providers, and the results from testing related to missing data? (*e.g., results of sensitivity analysis of the effect of various rules for missing data/nonresponse; if no empirical sensitivity analysis, identify the approaches for handling missing data that were considered and pros and cons of each*)
Not applicable

2b7.3. What is your interpretation of the results in terms of demonstrating that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias**?** (i.*e., what do the results mean in terms of supporting the selected approach for missing data and what are the norms for the test conducted; if no empirical analysis, provide rationale for the selected approach for missing data*)

Not applicable

2d. EMPIRICAL ANALYSIS TO SUPPORT COMPOSITE CONSTRUCTION APPROACH

Note: *If empirical analyses do not provide adequate results—or are not conducted—justification must be provided and accepted in order to meet the must-pass criterion of Scientific Acceptability of Measure Properties. Each of the following questions has instructions if there is no empirical analysis.*

2d1. Empirical analysis demonstrating that the component measures fit the quality construct, add value to the overall composite, and achieve the object of parsimony to the extent possible.

The PAC measures, as we define them, look at many "care defects" comprehensively. They are composed of several cross-cutting measures and together they paint a global picture of the provider's overall performance.

PACs may occur any time during the episode time window. PACs are counted as a dichotomous (yes/no) outcome. If a patient had one or more PACs, they get counted as a "yes" or a 1. The enclosed workbook entitled NQF_HTN_all_codes_risk_adjustment_06.30.15.xls provides outputs from empirical analysis. The tab labeled "PAC overview" demonstrates percentage of episodes that had at least one PAC, and provides the breakdown of PACs: 1) by the type of PAC whether directly related to index condition or due to patient safety failures; 2) the setting of the PAC, whether seen in the in-patient setting, out-patient facility or during professional visits; and 3) preventable hospitalizations.

The "PAC Drill Down Graph" provides further detail on each component of the PAC and their frequency. As can be seen by the individual counts and the graph, while each individual PAC may have such small occurrences that no meaningful comparisons in provider performances could be made; together, they add value to provide a comprehensive picture that result in meaningful numbers. The aggregation of PACs to a comprehensive, composite measure, in itself provides the parsimony that is so desirable.

2d1.1 Describe the method used (*describe the steps—do not just name a method; what statistical analysis was used; if no empirical analysis, provide justification)*

All PACs, as clinically defined by the subject matter experts were used with equal weighting. Since the emphasis of the PAC measure is to identify the occurrence of PACs in any setting, a simple and straightforward approach was adopted.

2d1.2. What were the statistical results obtained from the analysis of the components? (e.g., *correlations, contribution of each component to the composite score, etc*.; *if no empirical analysis, identify the components that were considered and the pros and cons of each*)

No formal analysis was performed.

2d1.3. What is your interpretation of the results in terms of demonstrating that the components included in the composite are consistent with the described quality construct and add value to the overall composite? (i.*e., what do the results mean in terms of supporting inclusion of the components; if no empirical analysis, provide rationale for the components that were selected)*

Since our premise is that all PACs are potentially avoidable, we adopted the approach to count all PACs and give them equal weights. The overall composite score results in the quality construct that could be measured and interpreted.

2d2. Empirical analysis demonstrating that the aggregations and weighting rules are consistent with the quality construct and achieve the objective of simplicity to the extent possible

2d2.1 Describe the method used (*describe the steps—do not just name a method; what statistical analysis was used; if no empirical analysis, provide justification)*

Within our measure constructs, presence of potentially avoidable complications are identified from administrative claims data. Additionally, if a patient had one or more PACs, it is simply counted as a 1, i.e., flagged as having a PAC. The measure only considers whether any PAC occurred regardless of the type, or the site, and all PAC types are weighted equally. Therefore, no formal analysis of individual components was performed.

2d2.2. What were the statistical results obtained from the analysis of the aggregation and weighting rules? (e.g., *results of sensitivity analysis of effect of different aggregations and/or weighting rules; if no empirical analysis, identify the aggregation and weighting rules that were considered and the pros and cons of each*)

We chose not to weight the components of the measure.

Considerations were given to the fact that preventable hospitalizations may be given more weight, than PACs identified in a doctor's office. Similarly PACs in an in-patient setting may have more serious implications on a patient's ultimate outcome, than PACs occurring in an outpatient setting. Additionally, preventable hospitalizations as well as index hospitalizations, each with longer lengths of stay, may have serious PACs. But how do we weigh these effects? An alternative model was considered, where cost could be considered as a surrogate for the weights. Higher cost PACs could imply more serious PACs. However, differences in costs could be driven by many issues other than the PAC itself, such as unit price of the service, method of reimbursements, contracting arrangements etc.

Furthermore, in-patient facility billing does not allow for the distinction of PAC related costs from other costs within the stay. We would fail to capture PAC related costs within the stay and potentially underweight those. As a result, the decision was made to avoid weighting and keep the measure as a straightforward count.

2d2.3. What is your interpretation of the results in terms of demonstrating the aggregation and weighting rules are consistent with the described quality construct? (i.*e., what do the results mean in terms of supporting the selected rules for aggregation and weighting; if no empirical analysis, provide rationale for the selected rules for aggregation and weighting*)

Measuring all providers with the same yardstick will provide consistent results and reasonable comparisons over time. If the goal is to reduce PACs, then the PAC measure as was constructed with the help of various experts in the field would provide reasonable comparisons. A word of caution however pertains to the sample size of the provider panel before making any reasonable conclusions.

Minimum sample size requirements for PAC measures are a function of the reliability testing of the measures on every dataset on which the measures are applied. Our research suggests that minimum sample sizes to achieve high degrees of reliability in the measures are a function of the dataset analyzed, and as such may vary from dataset to dataset. One should not infer that a minimum sample size achieved for high reliability in one dataset would apply to another.

2d3. Empirical analysis demonstrating that the approach for handling missing data minimizes bias (*i.e., achieves scores that are an accurate reflection of quality*)**.**

Note: *Applies to the overall composite measure; the focus is on missing data rather than exclusions, which are considered in 2b3.*

Please refer to section 2b7

2d3.1. What is the overall frequency of missing data and the distribution of missing data across providers?

2d3.2. Describe the method used to compare approaches for handling missing data (*describe the steps—do not just name a method; what statistical analysis was used; if no empirical analysis, provide justification*

2d3.3. What were the statistical results obtained from the analysis of missing data? (e.g., *results of sensitivity analysis of effect of various rules for missing data; if no empirical analysis, identify the approaches for handling missing data that were considered and pros and cons of each*)

2d3.4. What is your interpretation of the results in terms of demonstrating that the approach used for missing data minimizes bias? (i.*e., what do the results mean in terms of supporting the selected approach for missing data; if no empirical analysis, provide rationale for the selected approach for missing data*)

3. Feasibility

Extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

3a. Byproduct of Care Processes

For clinical measures, the required data elements are routinely generated and used during care delivery (e.g., blood pressure, lab test, diagnosis, medication order).

3a.1. **Data Elements Generated as Byproduct of Care Processes.**

Coded by someone other than person obtaining original information (e.g., DRG, ICD-9 codes on claims)

If other:

3b. Electronic Sources

The required data elements are available in electronic health records or other electronic sources. If the required data are not in electronic health records or existing electronic sources, a credible, near-term path to electronic collection is specified.

3b.1. **To what extent are the specified data elements available electronically in defined fields?** *(i.e., data elements that are needed to compute the performance measure score are in defined, computer-readable fields)*

ALL data elements are in defined fields in electronic claims

3b.2. **If ALL the data elements needed to compute the performance measure score are not from electronic sources, specify a credible, near-term path to electronic capture, OR provide a rationale for using other than electronic sources.**

3b.3. **If this is an eMeasure, provide a summary of the feasibility assessment in an attached file or make available at a measure-specific URL.**

Attachment:

3c. Data Collection Strategy

Demonstration that the data collection strategy (e.g., source, timing, frequency, sampling, patient confidentiality, costs associated with fees/licensing of proprietary measures) can be implemented (e.g., already in operational use, or testing demonstrates that it is ready to put into operational use). For eMeasures, a feasibility assessment addresses the data elements and measure logic and demonstrates the eMeasure can be implemented or feasibility concerns can be adequately addressed.

3c.1. **Describe what you have learned/modified as a result of testing and/or operational use of the measure regarding data collection, availability of data, missing data, timing and frequency of data collection, sampling, patient confidentiality, time and cost of data collection, other feasibility/implementation issues.**

IF a PRO-PM, consider implications for both individuals providing PROM data (patients, service recipients, respondents) and those whose performance is being measured.

As part of our general implementation of these measures and related analyses, we have worked through dozens of different and sometimes very large datasets. From Medicare to Medicaid to regional and national commercial carriers, as well as individual employers, the principal lesson learned is the heterogeneity of the data sets and the significant variability in fill rate of critical data elements. As a result, we have created highly specific recommendations for which data elements are required to ensure measure validity, the accuracy of those data elements, and their completeness in the dataset. When claims datasets are organized in the way we specify in the measure analysis, and contain the coding information required, the analysis of the measure and its results are highly reliable.

3c.2. **Describe any fees, licensing, or other requirements to use any aspect of the measure as specified** *(e.g., value/code set, risk model, programming code, algorithm)*.

The calculations of rates of potentially avoidable complications can be replicated by anyone that uses the measure specifications along with the metadata file that is available for free on our web site at http://www.hci3.org/ecre/xml-agreement.html.

We also plan on providing a limited automated analysis, at no cost, on our website.

4. Usability and Use

Extent to which potential audiences (e.g., consumers, purchasers, providers, policy makers) are using or could use performance results for both accountability and performance improvement to achieve the goal of high-quality, efficient healthcare for individuals or populations.

4a. Accountability and Transparency

Performance results are used in at least one accountability application within three years after initial endorsement and are publicly reported within six years after initial endorsement (or the data on performance results are available). If not in use at the time of initial endorsement, then a credible plan for implementation within the specified timeframes is provided.

4.1. Current and Planned Use

NQF-endorsed measures are expected to be used in at least one accountability application within 3 years and publicly reported within 6 years of initial endorsement in addition to performance improvement.

Planned	Current Use (for current use provide URL)
Public Reporting Professional Certification or Recognition Program Quality Improvement with Benchmarking (external benchmarking to multiple organizations)	Payment Program Blue Cross Blue Shield of North Carolina https://www.bcbsnc.com/ Blue Cross Blue Shield of New Jersey http://www.horizonblue.com/ Pennsylvania Employee Benefits Trust Fund https://www.pebtf.org/ Quality Improvement (Internal to the specific organization) Blue Cross Blue Shield of North Carolina https://www.bcbsnc.com/

4a.1. For each CURRENT use, checked above, provide:

- Name of program and sponsor
- Purpose
- Geographic area and number and percentage of accountable entities and patients included

Measures associated to potentially avoidable complications (PACs) are in use today with some private sector payers and gaining further acceptance among a wide variety of organizations across the health system (public and private payers, clinicians, consultants, all-payer claims database stewards, etc.) [1-8]. They are being used in various capacities in different pilot site implementations. To name a few:

•BCBSA (Blue Cross Blue Shield Association) – uses them for their Centers of Excellence (COE) programs: Blue Distinction
•BCBSNC (Blue Cross Blue Shield of North Carolina) – is using them for tiering providers

In addition, the PAC measures are incorporated by the following organizations in their bundled payment programs:

•BCBSSC – for CABG and PCI programs
•Horizon BCBSNJ– for CHF and CABG programs
•BCBSNC
•PEBTF in PA

http://www.ajmc.com/interviews/Lili-Brillstein-on-How-Bundled-Payments-Are-Tranforming-Healthcare

In these programs they look at PACs related to the measure for process improvement activities and for practice re-engineering.

We have created reports for rates of PACs for the following organizations:
-Vermont Payment Reform

-Maine Health Management Coalition
-WellPoint / Anthem CT
-NY State Medicaid
-CT Medicaid
-CO All-payer Claims Database, Center for Improving Value in Health Care

There are several companies that are leveraging these measures to create analytics and software for customers – these include HealthQx, Aver Informatics, McKesson, and TriZetto.

Below are some references that highlight our work with Potentially Avoidable Complications (PACs).

4a.2. If not currently publicly reported OR used in at least one other accountability application (e.g., payment program, certification, licensing) what are the reasons? (*e.g., Do policies or actions of the developer/steward or accountable entities restrict access to performance results or impede implementation?*)
N/A

4a.3. If not currently publicly reported OR used in at least one other accountability application, provide a credible plan for implementation within the expected timeframes -- any accountability application within 3 years and publicly reported within 6 years of initial endorsement. (*Credible plan includes the specific program, purpose, intended audience, and timeline for implementing the measure within the specified timeframes. A plan for accountability applications addresses mechanisms for data aggregation and reporting.*)
Measures associated with PACs are currently in use as described in the prior section. In addition, we are working with several not-for-profit and for-profit organizations to provide them with the algorithms needed to calculate rates of potentially avoidable complications. Some of these organizations include:

Fair Health – based in NY and whose mission is to increase transparency of provider cost and quality,

CastLight – based in CA and serving large employers. We currently provide CastLight with Bridges To Excellence recognitions and will work with them to augment provider transparency by using PAC measures,

MA APCD (Massachusetts All Payers Claims Database) Council – we currently have an agreement in place with the MA APCD Council to produce PAC measures on hospitals and physicians and report back to the council with tests of reliability and validity of the measures. The purpose is to authorize the publication of these measures,
Maryland Health Care Cost Commission – we have a two year agreement to produce measures of cost and quality for public

dissemination.

4b. Improvement

Progress toward achieving the goal of high-quality, efficient healthcare for individuals or populations is demonstrated. If not in use for performance improvement at the time of initial endorsement, then a credible rationale describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.

4b.1. **Progress on Improvement. (Not required for initial endorsement unless available.)**
Performance results on this measure (current and over time) should be provided in 1b.2 and 1b.4. Discuss:

- **Progress (trends in performance results, number and percentage of people receiving high-quality healthcare)**
- **Geographic area and number and percentage of accountable entities and patients included**

We do not have any public information to share about the improvements in rates of potentially avoidable complications, as the implementation of these measures is too recent to provide valid comparisons. Further, some of the definitions of PACs have changed since the measures were initially endorsed, making comparisons even more difficult and unreliable.

Nevertheless, the variation in performance scores presented in Section 1b.2 indicates that there are differences between providers in their risk-adjusted PAC rates (higher scores equal worse performance). This suggests that real opportunities exist to identify lower performing providers and reduce the overall occurrence of PACs.

4b.2. **If no improvement was demonstrated, what are the reasons? If not in use for performance improvement at the time of initial endorsement, provide a credible rationale that describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.**
Performance results provide summary PACs rates by provider, which can be used by payers and providers in a number of ways to improve the quality of care.

From the payer perspective, payers can use this information to 1) create a high-value provider networks, 2) work with high-value providers to share best practices, 3) incentivize low-value providers to improve, 4) modify their insurance design to activate consumers to select the right care from the right providers at the right time.

From the provider perspective, providers can 1) view services and activity for their patients longitudinally across the entire care continuum, such as frequency of readmissions and ED visits and drill down on patients with high PAC rates, 2) review actionable drill down reports to identify the most frequent PACs across all patients to create care pathways and process improvement plans to impact the most frequent PACs.

4c. Unintended Consequences

The benefits of the performance measure in facilitating progress toward achieving high-quality, efficient healthcare for individuals or populations outweigh evidence of unintended negative consequences to individuals or populations (if such evidence exists).

4c.1. **Were any unintended negative consequences to individuals or populations identified during testing; OR has evidence of unintended negative consequences to individuals or populations been reported since implementation? If so, identify the negative unintended consequences and describe how benefits outweigh them or actions taken to mitigate them.**
No unintended consequences were reported, but there is the potential for:
1. Under-coding of PACs in the claim stream resulting in under-reporting the actual rate and/or providers gaming the measures
2. Payers calculating the measures even with inadequate sample sizes and using the results to penalize providers

The measure is designed for transparency efforts and to spur quality improvement. Detailed PAC reports can help providers identify areas of quality improvement. Even detailed reports of small samples of patients can be helpful for quality improvement purposes, but not for public reporting. To mitigate the potential for invalid provider comparisons, we specify in this submission the minimum sample size needed to ensure the reliability of a provider's score. Ultimately, there isn't any good way to prevent provider gaming of the measure by under-coding claims, however, under the current DRG payment methodology, many providers would be penalized by under-coding PACs since these codes often result in the assignment of more complicated DRGs.

5. Comparison to Related or Competing Measures

If a measure meets the above criteria and there are endorsed or new related measures (either the same measure focus or the same target population) or competing measures (both the same measure focus and the same target population), the measures are compared to address harmonization and/or selection of the best measure.

5. Relation to Other NQF-endorsed Measures

Are there related measures (conceptually, either same measure focus or target population) or competing measures (conceptually both the same measure focus and same target population)? If yes, list the NQF # and title of all related and/or competing measures.

Yes

5.1a. List of related or competing measures (selected from NQF-endorsed measures)

0337 : Pressure Ulcer Rate (PDI 2)
0450 : Perioperative Pulmonary Embolism or Deep Vein Thrombosis Rate (PSI 12)
0705 : Proportion of Patients Hospitalized with Stroke that have a Potentially Avoidable Complication (during the Index Stay or in the 30-day Post-Discharge Period)
0708 : Proportion of Patients Hospitalized with Pneumonia that have a Potentially Avoidable Complication (during the Index Stay or in the 30-day Post-Discharge Period)
0709 : Proportion of patients with a chronic condition that have a potentially avoidable complication during a calendar year.
1789 : Hospital-Wide All-Cause Unplanned Readmission Measure (HWR)

5.1b. If related or competing measures are not NQF endorsed please indicate measure title and steward.

-0531 Patient Safety for Selected Indicators (Composite Measure, endorsed) (AHRQ)
-CMS defined hospital acquired conditions (HACs) are a subset of our PACs. We have pain-stakingly matched the definitions to provide as much consistency as possible. http://www.cms.gov/Medicare/Quality-Initiatives-Patient-Assessment-Instruments/HospitalQualityInits/HospitalRHQDAPU.html

5a. Harmonization

The measure specifications are harmonized with related measures;
OR
The differences in specifications are justified

5a.1. If this measure conceptually addresses EITHER the same measure focus OR the same target population as NQF-endorsed measure(s):
Are the measure specifications completely harmonized?

No

5a.2. If the measure specifications are not completely harmonized, identify the differences, rationale, and impact on interpretability and data collection burden.

Some of the measures listed in the prior section are, fully harmonized with the submitted measure, in particular, 0705, 0708, and 0709. Other measures such as 0337 and 0450 are in fact, subsets of our measure. However, there are some measures that are not harmonized, in particular the 30-day all-cause readmission measures and the Hospital wide all-cause readmission measure. While the submitted PAC measure include hospitalizations and readmissions that occur during the episode time window, the hospitalizations, by definition, have to be relevant to the underlying condition. For chronic conditions, most relevant hospitalizations within the entire episode time window are considered potentially avoidable. PACs include readmissions and are designed to enable accountability at the locus of provider control as well as some shared accountability between settings, centered around a patient, and for a specific medical episode of care. In that sense, they are consistent with the all-cause 30-day readmission rates, but represent a subset of those admissions. However, they do extend to the entire episode time window. As such, the PAC measures, as submitted, don't create added burden of reporting because the readmissions reported are simply a part of the broader 30-day all-cause readmission measures already endorsed by NQF. Because PAC measures are comprehensive, they include patient safety events as well as other adverse events, including hospitalizations and ED visits during the entire continuum of care. As a result, they are a comprehensive measure of avoidable complications for a specific medical episode. The data collection for all of the HCI3 measures is automated by a software package and is fully harmonized with all other PAC measures. A single download automates creation of all reports related to each of the PAC measures.

5b. Competing Measures

The measure is superior to competing measures (e.g., is a more valid or efficient way to measure);
OR

Multiple measures are justified.

5b.1. **If this measure conceptually addresses both the same measure focus and the same target population as NQF-endorsed measure(s):**
Describe why this measure is superior to competing measures (e.g., a more valid or efficient way to measure quality); OR provide a rationale for the additive value of endorsing an additional measure. (Provide analyses when possible.)
PAC measures are composite measures representing "all-cause harms". They look at many "care defects" comprehensively. They are composed of several cross-cutting measures and together they paint a global picture of the provider's overall performance.

PACs may occur any time during the episode time window. Furthermore, the measure is constructed so that the occurrence of any number of PACs during a defined episode would only count as one occurrence. PACs look at readmissions, emergency room visits, adverse events due to errors of omission or commission. They look at complications that are due to patient safety failures, and also those directly related to the index condition. These are all a cause of significant waste and quality concerns. As such, the measure can provide clinicians with an overall and comprehensive view, in one measure, of all potentially avoidable complications for a patient and drive quality improvement efforts.

For clinicians and facilities increasingly engaged in value-based payment efforts and/or driving quality improvement for population health, the value of a PAC measure over a series of related, but more discrete measures, is that one can better determine if the sources of complications primarily stem from activities within the facility or outside the facility, and the specific nature of the complications that have a higher frequency of occurrence. While individual components of the PAC measure may have small frequencies and may be difficult to interpret with regards to provider performance or actionability, aggregating all the PACs into a comprehensive, composite measure provides the parsimony that is so desirable. For providers, it's far easier to construct a quality dashboard from a parsimonious set of measures, and that's what PAC measures offer.

Further, as a comprehensive outcome measure, PACs are also useful for public transparency of quality, as substantiated by the research from Judy Hibbard and colleagues previously cited in the "testing" section of this submission. As a comprehensive outcome measure, they are easier to explain to the average consumer. From a patient's point of view, any bad outcome has an impact on their health with respect to return to work, functional limitations and need for additional support. If a provider has a high PAC rate with regards to one component PAC but not the other PACs, the impact on the patient is still adverse. In selecting providers, individual component PAC scores would mean nothing to a patient, but aggregating it to a comprehensive quality score could be a measure of "all-cause" harms and easier to interpret and act on.

Appendix

A.1 Supplemental materials may be provided in an appendix. All supplemental materials (such as data collection instrument or methodology reports) should be organized in one file with a table of contents or bookmarks. If material pertains to a specific submission form number, that should be indicated. Requested information should be provided in the submission form and required attachments. There is no guarantee that supplemental materials will be reviewed.

Additional Information

Ad.1 **Workgroup/Expert Panel involved in measure development**
Provide a list of sponsoring organizations and workgroup/panel members' names and organizations. Describe the members' role in measure development.
From 2006 onwards, and under the auspices of various funding organizations, HCI3 has convened and managed, or helped to convene and manage, Clinical Working Groups to inform the development and refinement of the measures. For example, in 2011,

2012 and 2013, HCI3 worked collaboratively with the American Board of Medical Specialties and the American Medical Association's Physicians Consortium for Performance Improvement, under a federal contract, to convene and get input from various clinical experts on definitions of episodes of care and their sequelae, including avoidable complications.

Some of the clinical experts that have contributed to our work include:
-Dr. John Allen, American Gastroenterology Association (AGA)
-Dr. Morton Arnsdorf, Cardiologist, University of Chicago, IL
-Dr. Peter Bach, Memorial Sloan Kettering Cancer Center (MSKCC)
-Dr. Peter Basch, Primary Care, Medstar Health, DC
-Dr. Justin Beckelman, Radiation Oncology, University of Pennsylvania, PA
-Dr. Debra Bingham, Executive Director, California Maternal Quality Care Collaborative (CMQCC) at Stanford University, CA
-Dr. John Birkmeyer, American Society of Metabolic and Bariatric Surgery (ASMBS)
-Dr. Linda Bosserman, Wilshire Oncology Medical Group, CA
-Dr. Matthew Brengman, American Society of Metabolic and Bariatric Surgery (ASBMS)
-Dr. Joel Brill, American Gastroenterology Association (AGA)
-Dr. George Cautilli, Cautilli Orthopedic Surgical Specialists PC, Yardley, PA
-Dr. Ashwini Davison, Internist, Johns Hopkins Hospital, MD
-Dr. James Denneny, III, American Academy of Otolaryngology – Head and Neck Surgery (AAO-HNS)
-Dr. Chris Gallagher, American Society of Metabolic and Bariatric Surgery (ASMBS)
-Dr. Robert Haralson, III, American Academy of Orthopedic Surgeons (AAOS)
-Ms. Dawn Holcombe, Executive Director, Connecticut Oncology Association, CT
-Dr. Colin Howden, American Gastroenterology Association (AGA)
-Dr. John Knightly, American Association of Neurological Surgeons (AANS)
-Dr. Larry Kosinski, American Gastroenterology Association (AGA)
-Dr. Nalini Krishnan, Obstetrics & Gynecology, MN
-Dr. Kelly Kyanko, Internist, NYU School of Medicine, NY
-Dr. Tara Lagu, Internist & Infectious Disease, Baystate Medical Center, MA
-Dr. Robert Lee, Society of Thoracic Surgeons (STS)
-Dr. Alex Little, Society of Thoracic Surgeons (STS)
-Dr. Michael London, Orthopedic Surgeon, OMNI Orthopedics, OH
-Dr. Elliott Main, Obstetrics & Gynecology, California Pacific Medical Center, CA
-Dr. Constantine Mantz, 21st Century Oncology, FL
-Dr. Joseph Messer, Cardiologist, Rush University Medical Center, IL
-Dr. David Metz, American Gastroenterology Association (AGA)
-Dr. Ronald Nahass, Infectious Disease Care, NJ
-Dr. Ajay Nehra, Urologist, Rush University Medical Center, IL
-Dr. Francis Nichols, Society of Thoracic Surgeons (STS)
-Dr. Patrick O'Connor, Primary Care, HealthPartners, MN
-Dr. Sara Perkel, National Comprehensive Cancer Network, PA
-Dr. David Peura, American Gastroenterology Association (AGA)
-Dr. John Ratliff, American Association of Neurological Surgeons (AANS)
-Dr. Steven Schutzer, Connecticut Joint Replacement Institute, CT
-Dr. Leif Solberg, Primary Care, HealthPartners, MN
-Dr. Scott Sporer, Midwest Orthopedics at Rush, Chicago IL
-Dr. Bonnie Weiner, Cardiologist, Worcester Medical Center, MA
-Dr. Jonathan Weiner, Bariatric Surgery codes, Prof of Health Policy and Management, Johns Hopkins University, MD
-Dr. Janet Wright, Cardiologist, Northstate Cardiology Consultants, CA

#2749 Proportion of Patients with Arrhythmias (ARR) that have a Potentially Avoidable Complication (during the episode time window), Last Updated: Aug 18, 2015

NATIONAL QUALITY FORUM

Measure Information - Composite

This document contains the information submitted by measure developers/stewards, but is organized according to NQF's measure evaluation criteria and process. The item numbers refer to those in the submission form but may be in a slightly different order here. In general, the item numbers also reference the related criteria (e.g., item 1b.1 relates to subcriterion 1b).

To navigate the links in the worksheet: Ctrl + click link to go to the link; ALT + LEFT ARROW to return

Brief Measure Information

NQF #: 2749
De.2. **Measure Title:** Proportion of Patients with Arrhythmias (ARR) that have a Potentially Avoidable Complication (during the episode time window)
Co.1.1. **Measure Steward:** Health Care Incentives Improvement Institute Inc. (HCI3)
De.3. **Brief Description of Measure:** Percent of adult population aged 18 + years who triggered an episode of arrhythmias (ARR), are followed for at least one-year, and have one or more potentially avoidable complications (PACs). PACs may occur any time during the episode time window. Please reference attached document labeled NQF_ARR_all_codes_risk_adjustment_06.30.15.xls, in the tabs labeled PACs I-9 and PAC I-10 for a list of code definitions of PACs relevant to ARR.

We define PACs as one of two types:
(1) Type 1 PACs - PACs directly related to the index condition: Patients are considered to have a PAC, if they receive services during the episode time window for any of the complications directly related to ARR, such as for hypotension, cardiac arrest, fluid and electrolyte disturbances etc.
(2) Type 2 PACs - PACs suggesting Patient Safety Failures: Patients are also considered to have a PAC, if they receive services during the episode time window for any of the complications related to patient safety failures such as for sepsis, infections, phlebitis, deep vein thrombosis, pressure sores etc.
All relevant admissions in a patient with ARR are considered potentially avoidable and flagged as PACs.

PACs are counted as a dichotomous (yes/no) outcome. If a patient had one or more PACs, they get counted as a "yes" or a 1. The enclosed workbook labeled NQF_ARR_all_codes_risk_adjustment_06.30.15.xls serves as an example. The tab labeled PAC overview gives the percent of ARR episodes that have a PAC and the tab labeled "PAC drill down" gives the types of PACs and their frequencies in ARR episodes within this dataset.

The information is based on a two-year claims database from a large regional commercial insurer. The database had over 3.2 million covered lives and over $25.9 billion in "allowed amounts" for claims costs. The database is an administrative claims database with medical as well as pharmacy claims.
1b.1. **Developer Rationale:** Each individual PAC, when measured in isolation, provides a very limited picture of the performance of the provider(s) who are managing or co-managing the care of the patient. However, looking at all the PACs that may occur individually or concurrently in a patient with a given episode provides a comprehensive picture of the care received by the patient for that particular condition or illness.

Additionally, the frequency of occurrence of individual PACs may be so low that it may require very high sample sizes from individual providers to achieve any meaningful and reliable comparisons. But aggregating all the PACs into a single quality metric creates meaningful scores that can be compared across providers even with relatively smaller sample sizes.

Additionally, a comprehensive measure is easier to explain to the average consumer. From a patient's point of view, any bad outcome has an impact on their health with respect to return to work, functional limitations and need for additional support. If a provider has a high PAC rate with regards to one component PAC but not the other PACs, the impact on the patient is still adverse. In selecting providers, individual component PAC scores would mean nothing to a patient, but aggregating it to a comprehensive quality score could be a measure of "all-cause" harms and easier to interpret and act on.

S.4. **Numerator Statement:** Outcome: Number of patients who triggered an episode of arrhythmias (ARR), are followed for at least one-year, and had one or more potentially avoidable complications (PACs) during the episode time window.
S.7. **Denominator Statement:** Adult patients aged 18 years and above who triggered an episode of arrhythmias (ARR) and are followed for at least one-year.
S.10. **Denominator Exclusions:** Denominator exclusions include exclusions of either "patients" or "claims" based on the following criteria:
1. "Patients" excluded are those that do not meet the enrollment criteria. If patient has an enrollment gap for more than 30 days during the episode time window, it is considered as an enrollment gap
2. "Patients" are also excluded if the cost of the episode is an outlier at greater than 99th percentile or less than 1st percentile value for all episodes. This is another way to ensure that episodes are complete as well as they do not bring in random noise into the analysis due to inappropriate codes or services.
3. "Claims" are excluded from the ARR measure if they are considered not relevant to ARR care.

De.1. **Measure Type:** Outcome
S.23. **Data Source:** Administrative claims
S.26. **Level of Analysis:** Clinician : Group/Practice, Clinician : Individual, Clinician : Team
Is this an eMeasure? ☐ **Yes** ☒ **No** **If Yes, was it re-specified from a previously endorsed measure?** ☐ **Yes** ☐ **No**

Is this a MAINTENANCE measure submission? ☐ **Yes** ☒ **No, this is a NEW measure submission.**
For MAINTENANCE, state the Original Endorsement Date: n/a **Most Recent Endorsement Date:** n/a

1d.1. **Composite Measure Construction:** any-or-none measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient)
Component Measures (if endorsed or submitted for endorsement):

Preliminary Analysis

The preliminary analysis was developed in response to recommendations from NQF's Consensus Task Force and measurement stakeholders as a way to enhance and streamline the measures evaluation and voting processes. The preliminary analysis will help to guide the Standing Committee evaluation of each measure by summarizing the measure developer submission, guide measure evaluation discussion, an
d identify topic areas for additional input. **NQF staff would like to stress that the preliminary analysis is intended to be used as a guide to facilitate the Committee's discussion and evaluation.**

Criteria 1: Importance to Measure and Report

1a. Evidence

1a. Evidence. The evidence requirements for this *health outcomes* measure include providing rationale that supports the relationship of the health outcome to processes or structures of care. The guidance for evaluating the clinical evidence asks if health outcomes measures agree the relationship between the measured health outcome and at least one clinical action is identified and supported by the stated rationale.

- This new risk-adjusted (by age, gender and clinical co-morbidities) outcomes measure that assesses the proportion of adult patients with claims triggered cardiac arrhythmias (ARR) with at least one Potentially Avoidable Complications (PAC) within 12 months of ARR triggered claims data. Based on NQF's criteria, this measure is considered an "any or none" composite measure that assesses if 1 or more PACs or "care defects" have occurred for the index episode. For this composite measure, the individual complications considered the measurable components
- PACs are classified in two types: 1) related to ARR, and 2) related to Patient Safety Failures, combining the 2 types into a single PAC rate to calculate the proportion of patient with 1 or more PAC. PACs are considered unwarranted health outcomes that combine concepts from AHRQ PSIs, PQIs and the CMS HACs and episode-specific PACs into all-cause patient harms that is measured during an index condition for use at the practice, medical group, provider system or purchaser/payer levels to identify quality of care gaps between practices and hospitals.
- The developer links primary & secondary prevention care gaps, poor patient education, poor care coordination and poor follow-up increase unnecessary ER visits, hospitalizations, readmissions, and mortalities to increased PACs, and

state that PACs for ARR patients should occur rarely in well-managed patients.

- The evidence for Patient Safety Failure PACs is described to be within the influence of the measured entity, and does not describe the influence of non-healthcare-related impacts on PAC rates. The progression of the episode condition, illness or disease is also not mentioned as a contributor to PAC rates in the evidence.
- In addition to linking processes of care to outcomes, the developer provides an extensive PAC literature review in sections 1a.2. and 1a.2.1. for ARR, Patient Safety Failures & processes of care, as well as background information on the process for PAC development.

Questions for the Committee:

- *Does sufficient evidence exist connecting Patient Safety Failures to the ARR index episode?*
- *For possible exception to the evidence criteria:*
  - *Are there, or could there be, performance measures of a related health outcome, OR evidence-based intermediate clinical outcomes, intervention/treatment?*
  - *Is there evidence of a systematic assessment of expert opinion beyond those involved in developing the measure?*

1b. Gap in Care/Opportunity for Improvement and 1b. Disparities

1b. Performance Gap. The performance gap requirements include demonstrating quality problems and opportunity for improvement.

- The developer provides ARR prevalence & impacts data, rationales and general information on PAC measure utility and applicable setting use. The developer identifies ARR as a predictor of stroke, and provides 2012 stoke & ARR prevalence, prevention, cost and readmission data.
- ARR PAC performance gap data are calculated from PROMETHEUS administrative claims data from April 1, 2012 through December 17, 2014, for providers with ≥ 10 attributable index episodes. The data includes 575 of 6,728 (8.5%) providers from 38,207 of 81,216 (47.0%) index episodes in 3,258,706 unique beneficiaries.

Unadjusted PAC Rates:		**Risk-Standardized PAC Rates (RSPR):**	
Median (IQR):	35.7% (26.3%, 45.5%)	Median (IQR):	35.9% (29.2%, 42.1%)
Range:	0% - 100%	Range:	0% - 91.9%

- Limited descriptive data on the patient, provider and payer are provided. The developer provides "Overview" and "Drill Down" PAC rates in the spreadsheet demonstrating gap, though PAC rates for individual complications are not provided.
- No disparities data was provided.

Questions for the Committee:

- *Is there a gap in care that warrants a national performance measure?*
- *If no disparities information is provided, are you aware of evidence that disparities exist in this area of healthcare?*
- *Should this measure be indicated as disparities sensitive?*

1c. Priority

1c. High Priority (previously "High Impact") requires measures to address national health goal/priority or a demonstrated high-impact aspect of care.

- *Beginning in 2015, priority is no longer an NQF measure evaluation criterion.*

Committee pre-evaluation comments

Criteria 1: Importance to Measure and Report (including 1a, 1b, 1c)

1. ***Committee's Overview Comments***:
   - None

1a. ***Committee's Comments on Evidence to Support Measure Focus:***

- The evidence to support the measure shows from prior studies that gaps in dysrhytmia management can lead to potentially avoidable complications.

1b. ***Committee's Comments on Performance Gap:***

- The developer provides ARR prevalence and impact data, rationale and general info on PAC measure utility.
- PAC date calculated from the PROMETHEUS admin claims data showed an unadjusted PAC rate vs. risk standardized PAC rate of 35.7% vs. 35.9%, however no disparity data was provided.

1c. ***Committee's Comments on Composite Performance Measure:***

- They are not clearly stated and logical.

Criteria 2: Scientific Acceptability of Measure Properties

2a. Reliability

2a1. Reliability Specifications

2a1. Specifications requires the measure, as specified, to produce consistent (reliable) and credible (valid) results about the quality of care when implemented.

- The measure assesses the rate of patients with 1 or more PAC(s) during index episodes. This new risk adjusted outcomes measure is specified for use at the clinician group and team levels of analyses.
- The measure exclusively uses electronically available administrative claims data to calculation the measure score, and for this measure, better care equals lower scores.
- The developer describes non-patient-related PACs as controllable by provider processes without further analysis as other influencers that may contribute to PAC rates beyond the patient and provider (e.g., payer, access, suppliers, etc.).
- Patient- and claims-based exclusions are provided to promote the availability and consistency of claims data capture, including payer enrollment requirements, cost outliers of < 1% or > 99%, and claims not relevant to ARR.
- Developers provide administrative claims for ARR & PAC (ARR - & Patient Safety Failure-related) triggers, describe a complete 12-month episode time window. A calculation algorithm.
- ICD-9 & ICD-10 codes are provided, though ICD-10 descriptions & an ICD-9 to ICD-10 crosswalk methodology are not provided.
- A conceptual risk model and statistical method using logistic regression model for determining the probability of a patient incurring a PAC are provided. After adjusting for patient-related factors, the developers state the remaining PAC variance is due to factors potentially controlled by the provider during and after hospitalization. "Predicted" coefficients from the risk adjustment models are summed to give predicted probabilities of PAC occurrence.

Questions for the Committee:

- *Are all the data elements clearly defined? Are all appropriate codes included?*
- *Is the logic or calculation algorithm clear?*
- *Is this measure specified to pertain only to providers with at least 10 episodes (per the reliability testing described below)?*
- *Is it likely this measure can be consistently implemented?*
- *Is additional evidence required to determine whether group/practice/team level of analysis is appropriate?*

2a2. Reliability Testing Testing attachment

2a2. Reliability testing demonstrates if the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is

precise enough to distinguish differences in performance across providers.

- The developer tested reliability at the performance measure score, and used a beta-binomial model and a signal-to-noise analysis, which is appropriate for this type of measure, to differentiate the true difference between measured entities (the signal) to random measurement error (the noise). A value of 0 indicates that all variation is due to measurement error and a value of 1 indicates that all variation is due to real differences in between hospital performance. A value of 0.7 is often regarded as a minimum acceptable reliability value.
- The measure is specified for patients with arrhythmias ≥ 18 years, though the testing sample includes patients 18 through 64 years.
- Providers with < 10 ARR episodes were excluded from reliability testing, though the measure is specified for patient without episode restrictions A sample of 5840 providers was initially included in the data set, though providers with less than 10 ARR episodes were excluded, allowing for 468 remaining providers. There were 38,207 episodes of ARR with a mean age of 49.1 (18-64 years) and 54% female in the testing analysis exclusively using administrative claims data.
- The developer states, "Minimum sample size requirements for PAC measures are a function of the reliability testing of the measures on every dataset on which the measures are applied. Our research suggests that minimum sample sizes to achieve high degrees of reliability in the measures are a function of the dataset analyzed, and as such may vary from dataset to dataset. One should not infer that a minimum sample size achieved in one dataset will apply to another." The developer also states that very high sample sizes are to achieve any meaningful and reliable comparisons.
- A patient may have more than one condition-specific concurrent episode with claims applied to both episodes. If an inpatient claim corresponds to a procedure index episode and to a condition index episode, the claim would be assigned to the procedure index episode, rather than the condition index episode (e.g., for a claim that corresponds to both index episodes of HF & CABG, the claim would be assigned to CABG).
- Patient with missing gender were excluded from the denominator, and no other missing data was identified.
- Reliability results are provided in the table below, as well as in great detail in the accompanied spreadsheet with median (IQR) results demonstrating reliability of 0.66 (0.54,0.79) for ≥ 10 providers, increasing with the number of providers, demonstrating the measure is able to demonstrate differences in performance. For reliability analysis, providers were restricted to the minimum of 10 ARR episodes, though all episodes were included in the risk model.

Reliability Scores	Minimum # Episodes Per Provider		
	>=10	>=25	>=50
# of Providers (%)	575 (100)	232 (40)	103 (18)
Median (IQR)	0.66 (0.54,0.79)	0.80 (0.74,0.87)	0.88 (0.84,0.93)
Range	0.42-1.00	0.65-0.99	0.79-0.99

The table provides a summary reliability scores minimum sample size thresholds. Complete results are provided in the workbook entitled, NQF_ARR_all_codes_risk_adjustment_06.30.15.xls, under the "ProviderAttribution Reliability" tab.

Questions for the Committee:

- *Reliability testing was conducted only for those providers with at least 10 episodes. Can differences in performance be identified for providers with fewer than 10 episodes? Should the measure be specified to include only those providers with at least 10 episodes? Is the test sample adequate to generalize for widespread implementation?*
- *Do the results demonstrate sufficient reliability so that differences in performance can be identified?*

2b. Validity

2b1. Validity: Specifications

2b1. Validity Specifications. This section should determine if the measure specifications are consistent with the evidence.

- Because this is an outcome measure, the rationale that is presented for subcriterion 1a does not necessarily have to address all of the variables used to calculate the measure.
- The measure uses a statistical risk model with 170 risk factors and episode-specific subtypes/severity markers including age, gender and clinical comorbidities, on at least 10 claims to determine "stable" covariates and assess comorbidity or procedure impact on the PAC. All covariates must be present prior to an episode trigger. No formal covariate analysis was conducted to select risk factors beyond the present on a minimum of 10 claims threshold. The developer describes the heterogeneity of the provided data sets as crucial to ensure measure validity, and the accuracy and completeness of the data sets.
- The developers did not provide disparities data, an exploration of a conceptual relation to SDS, or SD S factors in the risk model.

Question for the Committee:

- *Are the specifications consistent with the evidence?*
- *Are these variables available and generally accessible for the measured patient population?*

2b2. Validity testing

2b2. Validity Testing should demonstrate the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality.

- The developer conducted systematic assessment of face validity for the performance measure score for validity testing in numerous ways, including the use of monthly multi-specialty clinical working groups, and other tests of face validity, along with focus groups, face validity comparisons of the measure to other national accountability measures, as well as additional literature for the measure & PAC development process.
- No empiric results are provided for the face validity tests described above.

Questions for the Committee:

- *Is the test sample adequate to generalize for widespread implementation?*
- *Do the results demonstrate sufficient validity so that conclusions about quality can be made?*
- *Do you agree that the score from this measure as specified is an indicator of quality?*
-

2b3-2b7. Threats to Validity

2b3. Exclusions:

- The developer describes patient- (demographic, enrollment or low/high claims cost) and claims-based (due to missing or non-relevant data) exclusions for the measure. They further state nearly half of the original population of ARR patients was removed from the denominator with applied exclusions.
- A significant number of patients were eliminated from the measure due to exclusion criteria, including 38,207 of 81,216 (47.0%) ARR episodes (in 3,258,706 unique beneficiaries) and 575 of 6,728 (8.6%) providers.

Questions for the Committee:

- *Are high cost outliers (> 99%) exclusions an opportunity to identify PACs?*
- *Does the high number of exclusions restrict the measure use?*
- *Are the exclusions consistent with the evidence?*
- *Are any patients or patient groups inappropriately excluded from the measure?*

- *Are the exclusions/exceptions of sufficient frequency and variation across providers to be needed (and outweigh the data collection burden)?*

2b4. Risk adjustment:

- The risk model (detailed in the accompanied spreadsheet) includes 170 factors and subtypes including age, gender, 12-month enrollment markers, co-morbidities, and episode severity markers.
- No SDS factors beyond age and gender was included in the risk-adjustment approach. Beyond noting that race was not available for analysis, no description of the of the conceptual relationships between patient sociodemographic factors, patient clinical factors, quality of care, and the outcomes (PAC rates) were provided, nor do they discuss a conceptual relationship or variables of SDS to the risk model.
- Logistic regression was used to model the probability of at least one PAC during an episode. The reasoning for no additional modeling performed is described.
- The performance of the model was determined with a split sample method by estimating the model coefficients using a development dataset (80% of the sample) and applying those coefficients to a validation dataset (20% of the sample). C-statistics for the development and validation samples with c-statistic results of 0.781 and 0.773, respectively. C-statistics measures the extent of a statistical model to discriminate between a patient with and without PAC, with an ability to predict if a PAC is or is not present about 75% of the time. A c-statistic of 0.50 indicates the model is no better than random prediction, implying that the patient risk factors do not predict variation in the outcome; conversely, a c-statistic of 1.0 indicates perfect prediction, implying patients' outcomes can be predicted completely by their risk factors, and physicians and hospitals play little role in patients' outcomes. Models with c-statistic values of at least 0.7 are considered good and those above 0.8 are considered strong.
- Both Hosmer-Lemeshow Goodness-of-Fit statistics and risk-decide plots were provided to indicate model fit. Results from the Hosmer-Lemeshow test suggest that the fit is not good; however, this test is sensitive to the number of groupings and sample sizes. Results from the risk decile plot indicate that the predicted PAC rates are similar to the observed PAC rates across all deciles of risk. The developer states the model demonstrates strong predictive power.

Questions for the Committee:

- *Is the Committee aware of conceptual relationship(s) between additional patient-level SDS factors, patient clinical factors, quality of care, and PACs (other than gender and age)? If so, what data might be available to allow an empirical analysis of these relationships?*
- *Is an appropriate risk-adjustment strategy included in the measure?*
- *Are the candidate and final variables included in the risk adjustment model adequately described for the measure to be implemented?*

2b5. Meaningful difference:

- The developer presents PAC rates across providers and also providers adjusting for differences in patient severity in a ratio of observed to expected attributable episodes to PACS accounting for patient severity, and calculates estimates from the risk model, for risk-standardized PAC rates for the provider.

Summary of Unadjusted and Adjusted Performance Scores Across Providers

PAC Rates	Minimum # Episodes Per Provider	
	>=10	>=25
Unadjusted		
Median (IQR)	36% (26%, 45%)	34% (28%, 44%)
Range	0%-100%	6%-98%
Adjusted (RSPR)*		

Median (IQR)	36% (29%, 42%)	36% (31%, 41%)
Range	0%-92%	8%-67%

***RSPR = Risk Standardized PAC Rate**

Please refer to the NQF_ARR_all_codes_risk_adjustment_06.30.15.xls workbook under the "ProviderAttribution Reliability" tab to see specific results for each provider.

Question for the Committee:

- *Does this measure identify meaningful differences about quality?*

2b6. Comparability of data sources/methods:

- As there is only one data source used for measure calculation (administrative claims), comparability of data sources or methods is not applicable.

Question for the Committee:

- *Are the candidate and final variables included in the risk adjustment model adequately described for the measure to be implemented?*

2b7. Missing Data

- No formal analysis of missing data is provided. As the measure assesses the rate of patients with PACs, rather than the rate of PACs per index episode, the total number of PACs is not included in the PAC rate.
- Patient with missing gender were excluded from the denominator, and no other missing data was identified.
- The developers state the under-coding of claims is unavoidable in the current DRG payment structure which could lead to under capture or missing PACs.

2d. Empirical Analysis to Support Composite Construction

- As an "any or none" composite, the individual complications are considered measurable components of the composite. Frequency and distribution statistics are provided in the PAC Overview and PAC Drill Down tabs in the measure spreadsheet, which detail PAC types and subtypes. The identification of individual PACs are not provided (e.g., sepsis, unattended falls, DVT).
- PACs are counted as a dichotomous (yes/no) outcome. If a patient had one or more PACs, they get counted as a "yes" or a 1. Since our premise is that all PACs are potentially avoidable, we adopted the approach to count all PACs and give them equal weights. The overall composite score results in the quality construct that could be measured and interpreted.
- The developer states that no formal analysis was performed on missing data. For details, see 2b7 above.

Committee pre-evaluation comments

Criteria 2: Scientific Acceptability of Measure Properties (including all 2a, 2b, and 2d)

2a1. &2b1.: ***Committee's Comments on Reliability-Specifications:***

- The conceptual risk model which is a logistic regression model is not clearly defined.

2a2.: ***Committee's Comments on Reliability-Testing:***

- The reliability testing performed had a value of less than 0.7

2b1.: ***Committee's Comments on Validity-Specifications***:

- The risk model using 170 risk factors, it does not show if all of these risk factors are available for every patient.

2b2.: ***Committee's Comments on Validity-Testing:***

- Validity was not tested well enough to allow for generalization

2b3-7.: ***Committee's Comments on Threats to Validity:***

- High number of exclusions will affect the data
- Once again the risk model will not be effective due to possible missing data.

2d.: ***Committee's Comments on Composite Performance Measure:***

- Not Applicable

Criterion 3. Feasibility

3. Feasibility is the extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

- All measure elements are readily available in electronic sources via administrative claims data, and coded by someone other than the person obtaining the original information (e.g., DRG, ICD-9 codes on claims).
- The developer provides an excel spreadsheet attachment including diagnoses, visits, hospitalizations, post-acute facility stays, procedures, laboratory tests and procedures/surgeries, for ARR & PAC triggers, and describe the time window for measuring PACs as 12 months following a ARR episode triggers, as well as a decision tree for measure calculation and implementation.
- The measure specifications, metadata and calculation algorithms are available free of charge on the developer's website. Limited analytics are planned at no cost to the end user.
- This is not an eMeasure.

Questions for the Committee:

- *Are the required data elements routinely generated and used during care delivery?*
- *Are the required data elements available in electronic form, e.g., EHR or other electronic sources?*
- *Is the data collection strategy ready to be put into operational use?*

Committee pre-evaluation comments

Criteria 3: Feasibility

Committee's Comments on Feasibility:

- Data elements are not routinely generated and used during care delivery.

Criterion 4: Usability and Use

4. Usability and Use evaluate the extent to which audiences (e.g., consumers, purchasers, providers, policymakers) use or could use performance results for both accountability and performance improvement activities.

- This is a newly developed claims measure is current used in accountability programs for payers, states, and planned for public reporting, professional certification or recognition programs, and external quality improvement for benchmarking purposes.
- The developer states that PAC measures provide a foundation for the relationship between healthcare quality and cost and assist in the exploration of practice reengineering and alternative payment models, act as indicators of potential harm, and is spurring the development of private-based analytics software for further outcomes exploration. No public improvement rates are available due to recent implementation and variation in PAC definitions have also modified, though the provided PROMETHEUS data suggest wide variation in performance and improvement opportunities. Payer and Provider improvement use perspectives are also outlined.
- The developer found no noted unintended consequences, though they state the measure is intended for transparency

and QI activities only. They also state the under-coding of claims is unavoidable in the current DRG payment structure could be an unintended consequences of the measure, and payers calculating the measures even with inadequate sample sizes and using the results to penalize providers could lead to invalid provider comparisons.

- If the measure was theoretically to be used for accountability purposes to "ding" the measured entity as defined in the level of analysis, further exploration of PAC antecedents and the measured entity is warranted, especially with small group practices and very small PAC rates. In the original testing sample of 6,728 providers, when providers with fewer than 10 ARR episodes were eliminated from analysis due to less reliability estimates with small numbers, 575 (8.6%) remained for analysis.

***Questions for the Committee**:*

- *Is the measure publicly reported?*
- *How can the performance results be used to further the goal of high-quality, efficient healthcare?*
- *Should PAC measures also include the clinician: group in the analysis or include population-level only entities?*
- *Do the benefits of the measure outweigh any potential unintended consequences?*

Committee pre-evaluation comments

Criteria 4: Usability and Use

4.: ***Committee's Comments on Usability and Use:***

- It may be difficult to implement the measure as it is proposed

Criterion 5: Related and Competing Measures

5.1a. List of related or competing measures (selected from NQF-endorsed measures)

0337 : Pressure Ulcer Rate (PDI 2)
0450 : Perioperative Pulmonary Embolism or Deep Vein Thrombosis Rate (PSI 12)
0705 : Proportion of Patients Hospitalized with Stroke that have a Potentially Avoidable Complication (during the Index Stay or in the 30-day Post-Discharge Period)
0708 : Proportion of Patients Hospitalized with Pneumonia that have a Potentially Avoidable Complication (during the Index Stay or in the 30-day Post-Discharge Period)
0709 : Proportion of patients with a chronic condition that have a potentially avoidable complication during a calendar year.
1789 : Hospital-Wide All-Cause Unplanned Readmission Measure (HWR)

5.1b. If related or competing measures are not NQF endorsed please indicate measure title and steward.

-0531 Patient Safety for Selected Indicators (Composite Measure, endorsed) (AHRQ)
-CMS defined hospital acquired conditions (HACs) are a subset of our PACs. We have pain-stakingly matched the definitions to provide as much consistency as possible. http://www.cms.gov/Medicare/Quality-Initiatives-Patient-Assessment-Instruments/HospitalQualityInits/HospitalRHQDAPU.html

Pre-meeting public and member comments

-

NATIONAL QUALITY FORUM—Evidence (subcriterion 1a)

Measure Number (*if previously endorsed*)**:** 2749

Measure Title: Proportion of Patients with Arrhythmias (ARR) that have a Potentially Avoidable Complication (during the episode time window)

IF the measure is a component in a composite performance measure, provide the title of the Composite Measure here: Click here to enter composite measure #/ title

Date of Submission: 6/30/2015

Instructions

- *For composite performance measures:*
  - *A separate evidence form is required for each component measure unless several components were studied together.*
  - *If a component measure is submitted as an individual performance measure, attach the evidence form to the individual measure submission.*
- Respond to all questions as instructed with answers immediately following the question. All information needed to demonstrate meeting the evidence subcriterion (1a) must be in this form. An appendix of *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 10 pages (*incudes questions/instructions*; minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the evidence for this measure meets NQF's evaluation criteria.

1a. Evidence to Support the Measure Focus

The measure focus is evidence-based, demonstrated as follows:

- Health outcome: [3] a rationale supports the relationship of the health outcome to processes or structures of care. Applies to patient-reported outcomes (PRO), including health-related quality of life/functional status, symptom/symptom burden, experience with care, health-related behavior.
- Intermediate clinical outcome: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured intermediate clinical outcome leads to a desired health outcome.
- Process: [5] a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured process leads to a desired health outcome.
- Structure: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured structure leads to a desired health outcome.
- Efficiency: [6] evidence not required for the resource use component.

Notes

3. Generally, rare event outcomes do not provide adequate information for improvement or discrimination; however, serious reportable events that are compared to zero are appropriate outcomes for public reporting and quality improvement.

4. The preferred systems for grading the evidence are the U.S. Preventive Services Task Force (USPSTF) grading

definitions and methods, or Grading of Recommendations, Assessment, Development and Evaluation (GRADE) guidelines.

5. Clinical care processes typically include multiple steps: assess → identify problem/potential problem → choose/plan intervention (with patient input) → provide intervention → evaluate impact on health status. If the measure focus is one step in such a multistep process, the step with the strongest evidence for the link to the desired outcome should be selected as the focus of measurement. Note: A measure focused only on collecting PROM data is not a PRO-PM.

6. Measures of efficiency combine the concepts of resource use and quality (see NQF's Measurement Framework: Evaluating Efficiency Across Episodes of Care; AQA Principles of Efficiency Measures).

1a.1.This is a measure of: (*should be consistent with type of measure entered in De.1*)

Outcome

☒ Health outcome: Potentially Avoidable Complications

☐Patient-reported outcome (PRO): Click here to name the PRO

PROs include HRQoL/functional status, symptom/symptom burden, experience with care, health-related behaviors

☐ Intermediate clinical outcome (*e.g., lab value*): Click here to name the intermediate outcome

☐ Process: Click here to name the process

☐ Structure: Click here to name the structure

☐ Other: Click here to name what is being measured

HEALTH OUTCOME/PRO PERFORMANCE MEASURE *If not a health outcome or PRO, skip to 1a.3*

1a.2. Briefly state or diagram the path between the health outcome (or PRO) and the healthcare structures, processes, interventions, or services that influence it.

There are significant gaps in the management of patients with dysrhythmias leading to potentially avoidable complications (PACs) contributing to unnecessary inefficiencies and waste in health care with the consequent increased socioeconomic burden. The Framingham study showed a 23.5% risk of stroke attributable to AF (Wolf 1991). Despite this a shocking 30% to 50% of eligible AF patients do not receive preventive anticoagulation (Reynolds 2012). The use of optimal anticoagulation therapy in just half of these patients could prevent 19,000 strokes and save more than $1.1 billion in direct costs annually. Additionally, frequent hospitalizations are common in patients with AF and a study showed that 1 in 8 patients are readmitted (Kim 2005).

There is enough evidence in the literature that highlights significant "gaps in care" in management of patients with chronic conditions (McGlynn 2003). Gaps in care, in turn lead to process failures that cause patients to incur unnecessary services and some harm (Jha 2013). For example, a report by the Agency of Health Care Research and Quality (AHRQ) highlighted the fact that in 2008, $4.4 million out of a total of 39 million (11 percent) hospital-stays that could have been prevented (Stranges 2008); and for Medicare beneficiaries one in five admissions were for a potentially preventable condition (Jiang 2006). To improve accountability in the delivery of medical care, AHRQ has developed a list of patient safety indicators (PSIs) to identify potential harms to patients (Miller 2001). Additionally, the Centers for Medicare and Medicaid Services (CMS) have

taken a "Six Sigma" approach and defined Hospital Acquired Conditions (HACs) and "never events" that should almost never occur and are applying financial penalties when these events do occur (CMS 2012).

The Potentially avoidable complications (PAC) measure goes beyond the AHRQ PSIs and the CMS HACs and creates a single comprehensive measure that measures all-cause harms for a patient with the index condition. Potentially avoidable complications (PACs) are the unwarranted health outcomes that this measure addresses (deBrantes 2010). Lack of patient education on self care techniques, poor care coordination, and poor arrangements of patient follow-up could lead to unnecessary ER visits, hospitalizations and gaps in care leading to increased morbidity. All these adverse events are aggregated together as a single comprehensive measure to study the overall rate of PACs in the arrhythmia / heart block population.

Adult patient diagnosed with Arrhythmia or a heart block (ARR)

↓

Physician practices fail to educate patients / Physician practices have poor access

↓

Patient visits ER / gets hospitalized

↓

Patient discharged with management advise / remains in hospital for treatment of PAC

Well-managed patients with ARR should rarely incur a potentially avoidable complication such as an emergency room visit, and hospitalizations related to ARR should occur only in the rarest of circumstances.

The enclosed workbook entitled NQF_ARR_all_codes_risk_adjustment_06.30.15.xls lists the types of PACs and their frequency as calculated in a large regional database (see tab PAC overview). Over 36% of patients with ARR had a PAC, with about 12% of PACs directly related to ARR itself, such as fluid and electrolyte disorders, acute heart failure or pulmonary edema etc.(see tab PAC Drill Down Graph). Although the preventable hospitalizations in the ARR population were low, at only 8.2% of all ARR episodes; approximately 30% of patients with ARR had PACs related to patient centered care failures such as poor control of diabetes, respiratory insufficiency and acute gastritis, many of them being managed in an outpatient setting in physician offices. As a result over 34% of episodes had a PAC indicator on the professional claims.

While PACs may not be eliminated completely, identifying the magnitude of PACs and knowledge of the cause for the most frequent or the most expensive PACs could place an emphasis in reducing them and as a consequence improving patient outcomes. The ability to clearly identify the type and frequency of each PAC, creates a highly actionable measure for all providers that are managing or co-managing the patient; as well as for the health plan with whom the patient is a member (de Brantes 2009).

1a.2.1. State the rationale supporting the relationship between the health outcome (or PRO) to at least one healthcare structure, process, intervention, or service (*i.e., influence on outcome/PRO*).

Note: For health outcome/PRO performance measures, no further information is required; however, you may provide evidence for any of the structures, processes, interventions, or service identified above.

Rationale: Better processes of care create an atmosphere of proactive management, consistency in care and standardized care patterns (Shekelle 2013) (Fenter 2006). Patient education and adopting safe practices significantly reduces occurrence of potentially avoidable complications (PACs) in all settings (Klein 2011) (Wachter 2013) (Berwick 2006) (Kovner 2011) (Farley 2013). It is known that by holding providers accountable for occurrence and costs of PACs, an built-in warranty is created around care of the index condition (de Brantes 2009).

In 2014, the AHA/ACC/HRS published their evidence-based guidelines for management of patients with Atrial Fibrillation with an aim to prevent the consequences of poorly managed arrhythmia, namely, stroke, congestive heart failure, increased hospitalizations, cognitive decline and death (Stewart 2002) (Wolf 1991) (Benjamin 1998). Additionally, the 2012 ACCF/AHA/HRS Focused Update of the 2008 Guidelines for Device-Based Therapy (DBT) of Cardiac Rhythm Abnormalities is a report of the American College of Cardiology Foundation/American Heart Association Task Force on Practice Guidelines for device use in patients with arrhythmias and heart block (Tracy 2012). Utilization of these evidence-based guidelines has a potential to reduce unnecessary hospitalizations and complications in patients with arrhythmias. The use of optimal anticoagulation therapy could by itself lead to prevention of some of the major complications of heart rhythm abnormalities. Advances in understanding the mechanisms underlying rhythm abnormalities, clinical implementation of ablation techniques to maintain sinus rhythm and newer drugs for stroke prevention, if incorporated appropriately into clinical practice, could potentially bring down the rate of complications.

Data from the Healthcare Cost and Utilization Project indicate that roughly 60% of hospital admissions for a principal diagnosis of AF result from emergency department visits (HCUP). Evidence suggests that AF can be safely treated on an outpatient basis and unnecessary hospitalizations can be avoided. For example, electrical cardioversion can be safely performed as an outpatient at a much lower cost than as an inpatient (Birger 2003).

Hospitalizations in patients for medical management of Arrhythmias or heart blocks should be rare and mostly avoidable. However, if patients do get hospitalized, careful management while in the hospitals and good discharge planning and follow-up prevents unnecessary complications, ER visits and readmissions (Weaver 2013) (Mittler 2013). Another study from the Boston Medical Center, demonstrated that although one in five hospitalizations are complicated by post-discharge adverse events, development of a strong discharge services program for patients admitted for medical conditions reduced hospital utilization within 30 days of discharge (Jack 2009). In addition, while in the hospital, safe practices reduce the burden of healthcare associated complications (Ranji 2007). Some of these are listed below:

1. Frequent hand-washing reduce hospital acquired infections (WHO 2007)
2. Carefully implemented protocols lead to reduced line sepsis (Pronovost 2010)
3. Discharge planning and good follow-up prevents unnecessary ER visits and readmissions (Weaver 2013)
4. DVT prophylaxis in patients on bed rest avoids pulmonary embolism (Shekelle 2013)
5. Frequent change in position of ARR patients in the CCU avoids pressure sores (Shekelle 2013)

PAC measures in the setting of arrhythmias and / or heart blocks look at all-cause harms, such as the ones highlighted above, arising from poor management of these patients.

Note: For health outcome/PRO performance measures, no further information is required; however, you may provide evidence for any of the structures, processes, interventions, or service identified above.

INTERMEDIATE OUTCOME, PROCESS, OR STRUCTURE PERFORMANCE MEASURE

1a.3. Briefly state or diagram the path between structure, process, intermediate outcome, and health outcomes. Include all the steps between the measure focus and the health outcome.

1a.3.1. What is the source of the systematic review of the body of evidence that supports the performance measure?

☒ Clinical Practice Guideline recommendation – ***complete sections 1a.4, and 1a.7***

☐ US Preventive Services Task Force Recommendation – ***complete sections 1a.5 and 1a.7***

☐ Other systematic review and grading of the body of evidence (*e.g., Cochrane Collaboration, AHRQ Evidence Practice Center*) – ***complete sections 1a.6 and 1a.7***

☐ Other – ***complete section 1a.8***

Please complete the sections indicated above for the source of evidence. You may skip the sections that do not apply.

1a.4. CLINICAL PRACTICE GUIDELINE RECOMMENDATION

1a.4.1. Guideline citation (*including date*) and **URL for guideline** (*if available online*):

1a.4.2. Identify guideline recommendation number and/or page number and **quote verbatim, the specific guideline recommendation**.

1a.4.3. Grade assigned to the quoted recommendation with definition of the grade:

1a.4.4. Provide all other grades and associated definitions for recommendations in the grading system. (*Note: If separate grades for the strength of the evidence, report them in section 1a.7.*)

1a.4.5. Citation and URL for methodology for grading recommendations (*if different from 1a.4.1*)**:**

1a.4.6. If guideline is evidence-based (rather than expert opinion), are the details of the quantity, quality, and consistency of the body of evidence available (e.g., evidence tables)?

☐ Yes → ***complete section 1a.7***

☐ No → ***report on another systematic review of the evidence in sections 1a.6 and 1a.7; if another review does not exist, provide what is known from the guideline review of evidence in 1a.7***

1a.5. UNITED STATES PREVENTIVE SERVICES TASK FORCE RECOMMENDATION

1a.5.1. Recommendation citation (*including date*) and **URL for recommendation** (*if available online*):

1a.5.2. Identify recommendation number and/or page number and **quote verbatim, the specific recommendation**.

1a.5.3. Grade assigned to the quoted recommendation with definition of the grade:

1a.5.4. Provide all other grades and associated definitions for recommendations in the grading system. (*Note: the grading system for the evidence should be reported in section 1a.7.*)

1a.5.5. Citation and URL for methodology for grading recommendations (*if different from 1a.5.1*)**:**

Complete section 1a.7

1a.6. OTHER SYSTEMATIC REVIEW OF THE BODY OF EVIDENCE

1a.6.1. Citation (*including date*) and **URL** (*if available online*):

1a.6.2. Citation and URL for methodology for evidence review and grading (*if different from 1a.6.1*)**:**

Complete section 1a.7

1a.7. FINDINGS FROM SYSTEMATIC REVIEW OF BODY OF THE EVIDENCE SUPPORTING THE MEASURE

If more than one systematic review of the evidence is identified above, you may choose to summarize the one (or more) for which the best information is available to provide a summary of the quantity, quality, and consistency of the body of evidence. Be sure to identify which review is the basis of the responses in this section and if more than one, provide a separate response for each review.

1a.7.1. What was the specific structure, treatment, intervention, service, or intermediate outcome addressed in the evidence review?

1a.7.2. Grade assigned for the quality of the quoted evidence with definition of the grade:

1a.7.3. Provide all other grades and associated definitions for strength of the evidence in the grading system.

1a.7.4. What is the time period covered by the body of evidence? (*provide the date range, e.g., 1990-2010*).
Date range: Click here to enter date range

QUANTITY AND QUALITY OF BODY OF EVIDENCE

1a.7.5. How many and what type of study designs are included in the body of evidence? (*e.g., 3 randomized controlled trials and 1 observational study*)

1a.7.6. What is the overall quality of evidence across studies in the body of evidence? (*discuss the certainty or confidence in the estimates of effect particularly in relation to study factors such as design flaws, imprecision due to small numbers, indirectness of studies to the measure focus or target population*)

ESTIMATES OF BENEFIT AND CONSISTENCY ACROSS STUDIES IN BODY OF EVIDENCE

1a.7.7. What are the estimates of benefit—magnitude and direction of effect on outcome(s) across studies in the body of evidence? (*e.g., ranges of percentages or odds ratios for improvement/ decline across studies, results of meta-analysis, and statistical significance*)

1a.7.8. What harms were studied and how do they affect the net benefit (benefits over harms)?

N/A

UPDATE TO THE SYSTEMATIC REVIEW(S) OF THE BODY OF EVIDENCE

1a.7.9. If new studies have been conducted since the systematic review of the body of evidence, provide for each new study: 1) citation, 2) description, 3) results, 4) impact on conclusions of systematic review.

1a.8 OTHER SOURCE OF EVIDENCE

If source of evidence is NOT from a clinical practice guideline, USPSTF, or systematic review, please describe the evidence on which you are basing the performance measure.

1a.8.1 What process was used to identify the evidence?

1a.8.2. Provide the citation and summary for each piece of evidence.

1. Evidence, Performance Gap, Priority – Importance to Measure and Report

Extent to which the specific measure focus is evidence-based, important to making significant gains in healthcare quality, and improving health outcomes for a specific high-priority (high-impact) aspect of healthcare where there is variation in or overall less-than-optimal performance. ***Measures must be judged to meet all subcriteria to pass this criterion and be evaluated against the remaining criteria.***

1a. Evidence to Support the Measure Focus – See attached Evidence Submission Form

2749_ARR_Evidence_Attachment_HCI3-635717850211232805.docx

1b. Performance Gap

Demonstration of quality problems and opportunity for improvement, i.e., data demonstrating:

- considerable variation, or overall less-than-optimal performance, in the quality of care across providers; and/or
- disparities in care across population groups.

1b.1. **Briefly explain the rationale for this measure** *(e.g., the benefits or improvements in quality envisioned by use of this measure)*

Measures associated to potentially avoidable complication (PAC) have been used as comprehensive outcomes measures since 2007 for several conditions and procedures (de Brantes 2010) (Joynt 2013 (James 2013). In 2011, following the NQF endorsement of these measures for certain acute medical conditions (AMI, Pneumonia and Stroke), and for chronic conditions, they were adopted for various purposes, including the creation of related measures (NQF – Measure #1550). Some commercial payers have used them as a means for tracking outcomes (Yong 2010) and for tiering providers for pay for performance programs (BCBSNC). In addition, some provider organizations have used them in quality improvement efforts by homing in on the detailed specifications of the measures to reveal opportunities for care improvement (CALPERS – link below). Identification of PACs has spurred provider innovation (Bundled Payment Summit 2015) for practice re-engineering, to create proactive care pathways, and to focus on areas of high variability (McVary 2010). Some employers are also using measures of avoidable complications as public measures of quality (Colorado Business Group on Health) given the research that demonstrated the potential efficacy of these measures to differentiate provider quality and cost (Hibbard 2012). In fact in a series of focus groups led by Judy Hibbard and colleagues, the researchers found that the very framing of potentially avoidable complications as an indicator of potential harm, is an effective way of communicating the quality of care. And when measures of PACs were presented in conjunction with price, consumers intuitively accepted the logical relationship between low PACs – fewer "defects" – and lower price.

Accountability for and measurement of PACs occurs at the practice, medical group, provider system or purchaser/payer level. PAC rates are calculated as absolute values. For example, a health plan would report that 50% of its plan members with arrhythmia / heart block incurred PACs in the study time window. The objective of the measure is to encourage the unit being measured to progressively reduce that amount over time. In addition, comparisons of PAC rates across plans or provider systems should be encouraged and publicly reported. An organization that uses the measure should be able to identify the leading causes of PACs and implement improvements to existing processes that will decrease PACs. There are several tools available for provider systems and health plans to impact PAC rates. These include care coordination across care settings; post-discharge planning and patient follow-up, active care management, sharing medical record data between care settings and providers, total quality management within hospitals and active reduction of patient safety failures. Reducing PACs has the potential to significantly improve the overall level of quality.

Creating a single measure of accountability for physicians and hospitals tied to gaps in quality is likely to yield much improved outcomes for patients. A measure of accountability for health plans helps them review trends over time and work with physicians and hospitals to improve the ways in which they engage patients using more optimal care management and care coordination (Cassel 2014). In addition, PAC measures could be used as a surrogate for quality in a consumer transparency tool to differentiate providers with regards to their performance.

Moreover, since these measures are claims based, there is minimal added burden for collecting the data, and it also avoids potential gaming that may occur for other measures that require reporting information to registries. Although use of administrative claims data in identifying conditions and measuring provider quality has been questioned, there are several studies in literature that acknowledge validity of its use (Normand 2007) (Quan 2009). Until more readily available data are at hand, use of administrative

data to measure provider performance has steadily increased (Miller 2001), (NQF Quality Positioning System). Interestingly, in the current fee for service system, services for most PACs are rewarded by continued payment (except the CMS defined "never events") and hence to our advantage, adverse events surface in billing data. Claims based PAC measures; therefore serve as an alternative method to track adverse outcomes that do occur (Leibson 2008).

1b.2. Provide performance scores on the measure as specified (current and over time) at the specified level of analysis. *(This is required for endorsement maintenance. Include mean, std dev, min, max, interquartile range, scores by decile. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities included). This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*
The data included two years of administrative claims covering the period April 1, 2012 through December 17, 2014. There were a total 38,207 episodes of ARRBLK.

Because providers with small volumes may provide unreliable estimates, we excluded any with fewer than 10 attributed episodes prior to the calculations. After this exclusion 575 (out of 6728) providers remained. Performance scores of these providers are summarized in the following table:

Unadjusted PAC Rates:
Median (IQR): 35.7% (26.3%, 45.5%)
Range: 0% - 100%

Risk-Standardized PAC Rates (RSPR):
Median (IQR): 35.9% (29.2%, 42.1%)
Range: 0% - 91.9%

Please refer to the NQF_ARRBLK_all_codes_risk_adjustment_06.30.15.xls workbook under the "ProviderAttribution Reliability" tab to see specific results for each provider.

1b.3. If no or limited performance data on the measure as specified is reported in 1b2, then provide a summary of data from the literature that indicates opportunity for improvement or overall less than optimal performance on the specific focus of measurement.
The economic burden to Medicare for stroke in AF patients is estimated to be $2.6 billion. Atrial fibrillation (AF) is an independent predictor of stroke and heart failure. Stroke, in particular, is more severe and costly in AF than in non-AF patients. The Framingham study showed a 23.5% risk of stroke attributable to AF (Wolf 1991). Despite this a shocking 30% to 50% of eligible AF patients do not receive preventive anticoagulation (Reynolds 2012). The use of optimal anticoagulation therapy in just half of these patients could prevent 19,000 strokes and save more than $1.1 billion in direct costs annually.

A retrospective analysis of 3 federally funded US databases showed that cardiac dysrhythmias particularly AF majorly contributes to the substantial health care cost burden of $6.65 billion annually (2005 US dollars) and up to 75% of this cost is attributable to the direct and indirect costs of hospitalizations (Coyne 2006). Frequent readmissions are common in patients of AF and a study showed that 1 in 8 patients are readmitted (Kim 2009). In a retrospective analysis by Coyne et al., the incremental costs due to AF per hospitalization for congestive heart failure and acute myocardial infarction were $1682 and $4422, respectively, and incremental costs due to AF annually for congestive heart failure and acute myocardial infarction were $372,060,082 and $243,917,520, respectively (Coyne 2006).

More broadly, the June 2007 MedPAC report to Congress on "Promoting Greater Efficiency in Medicare" highlighted the fact that in 2005, $12 billion were spent on potentially preventable readmissions alone within 30 days of discharge from the hospital. Another study by Jencks and colleagues found that roughly 19.6% of Medicare patients incurred re-hospitalizations within 30 days of discharge. When hospitalizations do occur, they must be managed expeditiously and readmissions following discharge should be avoided (MedPac 2007).

While PACs may not be completely eliminated, identifying their magnitude and understanding their causality, in particular for the most frequent or the most expensive, could lead to improving patient outcomes.

1c. High Priority (previously referred to as High Impact)

The measure addresses:

- a specific national health goal/priority identified by DHHS or the National Priorities Partnership convened by NQF; OR
- a demonstrated high-priority (high-impact) aspect of healthcare (e.g., affects large numbers of patients and/or has a substantial impact for a smaller population; leading cause of morbidity/mortality; high resource use (current and/or future); severity of illness; and severity of patient/societal consequences of poor quality).

1c.1. **Demonstrated high priority aspect of healthcare**
Affects large numbers, A leading cause of morbidity/mortality, High resource use, Patient/societal consequences of poor quality, Severity of illness
1c.2. **If Other:**

1c.3. **Provide epidemiologic or resource use data that demonstrates the measure addresses a high priority aspect of healthcare. List citations in 1c.4.**
An estimated 2-3 million Americans suffer from atrial fibrillation (AF) making it the most common cause of cardiac arrhythmia encountered in clinical practice. The incidence of cardiac arrhythmias including heart block increases with age. The incidence of third-degree heart block is highest in people older than 70 years. With the aging population of baby boomers and improved survival of patients with cardiac disease, the prevalence of atrial fibrillation is estimated to increase to 15.9 million cases by the year 2050 and more than half of these patients will be 80 years or older (Reynolds 2012).

There are significant gaps in the management of patients with dysrhythmias leading to potentially avoidable complications (PACs) contributing to unnecessary inefficiencies and waste in health care with the consequent increased socioeconomic burden. The consequences of poorly managed arrhythmias are thromboembolic disease, particularly stroke, 3-3.5 fold increase in risk of heart failure, increased hospitalizations and all cause mortality (Stewart 2002) (Wolf 1991) (Benjamin 1998).

The economic burden to Medicare for stroke in AF patients is estimated to be $2.6 billion. Atrial fibrillation (AF) is an independent predictor of stroke and heart failure. Stroke, in particular, is more severe and costly in AF than in non-AF patients. The Framingham study showed a 23.5% risk of stroke attributable to AF (Wolf 1991). Despite this a shocking 30% to 50% of eligible AF patients do not receive preventive anticoagulation (Reynolds 2012). The use of optimal anticoagulation therapy in just half of these patients could prevent 19,000 strokes and save more than $1.1 billion in direct costs annually.

A retrospective analysis of 3 federally funded US databases showed that cardiac dysrhythmias particularly AF majorly contributes to the substantial health care cost burden of $6.65 billion annually (2005 US dollars) and up to 75% of this cost is attributable to the direct and indirect costs of hospitalizations (Coyne 2006). Frequent readmissions are common in patients with AF and a study showed that 1 in 8 patients are readmitted (Kim 2009). In a retrospective analysis by Coyne et al., the incremental costs due to AF per hospitalization for congestive heart failure and acute myocardial infarction were $1682 and $4422, respectively, and incremental costs due to AF annually for congestive heart failure and acute myocardial infarction were $372,060,082 and $243,917,520, respectively (Coyne 2006).

Therefore, there are many areas where improvement is possible in patients with arrhythmia or heart block, making it a high priority aspect of health care. The PAC measures go beyond simple readmission rates and look for all-cause harms in these patients.

1d. Composite Quality Construct and Rationale

1d.1. **A composite performance measure is a combination of two or more component measures, each of which individually reflects quality of care, into a single performance measure with a single score.**

For purposes of NQF measure submission, evaluation, and endorsement, the following will be considered composites:

- Measures with two or more individual performance measure scores combined into one score for an accountable entity.
- Measures with two or more individual component measures assessed separately for each patient and then aggregated into one score for an accountable entity:
  - all-or-none measures (e.g., all essential care processes received, or outcomes experienced, by each patient); or
  - any-or-none measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient).

1d.1. Please identify the composite measure construction: any-or-none measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient)

1d.2. **Describe the quality construct, including:**

- the overall area of quality
- included component measures and
- the relationship of the component measures to the overall composite and to each other.

The PAC measures, as we define them, look at many "care defects" comprehensively. They are composed of several cross-cutting measures and together they paint a global picture of the provider's overall performance.

We classify PACs into two types: Type 1 PACs are directly related to the index condition and are often controlled by the servicing provider; Type 2 PACs, on the other hand result from patient safety failures and could be reduced by better systems and better processes in care. Both types of PACs could occur in any setting and so could be identified through any type of claims coming in the administrative dataset, including in-patient, out-patient, or professional claims. PACs may occur any time during the episode time window. PACs are counted as a dichotomous (yes/no) outcome. If a patient had one or more PACs, they get counted as a "yes" or a 1.

The PAC measure definitions encompass several other measures that are accepted as being valid complications of care and are widely used throughout the country. These include CMS defined Hospital Acquired Conditions (HACs), Hospital Inpatient Quality Reporting measures, Avoidable Readmissions, AHRQ defined patient safety indicators (PSIs), NQF endorsed patient safety measures such as patient fall rates, pressure ulcer rates, and peri-operative pulmonary embolism or deep vein thrombosis rates.

All defined PACs, irrespective of their type, or site of occurrence, are aggregated to create an overall comprehensive, composite measure. They all have equal weighting, since they are measured simply by the frequency of their occurrence.

1d.3. **Describe the rationale for constructing a composite measure, including how the composite provides a distinctive or additive value over the component measures individually.**

Each individual PAC, when measured in isolation, provides a very limited picture of the performance of the provider(s) who are managing or co-managing the care of the patient. However, looking at all the PACs that may occur individually or concurrently in a patient with a given episode provides a comprehensive picture of the care received by the patient for that particular condition or illness.

Additionally, the frequency of occurrence of individual PACs may be so low that it may require very high sample sizes from individual providers to achieve any meaningful and reliable comparisons. But aggregating all the PACs into a single quality metric creates meaningful scores that can be compared across providers even with relatively smaller sample sizes.

Additionally, a comprehensive measure is easier to explain to the average consumer. From a patient's point of view, any bad outcome has an impact on their health with respect to return to work, functional limitations and need for additional support. If a provider has a high PAC rate with regards to one component PAC but not the other PACs, the impact on the patient is still adverse. In selecting providers, individual component PAC scores would mean nothing to a patient, but aggregating it to a comprehensive quality score could be a measure of "all-cause" harms and easier to interpret and act on.

1d.4. **Describe how the aggregation and weighting of the component measures are consistent with the stated quality construct and rationale.**

In constructing the comprehensive composite PAC measure, each component PAC, as clinically defined by the subject matter experts, was given the same weight so that arbitrary weights may not bias the results. Furthermore, the measure is constructed so that the occurrence of any number of PACs during a defined episode would only count as one occurrence. As such, the patient is the ultimate unit of measurement and if the patient incurred any PAC during the episode, then that counts against the numerator.

Since the emphasis of the PAC measure was to simply identify the occurrence of PACs in any setting, aggregation of the PAC counts to create a comprehensive quality score with equal weights has been met with overall support from the clinical working groups as well as from the implementation sites.

2. Reliability and Validity—Scientific Acceptability of Measure Properties

Extent to which the measure, as specified, produces consistent (reliable) and credible (valid) results about the quality of care when implemented. ***Measures must be judged to meet the subcriteria for both reliability and validity to pass this criterion and be evaluated against the remaining criteria.***

2a.1. Specifications The measure is well defined and precisely specified so it can be implemented consistently within and across

organizations and allows for comparability. eMeasures should be specified in the Health Quality Measures Format (HQMF) and the Quality Data Model (QDM).

This is not an eMeasure **Attachment:**

S.2b. **Data Dictionary, Code Table, or Value Sets** *(and risk model codes and coefficients when applicable) must be attached. (Excel or csv file in the suggested format preferred - if not, contact staff)*
Attachment **Attachment:** NQF_ARR_all_codes_risk_adjustment_06.30.15-635719684977642819.xlsx

S.3. **For endorsement maintenance**, please briefly describe any changes to the measure specifications since last endorsement date and explain the reasons.
Not applicable

S.4. **Numerator Statement** *(Brief, narrative description of the measure focus or what is being measured about the target population, i.e., cases from the target population with the target process, condition, event, or outcome)*
IF an OUTCOME MEASURE, state the outcome being measured. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
Outcome: Number of patients who triggered an episode of arrhythmias (ARR), are followed for at least one-year, and had one or more potentially avoidable complications (PACs) during the episode time window.

S.5. **Time Period for Data** *(What is the time period in which data will be aggregated for the measure, e.g., 12 mo, 3 years, look back to August for flu vaccination? Note if there are different time periods for the numerator and denominator.)*
The time window is the most recent 12 months of the episode, once a patient has triggered an ARR episode.

S.6. **Numerator Details** *(All information required to identify and calculate the cases from the target population with the target process, condition, event, or outcome such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
IF an OUTCOME MEASURE, describe how the observed outcome is identified/counted. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
Patients that have triggered a ARR episode, and are identified as having services for potentially avoidable complications (PACs), during the most recent 12 months of the episode. The enclosed excel workbook entitled NQF_ARR_all_codes_risk_adjustment_06.30.15 gives the detailed codes for PACs in the tabs entitled PACs I-9 and PACs I-10. PACs are identified only based on diagnosis codes.

Services for PACs are identified as follows:
a. Any service (professional, outpatient facility, ancillary) that is relevant to ARR and has a PAC code in any position on the claim
b. Any admission to an acute care facility, that is relevant to ARR
c. Any admission to a post-acute care facility that is relevant to ARR and has a PAC code in any position on the claim

S.7. **Denominator Statement** *(Brief, narrative description of the target population being measured)*

Adult patients aged 18 years and above who triggered an episode of arrhythmias (ARR) and are followed for at least one-year.

S.8. **Target Population Category** *(Check all the populations for which the measure is specified and tested if any):*
Populations at Risk, Populations at Risk : Dual eligible beneficiaries, Populations at Risk : Individuals with multiple chronic conditions, Populations at Risk : Veterans, Senior Care

S.9. **Denominator Details** *(All information required to identify and calculate the target population/denominator such as definitions, specific data collection items/responses , code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
Please refer to the enclosed excel workbook entitled
NQF_ARR_all_codes_risk_adjustment 06.30.15

The target population is identified using the following criteria:
1.Using administrative claims database, patients with ARR are identified using one of the following criteria:
a. Patients having an office visit with a trigger code of ARR in any position, followed by a second confirmatory office visit (with a trigger code of ARR in any position), at least 30 days apart.
b. Patients with a Principal Dx of an ARR trigger code on an in-hospital stay claim.
The trigger codes for ARR are provided in the tab called "Triggers I-9" or "Triggers I-10".
2. The patient should have continuous enrollment for the entire time window with no more than 30 days as an enrollment gap, with the entity providing the data (so we can ensure that the database has captured most of the claims for the patient during the episode time window).
3. The patient should have a complete episode time window in the claims data – so there are at least 12 months of claims in the database for the patient.
4. Patient should be at least 18 years of age

Once the episode is triggered all relevant claims are assigned to the episode. Relevant claims could be inpatient facility claims, outpatient facility claims, professional services, laboratory services, imaging services, ancillary claims, home health, durable medical equipment as well as pharmacy claims across the entire continuum of care centered around the patient's episode of care. Relevant claims are identified as those that have a diagnosis code that matches the codes in the typical Dx codes tabs (Typical Dx I-9 or Typical Dx I-10), or in the PAC Dx codes tab (PACs I-9 or PACs I-10) AND a procedure code as identified in the Relevant Procedures I-9 & I-10 tab in the enclosed workbook. Relevant admissions to acute and post-acute care facilities are also included in the denominator.

S.10. **Denominator Exclusions** *(Brief narrative description of exclusions from the target population)*
Denominator exclusions include exclusions of either "patients" or "claims" based on the following criteria:
1. "Patients" excluded are those that do not meet the enrollment criteria. If patient has an enrollment gap for more than 30 days during the episode time window, it is considered as an enrollment gap
2. "Patients" are also excluded if the cost of the episode is an outlier at greater than 99th percentile or less than 1st percentile value for all episodes. This is another way to ensure that episodes are complete as well as they do not bring in random noise into the analysis due to inappropriate codes or services.
3. "Claims" are excluded from the ARR measure if they are considered not relevant to ARR care.

S.11. **Denominator Exclusion Details** *(All information required to identify and calculate exclusions from the denominator such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
Denominator exclusions include exclusions of "patients" as well as "claims" not relevant to ARR care. Please refer to the enclosed excel workbook entitled (NQF_ARR_all_codes_risk_adjustment 06.30.15.xls)

1. "Patients" are excluded from the measure if they meet one of the following criteria:
a. If age is < 18 years
b. If gender is missing
c. If they do not have continuous enrollment for the entire time window with a maximum of 30 day enrollment gap with the entity providing the data (this helps determine if the database has captured most of the claims for the patient in the time window).
d. If the patient does not have at least 12 months of claims in the database (this helps eliminate incomplete episodes).

e. The episode cost is an outlier (less than 1st percentile or greater than 99th percentile value for all episodes of the same type). This eliminates extreme variation that may result from random outlier events.

2. "Claims" are excluded from the measure if they meet one of the following criteria:
a. If none of the diagnosis codes on the claim are on the list of "triggers" or relevant diagnosis codes (either typical Dx or PAC Dx) for ARR.
b. If none of the procedure / CPT codes on the claim are on the list of relevant procedure codes for ARR.
c. If the ARR trigger hospitalization also triggers a major surgical procedure such as coronary bypass procedure or angioplasty, suggesting that ARR may be a comorbidity or an indication for the surgery.
d. The "principal" diagnosis on an inpatient stay claim during the episode time window triggers its own episode
e. The procedure code on a claim during the episode time window triggers its own episode

S.12. Stratification Details/Variables *(All information required to stratify the measure results including the stratification variables, definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format with at S.2b)*
None

S.13. Risk Adjustment Type (Select type. Provide specifications for risk stratification in S.12 and for statistical model in S.14-15)
Statistical risk model
If other:

S.14. Identify the statistical risk model method and variables *(Name the statistical method - e.g., logistic regression and list all the risk factor variables. Note - risk model development and testing should be addressed with measure testing under Scientific Acceptability)*
Conceptual Model
Variations in outcomes across populations may be due to patient-related factors or due to provider-controlled factors. When we adjust for patient-related factors, the remaining variance in PACs are due to factors that could be controlled by all providers that are managing or co-managing the patient, both during and after hospitalization.

Statistical Method:
Logistic Regression model to determine the probability of a patient incurring a PAC
Demographic variables, comorbid conditions, as well as clinical severity indicators are fed as independent risk factors into the model. Risk Factors are collected historically. Subtype information is collected from the index claim and any look-back period, if relevant. Subtypes are clinical severity indicators suggesting severity of the episode itself, for example, diagnosis of ventricular arrhythmias in a ARR patient. For each patient the "predicted" coefficients from the risk adjustment models are summed to give the predicted probabilities of the occurrence of a PAC.

Risk Factors :(Please refer to the enclosed excel workbook entitled (NQF_ARR_all_codes_risk_adjustment 06.30.15.xls). The risk factors along with their codes are listed in the tabs called "All Risk Factors I-9" and "All Risk Factors I-10" and also listed below:

AGE CONTINUOUS VARIABLE
GENDER FEMALE = 1 (MALE IS REFERENCE = 0)

Risk Factor #	Risk Factor Name
RF0101	Anoxic Brain Damage, persistent vegetative state
RF0102	Delirium, Meningitis, Encephalitis
RF0103	Previous Stroke, Paralysis
RF0104	Cerebral Palsy and Other Paralytic Syndromes
RF0105	Spinal Cord Disorders/Injuries
RF0106	Polyneuropathy
RF0107	Multiple Sclerosis
RF0108	Convulsions, Epilepsy
RF0109	Dementia
RF0110	Parkinson´s and Huntington´s Diseases

RF0111 Cerebrovascular Disease
RF0115 after care, rehabilitation
RF0201 visual loss, blindness, retinal tear, detachment

Sinus Node Dysfunction
Supraventricular Tachyarrhythmias
Ventricular Arrhythmias

The prevalence of the risk factors in our reference dataset are listed in the enclosed workbook entitled NQF_ARR_all_codes_risk_adjustment 06.30.15.xls – see tab "Risk Factor Prevalence". The output of the regression model are given in the same workbook in the tab 'Risk Model'.

S.15. **Detailed risk model specifications** *(must be in attached data dictionary/code list Excel or csv file. Also indicate if available at measure-specific URL identified in S.1.)*
Note: Risk model details (including coefficients, equations, codes with descriptors, definitions), should be provided on a separate worksheet in the suggested format in the Excel or csv file with data dictionary/code lists at S.2b.
Available in attached Excel or csv file at S.2b

S.15a. **Detailed risk model specifications** (*if not provided in excel or csv file at S.2b*)

S.16. **Type of score:**
Rate/proportion
If other:

S.17. **Interpretation of Score** *(Classifies interpretation of score according to whether better quality is associated with a higher score, a lower score, a score falling within a defined interval, or a passing score)*
Better quality = Lower score

S.18. **Calculation Algorithm/Measure Logic** *(Describe the calculation of the measure score as an ordered sequence of steps including identifying the target population; exclusions; cases meeting the target process, condition, event, or outcome; aggregating data; risk adjustment; etc.)*
Please refer to the enclosed excel workbook entitled (NQF_ARR_all_codes_risk_adjustment 06.30.15.xls).

Assembling the Denominator:

Using administrative claims database, patients with ARR are identified using one of two criteria: 1) Patients having an office visit with a trigger code of ARR in any position, followed by a second confirmatory office visit (with a trigger code of ARR in any position), at least 30 days apart, 2) Patients a Principal Dx of a ARR trigger code on an in-hospital stay claim. The trigger codes for ARR are provided in the tab called "Triggers I-9" or "Triggers I-10".

Patients are retained if they are 18 years of age or more, do not have a missing gender, have at least 12 month of claims in the database, have a maximum of 30-day enrollment gap for the entire episode time window, and have no outlier episode costs. All relevant professional, laboratory, imaging, ancillary and other claims that are incurred during the episode time window are included as part of the episode. Claims are considered relevant to ARR care if they have one of the diagnosis codes, as listed on the tab entitled Triggers I-9, Triggers 1-10, PACs I-9, PACs I-10, Typical Dx I-9, or Typical Dx I-10 in any position on the claim AND a procedure code as identified in the Relevant Procedures I-9 & I-10 tab in the enclosed workbook.. Relevant admissions to acute and post-acute care facilities are also included in the denominator. All relevant pharmacy claims carrying codes that match the ingredients listed in the Pharmacy tab of the enclosed workbook are also included as part of the episode. Services are pulled as part of the ARR episode

based on the diagnosis codes as defined above or if they have a service code that is marked as "sufficient" for that episode.

If a patient has more than one concurrent episode, and the claim is relevant to both episodes, the claim could get multi-assigned, except in the case of procedural episodes that get carved out with respect to the index stay. So if an inpatient stay claim carried a principal Dx code that matched the trigger diagnosis code for ARR but they also had a procedure code for CABG (coronary artery bypass surgery), the stay claim would get uniquely assigned to CABG and not be counted with ARR.

Once all the episodes are assembled, episodes that match the exclusion criteria, such as those with outlier costs, are flagged (those with total episode costs less than 1st percentile or greater than 99th percentile), and excluded from the final analysis.

Assembling the Numerator:

For every episode included in the denominator, services are flagged as having a PAC (potentially avoidable complication) based on the criteria listed below:

Any service (professional, outpatient facility, ancillary) with a PAC code in any position on the claim

Any admission to an acute care facility, that is relevant to ARR

Relevant claims that do not have any PAC codes, and do not qualify as a PAC based on the criteria outlined above, are listed as typical claims. All included relevant pharmacy services are flagged as typical. Patients that have even a single PAC claim are counted as part of the numerator.

Calculating the measure:

Proportion of ARR patients that have PACs, is simply the ratio of patients with PACs within the HTN ARR population and is called the PAC rate as shown in the equation below:

PAC rate = Patients with ARR that have at least one PAC claim / Total number of ARR patients

A flow chart demonstrating the series of steps and the counts of patients at each step is shown in tab entitled Decision Tree of the enclosed workbook called NQF_ARR_all_codes_risk_adjustment 06.30.15.xls

Drill Down Calculations:

Further analysis from this construct helps create actionable reports.

For example as shown in the tab labeled PAC overview, not only do we have the PAC rate for a population, we can break them down by the PAC type – type 1 being directly related to ARR and so actionable by the servicing physician, while type 2 PACs are related to patient safety failures and can be improved by process improvement. Additionally, analyzing potentially avoidable admissions helps focus strategies in reducing them.

Risk Adjustment:

Once we have the observed PAC rates, we risk-adjust them for patient factors such as patient demographics, comorbidities collected historically, and for severity of illness or procedure using subtypes collected from the index stay and / or look-back period. This helps adjust for factors outside the providers control and levels the playing field for provider performance comparisons.

Unit of Analysis:
The unit of analysis is the individual episode.

Dependent Variable:
The dependent variable is a dichotomous variable indicating whether an episode had one or more claims assigned as a PAC (=1) or not (=0).

Independent Variables:
A number of patient-related "risk factors" or covariates are included in the models:

Patient demographics: age, gender, and an indicator of whether a member has enrolled within the previous 6 months. This latter risk factor is intended to account for the patient's lack of claims history, which limits the number of potential comorbidities that can be identified.

Comorbidities: These are conditions or events that occurred prior to the start of the episode that can have a potential impact on the patient's risk of having a PAC. The risk factors are 170 disease indicators (0/1) identified through the presence of ICD diagnosis codes on individual medical claims and collected from the historical claims data before the start of an episode. These are universally applied across all episodes. Please see the tab labeled "All Risk Factors I-9" and "All Risk Factors I-10" for a list of risk factors and their corresponding codes in the enclosed workbook called NQF_ARR_all_codes_risk_adjustment 06.30.15.xls

Episode Subtypes or Severity Markers: These are markers that distinguish an episode as being more severe than another. They indicate either specific patient comorbidities that are known to make the procedure or condition more difficult to treat (e.g., heart aneurysmobesity) or severity of the illness itself (e.g., unstable ventricular arrhythmiaangina). Please see the tab labeled "Subtypes I-9" and "Subtypes I-10" for a list of subtypes and their corresponding codes in the enclosed workbook called NQF_ARR_all_codes_risk_adjustment 06.30.15.xls

As mentioned previously, to avoid creating perverse incentives all comorbidities and subtypes are identified prior to or at the very start of the episode. None are identified during the episode period.

Statistical Methods

We use logistic regression to model the probability of at least one PAC occurring during the episode. Only comorbidities and subtypes are included in the models as covariates if they are present in at least 10 episodes to prevent unstable coefficients. No further model building is conducted after the initial models are built. This reflects a desire to explain as much variation in the probability of having a PAC as possible, but it does not make it a priority that all covariates in the model be individually significant or even uncorrelated with each other. Accordingly, the model uses a very large group of covariates. This modeling approach allows for fewer potentially artificial constraints around the definitions of what constitutes severity of a episode condition, and lets each regression model determine for itself which of the factors are more significant for a specific episode. Non-significant covariates in episode models can not overly influence predicted outcomes, nor is much harm realized, if a group of correlated covariates work together to explain variation rather than having the variation explained by a single best factor.

When more than one line of business is included in the data, separate models are calculated for each sample (i.e., commercial, Medicaid etc.).

Provider Attribution and calculating PAC rates by provider:

Once episodes are constructed they are attributed to providers based on one of the various attribution rules. For ARR, episodes are attributed to the primary care physician or cardiologist with the highest count of office visits.

Using the logistic regression technique described above, a model is developed that gives estimates for each risk factor and subtype for the patients in the population analyzed. These estimates are used to develop patient-level probabilities for the occurrence of PACs. The patient-level probability estimates are summed to construct aggregated measures (e.g., facility/provider-level). This method is similar to the methods employed by the Centers for Medicare and Medicaid Services (CMS) and endorsed by the National Quality Forum (NQF) to construct similar facility- and practice-level measures (i.e., mortality, readmissions, etc.):

1. For each provider, the number of actual observed occurrences of the outcome is summed across all attributed patients with that episode, to give the observed PAC rates for the provider.
2. Similarly adjusted probabilities from the risk adjustment models are summed across all attributed patients to give expected PACs for the provider.
3. The observed sum is then divided by the summed probabilities (O/E). This number yields whether the provider or facility had more PACs than expected (ratio>1), as expected (ratio=1), or less than expected (ratio<1). This calculation yields a practice-level unstandardized performance ratio.
4. To facilitate accurate comparisons of rates across units of analysis, this ratio is then standardized to the community rate using the indirect method. Specifically, the provider-level rate is multiplied by the expected community rate, calculated as the sum of adjusted probabilities for every individual in the sample across all providers in the analysis. This measure, known as the standardized rate, represents what the unit's risk-adjusted rate would be for the outcome of interest if its patient population was reflective of the of the overall community.

The formula for this calculation is as follows:

Adj Outcome_j={(SUM Observed_ij)/(SUM Prob_ij)} × {(SUM Prob_i) / (# of episodes)}
Where individual is attributed to unit of analysis j (e.g., practice, provider, etc.)

Minimum sample size requirements for PAC measures are a function of the reliability testing of the measures on every dataset on which the measures are applied. Our research suggests that minimum sample sizes to achieve high degrees of reliability in the measures are a function of the dataset analyzed, and as such may vary from dataset to dataset. One should not infer that a minimum sample size achieved in one dataset would apply to another.

S.19. **Calculation Algorithm/Measure Logic Diagram URL or Attachment** *(You also may provide a diagram of the Calculation Algorithm/Measure Logic described above at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
Available in attached appendix at A.1

S.20. **Sampling** *(If measure is based on a sample, provide instructions for obtaining the sample and guidance on minimum sample size.)*
IF a PRO-PM, identify whether (and how) proxy responses are allowed.
Not applicable

S.21. **Survey/Patient-reported data** *(If measure is based on a survey, provide instructions for conducting the survey and guidance on minimum response rate.)*
IF a PRO-PM, specify calculation of response rates to be reported with performance measure results.
Not applicable

S.22. **Missing data** (specify how missing data are handled, e.g., imputation, delete case.)
Required for Composites and PRO-PMs.
If patient related data is missing, the entire patient is excluded from the numerator as well as the denominator.

S.23. **Data Source** *(Check ONLY the sources for which the measure is SPECIFIED AND TESTED).*
If other, please describe in S.24.
Administrative claims

S.24. **Data Source or Collection Instrument** *(Identify the specific data source/data collection instrument e.g. name of database, clinical registry, collection instrument, etc.)*
IF a PRO-PM, identify the specific PROM(s); and standard methods, modes, and languages of administration.
The information is based on a two-year claims database from a large regional commercial insurer. The database has over 3.2 million covered lives and $25.9 billion in “allowed amounts” for claims costs. The database is an administrative claims database with medical as well as pharmacy claims.

The methodology can be used on any claims database with at least two years of data and a minimum of 150 patients with the index condition or hospitalization. Having pharmacy data adds to the richness of the risk-adjustment models.
?The calculations of rates of potentially avoidable complications can be replicated by anyone that uses the measure specifications along with the metadata file that is available for free on our web site at http://www.hci3.org/ecre/xml-agreement.html.
We also plan on providing a limited automated analysis, at no cost, on our website.
The methodology has been tested on databases of several health plans as well as on a few employer databases.

No data collection instrument was used.

S.25. **Data Source or Collection Instrument** *(available at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
No data collection instrument provided

S.26. **Level of Analysis** *(Check ONLY the levels of analysis for which the measure is SPECIFIED AND TESTED)*
Clinician : Group/Practice, Clinician : Individual, Clinician : Team

S.27. **Care Setting** *(Check ONLY the settings for which the measure is SPECIFIED AND TESTED)*
Ambulatory Care : Ambulatory Surgery Center (ASC), Ambulatory Care : Clinician Office/Clinic, Other
If other: Across the care continuum

S.28. **COMPOSITE Performance Measure** - Additional Specifications *(Use this section as needed for aggregation and weighting rules, or calculation of individual performance measures if not individually endorsed.)*

2a. Reliability – See attached Measure Testing Submission Form
2b. Validity – See attached Measure Testing Submission Form
2749_ARR_Testing_Reliability_Validity_HCI3.docx

NATIONAL QUALITY FORUM—Composite Measure Testing (subcriteria 2a2, 2b2-2b7, 2d)

Measure Number (*if previously endorsed*)**:** 2749
Measure Title: Proportion of Patients with Arrhythmias (ARR) that have a Potentially Avoidable Complication (during the episode time window)
Date of Submission: 06/30/15
Composite Construction:

☐ Two or more individual performance measure scores combined into one score
☐ All-or-none measures (e.g., all essential care processes received or outcomes experienced by each patient)
☐ Any-or-none measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient)

Instructions

- Measures must be tested for all the data sources and levels of analyses that are specified. ***If there is more than one set of data specifications or more than one level of analysis, contact NQF staff*** about how to present all the testing information in one form.
- **For all measures, sections 1, 2a2, 2b2, 2b3, and 2b5 must be completed.**
- **For outcome and resource use measures**, section **2b4** also must be completed.
- If specified for **multiple data sources/sets of specificaitons** (e.g., claims and EHRs), section **2b6** also must be completed.
- Respond to all questions as instructed with answers immediately following the question. All information on testing to demonstrate meeting the subcriteria for reliability (2a2) and validity (2b2-2b6) must be in this form. An appendix for *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 20 pages (*incuding questions/instructions;* minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the testing results for this measure meet NQF's evaluation criteria for testing.

2a2. Reliability testing [10] demonstrates the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise. For **PRO-PMs and composite performance measures**, reliability should be

demonstrated for the computed performance score.

2b2. Validity testing [11] demonstrates that the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality. For **PRO-PMs and composite performance measures**, validity should be demonstrated for the computed performance score.

2b3. Exclusions are supported by the clinical evidence; otherwise, they are supported by evidence of sufficient frequency of occurrence so that results are distorted without the exclusion; [12]
AND
If patient preference (e.g., informed decisionmaking) is a basis for exclusion, there must be evidence that the exclusion impacts performance on the measure; in such cases, the measure must be specified so that the information about patient preference and the effect on the measure is transparent (e.g., numerator category computed separately, denominator exclusion category computed separately). [13]

2b4. For outcome measures and other measures when indicated (e.g., resource use):

- **an evidence-based risk-adjustment strategy** (e.g., risk models, risk stratification) is specified; is based on patient factors that influence the measured outcome (but not factors related to disparities in care or the quality of care) and are present at start of care; [14,15] and has demonstrated adequate discrimination and calibration

OR

- rationale/data support no risk adjustment/ stratification.

2b5. Data analysis of computed measure scores demonstrates that methods for scoring and analysis of the specified measure allow for **identification of statistically significant and practically/clinically meaningful** [16] **differences in performance**;
OR
there is evidence of overall less-than-optimal performance.

2b6. If multiple data sources/methods are specified, there is demonstration they produce comparable results.

2b7. For **eMeasures, composites, and PRO-PMs** (or other measures susceptible to missing data), analyses identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias.

Notes
10. Reliability testing applies to both the data elements and computed measure score. Examples of reliability testing for data elements include, but are not limited to: inter-rater/abstractor or intra-rater/abstractor studies; internal consistency for multi-item scales; test-retest for survey items. Reliability testing of the measure score addresses precision of measurement (e.g., signal-to-noise).
11. Validity testing applies to both the data elements and computed measure score. Validity testing of data elements typically analyzes agreement with another authoritative source of the same information. Examples of validity testing of the measure score include, but are not limited to: testing hypotheses that the measures scores indicate quality of care, e.g., measure scores are different for groups known to have differences in quality assessed by another valid quality measure or method; correlation of measure scores with another valid indicator of quality for the specific topic; or relationship to conceptually related measures (e.g., scores on process

measures to scores on outcome measures). Face validity of the measure score as a quality indicator may be adequate if accomplished through a systematic and transparent process, by identified experts, and explicitly addresses whether performance scores resulting from the measure as specified can be used to distinguish good from poor quality.

12. Examples of evidence that an exclusion distorts measure results include, but are not limited to: frequency of occurrence, variability of exclusions across providers, and sensitivity analyses with and without the exclusion.

13. Patient preference is not a clinical exception to eligibility and can be influenced by provider interventions.

14. Risk factors that influence outcomes should not be specified as exclusions.

15. Risk models should not obscure disparities in care for populations by including factors that are associated with differences/inequalities in care, such as race, socioeconomic status, or gender (e.g., poorer treatment outcomes of African American men with prostate cancer or inequalities in treatment for CVD risk factors between men and women). It is preferable to stratify measures by race and socioeconomic status rather than to adjust out the differences.

16. With large enough sample sizes, small differences that are statistically significant may or may not be practically or clinically meaningful. The substantive question may be, for example, whether a statistically significant difference of one percentage point in the percentage of patients who received smoking cessation counseling (e.g., 74 percent v. 75 percent) is clinically meaningful; or whether a statistically significant difference of $25 in cost for an episode of care (e.g., $5,000 v. $5,025) is practically meaningful. Measures with overall less-than-optimal performance may not demonstrate much variability across providers.

1. DATA/SAMPLE USED FOR ALL TESTING OF THIS MEASURE

Often the same data are used for all aspects of measure testing. In an effort to eliminate duplication, the first five questions apply to all measure testing. If there are differences by aspect of testing,(e.g., reliability vs. validity) be sure to indicate the specific differences in question 1.7.

1.1. What type of data was used for testing? (*Check all the sources of data identified in the measure specifications and data used for testing the measure. Testing must be provided for all the sources of data specified and intended for measure implementation.* ***If different data sources are used for the numerator and denominator, indicate N [numerator] or D [denominator] after the checkbox.***)

Measure Specified to Use Data From: (*must be consistent with data sources entered in S.23*)	**Measure Tested with Data From:**
☐ abstracted from paper record	☐ abstracted from paper record
☐ administrative claims	☐ administrative claims
☐ clinical database/registry	☐ clinical database/registry
☐ abstracted from electronic health record	☐ abstracted from electronic health record
☐ eMeasure (HQMF) implemented in EHRs	☐ eMeasure (HQMF) implemented in EHRs
☐ other: Click here to describe	☐ other: Click here to describe

1.2. If an existing dataset was used, identify the specific dataset (*the dataset used for testing must be consistent with the measure specifications for target population and healthcare entities being measured; e.g., Medicare Part A claims, Medicaid claims, other commercial insurance, nursing home MDS, home health OASIS, clinical registry*).

The information is based on a two-year administrative claims database from a large regional commercial insurer. The database contains medical and pharmacy claims on over 3.2 million covered lives and more than $25.9 billion in "allowed amounts" for costs.

1.3. What are the dates of the data used in testing? April 1, 2012 – December 17, 2014

1.4. What levels of analysis were tested? (*testing must be provided for all the levels specified and intended for measure implementation, e.g., individual clinician, hospital, health plan*)

Measure Specified to Measure Performance of: (***must be consistent with levels entered in item S.26***)	**Measure Tested at Level of:**
☒ individual clinician	☒ individual clinician
☒ group/practice	☒ group/practice
☐ hospital/facility/agency	☐ hospital/facility/agency
☐ health plan	☐ health plan
☒ other: Integrated Delivery System	☐ other: Click here to describe

1.5. How many and which measured entities were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of measured entities included in the analysis (e.g., size, location, type); if a sample was used, describe how entities were selected for inclusion in the sample*)

There were a total of 6,728 providers in the data set. Because providers with small volumes may provide unreliable estimates, we excluded any with fewer than 10 attributed episodes prior to the reliability calculations. After this exclusion, there were 575 providers left.

1.6. How many and which patients were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of patients included in the analysis (e.g., age, sex, race, diagnosis); if a sample was used, describe how patients were selected for inclusion in the sample*)

After exclusions (see 2b.3.1 below), there were a total of 38,207 episodes of ARR included in the testing and analysis. Patients in these episodes were, on average, 49.1 years of age (range 18-64) and 54% were female. We did not have race information on these patients. All patients for this analysis met the trigger criteria of ARR as identified in our code tables and our programming rules.

1.7. If there are differences in the data or sample used for different aspects of testing (e.g., reliability, validity, exclusions, risk adjustment), identify how the data or sample are different for each aspect of testing reported below.

For the reliability analysis, we restricted the data to only providers with at least 10 attributed episodes. For risk adjustment, all episodes were used in the analysis, regardless of the provider to which they were attributed.

1.8 What were the patient-level sociodemographic (SDS) variables that were available and analyzed in the data or sample used? For example, patient-reported data (e.g., income, education, language), proxy variables when SDS data are not collected from each patient (e.g. census tract), or patient community characteristics (e.g. percent vacant housing, crime rate).
None of the analyses included SDS variables.

2a2. RELIABILITY TESTING

Note: *If accuracy/correctness (validity) of data elements was empirically tested, separate reliability testing of data elements is not required – in 2a2.1 check critical data elements; in 2a2.2 enter "see section 2b2 for validity testing of data elements"; and skip 2a2.3 and 2a2.4.*

2a2.1. What level of reliability testing was conducted? (*may be one or both levels*)

☐ **Critical data elements used in the measure** (*e.g., inter-abstractor reliability; data element reliability must address ALL critical data elements*)

☐ **Performance measure score** (e.g., *signal-to-noise analysis*)

2a2.2. For each level checked above, describe the method of reliability testing and what it tests (*describe the steps—do not just name a method; what type of error does it test; what statistical analysis was used*)

We assessed the reliability of the measure to demonstrate that it sufficiently differentiates performance between providers using the beta-binomial method, which is applicable to measures of this type. Reliability is a measure that distinguishes the signal (the extent of performance variation between entities that is due to true differences in performance) from statistical noise. Our approach follows directly from the methods outlined in the technical report "The Reliability of Provider Profiling: A Tutorial" by J.L. Adams.

Reference:

Adams JL. The Reliability of Provider Profiling: A Tutorial. Rand Corporation. http://www.rand.org/pubs/technical_reports/TR653.html.

2a2.3. For each level of testing checked above, what were the statistical results from reliability testing? (e.g., *percent agreement and kappa for the critical data elements; distribution of reliability statistics from a signal-to-noise analysis*)

The table below provides a summary of the reliability score for different minimum sample size thresholds. For complete results, refer to the workbook entitled, NQF_ARR_all_codes_risk_adjustment_06.30.15.xls, under the "ProviderAttribution Reliability" tab to see provider-specific results.

Reliability Scores	**Minimum # Episodes Per Provider**		
	>=10	**>=25**	**>=50**
# of Providers (%)	575 (100)	232 (40)	103 (18)
Median (IQR)	0.66 (0.54,0.79)	0.80 (0.74,0.87)	0.88 (0.84,0.93)
Range	0.42-1.00	0.65-0.99	0.79-0.99

2a2.4 What is your interpretation of the results in terms of demonstrating reliability? (i.e., *what do the results mean and what are the norms for the test conducted?*)

Reliability scores can vary from 0.0 to 1.0, with a score of zero indicating that all variation is attributable to measurement error (noise, or variation across patients within providers) whereas a reliability of 1.0 implies that all variation is caused by real difference in performance across accountable entities.

There is not a clear cut-off for minimum reliability level. Values above 0.7, however, are considered sufficient to see differences between some physicians and the mean, and values above 0.9 are considered sufficient to see differences between pairs of physicians (see Adams, 2009 cited above).

Although there was a wide range of scores across all providers with at least 10 episodes and scores for many were low, those among providers with at least 25 episodes were consistently good and continued to improve as provider sample size increased. This demonstrates that for providers with a minimum threshold number of episodes the measure sufficiently differentiates performance between them.

Minimum sample size requirements for PAC measures are a function of the reliability testing of the measures on every dataset on which the measures are applied. Our research suggests that minimum sample sizes to achieve high degrees of reliability in the measures are a function of the dataset analyzed, and as such may vary from dataset to dataset. One should not infer that a minimum sample size achieved in one dataset would apply to another.

2b2. VALIDITY TESTING

***Note**: Current guidance for composite measure evaluation states that validity should be demonstrated for the composite performance measure score. If not feasible for initial endorsement, acceptable alternatives include assessment of content or face validity of the composite OR demonstration of validity for each component. Empirical validity testing of the composite measure score is expected by the time of endorsement maintenance.*

2b2.1. What level of validity testing was conducted?

☐ **Composite performance measure score**

- ☐ **Empirical validity testing**
- ☐ **Systematic assessment of face validity of performance measure score as an indicator** of quality or resource use (*i.e., is an accurate reflection of performance on quality or resource use and can distinguish good from poor performance*)
- ☐ **Systematic assessment of content validity**

☐ **Validity testing for component measures** *(check all that apply)*

***Note**: applies to ALL component measures, unless already endorsed or are being submitted for individual endorsement.*

- ☐ **Endorsed (or submitted) as individual performance measures**
- ☐ **Critical data elements** (*data element validity must address ALL critical data elements*)
- ☐ **Empirical validity testing of the component measure score(s)**
- ☐ **Systematic assessment of face validity of component measure score(s) as an indicator** of quality or resource use (*i.e., is an accurate reflection of performance on quality or resource use and can distinguish good from poor performance*)

2b2.2. For each level of testing checked above, describe the method of validity testing and what it tests (*describe the steps—do not just name a method; what was tested, e.g., accuracy of data elements compared to authoritative source, relationship to another measure as expected; what statistical analysis was used)*

Content validity was built into the development of the definitions of potentially avoidable complications (PACs). This involved working with clinicians who are experts in their respective fields and specific to the episodes for which PACs are being measured. In particular, the clinical experts focused on whether or not a potentially avoidable complication can be deemed as such for a specific episode of care, and help

defined and review all of the diagnosis and procedure codes for each PAC. The enclosed link lists clinicians who have participated in the various Clinical Working Groups (http://www.hci3.org/content/clinical-working-group-contributors). Some of the clinical experts have also participated in monthly webinars that highlight the clinical aspects of these measures (http://www.hci3.org/content/using-ecrs-providers).

In addition, we illustrate that our measure has face validity in several ways.

Beyond the up front work performed by clinical experts, the validity of the measure has also been tested in various real world settings. For example, we have presented results of claims data analyses that reveal the frequency and costs of PACs to physicians in several different healthcare systems involved in our pilot site implementations, as well as to medical directors from the employer coalitions and the health plans that provided the dataset to run the analyses. Some of these implementations include the Pennsylvania Employee Benefits Trust Fund and local provider groups and hospital, Horizon Blue Cross Blue Shield of NJ and many physicians and health systems.

In addition, we have performed dozens of analyses of very large claims data sets and reported results of rates and costs of PACs to policy makers, health plan leaders and physician leaders from different states. These include:

- Vermont Payment Reform Commission
- Maine Health Management Coalition
- WellPoint / Anthem CT
- NY State Medicaid
- CT Medicaid
- CO All-payer Claims Database, Center for Improving Value in Health Care

These analyses and their results have influenced, and continue to influence, the development of various public reporting, payment reform and delivery system reform efforts. To-date, we have never experienced either wholesale or partial rejection of the results of analyses showing rates of PACs, which demonstrates the level of acceptability – face validity – of the measures from the payer, policymaker, employer and payer communities.

As importantly, measures of potentially avoidable complications have face-validity with consumers. In a series of focus groups, Judy Hibbard and colleagues[1] examined the impact of presenting information about price and quality of certain providers in influencing the decisions of consumers. They tested the validity of PACs as a discriminator of quality, as well as other measures of quality, and used the dollar symbol to illustrate the level of price, much like is done for restaurant reviews. When the PAC measure was used, respondents selected the providers with the lowest PAC rates with a high level of confidence in choice, and used it as a surrogate for a strong quality signal. To the contrary, when more standard measures of quality were used, consumers tended to ignore them and use price as a surrogate for quality. As such, what the researchers found is that the very framing of potentially avoidable complications as an indicator of potential harm, is an effective way of communicating the quality of care. And when measures of PACs were presented in conjunction with price, consumers intuitively accepted the logical relationship between low PACs – fewer “defects” – and lower price.

Finally, our measure definitions encompass several other measures that are accepted as being valid complications of care and are widely used throughout the country. These include CMS defined Hospital Acquired Conditions (HACs)[2], Hospital Inpatient Quality Reporting measures [3], Avoidable Readmissions [4,5], AHRQ defined patient safety indicators (PSIs) [6], NQF endorsed patient safety

measures such as patient fall rates, pressure ulcer rates, and peri-operative pulmonary embolism or deep vein thrombosis rates [7].

2b2.3. What were the statistical results from validity testing? (*e.g., correlation; t-test*)
Not applicable.

2b2.4. What is your interpretation of the results in terms of demonstrating validity? (i.*e., what do the results mean and what are the norms for the test conducted?*)

Given the significant clinical input that went into developing the measure, the widespread use and acceptance the measure has gained among a wide variety of individuals and organizations across the health system (public and private payers, clinicians, consultants, patients, etc.) [1-13], and the parallels between this measure and other measures that are in widespread use, this demonstrates that the measure has strong face validity.

2b3. EXCLUSIONS ANALYSIS

Note: *Applies to the composite performance measure, as well all component measures unless they are already endorsed or are being submitted for individual endorsement.*

NA ☐ no exclusions — *skip to section 2b4*

2b3.1. Describe the method of testing exclusions and what it tests (*describe the steps—do not just name a method; what was tested, e.g., whether exclusions affect overall performance scores; what statistical analysis*

was used)

No formal exclusion testing was done since no real exclusions were done. The only patients excluded were the ones that had incomplete or missing data and those that would not have given a homogenous population such as outliers.

Exclusions include exclusions of "patients" as well as "claims" not relevant to ARR care.

1. "Patients" are excluded from the measure if they meet one of the following criteria:
a. If age is < 18 years
b. If gender is missing
c. If they do not have continuous enrollment for the entire time window with a maximum of 30 day enrollment gap with the entity providing the data (this helps determine if the database has captured most of the claims for the patient in the time window).
d. If the patient does not have at least 12 months of claims in the database (this helps eliminate incomplete episodes).
e. The episode cost is an outlier (less than 1st percentile or greater than 99th percentile value for all episodes of the same type). This eliminates extreme variation that may result from random outlier events.

2. "Claims" are excluded from the measure if they meet one of the following criteria:
a. If none of the diagnosis codes on the claim are on the list of "triggers" or relevant diagnosis codes (either typical Dx or PAC Dx) for ARR.
b. If none of the procedure / CPT codes on the claim are on the list of relevant procedure codes for ARR.
c. If the ARR trigger hospitalization also triggers a major surgical procedure such as coronary bypass procedure or angioplasty, suggesting that ARR may be a comorbidity or an indication for the surgery.
d. The "principal" diagnosis on an inpatient stay claim during the episode time window triggers its own episode
e. The procedure code on a claim during the episode time window triggers its own episode.

2b3.2. What were the statistical results from testing exclusions? (*include overall number and percentage of individuals excluded, frequency distribution of exclusions across measured entities, and impact on performance measure scores*)

We started with a total ARR population of 81,216 episodes. After all the exclusions were applied, the remaining ARR population included in the analysis consisted of 38,207 episodes. As mentioned above, no real exclusions were done. The only patients excluded were the ones that had incomplete or missing data and those that would not have given a homogenous population such as outliers. As such, no formal exclusion testing was done.

2b3.3. What is your interpretation of the results in terms of demonstrating that exclusions are needed to prevent unfair distortion of performance results? (*i.e., the value outweighs the burden of increased data collection and analysis. Note: **If patient preference is an exclusion**, the measure must be specified so that the effect on the performance score is transparent, e.g., scores with and without exclusion*)

No formal analysis was done on the impact of exclusions on performance scores.

Descriptive Explanation:

Exclusions of patients were for the following reasons. Some are for comparative purposes and some for medical

reasons.

(a) Comparative Purposes:
We excluded patients that did not have complete enrollment for the entire episode time window. This was done to ensure that the database had complete information on patients to be able to create the entire episode. Including patients with only a partial episode window could distort the measure by artificially reducing the actual count of patients with PACs.

(b) Medical Reasons:
Patients with outlier costs (less than 1st percentile value or greater than 99th percentile) were considered to be different from the general pool, and excluded from both the numerator and the denominator. This is another way to ensure that episodes are complete (because incomplete episodes may have very low costs), and do not bring in random noise into the analysis due to inappropriate codes or services (high outliers).

2b4. RISK ADJUSTMENT/STRATIFICATION FOR OUTCOME OR RESOURCE USE MEASURES
Note: *Applies to all outcome or resource use component measures, unless already endorsed or are being submitted for individual endorsement.*
If not an intermediate or health outcome, or PRO-PM, or resource use measure, skip to section 2b5.

2b4.1. What method of controlling for differences in case mix is used? *(check all that apply)*
☐ **Endorsed (or submitted) as individual performance measures**
☐ **No risk adjustment or stratification**
☐ **Statistical risk model** with 170 potential risk factors and episode specific subtypes
☐ **Stratification by risk categories**
☐ **Other,** Click here to enter description

2b4.2. If an outcome or resource use component measure is not risk adjusted or stratified, provide rationale and analyses to demonstrate that controlling for differences in patient characteristics (case mix) is not needed to achieve fair comparisons across measured entities.

2b4.3. Describe the conceptual/clinical and statistical methods and criteria used to select patient factors used in the statistical risk model or for stratification by risk (*e.g., potential factors identified in the literature and/or expert panel; regression analysis; statistical significance of p<0.10; correlation of x or higher; patient factors should be present at the start of care and not related to disparities*)

Risk factors are comorbidity indicators collected from historical claims before the start of an episode. These are universally applied across all episodes. This list was selected based on input from clinical experts in clinical working groups. In addition, the Clinical Working Groups identified episode specific severity markers that were called episode subtypes and they help distinguish an episode as being more severe than another.

All risk factors and subtypes must be present prior to, or at the start of the episode and are identified using diagnosis codes in the patient's historical claims.

To be included in the risk adjustment models, any risk factor or subtype must be present in at least 10 episodes. Beyond this no further model building was conducted to add or remove risk factors or subtypes from the model after it was initially run. This reflects a desire to explain as much variation in the probability of having a PAC

as possible, but does not make it a priority that all covariates be individually significant or even uncorrelated with each other. Accordingly, the model uses a very large group of covariates. This modeling approach allows for fewer potentially artificial constraints around the definitions of what constitutes severity, and lets the model determine for itself which of the factors are more significant. Non-significant covariates cannot overly influence the predicted outcomes, nor is much harm realized, if a group of correlated covariates work together to explain variation rather than having the variation explained by a single best factor.

2b4.4. What were the statistical results of the analyses used to select risk factors?

As explained above, no formal analysis was conducted to select risk factors. In fact, all potential risk factors and subtypes with a count of at least 10 episodes were retained to serve as predictors. The goal was to achieve a more complete explanatory model rather than achieve parsimony.

Please reference the tabs titled Risk Model in the NQF_ARR_all_codes_risk_adjustment_06.30.15.xls workbook to see the list of risk factors that met the selection criteria.

2b4.4b. Describe the analyses and interpretation resulting in the decision to select SDS factors (e.g. prevalence of the factor across measured entities, empirical association with the outcome, contribution of unique variation in the outcome, assessment of between-unit effects and within-unit effects)

Not Applicable since our analysis did include SDS variables

2b4.5. Describe the method of testing/analysis used to develop and validate the adequacy of the statistical model or stratification approach (*describe the steps—do not just name a method; what statistical analysis was used*)

Model Development Approach

We used logistic regression to model the probability of at least one PAC occurring during the episode. The model included all covariates that were identified through the process above. No further model building was conducted after the initial model was run. This reflects a desire to explain as much variation in the probability of having a PAC as possible, but does not make it a priority that all covariates be individually significant or even uncorrelated with each other. Accordingly, the model uses a very large group of covariates. This modeling approach allows for fewer potentially artificial constraints around the definitions of what constitutes severity, and lets the model determine for itself which of the factors are more significant. Non-significant covariates can not overly influence the predicted outcomes, nor is much harm realized, if a group of correlated covariates work together to explain variation rather than having the variation explained by a single best factor.

For a more complete description of the risk adjustment approach, please see the document entitled, "PACs and Severity Adjustment Fact Sheet" that accompanies this submission.

Approach to Model Testing and Validation

To determine the validity and performance of the model, we used the split sample method to divide the patient sample randomly into: 1) the model building data set (80% of the sample) and 2) the test data set (20% of sample. The model was built using logistic regression on the first data set and then the coefficients from the development model were tested in the second dataset. Area under the curve (AUC) and the c-statistic were used to compare the predictive ability of the model in each of the data sets. Hosmer-Lemeshow Goodness-of-Fit tests and comparisons of observed to expected probabilities across risk deciles were further examined to assess the model's overall predictive accuracy.

Provide the statistical results from testing the approach to controlling for differences in patient characteristics (case mix) below.
If stratified, skip to 2b4.9

2b4.6. Statistical Risk Model Discrimination Statistics (*e.g., c-statistic, R-squared*)**:**

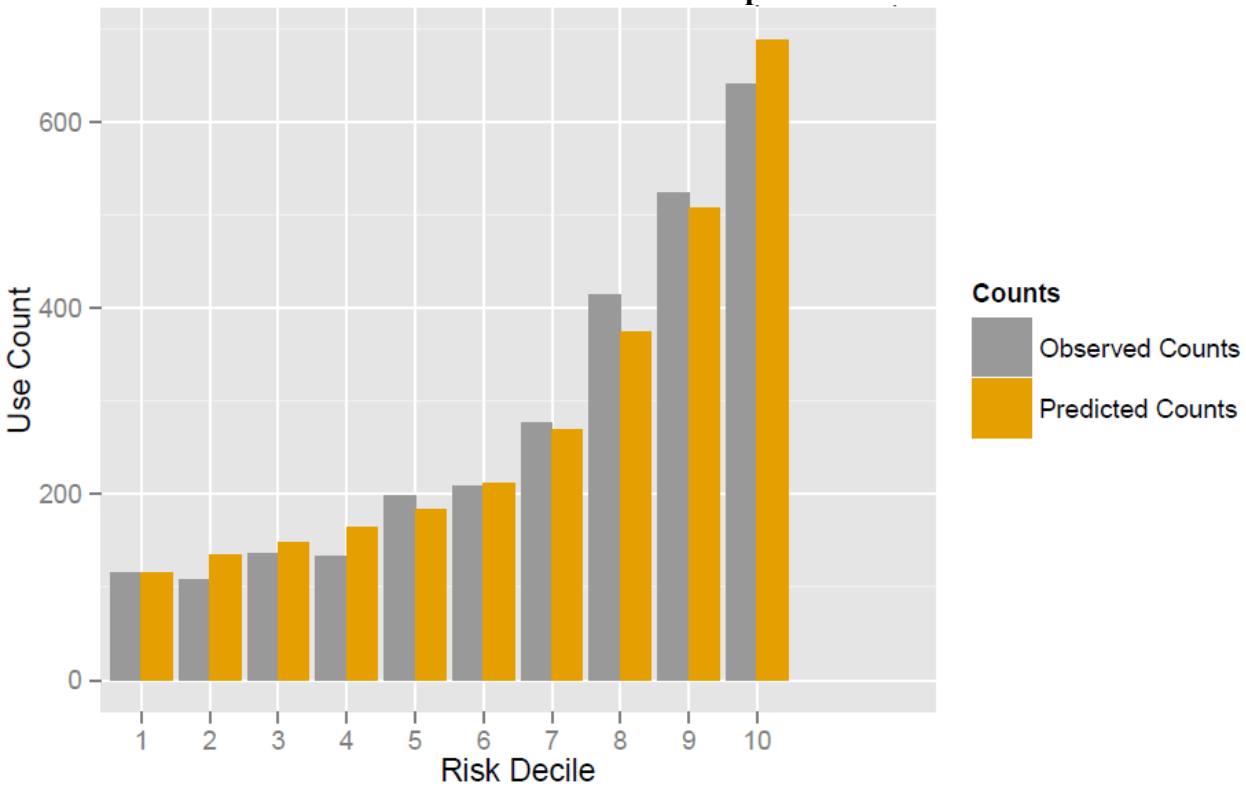
Sample	Accuracy (%)*	AUC
Test	75.2%	0.781
Validation	75.0%	0.773

*Episodes with predicted probabilities <50% were classified as having a predicted 0 (not having a PAC). Episodes with predicted probabilities >50% were classified as having a predicted 1 (having a PAC)

2b4.7. Statistical Risk Model Calibration Statistics (*e.g., Hosmer-Lemeshow statistic*):

Sample	Chi Square	Degrees of Freedom	p-value
Test	202.2	8	<0.0001
Validation	58.9	8	<0.0001

2b4.8. Statistical Risk Model Calibration – Risk decile plots or calibration curves:



2b4.9. Results of Risk Stratification Analysis:
Not applicable

2b4.10. What is your interpretation of the results in terms of demonstrating adequacy of controlling for differences in patient characteristics (case mix)? (i.*e., what do the results mean and what are the norms for the test conducted*)

The C statistic is a measure of the extent to which a statistical model is able to discriminate between a patient with and without an outcome. The c-statistic ranges from 0.5 to 1.0. A c-statistic of 0.50 indicates the model is no better than random prediction, implying that the patient risk factors do not predict variation in the outcome; conversely, a c-statistic of 1.0 indicates perfect prediction, implying patients' outcomes can be predicted completely by their risk factors, and physicians and hospitals play little role in patients' outcomes. Models with c-statistic values of at least 0.7 are considered good and those above 0.8 are considered strong [1]. The purpose of the model is to adjust for patient-related factors. The remaining unexplained differences in PAC rates are due to factors that could be controlled by all providers that are managing or co-managing the patient, during the entire episode time window.

The c-statistics of the testing and validation samples (0.781 and 0.773, respectively) indicate that the risk models have strong discriminatory power. Indeed, the accuracy values show that the model correctly predicts whether an episode had or did not have a PAC about 75% of the time, well above what would be expected if the predictions were made at random (i.e., 50%). Although the H-L test was significant for the testing sample, meaning that the model is not a good fit, this test is generally known to be sensitive to the number of groupings used and sample sizes. Nevertheless, the risk decile plot plot shows that the model predicts PACs similarly to the number of observed PACs across all deciles.

Overall, the results of the risk adjustment analysis strongly indicate that the model has sufficient predictive power.

2b4.11. Optional Additional Testing for Risk Adjustment (*not required, but would provide additional support of adequacy of risk model, e.g., testing of risk model in another data set; sensitivity analysis for missing data; other methods that were assessed*)

Not applicable

2b5. IDENTIFICATION OF STATISTICALLY SIGNIFICANT & MEANINGFUL DIFFERENCES IN PERFORMANCE

2b5.1. Describe the method for determining if statistically significant and clinically/practically meaningful differences in performance measure scores among the measured entities can be identified (*describe the steps—do not just name a method; what statistical analysis was used? Do not just repeat the information provided related to performance gap in 1b)*

To directly compare PAC rates across providers while also appropriately accounting for differences in patient severity, we calculated a risk-standardized PAC rate for each provider. This method is similar to calculations used by others for reporting outcomes measures [1]. For each provider, the ratio of observed attributed episodes with PACs to the expected number of attributed episodes with PACs given the patient's risk factor and estimated from the risk-adjustment model was calculated. This number yielded whether the provider had more PACs than expected (ratio>1), as expected (ratio=1), or less than expected (ratio<1). We then multiplied this ratio by the overall expected PAC rate across all providers to obtain the risk-standardized PAC rate for the provider. This measure represents what a provider's PAC rate would be if its patient population was reflective of the overall population.

Because providers with small volumes may provide unreliable estimates, we excluded any with fewer than 10 attributed episodes prior to the calculations. Comparison of risk-adjusted PAC rates gives a measure of the provider's relative performance. Our analysis compared risk-standardized PAC rates across providers. We analyzed various descriptive statistics including the range in PAC rates, medians, interquartile range, etc.

References:

[1] See, for example: NQF#1550: Hospital-level risk-standardized complication rate (RSCR) following elective primary total hip arthroplasty (THA) and / or total knee arthroplasty (TKA). Online version: http://bit.ly/1BWQTRt

2b5.2. What were the statistical results from testing the ability to identify statistically significant and/or clinically/practically meaningful differences in performance measure scores across measured entities? (e.g., *number and percentage of entities with scores that were statistically significantly different from mean or some benchmark, different from expected; how was meaningful difference defined*)

Summary of Unadjusted and Adjusted Performance Scores Across Providers

PAC Rates	Minimum # Episodes Per Provider	
	>=10	>=25
Unadjusted		
Median (IQR)	36% (26%, 45%)	34% (28%, 44%)
Range	0%-100%	6%-98%
Adjusted (RSPR)*		
Median (IQR)	36% (29%, 42%)	36% (31%, 41%)
Range	0%-92%	8%-67%

***RSPR = Risk Standardized PAC Rate**

Please refer to the NQF_ARR_all_codes_risk_adjustment_06.30.15.xls workbook under the "ProviderAttribution Reliability" tab to see specific results for each provider.

2b5.3. What is your interpretation of the results in terms of demonstrating the ability to identify statistically significant and/or clinically/practically meaningful differences in performance across measured entities? (i.e., *what do the results mean in terms of statistical and meaningful differences?*)
The variation in risk-adjusted rates suggests there are meaningful differences in performance between providers in risk-standardized PAC rates for patients with an episode of ARR.

Minimum sample size requirements for PAC measures are a function of the reliability testing of the measures on every dataset on which the measures are applied. Our research suggests that minimum sample sizes to achieve high degrees of reliability in the measures are a function of the dataset analyzed, and as such may vary from dataset to dataset. One should not infer that a minimum sample size achieved in one dataset would apply to another.

2b6. COMPARABILITY OF PERFORMANCE SCORES WHEN MORE THAN ONE SET OF SPECIFICATIONS

If only one set of specifications, this section can be skipped.

Note: *This criterion is directed to measures with more than one set of specifications/instructions (e.g., one set of specifications for how to identify and compute the measure from medical record abstraction and a different set of specifications for claims or eMeasures). It does not apply to measures that use more than one source of data in one set of specifications/instructions (e.g., claims data to identify the denominator and medical record abstraction for the numerator).* ***Comparability is not required when comparing performance scores with and without SDS factors in the risk adjustment model. However, if comparability is not demonstrated for measures with more than one set of specifications/instructions, the different specifications (e.g., for medical records vs. claims) should be submitted as separate measures.***

2b6.1. Describe the method of testing conducted to demonstrate comparability of performance scores for the same entities across the different data sources/specifications (*describe the steps—do not just name a method; what statistical analysis was used*)

2b6.2. What were the statistical results from testing comparability of performance scores for the same entities when using different data sources/specifications? (*e.g., correlation, rank order*)

2b6.3. What is your interpretation of the results in terms of demonstrating comparability of performance measure scores for the same entities across the different data sources/specifications? (i.*e., what do the results mean and what are the norms for the test conducted*)

2b7. MISSING DATA ANALYSIS AND MINIMIZING BIAS

2b7.1. Describe the method of testing conducted to identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias (*describe the steps—do not just name a method; what statistical analysis was used*)

If patient related data is missing, the entire patient is excluded from the numerator as well as the denominator.

Within our measure constructs, presence of potentially avoidable complications are identified from administrative claims data. Additionally, if a patient had one or more PACs, it is simply counted as a 1, i.e., flagged as having a PAC.

According to our measure definition, in constructing the measure it is possible for a provider to have only one or some types of PACs and not others. Alternatively, the provider may have all PAC types occur for their

patients. The measure only considers whether any PAC occurred regardless of the type, and all PAC types are weighted equally, therefore we believe, there is no potential for the absence of specific PAC types to bias performance scores for individual providers.

For these reasons, no formal analyses were done on missing data.

2b7.2. What is the overall frequency of missing data, the distribution of missing data across providers, and the results from testing related to missing data? (*e.g., results of sensitivity analysis of the effect of various rules for missing data/nonresponse; if no empirical sensitivity analysis, identify the approaches for handling missing data that were considered and pros and cons of each*)
Not applicable

2b7.3. What is your interpretation of the results in terms of demonstrating that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias**?** (i.*e., what do the results mean in terms of supporting the selected approach for missing data and what are the norms for the test conducted; if no empirical analysis, provide rationale for the selected approach for missing data*)

Not applicable

2d. EMPIRICAL ANALYSIS TO SUPPORT COMPOSITE CONSTRUCTION APPROACH
Note: *If empirical analyses do not provide adequate results—or are not conducted—justification must be provided and accepted in order to meet the must-pass criterion of Scientific Acceptability of Measure Properties. Each of the following questions has instructions if there is no empirical analysis.*

2d1. Empirical analysis demonstrating that the component measures fit the quality construct, add value to the overall composite, and achieve the object of parsimony to the extent possible.

The PAC measures, as we define them, look at many "care defects" comprehensively. They are composed of several cross-cutting measures and together they paint a global picture of the provider's overall performance.

PACs may occur any time during the episode time window. PACs are counted as a dichotomous (yes/no) outcome. If a patient had one or more PACs, they get counted as a "yes" or a 1. The enclosed workbook entitled NQF_ARR_all_codes_risk_adjustment_06.30.15.xls provides outputs from empirical analysis. The tab labeled "PAC overview" demonstrates percentage of episodes that had at least one PAC, and provides the breakdown of PACs: 1) by the type of PAC whether directly related to index condition or due to patient safety failures; 2) the setting of the PAC, whether seen in the in-patient setting, out-patient facility or during professional visits; and 3) preventable hospitalizations.

The "PAC Drill Down Graph" provides further detail on each component of the PAC and their frequency. As can be seen by the individual counts and the graph, while each individual PAC may have such small occurrences that no meaningful comparisons in provider performances could be made; together, they add value to provide a comprehensive picture that result in meaningful numbers. The aggregation of PACs to a comprehensive, composite measure, in itself provides the parsimony that is so desirable.

2d1.1 Describe the method used (*describe the steps—do not just name a method; what statistical analysis was used; if no empirical analysis, provide justification)*

All PACs, as clinically defined by the subject matter experts were used with equal weighting. Since the emphasis of the PAC measure is to identify the occurrence of PACs in any setting, a simple and straightforward approach was adopted.

2d1.2. What were the statistical results obtained from the analysis of the components? (e.g., *correlations, contribution of each component to the composite score, etc*.; *if no empirical analysis, identify the components that were considered and the pros and cons of each*)

No formal analysis was performed.

2d1.3. What is your interpretation of the results in terms of demonstrating that the components included in the composite are consistent with the described quality construct and add value to the overall composite? (i.e., *what do the results mean in terms of supporting inclusion of the components; if no empirical analysis, provide rationale for the components that were selected)*

Since our premise is that all PACs are potentially avoidable, we adopted the approach to count all PACs and give them equal weights. The overall composite score results in the quality construct that could be measured and interpreted.

2d2. Empirical analysis demonstrating that the aggregations and weighting rules are consistent with the quality construct and achieve the objective of simplicity to the extent possible

2d2.1 Describe the method used (*describe the steps—do not just name a method; what statistical analysis was used; if no empirical analysis, provide justification)*

Within our measure constructs, presence of potentially avoidable complications are identified from administrative claims data. Additionally, if a patient had one or more PACs, it is simply counted as a 1, i.e., flagged as having a PAC. The measure only considers whether any PAC occurred regardless of the type, or the site, and all PAC types are weighted equally. Therefore, no formal analysis of individual components was performed.

2d2.2. What were the statistical results obtained from the analysis of the aggregation and weighting rules? (e.g., *results of sensitivity analysis of effect of different aggregations and/or weighting rules; if no empirical analysis, identify the aggregation and weighting rules that were considered and the pros and cons of each*)

We chose not to weight the components of the measure.

Considerations were given to the fact that preventable hospitalizations may be given more weight, than PACs identified in a doctor's office. Similarly PACs in an in-patient setting may have more serious implications on a patient's ultimate outcome, than PACs occurring in an outpatient setting. Additionally, preventable hospitalizations as well as index hospitalizations, each with longer lengths of stay, may have serious PACs. But how do we weigh these effects? An alternative model was considered, where cost could be considered as a surrogate for the weights. Higher cost PACs could imply more serious PACs. However, differences in costs could be driven by many issues other than the PAC itself, such as unit price of the service, method of reimbursements, contracting arrangements etc.

Furthermore, in-patient facility billing does not allow for the distinction of PAC related costs from other costs within the stay. We would fail to capture PAC related costs within the stay and potentially underweight those. As a result, the decision was made to avoid weighting and keep the measure as a straightforward count.

2d2.3. What is your interpretation of the results in terms of demonstrating the aggregation and weighting rules are consistent with the described quality construct? (i.*e., what do the results mean in terms of supporting the selected rules for aggregation and weighting; if no empirical analysis, provide rationale for the selected rules for aggregation and weighting*)

Measuring all providers with the same yardstick will provide consistent results and reasonable comparisons over time. If the goal is to reduce PACs, then the PAC measure as was constructed with the help of various experts in the field would provide reasonable comparisons. A word of caution however pertains to the sample size of the provider panel before making any reasonable conclusions.

Minimum sample size requirements for PAC measures are a function of the reliability testing of the measures on every dataset on which the measures are applied. Our research suggests that minimum sample sizes to achieve high degrees of reliability in the measures are a function of the dataset analyzed, and as such may vary from dataset to dataset. One should not infer that a minimum sample size achieved for high reliability in one dataset would apply to another.

3. Feasibility

Extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

3a. Byproduct of Care Processes

For clinical measures, the required data elements are routinely generated and used during care delivery (e.g., blood pressure, lab test, diagnosis, medication order).

3a.1. **Data Elements Generated as Byproduct of Care Processes.**
Coded by someone other than person obtaining original information (e.g., DRG, ICD-9 codes on claims)
If other:

3b. Electronic Sources

The required data elements are available in electronic health records or other electronic sources. If the required data are not in electronic health records or existing electronic sources, a credible, near-term path to electronic collection is specified.

3b.1. **To what extent are the specified data elements available electronically in defined fields?** *(i.e., data elements that are needed to compute the performance measure score are in defined, computer-readable fields)*
ALL data elements are in defined fields in electronic claims

3b.2. **If ALL the data elements needed to compute the performance measure score are not from electronic sources, specify a credible, near-term path to electronic capture, OR provide a rationale for using other than electronic sources.**

3b.3. **If this is an eMeasure, provide a summary of the feasibility assessment in an attached file or make available at a measure-specific URL.**
Attachment:

3c. Data Collection Strategy

Demonstration that the data collection strategy (e.g., source, timing, frequency, sampling, patient confidentiality, costs associated with fees/licensing of proprietary measures) can be implemented (e.g., already in operational use, or testing demonstrates that it is ready to put into operational use). For eMeasures, a feasibility assessment addresses the data elements

and measure logic and demonstrates the eMeasure can be implemented or feasibility concerns can be adequately addressed.

3c.1. **Describe what you have learned/modified as a result of testing and/or operational use of the measure regarding data collection, availability of data, missing data, timing and frequency of data collection, sampling, patient confidentiality, time and cost of data collection, other feasibility/implementation issues.**
IF a PRO-PM, consider implications for both individuals providing PROM data (patients, service recipients, respondents) and those whose performance is being measured.
As part of our general implementation of these measures and related analyses, we have worked through dozens of different and sometimes very large datasets. From Medicare to Medicaid to regional and national commercial carriers, as well as individual employers, the principal lesson learned is the heterogeneity of the data sets and the significant variability in fill rate of critical data elements. As a result, we have created highly specific recommendations for which data elements are required to ensure measure validity, the accuracy of those data elements, and their completeness in the dataset. When claims datasets are organized in the way we specify in the measure analysis, and contain the coding information required, the analysis of the measure and its results are highly reliable.

3c.2. **Describe any fees, licensing, or other requirements to use any aspect of the measure as specified** *(e.g., value/code set, risk model, programming code, algorithm)*.
The calculations of rates of potentially avoidable complications can be replicated by anyone that uses the measure specifications along with the metadata file that is available for free on our web site at http://www.hci3.org/ecre/xml-agreement.html.
We also plan on providing a limited automated analysis, at no cost, on our website.

4. Usability and Use

Extent to which potential audiences (e.g., consumers, purchasers, providers, policy makers) are using or could use performance results for both accountability and performance improvement to achieve the goal of high-quality, efficient healthcare for individuals or populations.

4a. Accountability and Transparency

Performance results are used in at least one accountability application within three years after initial endorsement and are publicly reported within six years after initial endorsement (or the data on performance results are available). If not in use at the time of initial endorsement, then a credible plan for implementation within the specified timeframes is provided.

4.1. **Current and Planned Use**
NQF-endorsed measures are expected to be used in at least one accountability application within 3 years and publicly reported within 6 years of initial endorsement in addition to performance improvement.

Planned	Current Use (for current use provide URL)
Public Reporting Professional Certification or Recognition Program Quality Improvement with Benchmarking (external benchmarking to multiple organizations)	Payment Program Blue Cross Blue Shield of North Carolina Blue Cross Blue Shield of New Jersey Pennsylvania Employee Benefits Trust Fund https://www.bcbsnc.com/ http://www.horizonblue.com/ https://www.pebtf.org/ Quality Improvement (Internal to the specific organization) Blue Cross Blue Shield of North Carolina https://www.bcbsnc.com/assets/providers/public/pdfs/specialty_methodology.pdf

4a.1. **For each CURRENT use, checked above, provide:**

- Name of program and sponsor
- Purpose
- Geographic area and number and percentage of accountable entities and patients included

Measures associated to potentially avoidable complications (PACs) are in use today with some private sector payers and gaining further acceptance among a wide variety of organizations across the health system (public and private payers, clinicians, consultants, all-payer claims database stewards, etc.) [1-8]. They are being used in various capacities in different pilot site implementations. To name a few:

•BCBSA (Blue Cross Blue Shield Association) – uses them for their Centers of Excellence (COE) programs: Blue Distinction
•BCBSNC (Blue Cross Blue Shield of North Carolina) – is using them for tiering providers

In addition, the PAC measures are incorporated by the following organizations in their bundled payment programs:

•BCBSSC – for CABG and PCI programs
•Horizon BCBSNJ– for CHF and CABG programs
•BCBSNC
•PEBTF in PA

http://www.ajmc.com/interviews/Lili-Brillstein-on-How-Bundled-Payments-Are-Tranforming-Healthcare

In these programs they look at PACs related to the measure for process improvement activities and for practice re-engineering.

We have created reports for rates of PACs for the following organizations:
-Vermont Payment Reform
-Maine Health Management Coalition
-WellPoint / Anthem CT
-NY State Medicaid
-CT Medicaid
-CO All-payer Claims Database, Center for Improving Value in Health Care

There are several companies that are leveraging these measures to create analytics and software for customers – these include HealthQx, Aver Informatics, McKesson, and TriZetto.

4a.2. If not currently publicly reported OR used in at least one other accountability application (e.g., payment program, certification, licensing) what are the reasons? (*e.g., Do policies or actions of the developer/steward or accountable entities restrict access to performance results or impede implementation?*)

N/A

4a.3. **If not currently publicly reported OR used in at least one other accountability application, provide a credible plan for implementation within the expected timeframes -- any accountability application within 3 years and publicly reported within 6 years of initial endorsement.** (*Credible plan includes the specific program, purpose, intended audience, and timeline for implementing the measure within the specified timeframes. A plan for accountability applications addresses mechanisms for data aggregation and reporting.*)

Measures associated with PACs are currently in use as described in the prior section. In addition, we are working with several not-for-profit and for-profit organizations to provide them with the algorithms needed to calculate rates of potentially avoidable complications. Some of these organizations include:

Fair Health – based in NY and whose mission is to increase transparency of provider cost and quality,

CastLight – based in CA and serving large employers. We currently provide CastLight with Bridges To Excellence recognitions and will work with them to augment provider transparency by using PAC measures,

MA APCD (Massachusetts All Payers Claims Database) Council – we currently have an agreement in place with the MA APCD Council to produce PAC measures on hospitals and physicians and report back to the council with tests of reliability and validity of the measures. The purpose is to authorize the publication of these measures,

Maryland Health Care Cost Commission – we have a two year agreement to produce measures of cost and quality for public dissemination.

4b. Improvement

Progress toward achieving the goal of high-quality, efficient healthcare for individuals or populations is demonstrated. If not in use for performance improvement at the time of initial endorsement, then a credible rationale describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.

4b.1. **Progress on Improvement. (Not required for initial endorsement unless available.)**

Performance results on this measure (current and over time) should be provided in 1b.2 and 1b.4. Discuss:

- **Progress (trends in performance results, number and percentage of people receiving high-quality healthcare)**
- **Geographic area and number and percentage of accountable entities and patients included**

We do not have any public information to share about the improvements in rates of potentially avoidable complications, as the implementation of these measures is too recent to provide valid comparisons. Further, some of the definitions of PACs have changed since the measures were initially endorsed, making comparisons even more difficult and unreliable.

Nevertheless, the variation in performance scores presented in Section 1b.2 indicates that there are differences between providers in their risk-adjusted PAC rates (higher scores equal worse performance). This suggests that real opportunities exist to identify lower performing providers and reduce the overall occurrence of PACs.

4b.2. **If no improvement was demonstrated, what are the reasons? If not in use for performance improvement at the time of initial endorsement, provide a credible rationale that describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.**

Performance results provide summary PACs rates by provider, which can be used by payers and providers in a number of ways to improve the quality of care.

From the payer perspective, payers can use this information to 1) create a high-value provider networks, 2) work with high-value providers to share best practices, 3) incentivize low-value providers to improve, 4) modify their insurance design to activate consumers to select the right care from the right providers at the right time.

From the provider perspective, providers can 1) view services and activity for their patients longitudinally across the entire care continuum, such as frequency of readmissions and ED visits and drill down on patients with high PAC rates, 2) review actionable drill down reports to identify the most frequent PACs across all patients to create care pathways and process improvement plans to impact the most frequent PACs.

4c. Unintended Consequences

The benefits of the performance measure in facilitating progress toward achieving high-quality, efficient healthcare for individuals or populations outweigh evidence of unintended negative consequences to individuals or populations (if such evidence exists).

4c.1. **Were any unintended negative consequences to individuals or populations identified during testing; OR has evidence of unintended negative consequences to individuals or populations been reported since implementation? If so, identify the negative unintended consequences and describe how benefits outweigh them or actions taken to mitigate them.**

No unintended consequences were reported, but there is the potential for:
1. Under-coding of PACs in the claim stream resulting in under-reporting the actual rate and/or providers gaming the measures
2. Payers calculating the measures even with inadequate sample sizes and using the results to penalize providers

The measure is designed for transparency efforts and to spur quality improvement. Detailed PAC reports can help providers identify areas of quality improvement. Even detailed reports of small samples of patients can be helpful for quality improvement purposes, but not for public reporting. To mitigate the potential for invalid provider comparisons, we specify in this submission the minimum sample size needed to ensure the reliability of a provider's score. Ultimately, there isn't any good way to prevent provider gaming of the measure by under-coding claims, however, under the current DRG payment methodology, many providers would be penalized by under-coding PACs since these codes often result in the assignment of more complicated DRGs.

5. Comparison to Related or Competing Measures

If a measure meets the above criteria and there are endorsed or new related measures (either the same measure focus or the same target population) or competing measures (both the same measure focus and the same target population), the measures are compared to address harmonization and/or selection of the best measure.

5. Relation to Other NQF-endorsed Measures

Are there related measures (conceptually, either same measure focus or target population) or competing measures (conceptually both the same measure focus and same target population)? If yes, list the NQF # and title of all related and/or competing measures.

Yes

5.1a. **List of related or competing measures (selected from NQF-endorsed measures)**

0337 : Pressure Ulcer Rate (PDI 2)
0450 : Perioperative Pulmonary Embolism or Deep Vein Thrombosis Rate (PSI 12)
0705 : Proportion of Patients Hospitalized with Stroke that have a Potentially Avoidable Complication (during the Index Stay or in the 30-day Post-Discharge Period)
0708 : Proportion of Patients Hospitalized with Pneumonia that have a Potentially Avoidable Complication (during the Index Stay or in the 30-day Post-Discharge Period)
0709 : Proportion of patients with a chronic condition that have a potentially avoidable complication during a calendar year.
1789 : Hospital-Wide All-Cause Unplanned Readmission Measure (HWR)

5.1b. **If related or competing measures are not NQF endorsed please indicate measure title and steward.**

-0531 Patient Safety for Selected Indicators (Composite Measure, endorsed) (AHRQ)
-CMS defined hospital acquired conditions (HACs) are a subset of our PACs. We have pain-stakingly matched the definitions to provide as much consistency as possible. http://www.cms.gov/Medicare/Quality-Initiatives-Patient-Assessment-Instruments/HospitalQualityInits/HospitalRHQDAPU.html

5a. Harmonization

The measure specifications are harmonized with related measures;
OR
The differences in specifications are justified

5a.1. **If this measure conceptually addresses EITHER the same measure focus OR the same target population as NQF-endorsed measure(s):**
Are the measure specifications completely harmonized?

No

5a.2. If the measure specifications are not completely harmonized, identify the differences, rationale, and impact on interpretability and data collection burden.

Some of the measures listed in the prior section are, fully harmonized with the submitted measure, in particular, 0705, 0708, and 0709. Other measures such as 0337 and 0450 are in fact, subsets of our measure. However, there are some measures that are not harmonized, in particular the 30-day all-cause readmission measures and the Hospital wide all-cause readmission measure. While the submitted PAC measure include hospitalizations and readmissions that occur during the episode time window, the hospitalizations, by definition, have to be relevant to the underlying condition. For chronic conditions, most relevant hospitalizations within the entire episode time window are considered potentially avoidable. PACs include readmissions and are designed to enable accountability at the locus of provider control as well as some shared accountability between settings, centered around a patient, and for a specific medical episode of care. In that sense, they are consistent with the all-cause 30-day readmission rates, but represent a subset of those admissions. However, they do extend to the entire episode time window. As such, the PAC measures, as submitted, don't create added burden of reporting because the readmissions reported are simply a part of the broader 30-day all-cause readmission measures already endorsed by NQF. Because PAC measures are comprehensive, they include patient safety events as well as other adverse events, including hospitalizations and ED visits during the entire continuum of care. As a result, they are a comprehensive measure of avoidable complications for a specific medical episode. The data collection for all of the HCI3 measures is automated by a software package and is fully harmonized with all other PAC measures. A single download automates creation of all reports related to each of the PAC measures.

5b. Competing Measures

The measure is superior to competing measures (e.g., is a more valid or efficient way to measure);
OR
Multiple measures are justified.

5b.1. If this measure conceptually addresses both the same measure focus and the same target population as NQF-endorsed measure(s):

Describe why this measure is superior to competing measures (e.g., a more valid or efficient way to measure quality); OR provide a rationale for the additive value of endorsing an additional measure. (Provide analyses when possible.)

The PAC measure is a comprehensive measure representing "all-cause harms". It looks at all potentially avoidable complications in patients hospitalized with AMI during the stay or for 30-days post-discharge. It looks at readmissions, emergency room visits, adverse events due to errors of omission or commission. It looks at complications that are due to patient safety failures, and also those directly related to the index condition. These are a cause of significant waste and quality concerns for patients with an AMI episode. As such, the measure can provide clinicians with an overall and comprehensive view, in one measure, of all potentially avoidable complications for a patient and drive quality improvement efforts.

For clinicians and facilities increasingly engaged in value-based payment efforts and/or driving quality improvement for population health, the value of a PAC measure over a series of related, but more discrete measures, is that one can better determine if the sources of complications primarily stem from activities within the facility or outside the facility, and the specific nature of the complications that have a higher frequency of occurrence. For providers, it's far easier to construct a quality dashboard from a parsimonious set of measures, and that's what PAC measures offer.

Further, as a comprehensive outcome measures, PACs are also useful for public transparency of quality, as substantiated by the research from Judy Hibbard and colleagues previously cited in the "testing" section of this submission.The PAC measure is a comprehensive measure representing "all-cause harms". Additional Information

Ad.1 **Workgroup/Expert Panel involved in measure development**
Provide a list of sponsoring organizations and workgroup/panel members' names and organizations. Describe the members' role in measure development.
From 2006 onwards, and under the auspices of various funding organizations, HCI3 has convened and managed, or helped to convene and manage, Clinical Working Groups to inform the development and refinement of the measures. For example, in 2011, 2012 and 2013, HCI3 worked collaboratively with the American Board of Medical Specialties and the American Medical Association's Physicians Consortium for Performance Improvement, under a federal contract, to convene and get input from various clinical experts on definitions of episodes of care and their sequelae, including avoidable complications.

Some of the clinical experts that have contributed to our work include:
-Dr. John Allen, American Gastroenterology Association (AGA)
-Dr. Morton Arnsdorf, Cardiologist, University of Chicago, IL
-Dr. Peter Bach, Memorial Sloan Kettering Cancer Center (MSKCC)
-Dr. Peter Basch, Primary Care, Medstar Health, DC
-Dr. Justin Beckelman, Radiation Oncology, University of Pennsylvania, PA
-Dr. Debra Bingham, Executive Director, California Maternal Quality Care Collaborative (CMQCC) at Stanford University, CA
-Dr. John Birkmeyer, American Society of Metabolic and Bariatric Surgery (ASMBS)
-Dr. Linda Bosserman, Wilshire Oncology Medical Group, CA
-Dr. Matthew Brengman, American Society of Metabolic and Bariatric Surgery (ASBMS)
-Dr. Joel Brill, American Gastroenterology Association (AGA)
-Dr. George Cautilli, Cautilli Orthopedic Surgical Specialists PC, Yardley, PA
-Dr. Ashwini Davison, Internist, Johns Hopkins Hospital, MD
-Dr. James Denneny, III, American Academy of Otolaryngology – Head and Neck Surgery (AAO-HNS)
-Dr. Chris Gallagher, American Society of Metabolic and Bariatric Surgery (ASMBS)
-Dr. Robert Haralson, III, American Academy of Orthopedic Surgeons (AAOS)
-Ms. Dawn Holcombe, Executive Director, Connecticut Oncology Association, CT
-Dr. Colin Howden, American Gastroenterology Association (AGA)
-Dr. John Knightly, American Association of Neurological Surgeons (AANS)
-Dr. Larry Kosinski, American Gastroenterology Association (AGA)
-Dr. Nalini Krishnan, Obstetrics & Gynecology, MN
-Dr. Kelly Kyanko, Internist, NYU School of Medicine, NY
-Dr. Tara Lagu, Internist & Infectious Disease, Baystate Medical Center, MA
-Dr. Robert Lee, Society of Thoracic Surgeons (STS)
-Dr. Alex Little, Society of Thoracic Surgeons (STS)

-Dr. Michael London, Orthopedic Surgeon, OMNI Orthopedics, OH
-Dr. Elliott Main, Obstetrics & Gynecology, California Pacific Medical Center, CA
-Dr. Constantine Mantz, 21st Century Oncology, FL
-Dr. Joseph Messer, Cardiologist, Rush University Medical Center, IL

MEASURE WORKSHEET

This document summarizes the evaluation of the measure as it progresses through NQF's Consensus Development Process (CDP). The information submitted by measure developers/stewards is included after the Brief Measure Information, Preliminary Analysis, and Pre-meeting Public and Member Comments sections.

Brief Measure Information

NQF #: 2751

De.2. **Measure Title:** Proportion of Patients undergoing an Angioplasty Procedure (Percutaneous Coronary Intervention - PCI) that have a Potentially Avoidable Complication (during the episode time window)

Co.1.1. **Measure Steward:** Health Care Incentives Improvement Institute Inc. (HCI3)

De.3. **Brief Description of Measure:** Percent of adult population aged 18 + years who had a percutaneous coronary intervention (PCI) procedure, are followed for at least 90-days, and have one or more potentially avoidable complications (PACs). PACs may occur during the index stay or during the 90-day post discharge period.

Please reference attached document labeled NQF_PCI_all_codes_risk_adjustment_06.30.15.xls, in the tabs labeled PACs I-9 and PAC I-10 for a list of code definitions of PACs relevant to PCI.

We define PACs as one of two types:

(1) Type 1 PACs - PACs directly related to the index condition: Patients are considered to have a PAC, if they receive services during the episode time window for any of the complications directly related to PCI, such as for hypotension, cardiac arrest, fluid and electrolyte disturbances etc.

(2) Type 2 PACs - PACs suggesting Patient Safety Failures: Patients are also considered to have a PAC, if they receive services during the episode time window for any of the complications related to patient safety failures such as for sepsis, infections, phlebitis, deep vein thrombosis, pressure sores etc.

All readmissions in a patient with PCI are considered potentially avoidable and flagged as PACs.

PACs are counted as a dichotomous (yes/no) outcome. If a patient had one or more PACs, they get counted as a "yes" or a 1. The enclosed workbook labeled NQF_PCI_all_codes_risk_adjustment_06.30.15.xls serves as an example. The tab labeled PAC overview gives the percent of PCI episodes that have a PAC and the tab labeled "PAC drill down" gives the types of PACs and their frequencies in PCI episodes within this dataset.

The information is based on a two-year claims database from a large regional commercial insurer. The abase had over 3.2 million covered lives and over $25.9 billion in "allowed amounts" for claims costs. The database is an administrative claims database with medical as well as pharmacy claims.

1b.1. **Developer Rationale:** Measures associated to potentially avoidable complication (PAC) have been used as comprehensive outcomes measures since 2007 for several conditions and procedures (de Brantes 2010) (Joynt 2013) (James 2013). In 2011, following the NQF endorsement of these measures for certain acute medical conditions (AMI, Pneumonia and Stroke), and for chronic conditions, they were adopted for various purposes, including the creation of related measures (NQF – Measure #1550). Some commercial payers have used them as a means for tracking outcomes (Yong 2010) and for tiering providers for pay for performance programs (BCBSNC). In addition, some provider organizations have used them in quality improvement efforts by homing in on the detailed specifications of the measures to reveal opportunities for care improvement (CALPERS – link below). Identification of PACs has spurred provider innovation (Bundled Payment Summit 2015) for practice re-engineering, to create proactive care pathways, and to focus on areas of high variability (McVary 2010). Some employers are also using measures of avoidable complications as public measures of quality (Colorado Business Group on Health) given the research that demonstrated the potential efficacy of these measures to differentiate provider quality and cost (Hibbard 2012). In fact in a series of focus groups led by Judy Hibbard and colleagues, the researchers found that the very framing of potentially avoidable complications as an indicator of potential harm, is an effective way of communicating the quality of care. And when measures of PACs were presented in conjunction with price, consumers intuitively accepted the logical relationship between low PACs – fewer "defects" – and lower price.

Accountability for and measurement of PACs occurs at the practice, medical group, provider system or purchaser/payer level. PAC rates are calculated as absolute values. For example, a health plan would report that 40% of its plan members with hypertension

incurred PACs in the study time window. The objective of the measure is to encourage the unit being measured to progressively reduce that amount over time. In addition, comparisons of PAC rates across plans or provider systems should be encouraged and publicly reported. An organization that uses the measure should be able to identify the leading causes of PACs and implement improvements to existing processes that will decrease PACs. There are several tools available for provider systems and health plans to impact PAC rates. These include care coordination across care settings; post-discharge planning and patient follow- up, active care management, sharing medical record data between care settings and providers, total quality management within hospitals and active reduction of patient safety failures. Reducing PACs has the potential to significantly improve the overall level of quality.

Creating a single measure of accountability for physicians and hospitals tied to gaps in quality is likely to yield much improved outcomes for patients. A measure of accountability for health plans helps them review trends over time and work with physicians and hospitals to improve the ways in which they engage patients using more optimal care management and care coordination (Cassel 2014). In addition, PAC measures could be used as a surrogate for quality in a consumer transparency tool to differentiate providers with regards to their performance.

Moreover, since these measures are claims based, there is minimal added burden for collecting the data, and it also avoids potential gaming that may occur for other measures that require reporting information to registries. Although use of administrative claims data in identifying conditions and measuring provider quality has been questioned, there are several studies in literature that acknowledge validity of its use (Normand 2007) (Quan 2009). Until more readily available data are at hand, use of administrative data to measure provider performance has steadily increased (Miller 2001), (NQF Quality Positioning System). Interestingly, in the current fee for service system, services for most PACs are rewarded by continued payment (except the CMS defined "never events") and hence to our advantage, adverse events surface in billing data. Claims based PAC measures; therefore serve as an alternative method to track adverse outcomes that do occur (Leibson 2008).

S.4. **Numerator Statement:** Number of patients who underwent a percutaneous coronary intervention (PCI) procedure, are followed for at least 90-days, and have one or more potentially avoidable complications (PACs) during the episode time window.
S.7. **Denominator Statement:** Adult patients aged 18 years and above who underwent an Angioplasty (percutaneous coronary intervention - PCI) procedure and are followed for at least 90-days
S.10. **Denominator Exclusions:** Denominator exclusions include exclusions of either "patients" or "claims" based on the following criteria:
1. "Patients" excluded are those that do not meet the enrollment criteria. If patient has an enrollment gap for more than 30 days during the episode time window, it is considered as an enrollment gap
2. "Patients" are also excluded if the cost of the episode is an outlier at greater than 99th percentile or less than 1st percentile value for all episodes. This is another way to ensure that episodes are complete as well as they do not bring in random noise into the analysis due to inappropriate codes or services.
3. "Claims" are excluded from the PCI measure if they are considered not relevant to PCI care.

De.1. **Measure Type:** Composite, Outcome
S.23. **Data Source:** Administrative claims
S.26. **Level of Analysis:** Clinician : Group/Practice, Clinician : Team, Facility, Health Plan, Population : National, Population : Regional, Population : State
Is this an eMeasure? ☐ **Yes** ☒ **No** **If Yes, was it re-specified from a previously endorsed measure?** ☐ **Yes** ☐ **No**

IF this measure is included in a composite, NQF Composite#/title: n/a – 2751 is an "any or none" composite measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient)any-or-none measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient)
Component Measures (if endorsed or submitted for endorsement: n/a. The individual complications are considered measurable components.

Is this a MAINTENANCE measure submission? ☐ **Yes** ☒ **No, this is a NEW measure submission.**
For MAINTENANCE, state the Original Endorsement Date: n/a **Most Recent Endorsement Date:** n/a

Preliminary Analysis

The preliminary analysis was developed in response to recommendations from NQF's Consensus Task Force and measurement stakeholders as a way to enhance and streamline the measures evaluation and voting processes. The preliminary analysis will help to guide the Standing Committee evaluation of each measure by summarizing the measure developer submission, guide measure evaluation discussion, and identify topic areas for additional input. **NQF staff would like to stress that the preliminary analysis is intended to be used as a guide to facilitate the Committee's discussion and evaluation.**

Criteria 1: Importance to Measure and Report

1a. Evidence

1a. Evidence. The evidence requirements for a health outcomes measure include providing rationale that supports the relationship of the health outcome to processes or structures of care. The guidance for evaluating clinical evidence asks if the there is a relationship between the measured health outcome and at least one clinical action is identified and if it is supported by the stated rationale. For a composite measure, the developer must discuss the reasoning for the composite quality constructs, the rationale for constructing, & aggregation and weighting of measure components.

- This new risk-adjusted (by age, gender and clinical co-morbidities) outcomes measure that assesses the proportion of adult patients with claims triggered by undergoing Angioplasty Procedure (Percutaneous Coronary Intervention - PCI) with at least one Potentially Avoidable Complications (PAC) within 12 months of PCI triggered claims data.
- Based on NQF's criteria, this measure is considered an "any or none" composite measure that assesses if 1 or more PACs or "care defects" have occurred for the index episode. For this composite measure, the individual complications considered the measurable components. PACs are classified in two types: 1) related to PCI, and 2) related to Patient Safety Failures, combining the 2 types into a single PAC rate to calculate the proportion of patient with 1 or more PAC. PACs are considered unwarranted health outcomes that are measured during an index condition for use at the facility, provider system or purchaser/payer levels to identify quality of care gaps between practices and hospitals.
- The developer links primary & secondary prevention care gaps, poor patient education, poor care coordination and poor follow-up increase unnecessary ER visits, hospitalizations, readmissions, and mortalities to increased PACs, and state that PACs for PCI patients should occur rarely in well-managed patients, providing potential avoidable PCI complications, that include (but not limited to) peri-procedural bleeding, emergent CABG, and death.
- The evidence for Patient Safety Failure PACs is described to be within the influence of the measured entity, though the rationale for selecting some of the identified PACs is not clear (e.g., post procedural fever, oral bisphosphonates, hallucinations). The developer provides an extensive list of comorbidities as risk factor for increased PAC potential, though the severity is not captured in consistently within the claims data.
- In addition to linking processes of care to outcomes, the developer provides an extensive PAC literature review in sections 1a.2. and 1a.2.1. for PCI, Patient Safety Failures & processes of care, as well as background information on the process for PAC development.
- The developer discusses the rationale for constructing, aggregation and equal weighting for the measure.

Questions for the Committee:

- *Does sufficient evidence exist connecting Patient Safety Failures to the PCI index episode?*
- *Does sufficient evidence exist between the measured health outcome and at least one clinical action identified and supported by the stated rationale?*

1b. Gap in Care/Opportunity for Improvement and 1b. Disparities

1b. Performance Gap. The performance gap requirements include demonstrating quality problems and opportunity for improvement.

- PCI PCA performance gap data are calculated from PROMETHEUS administrative claims data from April 1, 2012 through December 17, 2014, for 5,898 of 10,177 (58.0%) PCI episodes (in 3,258,706 unique beneficiaries) and 41 of 565 (7.1%) facilities after excluding fewer than 10 attributable episodes due to unstable small samples

Unadjusted PAC Rates:		**Risk-Standardized PAC Rates (RSPR):**	
Median (IQR):	50% (44%, 55.6%)	Median (IQR):	50% (44%, 55.6%)
Range:	31.6% - 80%	Range:	31.6% - 80%

- Descriptive data on the patient, facility and payer are not provided. The developer provides "Overview" and "Drill Down" PAC rates in the spreadsheet demonstrating gap, though PAC rates for individual complications are not provided.
- The developer does not provide data on disparities.

Questions for the Committee:

- *Is there a gap in care that warrants a national performance measure?*

○ *If no disparities information is provided, are you aware of evidence that disparities exist in this area of healthcare?*

○ *Should this measure be indicated as disparities sensitive?*

1c. Priority

1c. High Priority (previously "High Impact") requires measures to address national health goal/priority or a demonstrated high-impact aspect of care.

○ *Beginning in 2015, priority is no longer an NQF measure evaluation criterion.*

Committee pre-evaluation comments

Criteria 1: Importance to Measure and Report (including 1a, 1b, 1c)

1. ***Committee's Comments on Overview***:
   - This is a composite outcome measure. Potentially avoidable complications (PACs) are classified as both type I (directly related; e.g., bleeding) or indirectly related (type 2; e.g., sepsis, phlebitis, DVT).

1a. ***Committee's Comments on Evidence to Support Measure Focus:***
   - Approximately 40% of PCIs had a potentially avoidable complication (PAC)

1b. ***Committee's Comments on Performance Gap:***
   - Unadjusted PAC Rates:
     - Median (IQR): 50% (44%, 55.6%)
     - Range: 31.6% - 80%
     - Risk-Standardized PAC Rates (RSPR):
     - Median (IQR): 50% (44%, 55.6%)
     - Range: 31.6% - 80%
   - No disparities information is provided. I am unaware of disparities. I don't think that it should be identified as disparities sensitive.

1c. ***Committee's Comments on Composite Performance Measure:***
   - The stated reason that this is an any-or-none measure is that many of the complications are quite rare and enormous sample sizes would be required to be significant. The components are not weighted.

Criteria 2: Scientific Acceptability of Measure Properties

2a. Reliability

2a1. Reliability Specifications

2a1. Specifications requires the measure, as specified, to produce consistent (reliable) and credible (valid) results about the quality of care when implemented.

- The measure assesses the rate of patients with 1 or more PAC(s) during index episodes. This new risk adjusted outcomes measure is specified for use at the individual clinician, group/practice, team, facility & integrated delivery system levels of analyses.
- The measure exclusively uses electronically available administrative claims data to calculation the measure score, and for this measure, better care equals lower scores.
- The developer describes non-patient-related PACs as controllable by facility processes without further analysis as other influencers that may contribute to PAC rates beyond the patient and facility (e.g., payer, access, suppliers, etc.).
- Patient- and claims-based exclusions are provided to promote the availability and consistency of claims data capture, including payer enrollment requirements, cost outliers of < 1% or > 99%, and claims not relevant to PCI.
- Developers provide a robust data set of administrative claims codes for PCI & PAC (PCI- & Patient Safety Failure-related) triggers, describe a 30-day look-back period and a 90-day look-forward time window.
- A calculation algorithm is provided, as well as ICD-9 & ICD-10 codes, though ICD-10 descriptions & an ICD-9 to ICD-10 crosswalk methodology are not provided.

- A conceptual risk model and statistical method using logistic regression model for determining the probability of a patient incurring a PAC are provided. After adjusting for patient-related factors, the developers state the remaining PAC variance is due to factors potentially controlled by the facility during and after hospitalization. "Predicted" coefficients from the risk adjustment models are summed to give predicted probabilities of PAC occurrence.

Questions for the Committee:

- *Are all the data elements clearly defined? Are all appropriate codes included?*
- *Is the logic or calculation algorithm clear?*
- *Is it likely this measure can be consistently implemented?*

2a2. Reliability Testing Testing attachment

2a2. Reliability testing demonstrates if the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise enough to distinguish differences in performance across providers.

- The developer tested reliability at the performance measure score, and used a beta-binomial model and a signal-to-noise analysis, which is appropriate for this type of measure, to differentiate the true difference between measured entities (the signal) to random measurement error (the noise). A value of 0 indicates that all variation is due to measurement error and a value of 1 indicates that all variation is due to real differences in between *facility* performance. A value of 0.7 is often regarded as a minimum acceptable reliability value, and the developer also states values above 0.9 are considered sufficient to see differences between pairs of physicians.
- The measure is specified for patients ≥ 18 years that underwent PCMDFR, though the testing sample includes patients 18 through 64 years.
- The measure is specified for use with individual clinician, group/practice, team, facility & integrated delivery system levels of analyses, though testing is provided for facilities. NQF's measure evaluation criterion requires testing for all measure specification levels.
- Facilities with < 10 PCI episodes were excluded from reliability testing, though the measure is specified for patient without episode restrictions. A sample of 565 facilities was initially included in the data set, though facilities with less than 10 PCI episodes were excluded, allowing for 41 remaining facilities. There were 5,898 episodes of PCI with a mean age of 55.6 (18-64 years) and 31% female in the testing analysis exclusively using administrative claims data.
- A patient may have more than one condition-specific concurrent episode with claims applied to both episodes. If an inpatient claim corresponds to a procedure index episode and to a condition index episode, the claim would be assigned to the procedure index episode, rather than the condition index episode (e.g., for a claim that corresponds to both index episodes of CAD & CABG, the claim would be assigned to CABG).
- Patient with missing gender were excluded from the denominator, and no other missing data was identified.
- Reliability results are provided in the table below, as well as in great detail in the accompanied spreadsheet with median (IQR) results demonstrating reliability of 0.51 (0.26, 0.62) for ≥ 10 PCIs per facility, and 0.74 (0.70, 0.83) ≥ 175 PCIs per facility. For reliability analysis, facilities were restricted to the minimum of 10 PCI episodes, though all episodes were included in the risk model.
- The developer states, "Minimum sample size requirements for PAC measures are a function of the reliability testing of the measures on every dataset on which the measures are applied. Our research suggests that minimum sample sizes to achieve high degrees of reliability in the measures are a function of the dataset analyzed, and as such may vary from dataset to dataset. One should not infer that a minimum sample size achieved in one dataset will apply to another." The developer also states that very high sample sizes are to achieve any meaningful and reliable comparisons.
- The developer provides a supplementary fact sheet (available for review on SharePoint) requiring a minimum of 185 index episodes for absolute reliability, and a minimum of 175 index episodes for median reliability of > 0.7.
- The developer provides an additional supplementary fact sheet related to PAC development & testing (available for review on SharePoint).

Reliability Scores	Minimum # Episodes Per Facility	
	>=10	>=175

# of Facilities (%)	41 (100)	8 (20)
Median (IQR)	0.51 (0.26,0.62)	0.74 (0.70,0.83)
Range	0.11-0.85	0.69-0.85

The table provides a summary reliability scores minimum sample size thresholds. Complete results are provided in the workbook entitled, NQF_PCI_all_codes_risk_adjustment_06.30.15.xls, under the "ProviderAttribution Reliability" tab.

Questions for the Committee:

- *Reliability testing was attempted only for those facilities with at least 10 episodes. Can differences in performance be identified for facilities with fewer than 10 or 175 episodes? For patients ≥ 65 years?*
- *Should the measure be specified to include only those facilities with at least 10 episodes?*
- *Is the test sample adequate to generalize for widespread implementation?*
- *Do the results demonstrate sufficient reliability so that differences in performance can be identified?*

2b. Validity

2b1. Validity: Specifications

2b1. Validity Specifications. This section should determine if the measure specifications are consistent with the evidence.

- Because this is an outcome measure, the rationale that is presented for subcriterion 1a does not necessarily have to address all of the variables used to calculate the measure.
- The measure uses a statistical risk model with 170 risk factors and episode-specific subtypes/severity markers including age, gender and clinical comorbidities, on at least 10 claims to determine "stable" covariates and assess comorbidity or procedure impact on the PAC. All covariates must be present prior to an episode trigger. No formal covariate analysis was conducted to select risk factors beyond the present on a minimum of 10 claims threshold. The developer describes the heterogeneity of the provided data sets as crucial to ensure measure validity, and the accuracy and completeness of the data sets.
- The developers did not provide disparities data, an exploration of a conceptual relation to SDS, or SDS factors in the risk model.

Question for the Committee:

- *Are the specifications consistent with the evidence?*
- *Are these variables available and generally accessible for the measured patient population?*

2b2. Validity testing

2b2. Validity Testing should demonstrate the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality.

- The developer conducted systematic assessment of face validity for the performance measure score for validity testing in numerous ways, including the use of monthly multi-specialty clinical working groups, and other tests of face validity, along with focus groups, face validity comparisons of the measure to other national accountability measures, as well as additional literature for the measure & PAC development process.
- No empiric results are provided for the face validity tests described above.

Questions for the Committee:

- *Is the test sample adequate to generalize for widespread implementation?*
- *Do the results demonstrate sufficient validity so that conclusions about quality can be made?*
- *Do you agree that the score from this measure as specified is an indicator of quality?*
- *Is there evidence of a systematic assessment of expert opinion beyond those involved in developing the measure?*

2b3-2b7. Threats to Validity

2b3. Exclusions:

- The developer describes patient- (demographic, enrollment or low/high claims cost) and claims-based (due to missing or non-relevant data) exclusions for the measure.
- A significant number of patients were eliminated from the measure due to exclusion criteria, including 5,898 of 10,177 (58.0%) PCI episodes (in 3,258,706 unique beneficiaries) and 41 of 565 (7.1%) facilities.

Questions for the Committee:

- *Are high cost outliers (> 99%) exclusions an opportunity to identify PACs?*
- *Does the high number of exclusions restrict the measure use?*
- *Are the exclusions consistent with the evidence?*
- *Are any patients or patient groups inappropriately excluded from the measure?*
- *Are the exclusions/exceptions of sufficient frequency and variation across facilities to be needed (and outweigh the data collection burden)?*

2b4. Risk adjustment:

- The risk model (detailed in the accompanied spreadsheet) includes 170 factors and subtypes including age, gender, 12-month enrollment markers, co-morbidities, and episode severity markers.
- No SDS factors beyond age and gender was included in the risk-adjustment approach. Beyond noting that race was not available for analysis, no description of the of the conceptual relationships between patient sociodemographic factors, patient clinical factors, quality of care, and the outcomes (PAC rates) were provided, nor do they discuss the availability of SDS variables, beyond stating that "race" as an SDS variable was not available for analysis.
- Logistic regression was used to model the probability of at least one PAC during an episode. The reasoning for no additional modeling performed is described.
- The performance of the model was determined with a split sample method by estimating the model coefficients using a development dataset (80% of the sample) and applying those coefficients to a validation dataset (20% of the sample). C-statistics for the development and validation samples with c-statistic results of 0.803 and 0.792, respectively. C-statistics measures the extent of a statistical model to discriminate between a patient with and without PAC, with an ability to predict if a PAC is or is not present about 75% of the time. A c-statistic of 0.50 indicates the model is no better than random prediction, implying that the patient risk factors do not predict variation in the outcome; conversely, a c-statistic of 1.0 indicates perfect prediction, implying patients' outcomes can be predicted completely by their risk factors, and physicians and hospitals play little role in patients' outcomes. Models with c-statistic values of at least 0.7 are considered good and those above 0.8 are considered strong.
- Both Hosmer-Lemeshow Goodness-of-Fit statistics and risk-decide plots were provided to indicate model fit. Results from the Hosmer-Lemeshow test suggest that the fit is not good; however, this test is sensitive to the number of groupings and sample sizes. Results from the risk decile plot indicate that the predicted PAC rates are similar to the observed PAC rates across all deciles of risk. The developer states the model demonstrates strong predictive power.

Questions for the Committee:

- *Is the Committee aware of conceptual relationship(s) between additional patient-level SDS factors, patient clinical factors, quality of care, and PACs (other than gender and age)? If so, what data might be available to allow an empirical analysis of these relationships?*
- *Is an appropriate risk-adjustment strategy included in the measure?*
- *Are the candidate and final variables included in the risk adjustment model adequately described for the measure to be implemented?*
- *Are all of the risk adjustment variables present at the start of care? If not, describe the rationale provided.*

2b5. Meaningful difference:

- The developer presents PAC rates across facilities and also facilities adjusting for differences in patient severity in a ratio of observed to expected attributable episodes to PACS accounting for patient severity, and calculates estimates from the risk model, for risk-standardized PAC rates for the facility.

Summary of Unadjusted and Adjusted Performance Scores Across Facilities:

PAC Rates	Minimum # Episodes Per Facility	
	>=10	>=175
Unadjusted		
Median (IQR)	50% (44%, 56%)	47% (44%, 52%)
Range	32% - 80%	43% - 58%
Adjusted (RSPR)*		
Median (IQR)	49% (44%, 52%)	49% (46%, 52%)
Range	24% - 61%	45% - 56%

***RSPR = Risk Standardized PAC Rate**

Please refer to the NQF_PCI_all_codes_risk_adjustment_06.30.15.xls workbook under the "ProviderAttribution Reliability" tab to see specific results for each provider.

Question for the Committee:

- *Does this measure identify meaningful differences about quality?*

2b6. Comparability of data sources/methods:

- As there is only one data source used for measure calculation (administrative claims), comparability of data sources or methods is not applicable.
-

2b7. Missing Data

- No formal analysis of missing data is provided. As the measure assesses the rate of patients with PACs, rather than the rate of PACs per index episode, the total number of PACs is not included in the PAC rate.
- Patient with missing gender were excluded from the denominator, and no other missing data was identified.
- The developers state the under-coding of claims is unavoidable in the current DRG payment structure which could lead to under capture or missing PACs.

2d. Empirical Analysis to Support Composite Construction

- As an "any or none" composite, the individual complications are considered measurable components of the composite. Frequency and distribution statistics are provided in the PAC Overview and PAC Drill Down tabs in the measure spreadsheet, which detail PAC types and subtypes. The identification of individual PACs are not provided (e.g., sepsis, unattended falls, DVT).
- PACs are counted as a dichotomous (yes/no) outcome. If a patient had one or more PACs, they get counted as a "yes" or a 1. Since our premise is that all PACs are potentially avoidable, we adopted the approach to count all PACs and give them equal weights. The overall composite score results in the quality construct that could be measured and interpreted.
- The developer states that no formal analysis was performed on missing data. For details, see 2b7 above.

Committee pre-evaluation comments

Criteria 2: Scientific Acceptability of Measure Properties (including all 2a, 2b, and 2d)

2a1. &2b1.: ***Committee's Comments on Reliability-Specifications:***

- All of the data elements appear to be clearly defined.

2a2.: ***Committee's Comments on Reliability-Testing:***

- Data presented by the stewards suggest that adequate reliability is achieved with >=175 episodes per facility. However, they issue a caveat that each data set has its own characteristics and that the number of cases required to discriminate between two providers cannot be specified a priori
  - Questions for the Committee:
    - Are all the data elements clearly defined? Are all appropriate codes included? yes
    - Is the logic or calculation algorithm clear? yes
    - Is it likely this measur0e can be consistently implemented? yes, but see above for a caveat about sample sizes
- Testing was only done at the facility level.

2b1.: ***Committee's Comments on Validity-Specifications***:

- No threats to validity.

2b2.: ***Committee's Comments on Validity-Testing:***

- The measure was developed with input from a large number of clinicians. This creates face validity.

2b3-7.: ***Committee's Comments on Threats to Validity:***

- Risk adjustment is by age, gender, recent enrollment and clinical co-morbidities.
- Text suggests that results may be sensitive to coding practices within an institution and the stewards cite references that document under-reporting. This suggests that absolute rates may not be comparable across institutions.

2d.: ***Committee's Comments on Composite Performance Measure:***

- The composite does fit the quality construct and appears to add value.

Criterion 3. Feasibility

3. Feasibility is the extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

- All measure elements are readily available in electronic sources via administrative claims data, and coded by someone other than the person obtaining the original information (e.g., DRG, ICD-9 codes on claims).
- The developer provides an excel spreadsheet attachment including diagnoses, visits, hospitalizations, post-acute facility stays, procedures, laboratory tests and procedures/surgeries, for CAD & PAC triggers, and describe the time window for measuring PAC triggers as a 30 day look back and 90 days after undergoing PCI, as well as a decision tree for measure calculation and implementation.
- The measure specifications, metadata and calculation algorithms are available free of charge on the developer's website. Limited analytics are planned at no cost to the end user.
- This is not an eMeasure.

Questions for the Committee:

- *Are the required data elements routinely generated and used during care delivery?*
- *Are the required data elements available in electronic form, e.g., EHR or other electronic sources?*
- *Is the data collection strategy ready to be put into operational use?*

Committee pre-evaluation comments

Criteria 3: Feasibility

3.: ***Committee's Comments on Feasibility:***

- The measure is entirely claims based, so all data are routinely collected. However, the developers present data that indicate that PaCs are under-reported.
  - Questions for the Committee:
    - Are the required data elements routinely generated and used during care delivery? A qualified "yes". The stewards write that "when the claims datasets are organized in the way we specify..." the results are highly reliable. This suggests to me that there are cases in which the feasibility of producing a reliable analysis is a problem.
    - Are the required data elements available in electronic form, e.g., EHR or other electronic sources?
    - Is the data collection strategy ready to be put into operational use

Criterion 4: Usability and Use

4. Usability and Use evaluate the extent to which audiences (e.g., consumers, purchasers, providers, policymakers) use or could use performance results for both accountability and performance improvement activities.

- This is a newly developed claims measure is current used in accountability programs for payers, states, and planned for public reporting, professional certification or recognition programs, and external quality improvement for benchmarking purposes.
- The developer states that PAC measures provide a foundation for the relationship between healthcare quality and cost and assist in the exploration of practice reengineering and alternative payment models, act as indicators of potential harm, and is spurring the development of private-based analytics software for further outcomes exploration. No public improvement rates are available due to recent implementation and variation in PAC definitions have also modified, though the provided PROMETHEUS data suggest wide variation in performance and improvement opportunities.
- The developer found no noted unintended consequences, though they state the measure is intended for transparency and QI activities only. They also state the under-coding of claims is unavoidable in the current DRG payment structure could be an unintended consequences of the measure, and payers calculating the measures even with inadequate sample sizes and using the results to penalize providers could lead to invalid provider comparisons.
- If the measure was theoretically to be used for accountability purposes to "ding" the measured entity as defined in the level of analysis, further exploration of PAC antecedents and the measured entity is warranted, especially with lower volume PCI facilities. In the original testing sample of 565 facilities, when facilities with fewer than 10 PCI episodes were eliminated from analysis due to less reliability estimates with small numbers, 41 remained for analysis.

***Questions for the Committee**:*

- *Is the measure publicly reported?*
- *How can the performance results be used to further the goal of high-quality, efficient healthcare?*
- *Should PAC measures also include the clinician: group in the analysis or include population-level only entities?*
- *Do the benefits of the measure outweigh any potential unintended consequences?*

Committee pre-evaluation comments

Criteria 4: Usability and Use

4.: ***Committee's Comments on Usability and Use***

- Not currently publicly reported.
  - Current use:
    - Payment Programs
    - Blue Cross Blue Shield of North Carolina
    - Blue Cross Blue Shield of New Jersey
    - Pennsylvania Employee Benefits Trust Fund
  - Quality Improvement (Internal to the specific organization)
    - Blue Cross Blue Shield of North Carolina
  - Planned use
    - Public Reporting
    - Professional Certification or Recognition Program
    - Quality Improvement with Benchmarking (external benchmarking to multiple organizations)

Criterion 5: Related and Competing Measures

5.1a. List of related or competing measures (selected from NQF-endorsed measures)

0141 : Patient Fall Rate
0202 : Falls with injury
0337 : Pressure Ulcer Rate (PDI 2)
0450 : Perioperative Pulmonary Embolism or Deep Vein Thrombosis Rate (PSI 12)
0695 : Hospital 30-Day Risk-Standardized Readmission Rates following Percutaneous Coronary Intervention (PCI)
0705 : Proportion of Patients Hospitalized with Stroke that have a Potentially Avoidable Complication (during the Index Stay or in the

30-day Post-Discharge Period)
0708 : Proportion of Patients Hospitalized with Pneumonia that have a Potentially Avoidable Complication (during the Index Stay or in the 30-day Post-Discharge Period)
0709 : Proportion of patients with a chronic condition that have a potentially avoidable complication during a calendar year.
1789 : Hospital-Wide All-Cause Unplanned Readmission Measure (HWR)

5.1b. **If related or competing measures are not NQF endorsed please indicate measure title and steward.**
-0531 Patient Safety for Selected Indicators (Composite Measure, endorsed) (AHRQ)
-CMS defined hospital acquired conditions (HACs) are a subset of our PACs. We have pain-stakingly matched the definitions to provide as much consistency as possible. http://www.cms.gov/Medicare/Quality-Initiatives-Patient-Assessment-Instruments/HospitalQualityInits/HospitalRHQDAPU.html

Pre-meeting public and member comments

Comment by: Ashish R. Trivedi, Pharm.D.
Organization: SPI-Lilly
Comment#5115: Lilly is supportive of this measure as it focuses on reducing risk for potentially avoidable (eg, via improvement in quality of treatment and care) recurrent major adverse cardiovascular events (MACE), at no expense of increased safety events.

NATIONAL QUALITY FORUM—Evidence (subcriterion 1a)

Measure Number (*if previously endorsed*)**:** 2751
Measure Title: Proportion of Patients undergoing an Angioplasty Procedure (Percutaneous Coronary Intervention - PCI) that have a Potentially Avoidable Complication (during the episode time window)
IF the measure is a component in a composite performance measure, provide the title of the Composite Measure here: Click here to enter composite measure #/ title

Date of Submission: 6/30/2015

Instructions

- *For composite performance measures:*
  - *A separate evidence form is required for each component measure unless several components were studied together.*
  - *If a component measure is submitted as an individual performance measure, attach the evidence form to the individual measure submission.*
- Respond to all questions as instructed with answers immediately following the question. All information needed to demonstrate meeting the evidence subcriterion (1a) must be in this form. An appendix of *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 10 pages (*incudes questions/instructions*; minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the evidence for this measure meets NQF's evaluation criteria.

1a. Evidence to Support the Measure Focus
The measure focus is evidence-based, demonstrated as follows:

- Health outcome: [3] a rationale supports the relationship of the health outcome to processes or structures of care. Applies to patient-reported outcomes (PRO), including health-related quality of life/functional status, symptom/symptom burden, experience with care, health-related behavior.

- Intermediate clinical outcome: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured intermediate clinical outcome leads to a desired health outcome.
- Process: [5] a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured process leads to a desired health outcome.
- Structure: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured structure leads to a desired health outcome.
- Efficiency: [6] evidence not required for the resource use component.

Notes

3. Generally, rare event outcomes do not provide adequate information for improvement or discrimination; however, serious reportable events that are compared to zero are appropriate outcomes for public reporting and quality improvement.

4. The preferred systems for grading the evidence are the U.S. Preventive Services Task Force (USPSTF) grading definitions and methods, or Grading of Recommendations, Assessment, Development and Evaluation (GRADE) guidelines.

5. Clinical care processes typically include multiple steps: assess → identify problem/potential problem → choose/plan intervention (with patient input) → provide intervention → evaluate impact on health status. If the measure focus is one step in such a multistep process, the step with the strongest evidence for the link to the desired outcome should be selected as the focus of measurement. Note: A measure focused only on collecting PROM data is not a PRO-PM.

6. Measures of efficiency combine the concepts of resource use and quality (see NQF's Measurement Framework: Evaluating Efficiency Across Episodes of Care; AQA Principles of Efficiency Measures).

1a.1.This is a measure of: (*should be consistent with type of measure entered in De.1*)

Outcome

☒ Health outcome: Potentially Avoidable Complications

☐ Patient-reported outcome (PRO): Click here to name the PRO

PROs include HRQoL/functional status, symptom/symptom burden, experience with care, health-related behaviors

☐ Intermediate clinical outcome (*e.g., lab value*): Click here to name the intermediate outcome

☐ Process: Click here to name the process

☐ Structure: Click here to name the structure

☐ Other: Click here to name what is being measured

_____

HEALTH OUTCOME/PRO PERFORMANCE MEASURE *If not a health outcome or PRO, skip to 1a.3*

1a.2. Briefly state or diagram the path between the health outcome (or PRO) and the healthcare structures, processes, interventions, or services that influence it.

This measure addresses potentially avoidable complications (PACs) in patients undergoing PCI. PACs could be both directly or indirectly related to healthcare services provided (or not provided) for a condition or procedure. When complications occur within PCI, the impact could be catastrophic for the patient. Peri-procedural bleeding which carries a high mortality rate, is more likely to occur in less competent hands or the need for emergency CABG is higher in low volume centers (Crudu 2011) (Harold 2013). The teams' experience, and the volume of PCIs in the center, plays a role in reducing complications like the need for emergency CABG, or periprocedural bleeding. Developed in 1997 by the American College of Cardiology, the National Cardiovascular Data Registry (NCDR 2015) is the most comprehensive database of post-PCI patients and a method by which hospitals are compared for quality of care and outcomes (NCDR 2015). This gives centers performing PCI's an opportunity to assess their efficacy and give an opportunity to improve quality at the provider, hospital, and/or health care system level. Some studies have shown that actual rate of complications post-PCI may be higher than the rate reported in NCDR. Access site related complications occurred 13% more than what was reported in NCDR and were associated with a greater than fourfold increase in in-hospital mortality (Crudu 2011). Additionally, a study

from the Mayo Clinic showed that nearly 1 in 10 patients undergoing PCI were readmitted within 30 days and were associated with a higher risk of 1-year mortality (Khawaja 2012).

Many of these adverse events are aggregated together in the PAC measure to study the overall rate of avoidable complications in the PCI population.

Adult patient undergoing a PCI procedure admitted to hospital or an outpatient facility

↓

Hospital/physician fails to carry out safe practices (error in commission/omission)

↓

Patient suffers complication stemming from hospital/physician potentially avoidable error

↓

Patient remains in hospital for treatment of PAC

OR

Patient readmitted to hospital with 1+ Potentially avoidable complication

Well-managed patients undergoing a PCI procedure should rarely incur a potentially avoidable complication such as bleeding, AMI, stroke, and readmissions after PCI should occur only in the rarest of circumstances. The enclosed workbook entitled NQF_PCI_all_codes_risk_adjustment 06.30.15.xls lists the types of PACs and their frequency as calculated in a large regional database (see tab PAC overview). Over 47% of PCI episodes had a PAC. Of these, 37.5% were incurred for direct complications of PCI, such as hypotension, syncope, complication of stents, shock and cardiac arrest (see tab PAC Drill Down Graph). Although the preventable readmissions in the PCI population were low, at only 4.2%; approximately 21.6% of patients with PCI procedures had PACs related to patient centered care failures such as poor control of diabetes, respiratory failure, and phlebitis and deep vein thrombosis, many of them being managed in an outpatient setting in physician offices. As a result 38.7% of episodes had a PAC indicator on their professional claims.

While PACs may not be eliminated completely, identifying the magnitude of PACs and knowledge of the cause for the most frequent or the most expensive PACs could place an emphasis in reducing them and as a consequence improving patient outcomes. The ability to clearly identify the type and frequency of each PAC creates a highly actionable measure for all providers that are managing or co-managing the patient, as well as for the health plan with whom the patient is a member.

4) Khawaja, FJ, et al. "Factors associated with 30-day readmission rates after percutaneous coronary intervention". *Arch Intern Med*. (2012): 172:112-117.

1a.2.1. State the rationale supporting the relationship between the health outcome (or PRO) to at least one healthcare structure, process, intervention, or service (*i.e., influence on outcome/PRO*).

Note: For health outcome/PRO performance measures, no further information is required; however, you may provide evidence for any of the structures, processes, interventions, or service identified above.

Rationale: Better processes of care create an atmosphere of proactive management, consistency in care and standardized care patterns (Shekelle 2013) (Fenter 2006). Patient education and adopting safe practices significantly reduces occurrence of potentially avoidable complications (PACs) in all settings (Klein 2011) (Wachter 2013) (Berwick 2006) (Kovner 2011) (Farley 2013). It is known that by holding providers accountable for occurrence and costs of PACs, an built-in warranty is created around care of the index condition (de Brantes 2009).

Percutaneous coronary intervention (PCI) is the preferred treatment strategy for ST-elevation myocardial infarction (STEMI) (Langabeer 2013). National quality improvement initiatives have focused on patient education and awareness of acute MI symptoms in order to reduce door-to-balloon times for primary PCI and improving outcomes in acute MI patients (Jollis 2007) (Jacobs 2007).

However, major PCI-related complications are not uncommon such as death, MI, emergency CABG surgery, and stroke, commonly denoted as MACCE (major adverse cardiovascular and cerebrovascular events). Other complications are vascular, bleeding and contrast nephropathy (Harold 2013). Low volume centers and low volume operators have a higher rate of complications for PCI, therefore the ACC/AHA/SCAI have adopted standards for minimally acceptable patient procedure volumes to be performed by cardiologists and hospitals (75 cases per annum per operator) (Harold 2013). The ACCF/AHA/SCAI in its 2013 Update of the Clinical Competence Statement on Coronary Artery Interventional Procedures has created guidelines to facilitate the attainment of optimal patient outcomes such as selection of clinically appropriate patients for interventional procedures and performing these procedures at a requisite level of proficiency and competency (Dehmer 2014). Opportunities for improvement exist in PCI by using the available tools (for example SYNTAX, ACC/AHA score and SCAI score) to optimize clinical decision-making to reduce complications and improve outcomes (Harold 2013).

In addition, to the direct complications related to the PCI procedure itself, there are several patient safety failures that may occur. There are a wide variety of ways to reduce these potentially avoidable complications or PACs. A few examples of better processes of care leading to reduced PACs are given below:

1. Good surgical technique reduces bleeding, perforation and complications directly from the procedure
2. Frequent hand-washing reduce hospital acquired infections (WHO 2007)
3. Carefully implemented protocols lead to reduced line sepsis (Pronovost 2010)
4. Aspirin on Discharge prevents repeat AMIs (Hall 2014)
5. Discharge planning and good follow-up prevents unnecessary ER visits and readmissions (Weaver 2013)
6. DVT prophylaxis in patients on bed rest avoids pulmonary embolism (Shekelle 2013)

PAC measures in the setting of PCI look at all-cause harms, such as the ones highlighted above, arising from poor management of a patient undergoing an angioplasty procedure.

INTERMEDIATE OUTCOME, PROCESS, OR STRUCTURE PERFORMANCE MEASURE

1a.3. Briefly state or diagram the path between structure, process, intermediate outcome, and health outcomes. Include all the steps between the measure focus and the health outcome.

1a.3.1. What is the source of the systematic review of the body of evidence that supports the performance measure?

☒ Clinical Practice Guideline recommendation – ***complete sections 1a.4, and 1a.7***

☐ US Preventive Services Task Force Recommendation – ***complete sections 1a.5 and 1a.7***

☐ Other systematic review and grading of the body of evidence (*e.g., Cochrane Collaboration, AHRQ Evidence Practice Center*) – ***complete sections 1a.6 and 1a.7***

☐ Other – ***complete section 1a.8***

Please complete the sections indicated above for the source of evidence. You may skip the sections that do not apply.

1a.4. CLINICAL PRACTICE GUIDELINE RECOMMENDATION

1a.4.1. Guideline citation (*including date*) and **URL for guideline** (*if available online*):

1a.4.2. Identify guideline recommendation number and/or page number and **quote verbatim, the specific guideline recommendation**.

1a.4.3. Grade assigned to the quoted recommendation with definition of the grade:

1a.4.4. Provide all other grades and associated definitions for recommendations in the grading system. (*Note: If separate grades for the strength of the evidence, report them in section 1a.7.*)

1a.4.5. Citation and URL for methodology for grading recommendations (*if different from 1a.4.1*)**:**

1a.4.6. If guideline is evidence-based (rather than expert opinion), are the details of the quantity, quality, and consistency of the body of evidence available (e.g., evidence tables)?

☐ Yes → ***complete section 1a.7***

☐ No → ***report on another systematic review of the evidence in sections 1a.6 and 1a.7; if another review does not exist, provide what is known from the guideline review of evidence in 1a.7***

1a.5. UNITED STATES PREVENTIVE SERVICES TASK FORCE RECOMMENDATION

1a.5.1. Recommendation citation (*including date*) and **URL for recommendation** (*if available online*):

1a.5.2. Identify recommendation number and/or page number and **quote verbatim, the specific recommendation**.

1a.5.3. Grade assigned to the quoted recommendation with definition of the grade:

1a.5.4. Provide all other grades and associated definitions for recommendations in the grading system. (*Note: the grading system for the evidence should be reported in section 1a.7.*)

1a.5.5. Citation and URL for methodology for grading recommendations (*if different from 1a.5.1*)**:**

Complete section 1a.7

1a.6. OTHER SYSTEMATIC REVIEW OF THE BODY OF EVIDENCE

1a.6.1. Citation (*including date*) and **URL** (*if available online*):

1a.6.2. Citation and URL for methodology for evidence review and grading (*if different from 1a.6.1*)**:**

Complete section 1a.7

1a.7. FINDINGS FROM SYSTEMATIC REVIEW OF BODY OF THE EVIDENCE SUPPORTING THE MEASURE

If more than one systematic review of the evidence is identified above, you may choose to summarize the one (or more) for which the best information is available to provide a summary of the quantity, quality, and consistency of the body of evidence. Be sure to identify which review is the basis of the responses in this section and if more than one, provide a separate response for each review.

1a.7.1. What was the specific structure, treatment, intervention, service, or intermediate outcome addressed in the evidence review?

1a.7.2. Grade assigned for the quality of the quoted evidence with definition of the grade:

1a.7.3. Provide all other grades and associated definitions for strength of the evidence in the grading system.

1a.7.4. What is the time period covered by the body of evidence? (*provide the date range, e.g., 1990-2010*). Date range: Click here to enter date range

QUANTITY AND QUALITY OF BODY OF EVIDENCE

1a.7.5. How many and what type of study designs are included in the body of evidence? (*e.g., 3 randomized controlled trials and 1 observational study*)

1a.7.6. What is the overall quality of evidence <u>across studies</u> in the body of evidence? (*discuss the certainty or confidence in the estimates of effect particularly in relation to study factors such as design flaws, imprecision due to small numbers, indirectness of studies to the measure focus or target population*)

ESTIMATES OF BENEFIT AND CONSISTENCY ACROSS STUDIES IN BODY OF EVIDENCE

1a.7.7. What are the estimates of benefit—magnitude and direction of effect on outcome(s) <u>across studies</u> in the body of evidence? (*e.g., ranges of percentages or odds ratios for improvement/ decline across studies, results of meta-analysis, and statistical significance*)

1a.7.8. What harms were studied and how do they affect the net benefit (benefits over harms)?

N/A

UPDATE TO THE SYSTEMATIC REVIEW(S) OF THE BODY OF EVIDENCE

1a.7.9. If new studies have been conducted since the systematic review of the body of evidence, provide for <u>each</u> new study: 1) citation, 2) description, 3) results, 4) impact on conclusions of systematic review.

_____

1a.8 OTHER SOURCE OF EVIDENCE

If source of evidence is NOT from a clinical practice guideline, USPSTF, or systematic review, please describe the evidence on which you are basing the performance measure.

1a.8.1 What process was used to identify the evidence?

1a.8.2. Provide the citation and summary for each piece of evidence.

1. Evidence, Performance Gap, Priority – Importance to Measure and Report

Extent to which the specific measure focus is evidence-based, important to making significant gains in healthcare quality, and improving health outcomes for a specific high-priority (high-impact) aspect of healthcare where there is variation in or overall less-than-optimal performance. ***Measures must be judged to meet all subcriteria to pass this criterion and be evaluated against the remaining criteria.***

1a. Evidence to Support the Measure Focus – See attached Evidence Submission Form

2751_PCI_Evidence_Attachment_HCI3.docx

1b. Performance Gap

Demonstration of quality problems and opportunity for improvement, i.e., data demonstrating:

- considerable variation, or overall less-than-optimal performance, in the quality of care across providers; and/or
- disparities in care across population groups.

1b.1. Briefly explain the rationale for this measure *(e.g., the benefits or improvements in quality envisioned by use of this measure)*

Measures associated to potentially avoidable complication (PAC) have been used as comprehensive outcomes measures since 2007 for several conditions and procedures (de Brantes 2010) (Joynt 2013) (James 2013). In 2011, following the NQF endorsement of these measures for certain acute medical conditions (AMI, Pneumonia and Stroke), and for chronic conditions, they were adopted for various purposes, including the creation of related measures (NQF – Measure #1550). Some commercial payers have used them as a means for tracking outcomes (Yong 2010) and for tiering providers for pay for performance programs (BCBSNC). In addition, some

provider organizations have used them in quality improvement efforts by homing in on the detailed specifications of the measures to reveal opportunities for care improvement (CALPERS – link below). Identification of PACs has spurred provider innovation (Bundled Payment Summit 2015) for practice re-engineering, to create proactive care pathways, and to focus on areas of high variability (McVary 2010). Some employers are also using measures of avoidable complications as public measures of quality (Colorado Business Group on Health) given the research that demonstrated the potential efficacy of these measures to differentiate provider quality and cost (Hibbard 2012). In fact in a series of focus groups led by Judy Hibbard and colleagues, the researchers found that the very framing of potentially avoidable complications as an indicator of potential harm, is an effective way of communicating the quality of care. And when measures of PACs were presented in conjunction with price, consumers intuitively accepted the logical relationship between low PACs – fewer "defects" – and lower price.

Accountability for and measurement of PACs occurs at the practice, medical group, provider system or purchaser/payer level. PAC rates are calculated as absolute values. For example, a health plan would report that 40% of its plan members with hypertension incurred PACs in the study time window. The objective of the measure is to encourage the unit being measured to progressively reduce that amount over time. In addition, comparisons of PAC rates across plans or provider systems should be encouraged and publicly reported. An organization that uses the measure should be able to identify the leading causes of PACs and implement improvements to existing processes that will decrease PACs. There are several tools available for provider systems and health plans to impact PAC rates. These include care coordination across care settings; post-discharge planning and patient follow- up, active care management, sharing medical record data between care settings and providers, total quality management within hospitals and active reduction of patient safety failures. Reducing PACs has the potential to significantly improve the overall level of quality.

Creating a single measure of accountability for physicians and hospitals tied to gaps in quality is likely to yield much improved outcomes for patients. A measure of accountability for health plans helps them review trends over time and work with physicians and hospitals to improve the ways in which they engage patients using more optimal care management and care coordination (Cassel 2014). In addition, PAC measures could be used as a surrogate for quality in a consumer transparency tool to differentiate providers with regards to their performance.

Moreover, since these measures are claims based, there is minimal added burden for collecting the data, and it also avoids potential gaming that may occur for other measures that require reporting information to registries. Although use of administrative claims data in identifying conditions and measuring provider quality has been questioned, there are several studies in literature that acknowledge validity of its use (Normand 2007) (Quan 2009). Until more readily available data are at hand, use of administrative data to measure provider performance has steadily increased (Miller 2001), (NQF Quality Positioning System). Interestingly, in the current fee for service system, services for most PACs are rewarded by continued payment (except the CMS defined "never events") and hence to our advantage, adverse events surface in billing data. Claims based PAC measures; therefore serve as an alternative method to track adverse outcomes that do occur (Leibson 2008).

1b.2. Provide performance scores on the measure as specified (current and over time) at the specified level of analysis. *(This is required for endorsement maintenance. Include mean, std dev, min, max, interquartile range, scores by decile. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities included). This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*

The data included two years of administrative claims covering the period April 1, 2012 through December 17, 2014. There were a total 5,898 episodes of PCI.

Because facilities with small volumes may provide unreliable estimates, we excluded any with fewer than 10 attributed episodes prior to the calculations. After this exclusion 41 (out of 565) facilities remained. Performance scores for these facilities are summarized in the following table:

Unadjusted PAC Rates:

Median (IQR):	50% (44%, 55.6%)
Range:	31.6% - 80%

Risk-Standardized PAC Rates (RSPR):

Median (IQR):	48.5% (43.7%, 52.2%)
Range:	24.2% - 61.5%

Please refer to the NQF_PCI_all_codes_risk_adjustment_06.30.15.xls workbook under the "ProviderAttribution Reliability" tab to see specific results for each provider.

1b.3. If no or limited performance data on the measure as specified is reported in 1b2, then provide a summary of data from the literature that indicates opportunity for improvement or overall less than optimal performance on the specific focus of measurement.

Despite an aging population in the US, current trends point towards a decrease in hospitalizations related to coronary artery disease events. This applies to both a decrease in acute myocardial infarcts, due to decrease in transmural AMI, as well as decreased

hospitalization rates in patients undergoing revascularization procedures (Nallamothu 2007). In fact in this study, rates of hospitalizations for coronary revascularizations dropped from 382 to 358 per 100,000 between 2002 and 2005. Interestingly, the decrease was primarily due to a decrease in rates of CABG procedures from 121 to 94 per 100,000. Numbers of PCIs, however, continued to increase from 264 to 267 per 100,000. Interestingly, with better availability of drug-eluting stents, and better techniques in PCI there has been dramatically lower incidence of restenosis rates following PCI and therefore decease in re-hospitalizations. However, high degree of variability in PCI related complications across different datasets (de Brantes 2011) suggest that short-term complications should be measured and reported.

1b.5. **If no or limited data on disparities from the measure as specified is reported in 1b4, then provide a summary of data from the literature that addresses disparities in care on the specific focus of measurement. Include citations.**
Not applicable

1c. High Priority (previously referred to as High Impact)

The measure addresses:

- a specific national health goal/priority identified by DHHS or the National Priorities Partnership convened by NQF; OR
- a demonstrated high-priority (high-impact) aspect of healthcare (e.g., affects large numbers of patients and/or has a substantial impact for a smaller population; leading cause of morbidity/mortality; high resource use (current and/or future); severity of illness; and severity of patient/societal consequences of poor quality).

1c.1. **Demonstrated high priority aspect of healthcare**
Affects large numbers, A leading cause of morbidity/mortality, Frequently performed procedure, High resource use, Patient/societal consequences of poor quality, Severity of illness
1c.2. **If Other:**

1c.3. **Provide epidemiologic or resource use data that demonstrates the measure addresses a high priority aspect of healthcare. List citations in 1c.4.**
PCI is the central therapy for patients with symptomatic coronary artery disease, particularly acute myocardial infarction (Roe 2010). Over 1 million Coronary revascularizations are performed annually, making it the most common major medical procedure in the US (Epstein 2008). It is also the most expensive procedure, with Medicare inpatient costs for revascularization procedures exceeding 3.2 billion annually in 2006 (Epstein 2008). The indications for PCI have been expanding, and technology including the availability of drug eluting stents has contributed to increased use of PCI (Epstein 2008). Longitudinal data obtained for 2003–2011 from the American Hospital Association, the U.S. Census, and the Centers for Disease Control and Prevention (CDC) showed centers performing PCI have grown 1.5 times faster than population growth in the same period (Langabeer 2013).

A study by de Brantes et al analyzed variability in episode costs in patients undergoing PCI and demonstrated that there was significant variation in episode costs within health plan data, and PACs contributed considerably to that variation (de Brantes 2011). This suggests that there is room for improvement. Another large study of over 400,000 patients across 1499 hospitals, analyzing 2005 Medicare FFS claims data, showed that approximately 1 in 7 Medicare patients undergoing PCI are readmitted within 30 days, and readmission rates vary across hospitals reflecting variations in quality of care (Curtis 2009). Readmissions are not only associated with higher revascularization rates (up to 25%), they also have a significantly higher mortality rate (Curtis 2009).

Major PCI-related complications include death, MI, emergency CABG surgery, and stroke, commonly denoted as MACCE (major adverse cardiovascular and cerebrovascular events). Other complications are vascular, bleeding and contrast nephropathy. Procedural success is defined as angiographic success without in-hospital major complications such as death, myocardial infarction (MI), stroke, and emergency coronary artery bypass graft (CABG) surgery (Harold 2013).

With the rise in use of PCI procedures, and the significant number of avoidable complications (Crudu 2011) (Mukherjee 2005) (Normand 2008) (Patel 2009) (Dehmer 2014) that are under the provider's control, PAC measures in the PCI population are a high priority aspect of health care. The PAC measures look for all-cause harms in patients receiving angioplasty.

1d. Composite Quality Construct and Rationale

1d.1. **A composite performance measure is a combination of two or more component measures, each of which individually reflects quality of care, into a single performance measure with a single score.**

For purposes of NQF measure submission, evaluation, and endorsement, the following will be considered composites:

- Measures with two or more individual performance measure scores combined into one score for an accountable entity.

- Measures with two or more individual component measures assessed separately for each patient and then aggregated into one score for an accountable entity:
    - all-or-none measures (e.g., all essential care processes received, or outcomes experienced, by each patient); or
    - any-or-none measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient).

1d.1. Please identify the composite measure construction: any-or-none measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient)any-or-none measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient)

1d.2. Describe the quality construct, including:

- the overall area of quality
- included component measures and
- the relationship of the component measures to the overall composite and to each other.

The PAC measures, as we define them, look at many "care defects" comprehensively. They are composed of several cross-cutting measures and together they paint a global picture of the provider's overall performance.

We classify PACs into two types: Type 1 PACs are directly related to the index condition and are often controlled by the servicing provider; Type 2 PACs, on the other hand result from patient safety failures and could be reduced by better systems and better processes in care. Both types of PACs could occur in any setting and so could be identified through any type of claims coming in the administrative dataset, including in-patient, out-patient, or professional claims. PACs may occur any time during the episode time window. PACs are counted as a dichotomous (yes/no) outcome. If a patient had one or more PACs, they get counted as a "yes" or a 1.

The PAC measure definitions encompass several other measures that are accepted as being valid complications of care and are widely used throughout the country. These include CMS defined Hospital Acquired Conditions (HACs), Hospital Inpatient Quality Reporting measures, Avoidable Readmissions, AHRQ defined patient safety indicators (PSIs), NQF endorsed patient safety measures such as patient fall rates, pressure ulcer rates, and peri-operative pulmonary embolism or deep vein thrombosis rates.

All defined PACs, irrespective of their type, or site of occurrence, are aggregated to create an overall comprehensive, composite measure. They all have equal weighting, since they are measured simply by the frequency of their occurrence.The PAC measures, as we define them, look at many "care defects" comprehensively. They are composed of several cross-cutting measures and together they paint a global picture of the provider's overall performance.

We classify PACs into two types: Type 1 PACs are directly related to the index condition and are often controlled by the servicing provider; Type 2 PACs, on the other hand result from patient safety failures and could be reduced by better systems and better processes in care. Both types of PACs could occur in any setting and so could be identified through any type of claims coming in the administrative dataset, including in-patient, out-patient, or professional claims. PACs may occur any time during the episode time window. Furthermore, the measure is constructed so that the occurrence of any number of PACs during a defined episode would only count as one occurrence.

The PAC measure definitions encompass several other measures that are accepted as being valid complications of care and are widely used throughout the country. These include CMS defined Hospital Acquired Conditions (HACs), Hospital Inpatient Quality Reporting measures, Avoidable Readmissions, AHRQ defined patient safety indicators (PSIs), NQF endorsed patient safety measures such as patient fall rates, pressure ulcer rates, and peri-operative pulmonary embolism or deep vein thrombosis rates.

All defined PACs, irrespective of their type, or site of occurrence, are aggregated to create an overall comprehensive, composite measure. They all have equal weighting, since they are measured simply by the frequency of their occurrence.

1d.3. Describe the rationale for constructing a composite measure, including how the composite provides a distinctive or additive value over the component measures individually.

Each individual PAC, when measured in isolation, provides a very limited picture of the performance of the provider(s) who are managing or co-managing the care of the patient. However, looking at all the PACs that may occur individually or concurrently in a patient with a given episode provides a comprehensive picture of the care received by the patient for that particular condition or illness.

Additionally, the frequency of occurrence of individual PACs may be so low that it may require very high sample sizes from individual

providers to achieve any meaningful and reliable comparisons. But aggregating all the PACs into a single quality metric creates meaningful scores that can be compared across providers even with relatively smaller sample sizes.

Additionally, a comprehensive measure is easier to explain to the average consumer. From a patient's point of view, any bad outcome has an impact on their health with respect to return to work, functional limitations and need for additional support. If a provider has a high PAC rate with regards to one component PAC but not the other PACs, the impact on the patient is still adverse. In selecting providers, individual component PAC scores would mean nothing to a patient, but aggregating it to a comprehensive quality score could be a measure of "all-cause" harms and easier to interpret and act on.

1d.4. **Describe how the aggregation and weighting of the component measures are consistent with the stated quality construct and rationale.**
In constructing the comprehensive composite PAC measure, each component PAC, as clinically defined by the subject matter experts, was given the same weight so that arbitrary weights may not bias the results. Furthermore, the measure is constructed so that the occurrence of any number of PACs during a defined episode would only count as one occurrence. As such, the patient is the ultimate unit of measurement and if the patient incurred any PAC during the episode, then that counts against the numerator.

Since the emphasis of the PAC measure was to simply identify the occurrence of PACs in any setting, aggregation of the PAC counts to create a comprehensive quality score with equal weights has been met with overall support from the clinical working groups as well as from the implementation sites.

2. Reliability and Validity—Scientific Acceptability of Measure Properties

Extent to which the measure, as specified, produces consistent (reliable) and credible (valid) results about the quality of care when implemented. ***Measures must be judged to meet the subcriteria for both reliability and validity to pass this criterion and be evaluated against the remaining criteria.***

2a.1. Specifications The measure is well defined and precisely specified so it can be implemented consistently within and across organizations and allows for comparability. eMeasures should be specified in the Health Quality Measures Format (HQMF) and the Quality Data Model (QDM).

De.5. **Subject/Topic Area** *(check all the areas that apply):*
Cardiovascular, Cardiovascular : Percutaneous Coronary Intervention (PCI)

S.2a. **If this is an eMeasure**, HQMF specifications must be attached. Attach the zipped output from the eMeasure authoring tool (MAT) - if the MAT was not used, contact staff. (Use the specification fields in this online form for the plain-language description of the specifications)
This is not an eMeasure **Attachment:**

S.2b. **Data Dictionary, Code Table, or Value Sets** *(and risk model codes and coefficients when applicable) must be attached. (Excel or csv file in the suggested format preferred - if not, contact staff)*
Attachment **Attachment:** NQF_PCI_all_codes_risk_adjustment_06.30.15-635719835998602641.xlsx

S.3. **For endorsement maintenance**, please briefly describe any changes to the measure specifications since last endorsement date and explain the reasons.
Not applicable

S.4. **Numerator Statement** *(Brief, narrative description of the measure focus or what is being measured about the target population, i.e., cases from the target population with the target process, condition, event, or outcome)*

IF an OUTCOME MEASURE, state the outcome being measured. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
Number of patients who underwent a percutaneous coronary intervention (PCI) procedure, are followed for at least 90-days, and have one or more potentially avoidable complications (PACs) during the episode time window.

S.5. **Time Period for Data** *(What is the time period in which data will be aggregated for the measure, e.g., 12 mo, 3 years, look back to August for flu vaccination? Note if there are different time periods for the numerator and denominator.)*
The time window includes a 30-day look-back period and a 90-day look-forward period from the PCI trigger claim.

S.6. **Numerator Details** *(All information required to identify and calculate the cases from the target population with the target process, condition, event, or outcome such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
IF an OUTCOME MEASURE, describe how the observed outcome is identified/counted. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
Patients that have triggered a PCI episode, are followed for at least 90-days, and are identified as having services for potentially avoidable complications (PACs). PACs may occur during the index stay or during the 90-day post discharge period. The enclosed excel workbook entitled NQF_PCI_all_codes_risk_adjustment_06.30.15 gives the detailed codes for PACs in the tabs entitled PACs I-9 and PACs I-10.

Services for PACs are identified as follows:
a. Any Index stay that has a PAC diagnosis code in any position except in the PRIMARY (principal) position is considered as having a potentially avoidable complication
b. Any readmission to an acute care facility 2 days or later after discharge but within 90-days post-discharge, that is relevant to PCI
c. Any admission to a post-acute care facility, that is relevant to PCI and has a PAC code in any position on the claim
d. Any other service (professional, outpatient facility, ancillary) that is relevant to PCI and has a PAC code in any position on the claim

S.7. **Denominator Statement** *(Brief, narrative description of the target population being measured)*
Adult patients aged 18 years and above who underwent an Angioplasty (percutaneous coronary intervention - PCI) procedure and are followed for at least 90-days

S.8. **Target Population Category** *(Check all the populations for which the measure is specified and tested if any):*
Populations at Risk, Populations at Risk : Dual eligible beneficiaries, Populations at Risk : Individuals with multiple chronic conditions, Populations at Risk : Veterans, Senior Care

S.9. **Denominator Details** *(All information required to identify and calculate the target population/denominator such as definitions, specific data collection items/responses , code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
Please refer to the enclosed excel workbook entitled
NQF_PCI_all_codes_risk_adjustment 06.30.15

The target population is identified using the following criteria:
1. Using administrative claims database, patients undergoing PCI are identified using one of the following criteria:
a. Patients with a procedure code of PCI in any position on an in-hospital stay claim with a qualifying diagnosis code relevant to the PCI procedure.
b. Patients with a procedure trigger code of PCI in any position on an outpatient facility claim with a qualifying diagnosis code relevant to the PCI procedure.
c. Patients having a professional service carrying a trigger code of PCI in any position.
The trigger codes for PCI and the qualifying diagnosis codes are provided in the tab called “Triggers I-9” or “Triggers I-10”.

2. The patient should have continuous enrollment for the entire time window with no more than 30 days as an enrollment gap, with the entity providing the data (so we can ensure that the database has captured most of the claims for the patient during the episode time window).
3. The patient should have a complete episode time window in the claims data – so the end date of the episode should not be past the database claims end date.

4. Patient should be at least 18 years of age
5. Patients that have a trigger code on a professional claim and have no associated facility bill are considered as having an orphan (incomplete) episode and are dropped from analysis.

Once the episode is triggered all relevant claims are assigned to the episode. Relevant claims could be inpatient facility claims, outpatient facility claims, professional services, laboratory services, imaging services, ancillary claims, home health, durable medical equipment as well as pharmacy claims across the entire continuum of care centered around the patient's episode of care. Relevant claims are identified as those that have a diagnosis code that matches the codes in the typical Dx codes tabs (Typical Dx I-9 or Typical Dx I-10), or in the PAC Dx codes tab (PACs I-9 or PACs I-10) AND a procedure code as identified in the Relevant Procedures I-9 & I-10 tab in the enclosed workbook. Relevant readmissions and relevant admissions to post-acute care facilities are also included in the denominator.

S.10. Denominator Exclusions *(Brief narrative description of exclusions from the target population)*
Denominator exclusions include exclusions of either "patients" or "claims" based on the following criteria:
1. "Patients" excluded are those that do not meet the enrollment criteria. If patient has an enrollment gap for more than 30 days during the episode time window, it is considered as an enrollment gap
2. "Patients" are also excluded if the cost of the episode is an outlier at greater than 99th percentile or less than 1st percentile value for all episodes. This is another way to ensure that episodes are complete as well as they do not bring in random noise into the analysis due to inappropriate codes or services.
3. "Claims" are excluded from the PCI measure if they are considered not relevant to PCI care.

S.11. Denominator Exclusion Details *(All information required to identify and calculate exclusions from the denominator such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
Denominator exclusions include exclusions of "patients" as well as "claims" not relevant to PCI care. Please refer to the enclosed excel workbook entitled (NQF_PCI_all_codes_risk_adjustment 06.30.15.xls)

1. "Patients" are excluded from the measure if they meet one of the following criteria:
 a. If age is < 18 years
 b. If gender is missing
 c. If they do not have continuous enrollment for the entire time window with a maximum of 30 day enrollment gap with the entity providing the data (this helps determine if the database has captured most of the claims for the patient in the time window).
 d. If the episode time window extends beyond the dataset end date (this helps eliminate incomplete episodes).
 e. The episode cost is an outlier (less than 1st percentile or greater than 99th percentile value for all episodes of the same type). This eliminates extreme variation that may result from random outlier events.

2. "Claims" are excluded from the measure based on the following criteria:
 a. If none of the diagnosis codes on the claim are on the list of relevant diagnosis codes (either typical Dx or PAC Dx) for PCI.
 b. If none of the procedure / CPT codes on the claim are on the list of relevant procedure codes for PCI.

S.12. Stratification Details/Variables *(All information required to stratify the measure results including the stratification variables, definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format with at S.2b)*
None

S.13. Risk Adjustment Type (Select type. Provide specifications for risk stratification in S.12 and for statistical model in S.14-15)
Statistical risk model
If other:

S.14. Identify the statistical risk model method and variables *(Name the statistical method - e.g., logistic regression and list all the risk factor variables. Note - risk model development and testing should be addressed with measure testing under Scientific Acceptability)*
Conceptual Model
Variations in outcomes across populations may be due to patient-related factors or due to provider-controlled factors. When we adjust for patient-related factors, the remaining variance in PACs are due to factors that could be controlled by all providers that are managing or co-managing the patient, both during and after hospitalization.

Statistical Method:
Logistic Regression model to determine the probability of a patient incurring a PAC
Demographic variables, comorbid conditions, as well as clinical severity indicators are fed as independent risk factors into the model. Risk Factors are collected historically. Subtype information is collected from the index claim and any look-back period, if relevant. Subtypes are clinical severity indicators suggesting severity of the episode itself, for example, diagnosis of unstable angina in a PCI patient. For each patient the "predicted" coefficients from the risk adjustment models are summed to give the predicted probabilities of the occurrence of a PAC.

Risk Factors :(Please refer to the enclosed excel workbook entitled (NQF_PCI_all_codes_risk_adjustment 06.30.15.xls). The risk factors along with their codes are listed in the tabs called "All Risk Factors I-9" and "All Risk Factors I-10" and also listed below:

AGE CONTINUOUS VARIABLE
GENDER FEMALE = 1 (MALE IS REFERENCE = 0)

Risk Factor #	Risk Factor Name
RF0101	Anoxic Brain Damage, persistent vegetative state
RF0102	Delirium, Meningitis, Encephalitis
RF0103	Previous Stroke, Paralysis
RF0104	Cerebral Palsy and Other Paralytic Syndromes
RF0105	Spinal Cord Disorders/Injuries
RF0106	Polyneuropathy
RF0107	Multiple Sclerosis
RF0108	Convulsions, Epilepsy
RF0109	Dementia
RF0110	Parkinson´s and Huntington´s Diseases
RF0111	Cerebrovascular Disease
RF0115	after care, rehabilitation
RF0201	visual loss, blindness, retinal tear, detachment

Obstructive sleep apnea
Sleep Apnea

The prevalence of the risk factors in our reference dataset are listed in the enclosed workbook entitled NQF_PCI_all_codes_risk_adjustment 06.30.15.xls – see tab “Risk Factor Prevalence”. The output of the regression model are given in the same workbook in the tab “Risk Model’.

S.15. Detailed risk model specifications *(must be in attached data dictionary/code list Excel or csv file. Also indicate if available at measure-specific URL identified in S.1.)*

Note: Risk model details (including coefficients, equations, codes with descriptors, definitions), should be provided on a separate worksheet in the suggested format in the Excel or csv file with data dictionary/code lists at S.2b.
Available in attached Excel or csv file at S.2b

S.15a. **Detailed risk model specifications** (*if not provided in excel or csv file at S.2b*)

S.16. **Type of score:**
Rate/proportion
If other:

S.17. **Interpretation of Score** *(Classifies interpretation of score according to whether better quality is associated with a higher score, a lower score, a score falling within a defined interval, or a passing score)*
Better quality = Lower score

S.18. **Calculation Algorithm/Measure Logic** *(Describe the calculation of the measure score as an ordered sequence of steps including identifying the target population; exclusions; cases meeting the target process, condition, event, or outcome; aggregating data; risk adjustment; etc.)*
Please refer to the enclosed excel workbook entitled (NQF_PCI_all_codes_risk_adjustment 06.30.15.xls).

Assembling the Denominator:

Using administrative claims database, patients undergoing a PCI are identified using one of the following criteria: 1) Patients with a procedure code of PCI in any position on an in-patient of an out-patient facility claim with a qualifying diagnosis code relevant to the PCI procedure, 2) Patients having a professional service carrying a trigger code of PCI in any position. The trigger codes for PCI are provided in the tab called "Triggers I-9" or "Triggers I-10".

Patients are retained if they are 18 years of age or more, do not have a missing gender, have a complete episode time window in the database, have a maximum of 30-day enrollment gap for the entire episode time window, and have no outlier episode costs. All relevant professional, laboratory, imaging, ancillary and other claims that are incurred during the episode time window are included as part of the episode. Claims are considered relevant to PCI care if they have one of the diagnosis codes, as listed on the tab entitled Triggers I-9, Triggers 1-10, PACs I-9, PACs I-10, Typical Dx I-9, or Typical Dx I-10 in any position on the claim AND a procedure code as identified in the Relevant Procedures I-9 & I-10 tab in the enclosed workbook. Relevant readmissions and relevant admissions to post-acute care facilities are also included in the denominator. All relevant pharmacy claims carrying codes that match the ingredients listed in the Pharmacy tab of the enclosed workbook are also included as part of the episode.

If a patient has more than one concurrent episode, and the claim is relevant to both episodes, the claim could get multi-assigned, except in the case of procedural episodes that get carved out with respect to the index stay. So if an inpatient stay claim carried a procedure code that matched the trigger procedure code for PCI but they also had a qualifying diagnosis code for CAD (coronary artery disease), the stay claim would trigger both episodes concurrently, but get uniquely assigned to PCI and not be counted with CAD.

Once all the episodes are assembled, episodes that match the exclusion criteria, such as those with outlier costs, are flagged (those with total episode costs less than 1st percentile or greater than 99th percentile), and excluded from the final analysis.

Assembling the Numerator:

For every episode included in the denominator, services are flagged as having a PAC (potentially avoidable complication) based on the criteria listed below:

Any Index stay that has a PAC diagnosis code in any position except in the PRIMARY (principal) position is considered as having a potentially avoidable complication

Any readmission to an acute care facility 2 days or later after discharge but within 90-days post-discharge, that is relevant to PCI

Any admission to a post-acute care facility, that is relevant to PCI and has a PAC code in any position on the claim

Any other service (professional, outpatient facility, laboratory, imaging, ancillary) that is relevant to PCI and has a PAC code in any position on the claim

Relevant claims that do not have any PAC codes, and do not qualify as a PAC based on the criteria outlined above, are listed as

typical claims. All included relevant pharmacy services are flagged as typical. Patients that have even a single PAC claim are counted as part of the numerator.

Calculating the measure:

Proportion of PCI patients that have PACs is simply the ratio of patients with PACs within the PCI population and is called the PAC rate as shown in the equation below:

PAC rate = Patients with PCI that have at least one PAC claim / Total number of PCI patients

A flow chart demonstrating the series of steps and the counts of patients at each step is shown in tab entitled Decision Tree of the enclosed workbook called NQF_PCI_all_codes_risk_adjustment 06.30.15.xls

Drill Down Calculations:

Further analysis from this construct helps create actionable reports.

For example as shown in the tab labeled PAC overview, not only do we have the PAC rate for a population, we can break them down by the PAC type – type 1 being directly related to PCI and so actionable by the servicing physician, while type 2 PACs are related to patient safety failures and can be improved by process improvement. Additionally, analyzing what portion of the PACs occur during the index stay, vs. in the post-discharge period and how many are due to readmissions helps focus strategies in reducing them.

Risk Adjustment:

Once we have the observed PAC rates, we risk-adjust them for patient factors such as patient demographics, comorbidities collected historically, and for severity of illness or procedure using subtypes collected from the index stay and / or look-back period. This helps adjust for factors outside the providers control and levels the playing field for provider performance comparisons.

Unit of Analysis:
The unit of analysis is the individual episode.

Dependent Variable:
The dependent variable is a dichotomous variable indicating whether an episode had one or more claims assigned as a PAC (=1) or not (=0).

Independent Variables:
A number of patient-related "risk factors" or covariates are included in the models:

Patient demographics: age, gender, and an indicator of whether a member has enrolled within the previous 6 months. This latter risk factor is intended to account for the patient's lack of claims history, which limits the number of potential comorbidities that can be identified.

Comorbidities: These are conditions or events that occurred prior to the start of the episode that can have a potential impact on the patient's risk of having a PAC. The risk factors are 170 disease indicators (0/1) identified through the presence of ICD diagnosis codes on individual medical claims and collected from the historical claims data before the start of an episode. These are universally applied across all episodes. Please see the tab labeled "All Risk Factors I-9" and "All Risk Factors I-10" for a list of risk factors and their corresponding codes in the enclosed workbook called NQF_PCI_all_codes_risk_adjustment 06.30.15.xls

Episode Subtypes or Severity Markers: These are markers that distinguish an episode as being more severe than another. They indicate either specific patient comorbidities that are known to make the procedure or condition more difficult to treat (e.g., obesity) or severity of the illness itself (e.g., unstable angina). Please see the tab labeled "Subtypes I-9" and "Subtypes I-10" for a list of subtypes and their corresponding codes in the enclosed workbook called NQF_PCI_all_codes_risk_adjustment 06.30.15.xls

As mentioned previously, to avoid creating perverse incentives all comorbidities and subtypes are identified prior to or at the very start of the episode. None are identified during the episode period.

Statistical Methods

We use logistic regression to model the probability of at least one PAC occurring during the episode. Only comorbidities and subtypes are included in the models as covariates if they are present in at least 10 episodes to prevent unstable coefficients. No further model building is conducted after the initial models are built. This reflects a desire to explain as much variation in the probability of having a PAC as possible, but it does not make it a priority that all covariates in the model be individually significant or even uncorrelated with each other. Accordingly, the model uses a very large group of covariates. This modeling approach allows for fewer potentially artificial constraints around the definitions of what constitutes severity of a episode condition, and lets each regression model determine for itself which of the factors are more significant for a specific episode. Non-significant covariates in episode models can not overly influence predicted outcomes, nor is much harm realized, if a group of correlated covariates work together to explain variation rather than having the variation explained by a single best factor.

When more than one line of business is included in the data, separate models are calculated for each sample (i.e., commercial, Medicaid etc.).

Provider Attribution and calculating PAC rates by provider:

Once episodes are constructed they are attributed to providers based on one of the various attribution rules. For PCI, episodes are attributed to the facility where the episode triggered, or, if the episode is triggered off a professional claim, it is attributed to the first facility claim that overlaps the professional trigger claim date.

Using the logistic regression technique described above, a model is developed that gives estimates for each risk factor and subtype for the patients in the population analyzed. These estimates are used to develop patient-level probabilities for the occurrence of PACs. The patient-level probability estimates are summed to construct aggregated measures (e.g., facility/provider-level). This method is similar to the methods employed by the Centers for Medicare and Medicaid Services (CMS) and endorsed by the National Quality Forum (NQF) to construct similar facility- and practice-level measures (i.e., mortality, readmissions, etc.):

1. For each provider, the number of actual observed occurrences of the outcome is summed across all attributed patients with that episode, to give the observed PAC rates for the provider.
2. Similarly adjusted probabilities from the risk adjustment models are summed across all attributed patients to give expected PACs for the provider.
3. The observed sum is then divided by the summed probabilities (O/E). This number yields whether the provider or facility had more PACs than expected (ratio>1), as expected (ratio=1), or less than expected (ratio<1). This calculation yields a practice-level unstandardized performance ratio.
4. To facilitate accurate comparisons of rates across units of analysis, this ratio is then standardized to the community rate using the indirect method. Specifically, the provider-level rate is multiplied by the expected community rate, calculated as the sum of adjusted probabilities for every individual in the sample across all providers in the analysis. This measure, known as the standardized rate, represents what the unit's risk-adjusted rate would be for the outcome of interest if its patient population was reflective of the of the overall community.

The formula for this calculation is as follows:

$$\text{Adj Outcome\_j} = \{(\text{SUM Observed\_ij})/(\text{SUM Prob\_ij})\} \times \{(\text{SUM Prob\_i}) / (\#\text{ of episodes})\}$$

Where individual is attributed to unit of analysis j (e.g., practice, provider, etc.)

S.19. Calculation Algorithm/Measure Logic Diagram URL or Attachment *(You also may provide a diagram of the Calculation Algorithm/Measure Logic described above at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*

Available in attached appendix at A.1

S.20. Sampling *(If measure is based on a sample, provide instructions for obtaining the sample and guidance on minimum sample size.)*

IF a PRO-PM, identify whether (and how) proxy responses are allowed.

Not applicable

S.21. Survey/Patient-reported data *(If measure is based on a survey, provide instructions for conducting the survey and guidance on minimum response rate.)*

IF a PRO-PM, specify calculation of response rates to be reported with performance measure results.

Not applicable

S.22. **Missing data** (specify how missing data are handled, e.g., imputation, delete case.)
Required for Composites and PRO-PMs.
If data is missing, the case is deleted from both the numerator and the denominator

S.23. **Data Source** *(Check ONLY the sources for which the measure is SPECIFIED AND TESTED).*
If other, please describe in S.24.
Administrative claims

S.24. **Data Source or Collection Instrument** *(Identify the specific data source/data collection instrument e.g. name of database, clinical registry, collection instrument, etc.)*
IF a PRO-PM, identify the specific PROM(s); and standard methods, modes, and languages of administration.
The information is based on a two-year claims database from a large regional commercial insurer. The database has over 3.2 million covered lives and $25.9 billion in "allowed amounts" for claims costs. The database is an administrative claims database with medical as well as pharmacy claims.

The methodology can be used on any claims database with at least two years of data and a minimum of 150 patients with the index condition or hospitalization. Having pharmacy data adds to the richness of the risk-adjustment models.
The calculations of rates of potentially avoidable complications can be replicated by anyone that uses the measure specifications along with the metadata file that is available for free on our web site at http://www.hci3.org/ecre/xml-agreement.html.
We also plan on providing a limited automated analysis, at no cost, on our website.
The methodology has been tested on databases of several health plans as well as on a few employer databases.

No data collection instrument was used.

S.25. **Data Source or Collection Instrument** *(available at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
No data collection instrument provided

S.26. **Level of Analysis** *(Check ONLY the levels of analysis for which the measure is SPECIFIED AND TESTED)*
Clinician : Group/Practice, Clinician : Team, Facility, Health Plan, Population : National, Population : Regional, Population : State

S.27. **Care Setting** *(Check ONLY the settings for which the measure is SPECIFIED AND TESTED)*
Ambulatory Care : Ambulatory Surgery Center (ASC), Hospital/Acute Care Facility, Other
If other: Across the care continuum

S.28. **COMPOSITE Performance Measure** - Additional Specifications *(Use this section as needed for aggregation and weighting rules, or calculation of individual performance measures if not individually endorsed.)*

2a. Reliability – See attached Measure Testing Submission Form
2b. Validity – See attached Measure Testing Submission Form
2751_PCI_Testing_Reliability_Validity_HCI3.docx

NATIONAL QUALITY FORUM—Composite Measure Testing (subcriteria 2a2, 2b2-2b7, 2d)

Composite Measure Number: 2751
Measure Title: Proportion of Patients undergoing an Angioplasty (Percutaneous Coronary Intervention - PCI) Procedure that have a Potentially Avoidable Complication (during the episode time window)
Date of Submission: 06/30/15
Composite Construction:
☐Two or more individual performance measure scores combined into one score
☐ All-or-none measures (e.g., all essential care processes received or outcomes experienced by each patient)

☐ Any-or-none measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient)

Instructions

- Measures must be tested for all the data sources and levels of analyses that are specified. ***If there is more than one set of data specifications or more than one level of analysis, contact NQF staff*** about how to present all the testing information in one form.
- **For all measures, sections 1, 2a2, 2b2, 2b3, and 2b5 must be completed.**
- **For outcome and resource use measures**, section **2b4** also must be completed.
- If specified for **multiple data sources/sets of specificaitons** (e.g., claims and EHRs), section **2b6** also must be completed.
- Respond to all questions as instructed with answers immediately following the question. All information on testing to demonstrate meeting the subcriteria for reliability (2a2) and validity (2b2-2b6) must be in this form. An appendix for *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 20 pages (*incuding questions/instructions;* minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the testing results for this measure meet NQF's evaluation criteria for testing.

2a2. Reliability testing [10] demonstrates the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise. For **PRO-PMs and composite performance measures**, reliability should be demonstrated for the computed performance score.

2b2. Validity testing [11] demonstrates that the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality. For **PRO-PMs and composite performance measures**, validity should be demonstrated for the computed performance score.

2b3. Exclusions are supported by the clinical evidence; otherwise, they are supported by evidence of sufficient frequency of occurrence so that results are distorted without the exclusion; [12]

AND

If patient preference (e.g., informed decisionmaking) is a basis for exclusion, there must be evidence that the exclusion impacts performance on the measure; in such cases, the measure must be specified so that the information about patient preference and the effect on the measure is transparent (e.g., numerator category computed separately, denominator exclusion category computed separately). [13]

2b4. For outcome measures and other measures when indicated (e.g., resource use):

- **an evidence-based risk-adjustment strategy** (e.g., risk models, risk stratification) is specified; is based on patient factors that influence the measured outcome (but not factors related to disparities in care or the quality of care) and are present at start of care; [14,15] and has demonstrated adequate discrimination and calibration

OR

- rationale/data support no risk adjustment/ stratification.

2b5. Data analysis of computed measure scores demonstrates that methods for scoring and analysis of the specified measure allow for **identification of statistically significant and practically/clinically meaningful** [16] **differences in performance**;
OR
there is evidence of overall less-than-optimal performance.

2b6. If multiple data sources/methods are specified, there is demonstration they produce comparable results.

2b7. For **eMeasures, composites, and PRO-PMs** (or other measures susceptible to missing data), analyses identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias.

Notes
10. Reliability testing applies to both the data elements and computed measure score. Examples of reliability testing for data elements include, but are not limited to: inter-rater/abstractor or intra-rater/abstractor studies; internal consistency for multi-item scales; test-retest for survey items. Reliability testing of the measure score addresses precision of measurement (e.g., signal-to-noise).
11. Validity testing applies to both the data elements and computed measure score. Validity testing of data elements typically analyzes agreement with another authoritative source of the same information. Examples of validity testing of the measure score include, but are not limited to: testing hypotheses that the measures scores indicate quality of care, e.g., measure scores are different for groups known to have differences in quality assessed by another valid quality measure or method; correlation of measure scores with another valid indicator of quality for the specific topic; or relationship to conceptually related measures (e.g., scores on process measures to scores on outcome measures). Face validity of the measure score as a quality indicator may be adequate if accomplished through a systematic and transparent process, by identified experts, and explicitly addresses whether performance scores resulting from the measure as specified can be used to distinguish good from poor quality.
12. Examples of evidence that an exclusion distorts measure results include, but are not limited to: frequency of occurrence, variability of exclusions across providers, and sensitivity analyses with and without the exclusion.
13. Patient preference is not a clinical exception to eligibility and can be influenced by provider interventions.
14. Risk factors that influence outcomes should not be specified as exclusions.
15. Risk models should not obscure disparities in care for populations by including factors that are associated with differences/inequalities in care, such as race, socioeconomic status, or gender (e.g., poorer treatment outcomes of African American men with prostate cancer or inequalities in treatment for CVD risk factors between men and women). It is preferable to stratify measures by race and socioeconomic status rather than to adjust out the differences.
16. With large enough sample sizes, small differences that are statistically significant may or may not be practically or clinically meaningful. The substantive question may be, for example, whether a statistically significant difference of one percentage point in the percentage of patients who received smoking cessation counseling (e.g., 74 percent v. 75 percent) is clinically meaningful; or whether a statistically significant difference of $25 in cost for an episode of care (e.g., $5,000 v. $5,025) is practically meaningful. Measures with overall less-than-optimal performance may not demonstrate much variability across providers.

1. DATA/SAMPLE USED FOR ALL TESTING OF THIS MEASURE

Often the same data are used for all aspects of measure testing. In an effort to eliminate duplication, the first five questions apply to all measure testing. If there are differences by aspect of testing,(e.g., reliability vs. validity) be sure to indicate the specific differences in question 1.7.

1.1. What type of data was used for testing? (*Check all the sources of data identified in the measure specifications and data used for testing the measure. Testing must be provided for all the sources of data specified and intended for measure implementation.* ***If different data sources are used for the numerator and denominator, indicate N [numerator] or D [denominator] after the checkbox.***)

Measure Specified to Use Data From: (*must be consistent with data sources entered in S.23*)	**Measure Tested with Data From:**
☐ abstracted from paper record	☐ abstracted from paper record
☐ administrative claims	☐ administrative claims
☐ clinical database/registry	☐ clinical database/registry
☐ abstracted from electronic health record	☐ abstracted from electronic health record
☐ eMeasure (HQMF) implemented in EHRs	☐ eMeasure (HQMF) implemented in EHRs
☐ other: Click here to describe	☐ other: Click here to describe

1.2. If an existing dataset was used, identify the specific dataset (*the dataset used for testing must be consistent with the measure specifications for target population and healthcare entities being measured; e.g., Medicare Part A claims, Medicaid claims, other commercial insurance, nursing home MDS, home health OASIS, clinical registry*).

The information is based on a two-year administrative claims database from a large regional commercial insurer. The database contains medical and pharmacy claims on over 3.2 million covered lives and more than $25.9 billion in "allowed amounts" for costs.

1.3. What are the dates of the data used in testing? April 1, 2012 – December 17, 2014

1.4. What levels of analysis were tested? (*testing must be provided for all the levels specified and intended for measure implementation, e.g., individual clinician, hospital, health plan*)

Measure Specified to Measure Performance of: (*must be consistent with levels entered in item S.26*)	**Measure Tested at Level of:**
☐ individual clinician	☐ individual clinician
☐ group/practice	☐ group/practice
☐ hospital/facility/agency	☐ hospital/facility/agency
☐ health plan	☐ health plan
☐ other: Clinician: Team, Pop: Nat, Reg, State	☐ other:

1.5. How many and which measured entities were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of measured entities included in the analysis (e.g., size, location, type); if a sample was used, describe how entities were selected for inclusion in the sample*)

There were a total of 565 facilities in the data set. Because providers or facilities with small volumes may provide unreliable estimates, we excluded any with fewer than 10 attributed episodes prior to the reliability calculations. After this exclusion, there were 41 facilities left.

1.6. How many and which <u>patients</u> were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of patients included in the analysis (e.g., age, sex, race, diagnosis); if a sample was used, describe how patients were selected for inclusion in the sample*)

After exclusions (see 2b.3.1 below), there were a total of 5,898 episodes of PCI were included in the testing and analysis. Patients in these episodes were, on average, 55.6 years of age (range 26-64) and 31% were female. We did not have race information on these patients. All patients for this analysis had a trigger inpatient claim of PCI as identified in our code tables.

1.7. If there are differences in the data or sample used for different aspects of testing (e.g., reliability, validity, exclusions, risk adjustment), identify how the data or sample are different for each aspect of testing reported below.

For the reliability analysis, we restricted the data to only facilities with at least 10 attributed episodes. For risk adjustment, all episodes were used in the analysis, regardless of the facility to which they were attributed.

1.8 What were the patient-level sociodemographic (SDS) variables that were available and analyzed in the data or sample used? For example, patient-reported data (e.g., income, education, language), proxy variables when SDS data are not collected from each patient (e.g. census tract), or patient community characteristics (e.g. percent vacant housing, crime rate).
None of the analyses included SDS variables.

2a2. RELIABILITY TESTING
***<u>Note</u>**: If accuracy/correctness (validity) of data elements was empirically tested, separate reliability testing of data elements is not required – in 2a2.1 check critical data elements; in 2a2.2 enter "see section 2b2 for validity testing of data elements"; and skip 2a2.3 and 2a2.4.*

2a2.1. What level of reliability testing was conducted? (*may be one or both levels*)
☐ **Critical data elements used in the measure** (*e.g., inter-abstractor reliability; data element reliability must address ALL critical data elements*)
☐ **Performance measure score** (e.g., *signal-to-noise analysis*)

2a2.2. For each level checked above, describe the method of reliability testing and what it tests (*describe the steps—do not just name a method; what type of error does it test; what statistical analysis was used*)

We assessed the reliability of the measure to demonstrate that it sufficiently differentiates performance between providers using the beta-binomial method, which is applicable to measures of this type. Reliability is a measure that distinguishes the signal (the extent of performance variation between entities that is due to true differences in performance) from statistical noise. Our approach follows directly from the methods outlined in the technical report "The Reliability of Provider Profiling: A Tutorial" by J.L. Adams.

<u>Reference</u>:

Adams JL. The Reliability of Provider Profiling: A Tutorial. Rand Corporation. http://www.rand.org/pubs/technical_reports/TR653.html.

2a2.3. For each level of testing checked above, what were the statistical results from reliability testing? (e.*g., percent agreement and kappa for the critical data elements; distribution of reliability statistics from a*

signal-to-noise analysis)

The table below provides a summary of the reliability score for different minimum sample size thresholds. For complete results, refer to the workbook entitled, NQF_PCI_all_codes_risk_adjustment_06.30.15.xls, under the "Provider Attribution" tab to see facility-specific results.

Reliability Scores	Minimum # Episodes Per Facility	
	>=10	>=175
# of Facilities (%)	41 (100)	8 (20)
Median (IQR)	0.51 (0.26,0.62)	0.74 (0.70,0.83)
Range	0.11-0.85	0.69-0.85

2a2.4 What is your interpretation of the results in terms of demonstrating reliability? (i*.e., what do the results mean and what are the norms for the test conducted?*)

Reliability scores can vary from 0.0 to 1.0, with a score of zero indicating that all variation is attributable to measurement error (noise, or variation across patients within providers) whereas a reliability of 1.0 implies that all variation is caused by real difference in performance across accountable entities.

There is not a clear cut-off for minimum reliability level. Values above 0.7, however, are considered sufficient to see differences between some physicians and the mean, and values above 0.9 are considered sufficient to see differences between pairs of physicians (see Adams, 2009 cited above).

Scores among facilities with at least 10 episodes and scores for many were low. However, scores were consistently high among facilities with around 175 or more episodes. These results suggest that the measure achieves sufficient differentiation in performance among high volume facilities.

Minimum sample size requirements for PAC measures are a function of the reliability testing of the measures on every dataset on which the measures are applied. Our research suggests that minimum sample sizes to achieve high degrees of reliability in the measures are a function of the dataset analyzed, and as such may vary from dataset to dataset. One should not infer that a minimum sample size achieved in one dataset would apply to another.

2b2. VALIDITY TESTING

2b2.1. What level of validity testing was conducted? (*may be one or both levels*)

☐ **Critical data elements** (*data element validity must address ALL critical data elements*)

☐ **Performance measure score**

☐ **Empirical validity testing**

☐ **Systematic assessment of face validity of performance measure score as an indicator** of quality or resource use (*i.e., is an accurate reflection of performance on quality or resource use and can distinguish good from poor performance*)

2b2.2. For each level of testing checked above, describe the method of validity testing and what it tests (*describe the steps—do not just name a method; what was tested, e.g., accuracy of data elements compared to*

authoritative source, relationship to another measure as expected; what statistical analysis was used)

Content validity was built into the development of the definitions of potentially avoidable complications (PACs). This involved working with clinicians who are experts in their respective fields and specific to the episodes for which PACs are being measured. In particular, the clinical experts focused on whether or not a potentially avoidable complication can be deemed as such for a specific episode of care, and help defined and review all of the diagnosis and procedure codes for each PAC. The enclosed link lists clinicians who have participated in the various Clinical Working Groups (http://www.hci3.org/content/clinical-working-group-contributors). Some of the clinical experts have also participated in monthly webinars that highlight the clinical aspects of these measures (http://www.hci3.org/content/using-ecrs-providers).

In addition, we illustrate that our measure has face validity in several ways.

Beyond the up front work performed by clinical experts, the validity of the measure has also been tested in various real world settings. For example, we have presented results of claims data analyses that reveal the frequency and costs of PACs to physicians in several different healthcare systems involved in our pilot site implementations, as well as to medical directors from the employer coalitions and the health plans that provided the dataset to run the analyses. Some of these implementations include the Pennsylvania Employee Benefits Trust Fund and local provider groups and hospital, Horizon Blue Cross Blue Shield of NJ and many physicians and health systems.

In addition, we have performed dozens of analyses of very large claims data sets and reported results of rates and costs of PACs to policy makers, health plan leaders and physician leaders from different states. These include:

- Vermont Payment Reform Commission
- Maine Health Management Coalition
- WellPoint / Anthem CT
- NY State Medicaid
- CT Medicaid
- CO All-payer Claims Database, Center for Improving Value in Health Care

These analyses and their results have influenced, and continue to influence, the development of various public reporting, payment reform and delivery system reform efforts. To-date, we have never experienced either wholesale or partial rejection of the results of analyses showing rates of PACs, which demonstrates the level of acceptability – face validity – of the measures from the payer, policymaker, employer and payer communities.

As importantly, measures of potentially avoidable complications have face-validity with consumers. In a series of focus groups, Judy Hibbard and colleagues[1] examined the impact of presenting information about price and quality of certain providers in influencing the decisions of consumers. They tested the validity of PACs as a discriminator of quality, as well as other measures of quality, and used the dollar symbol to illustrate the level of price, much like is done for restaurant reviews. When the PAC measure was used, respondents selected the providers with the lowest PAC rates with a high level of confidence in choice, and used it as a surrogate for a strong quality signal. To the contrary, when more standard measures of quality were used, consumers tended to ignore them and use price as a surrogate for quality. As such, what the researchers found is that the very framing of potentially avoidable complications as an indicator of potential harm, is an effective way of communicating the quality of care. And when measures of PACs were presented in conjunction with price, consumers intuitively accepted the logical relationship between low PACs – fewer “defects” – and lower price.

Finally, our measure definitions encompass several other measures that are accepted as being valid

complications of care and are widely used throughout the country. These include CMS defined Hospital Acquired Conditions (HACs)[2], Hospital Inpatient Quality Reporting measures [3], Avoidable Readmissions [4,5], AHRQ defined patient safety indicators (PSIs) [6], NQF endorsed patient safety measures such as patient fall rates, pressure ulcer rates, and peri-operative pulmonary embolism or deep vein thrombosis rates [7].

2b2.3. What were the statistical results from validity testing? (*e.g., correlation; t-test*)
Not applicable.

2b2.4. What is your interpretation of the results in terms of demonstrating validity? (i.*e., what do the results mean and what are the norms for the test conducted?*)

Given the significant clinical input that went into developing the measure, the widespread use and acceptance the measure has gained among a wide variety of individuals and organizations across the health system (public and private payers, clinicians, consultants, patients, etc.) [1-13], and the parallels between this measure and other measures that are in widespread use, this demonstrates that the measure has strong face validity.

2b3. EXCLUSIONS ANALYSIS

NA ☐ no exclusions — *skip to section 2b4*

2b3.1. Describe the method of testing exclusions and what it tests (*describe the steps—do not just name a method; what was tested, e.g., whether exclusions affect overall performance scores; what statistical analysis was used*)

No formal exclusion testing was done since no real exclusions were done. The only patients excluded were the ones that had incomplete or missing data and those that would not have given a homogenous population such as outliers.

Exclusions included exclusions of "patients" as well as "claims" not relevant to PCI care. Please refer to the enclosed excel workbook entitled (NQF_PCI_all_codes_risk_adjustment_06.30.15.xls)

1. "Patients" are excluded from the measure if they meet one of the following criteria:
   a. If age is < 18 years
   b. If gender is missing
   c. If they do not have continuous enrollment for the entire time window with a maximum of 30 day enrollment gap with the entity providing the data (this helps determine if the database has captured most of the claims for the patient in the time window).
   d. If the episode time window extends beyond the dataset end date (this helps eliminate incomplete episodes).
   e. The episode cost is an outlier (less than 1st percentile or greater than 99th percentile value for all episodes of the same type). This eliminates extreme variation that may result from random outlier events.
2. "Claims" are excluded from the measure based on the following criteria:
   a. If none of the diagnosis codes on the claim are on the list of relevant diagnosis codes (either typical Dx or PAC Dx) for PCI.
   b. If none of the procedure / CPT codes on the claim are on the list of relevant procedure codes for PCI.

2b3.2. What were the statistical results from testing exclusions? (*include overall number and percentage of individuals excluded, frequency distribution of exclusions across measured entities, and impact on performance measure scores*)

We started with a total PCI population of 10,177 episodes. After all the exclusions were applied, the remaining PCI population included in the analysis consisted of 5,898 episodes. As mentioned above, no real exclusions were done. The only patients excluded were the ones that had incomplete or missing data and those that would not have given a homogenous population such as outliers. As such, no formal exclusion testing was done.

2b3.3. What is your interpretation of the results in terms of demonstrating that exclusions are needed to prevent unfair distortion of performance results? (*i.e., the value outweighs the burden of increased data collection and analysis. Note: **If patient preference is an exclusion**, the measure must be specified so that the effect on the performance score is transparent, e.g., scores with and without exclusion*)

No formal analysis was done on the impact of exclusions on performance scores.

Descriptive Explanation:

Exclusions of patients were for the following reasons. Some are for comparative purposes and some for medical reasons.

(a) Comparative Purposes:
We excluded patients that did not have complete enrollment for the entire episode time window. This was done to ensure that the database had complete information on patients to be able to create the entire episode. Including patients with only a partial episode window could distort the measure by artificially reducing the actual count of patients with PACs.

(b) Medical Reasons:
Patients with outlier costs (less than 1st percentile value or greater than 99th percentile) were considered to be different from the general pool, and excluded from both the numerator and the denominator. This is another way to ensure that episodes are complete (because incomplete episodes may have very low costs), and do not bring in random noise into the analysis due to inappropriate codes or services (high outliers).

_____

2b4. RISK ADJUSTMENT/STRATIFICATION FOR OUTCOME OR RESOURCE USE MEASURES
If not an intermediate or health outcome, or PRO-PM, or resource use measure, skip to section 2b5.

2b4.1./S13 What method of controlling for differences in case mix is used?
☐ **No risk adjustment or stratification**
☐ **Statistical risk model with 170 potential risk factors** and episode specific subtypes
☐ **Stratification by** Click here to enter number of categories **risk categories**
☐ **Other,** Click here to enter description

2b4.1.2. If an outcome or resource use measure is <u>not risk adjusted or stratified</u>, provide <u>rationale and analyses</u> to demonstrate that controlling for differences in patient characteristics (case mix) is not needed to achieve fair comparisons across measured entities.

2b4.2/S14. Identify the statistical risk model variables (Name the statistical method – e.g., logistic regression and list all the risk factor variables.
A number of patient-related "risk factors" or covariates are included in the models:

Patient demographics: age, gender, and an indicator of whether a member has enrolled within the previous 6 months. This latter risk factor is intended to account for the patient's lack of claims history, which limits the number of potential comorbidities that can be identified.

Comorbidities: These are conditions or events that occurred prior to the start of the episode that can have a potential impact on the patient's risk of having a PAC. The risk factors are 170 disease indicators (0/1) identified through the presence of ICD diagnosis codes on individual medical claims and collected from the historical claims data before the start of an episode. These are universally applied across all episodes. Please see the tab labeled "All Risk Factors I-9" and "All Risk Factors I-10" for a list of risk factors and their corresponding codes in the enclosed workbook called NQF_PCI_all_codes_risk_adjustment_06.30.15.xls. This list was selected based on input from clinical experts in clinical working groups.

Episode Subtypes or Severity Markers: These are markers that distinguish an episode as being more severe than another. They indicate either specific patient comorbidities that are known to make the procedure or condition more difficult to treat (e.g., obesity) or severity of the illness itself (e.g., unstable angina). Subtypes are specific to each unique episode and are included in the models only if they are present at the start of the episode. Please see the tab labeled "Subtypes I-9" and "Subtypes I-10" for a list of subtypes and their

corresponding codes in the enclosed workbook called NQF_PCI_all_codes_risk_adjustment_06.30.15.xls. This list was selected based on input from clinical experts in clinical working groups.

Candidate comorbidities and subtypes were included in the models as covariates if they were present in at least 10 episodes to prevent unstable coefficients.

2b4.2.1/S15. Detailed risk model specifications including coefficients, equations, codes with descriptors, definitions(may be attached in an Excel or cvs file)
All Risk Factors with their coefficients are detailed in the enclosed workbook called
All Risk Factors with their coefficients are detailed in the enclosed workbook called NQF_PCI_all_codes_risk_adjustment_06.30.15.xls – Please reference the tabs titled Risk Factor Prevalence and Risk Model.

2b4.3. Describe the conceptual/clinical <u>and</u> statistical methods and criteria used to select patient factors (clinical factors or sociodemographic factors) used in the statistical risk model or for stratification by risk(*e.g., potential factors identified in the literature and/or expert panel; regression analysis; statistical significance of p<0.10; correlation of x or higher; patient factors should be present at the start of care*)

Risk factors are comorbidity indicators collected from historical claims before the start of an episode. These are universally applied across all episodes. This list was selected based on input from clinical experts in clinical working groups. In addition, the Clinical Working Groups identified episode specific severity markers that were called episode subtypes and they help distinguish an episode as being more severe than another.

All risk factors and subtypes must be present prior to, or at the start of the episode and are identified using diagnosis codes in the patient's historical claims.

To be included in the risk adjustment models, any risk factor or subtype must be present in at least 10 episodes. Beyond this no further model building was conducted to add or remove risk factors or subtypes from the model after it was initially run. This reflects a desire to explain as much variation in the probability of having a PAC as possible, but does not make it a priority that all covariates be individually significant or even uncorrelated with each other. Accordingly, the model uses a very large group of covariates. This modeling approach allows for fewer potentially artificial constraints around the definitions of what constitutes severity, and lets the model determine for itself which of the factors are more significant. Non-significant covariates cannot overly influence the predicted outcomes, nor is much harm realized, if a group of correlated covariates work together to explain variation rather than having the variation explained by a single best factor.

2b4.4a. What were the statistical results of the analyses used to select risk factors?
As explained above, no formal analysis was conducted to select risk factors. In fact, all potential risk factors and subtypes with a count of at least 10 episodes were retained to serve as predictors. The goal was to achieve a more complete explanatory model rather than achieve parsimony.

Please reference the tabs titled Risk Model in the NQF_PCI_all_codes_risk_adjustment_06.30.15.xls workbook to see the list of risk factors that met the selection criteria.

2b4.4b. Describe the analyses and interpretation resulting in the decision to select SDS factors (e.g. prevalence of the factor across measured entities, empirical association with the outcome, contribution of unique variation in the outcome, assessment of between-unit effects and within-unit effects)

Not Applicable since our analysis did include SDS variables

2b4.5. Describe the method of testing/analysis used to develop and validate the adequacy of the statistical model or stratification approach (*describe the steps—do not just name a method; what statistical analysis was used*)

Model Development Approach

We used logistic regression to model the probability of at least one PAC occurring during the episode. The model included all covariates that were identified through the process above. No further model building was conducted after the initial model was run. This reflects a desire to explain as much variation in the probability of having a PAC as possible, but does not make it a priority that all covariates be individually significant or even uncorrelated with each other. Accordingly, the model uses a very large group of covariates. This modeling approach allows for fewer potentially artificial constraints around the definitions of what constitutes severity, and lets the model determine for itself which of the factors are more significant. Non-significant covariates can not overly influence the predicted outcomes, nor is much harm realized, if a group of correlated covariates work together to explain variation rather than having the variation explained by a single best factor.

For a more complete description of the risk adjustment approach, please see the document entitled, "PACs and Severity Adjustment Fact Sheet" that accompanies this submission.

Approach to Model Testing and Validation

To determine the validity and performance of the model, we used the split sample method to divide the patient sample randomly into: 1) the model building data set (80% of the sample) and 2) the test data set (20% of sample. The model was built using logistic regression on the first data set and then the coefficients from the development model were tested in the second dataset. Area under the curve (AUC) and the c-statistic were used to compare the predictive ability of the model in each of the data sets. Hosmer-Lemeshow Goodness-of-Fit tests and comparisons of observed to expected probabilities across risk deciles were further examined to assess the model's overall predictive accuracy.

Provide the statistical results from testing the approach to controlling for differences in patient characteristics (case mix) below.
If stratified, skip to 2b4.9

2b4.6. Statistical Risk Model Discrimination Statistics (*e.g., c-statistic, R-squared*)**:**

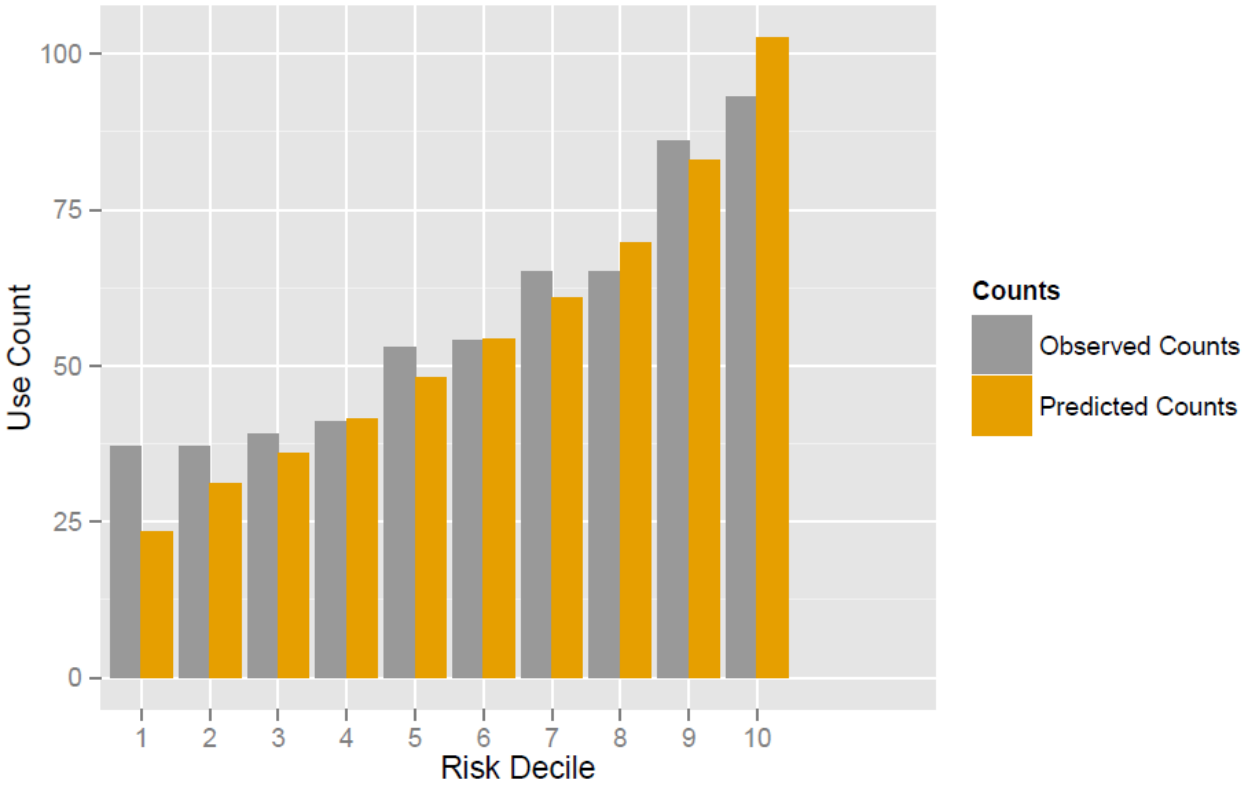
Sample	Accuracy (%)*	AUC
Test	65.9%	0.726
Validation	64.0%	0.680

*Episodes with predicted probabilities <50% were classified as having a predicted 0 (not having a PAC). Episodes with predicted probabilities >50% were classified as having a predicted 1 (having a PAC)

2b4.7. Statistical Risk Model Calibration Statistics (*e.g., Hosmer-Lemeshow statistic*):

Sample	Chi Square	Degrees of Freedom	p-value
Test	9.7	8	0.2826
Validation	20.9	8	0.0074

2b4.8. Statistical Risk Model Calibration – Risk decile plots or calibration curves:



2b4.9. Results of Risk Stratification Analysis:
Not applicable

2b4.10. What is your interpretation of the results in terms of demonstrating adequacy of controlling for differences in patient characteristics (case mix)? (i.*e., what do the results mean and what are the norms for the test conducted*)

The C statistic is a measure of the extent to which a statistical model is able to discriminate between a patient with and without an outcome. The c-statistic ranges from 0.5 to 1.0. A c-statistic of 0.50 indicates the model is no better than random prediction, implying that the patient risk factors do not predict variation in the outcome; conversely, a c-statistic of 1.0 indicates perfect prediction, implying patients' outcomes can be predicted completely by their risk factors, and physicians and hospitals play little role in patients' outcomes. Models with c-statistic values of at least 0.7 are considered good and those above 0.8 are considered strong [1]. The purpose of the model is to adjust for patient-related factors. The remaining unexplained differences in PAC rates are due to factors that could be controlled by all providers that are managing or co-managing the patient, during the entire episode time window.

The results above indicate that the C-statistics for the risk model on the testing and validation samples (0.726 and 0.680, respectively) were around the level at which the model is considered to have good discriminatory power. Also, the accuracy values show that the model correctly predicts whether an episode had or did not have a PAC nearly 65% of the time, well above what would be expected if the predictions were made at random (i.e., 50%). The H-L test was not significant for the testing sample, meaning that the model was a good fit for the data. Finally, with the exception of the first decile, the risk decile plot shows that the model predicts PACs similarly to observed PACs across each of the other deciles.

Overall, the results demonstrate that the model has sufficient predictive power.

_____

2b5. IDENTIFICATION OF STATISTICALLY SIGNIFICANT & MEANINGFUL DIFFERENCES IN PERFORMANCE

2b5.1. Describe the method for determining if statistically significant and clinically/practically meaningful differences in performance measure scores among the measured entities can be identified (*describe the steps—do not just name a method; what statistical analysis was used? Do not just repeat the information provided related to performance gap in 1b)*

To directly compare PAC rates across providers or facilities while also appropriately accounting for differences in patient severity, we calculated a risk-standardized PAC rate for each provider. This method is similar to calculations used by others for reporting outcomes measures [1]. For each provider or facility, the ratio of observed attributed episodes with PACs to the expected number of attributed episodes with PACs given the patient's risk factor and estimated from the risk-adjustment model was calculated. This number yielded whether the provider or facility had more PACs than expected (ratio>1), as expected (ratio=1), or less than expected (ratio<1). We then multiplied this ratio by the overall expected PAC rate across all providers or facilities to obtain the risk-standardized PAC rate for the provider or facility. This measure represents what a facility's PAC rate would be if its patient population was reflective of the overall population.

Because facilities with small volumes may provide unreliable estimates, we excluded any with fewer than 10 attributed episodes prior to the calculations. Comparison of risk-adjusted PAC rates gives a measure of the provider's relative performance. Our analysis compared risk-standardized PAC rates across facilities. We analyzed various descriptive statistics including the range in PAC rates, medians, interquartile range, etc.

References:

[1] See, for example: NQF#1550: Hospital-level risk-standardized complication rate (RSCR) following elective primary total hip arthroplasty (THA) and / or total knee arthroplasty (TKA). Online version: http://bit.ly/1BWQTRt

2b5.2. What were the statistical results from testing the ability to identify statistically significant and/or clinically/practically meaningful differences in performance measure scores across measured entities? (e.g., *number and percentage of entities with scores that were statistically significantly different from mean or some benchmark, different from expected; how was meaningful difference defined*)

Summary of Unadjusted and Adjusted Performance Scores Across Facilities:

PAC Rates	Minimum # Episodes Per Facility

	>=10	>=175
Unadjusted		
Median (IQR)	50% (44%, 56%)	47% (44%, 52%)
Range	32% - 80%	43% - 58%
Adjusted (RSPR)*		
Median (IQR)	49% (44%, 52%)	49% (46%, 52%)
Range	24% - 61%	45% - 56%

***RSPR = Risk Standardized PAC Rate**

Please refer to the NQF_PCMDFR_all_codes_risk_adjustment_06.30.15.xls workbook under the "ProviderAttribution Reliability" tab to see specific results for each facility.

2b5.3. What is your interpretation of the results in terms of demonstrating the ability to identify statistically significant and/or clinically/practically meaningful differences in performance across measured entities? (i*.e., what do the results mean in terms of statistical and meaningful differences?*)
The variation in risk-adjusted rates suggests there are differences in performance between facilities in risk-standardized PAC rates for patients with an episode of PCI.

Minimum sample size requirements for PAC measures are a function of the reliability testing of the measures on every dataset on which the measures are applied. Our research suggests that minimum sample sizes to achieve high degrees of reliability in the measures are a function of the dataset analyzed, and as such may vary from dataset to dataset. One should not infer that a minimum sample size achieved in one dataset would apply to another.

2b6. COMPARABILITY OF PERFORMANCE SCORES WHEN MORE THAN ONE SET OF SPECIFICATIONS
***If only one set of specifications, this section can be skipped*.**

Note: *This criterion is directed to measures with more than one set of specifications/instructions (e.g., one set of specifications for how to identify and compute the measure from medical record abstraction and a different set of specifications for claims or eMeasures). It does not apply to measures that use more than one source of data in one set of specifications/instructions (e.g., claims data to identify the denominator and medical record abstraction for the numerator).* ***Comparability is not required when comparing performance scores with and without SDS factors in the risk adjustment model. However, if comparability is not demonstrated for measures with more than one set of specifications/instructions, the different specifications (e.g., for medical records vs. claims) should be submitted as separate measures.***

2b6.1. Describe the method of testing conducted to demonstrate comparability of performance scores for the same entities across the different data sources/specifications (*describe the steps—do not just name a method; what statistical analysis was used*)

2b6.2. What were the statistical results from testing comparability of performance scores for the same entities when using different data sources/specifications? (*e.g., correlation, rank order*)

2b6.3. What is your interpretation of the results in terms of demonstrating comparability of performance measure scores for the same entities across the different data sources/specifications? (i.*e., what do the results mean and what are the norms for the test conducted*)

2b7. MISSING DATA ANALYSIS AND MINIMIZING BIAS

2b7.1. Describe the method of testing conducted to identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias (*describe the steps—do not just name a method; what statistical analysis was used*)

If patient related data is missing, the entire patient is excluded from the numerator as well as the denominator.

Within our measure constructs, presence of potentially avoidable complications are identified from administrative claims data. Furthermore, the measure is constructed so that the occurrence of any number of PACs during a defined episode would only count as one occurrence.

According to our measure definition, in constructing the measure it is possible for a provider to have only one or some types of PACs and not others. Alternatively, the provider may have all PAC types occur for their patients. The measure only considers whether any PAC occurred regardless of the type, and all PAC types are weighted equally, therefore we believe, there is no potential for the absence of specific PAC types to bias performance scores for individual providers.

For these reasons, no formal analyses were done on missing data.

2b7.2. What is the overall frequency of missing data, the distribution of missing data across providers, and the results from testing related to missing data? (*e.g., results of sensitivity analysis of the effect of various rules for missing data/nonresponse; if no empirical sensitivity analysis, identify the approaches for handling missing data that were considered and pros and cons of each*)
Not applicable

2b7.3. What is your interpretation of the results in terms of demonstrating that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias**?** (i.*e., what do the results mean in terms of supporting the selected approach for missing data and what are the norms for the test conducted; if no empirical analysis, provide rationale for the selected approach for missing data*)

Not applicable

2d. EMPIRICAL ANALYSIS TO SUPPORT COMPOSITE CONSTRUCTION APPROACH
Note: *If empirical analyses do not provide adequate results—or are not conducted—justification must be provided and accepted in order to meet the must-pass criterion of Scientific Acceptability of Measure Properties. Each of the following questions has instructions if there is no empirical analysis.*

2d1. Empirical analysis demonstrating that the component measures fit the quality construct, add value to the overall composite, and achieve the object of parsimony to the extent possible.

The PAC measures, as we define them, look at many "care defects" comprehensively. They are composed of several cross-cutting measures and together they paint a global picture of the provider's overall performance.

PACs may occur any time during the episode time window. PACs are counted as a dichotomous (yes/no) outcome. If a patient had one or more PACs, they get counted as a "yes" or a 1. The enclosed workbook entitled NQF_PCI_all_codes_risk_adjustment_06.30.15.xls provides outputs from empirical analysis. The tab labeled "PAC overview" demonstrates percentage of episodes that had at least one PAC, and provides the breakdown of PACs: 1) by the type of PAC whether directly related to index condition or due to patient safety failures; 2) the setting of the PAC, whether seen in the in-patient setting, out-patient facility or during professional visits; and 3) preventable hospitalizations.

The "PAC Drill Down Graph" provides further detail on each component of the PAC and their frequency. As can be seen by the individual counts and the graph, while each individual PAC may have such small occurrences that no meaningful comparisons in provider performances could be made; together, they add value to provide a comprehensive picture that result in meaningful numbers. The aggregation of PACs to a comprehensive, composite measure, in itself provides the parsimony that is so desirable.

2d1.1 Describe the method used (*describe the steps—do not just name a method; what statistical analysis was used; if no empirical analysis, provide justification)*

All PACs, as clinically defined by the subject matter experts were used with equal weighting. Since the emphasis of the PAC measure is to identify the occurrence of PACs in any setting, a simple and straightforward approach was adopted.

2d1.2. What were the statistical results obtained from the analysis of the components? (e.g., *correlations, contribution of each component to the composite score, etc*.; *if no empirical analysis, identify the components that were considered and the pros and cons of each*)

No formal analysis was performed.

2d1.3. What is your interpretation of the results in terms of demonstrating that the components included in the composite are consistent with the described quality construct and add value to the overall composite? (i.*e., what do the results mean in terms of supporting inclusion of the components; if no empirical analysis, provide rationale for the components that were selected)*

Since our premise is that all PACs are potentially avoidable, we adopted the approach to count all PACs and give them equal weights. The overall composite score results in the quality construct that could be measured and interpreted.

2d2. Empirical analysis demonstrating that the aggregations and weighting rules are consistent with the quality construct and achieve the objective of simplicity to the extent possible

2d2.1 Describe the method used (*describe the steps—do not just name a method; what statistical analysis was used; if no empirical analysis, provide justification)*

Within our measure constructs, presence of potentially avoidable complications are identified from administrative claims data. Additionally, if a patient had one or more PACs, it is simply counted as a 1, i.e., flagged as having a PAC. The measure only considers whether any PAC occurred regardless of the type, or the site, and all PAC types are weighted equally. Therefore, no formal analysis of individual components was performed.

2d2.2. What were the statistical results obtained from the analysis of the aggregation and weighting rules? (e.g., *results of sensitivity analysis of effect of different aggregations and/or weighting rules; if no*

empirical analysis, identify the aggregation and weighting rules that were considered and the pros and cons of each)

We chose not to weight the components of the measure.

Considerations were given to the fact that preventable hospitalizations may be given more weight, than PACs identified in a doctor's office. Similarly PACs in an in-patient setting may have more serious implications on a patient's ultimate outcome, than PACs occurring in an outpatient setting. Additionally, preventable hospitalizations as well as index hospitalizations, each with longer lengths of stay, may have serious PACs. But how do we weigh these effects? An alternative model was considered, where cost could be considered as a surrogate for the weights. Higher cost PACs could imply more serious PACs. However, differences in costs could be driven by many issues other than the PAC itself, such as unit price of the service, method of reimbursements, contracting arrangements etc.

Furthermore, in-patient facility billing does not allow for the distinction of PAC related costs from other costs within the stay. We would fail to capture PAC related costs within the stay and potentially underweight those. As a result, the decision was made to avoid weighting and keep the measure as a straightforward count.

2d2.3. What is your interpretation of the results in terms of demonstrating the aggregation and weighting rules are consistent with the described quality construct? (i.*e., what do the results mean in terms of supporting the selected rules for aggregation and weighting; if no empirical analysis, provide rationale for the selected rules for aggregation and weighting*)

Measuring all providers with the same yardstick will provide consistent results and reasonable comparisons over time. If the goal is to reduce PACs, then the PAC measure as was constructed with the help of various experts in the field would provide reasonable comparisons. A word of caution however pertains to the sample size of the provider panel before making any reasonable conclusions.

Minimum sample size requirements for PAC measures are a function of the reliability testing of the measures on every dataset on which the measures are applied. Our research suggests that minimum sample sizes to achieve high degrees of reliability in the measures are a function of the dataset analyzed, and as such may vary from dataset to dataset. One should not infer that a minimum sample size achieved for high reliability in one dataset would apply to another.

2d3. Empirical analysis demonstrating that the approach for handling missing data minimizes bias (*i.e., achieves scores that are an accurate reflection of quality*)**.**

Note: *Applies to the overall composite measure; the focus is on missing data rather than exclusions, which are considered in 2b3.*

Please refer to section 2b7

2d3.1. What is the overall frequency of missing data and the distribution of missing data across providers?

2d3.2. Describe the method used to compare approaches for handling missing data (*describe the steps—do not just name a method; what statistical analysis was used; if no empirical analysis, provide justification)*

2d3.3. What were the statistical results obtained from the analysis of missing data? (e.g., *results of sensitivity analysis of effect of various rules for missing data; if no empirical analysis, identify the approaches for handling missing data that were considered and pros and cons of each*)

2d3.4. What is your interpretation of the results in terms of demonstrating that the approach used for missing data minimizes bias? (i.*e., what do the results mean in terms of supporting the selected approach for missing data; if no empirical analysis, provide rationale for the selected approach for missing data*)

3. Feasibility

Extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

3a. Byproduct of Care Processes

For clinical measures, the required data elements are routinely generated and used during care delivery (e.g., blood pressure, lab test, diagnosis, medication order).

3a.1. **Data Elements Generated as Byproduct of Care Processes.**

Coded by someone other than person obtaining original information (e.g., DRG, ICD-9 codes on claims)

If other:

3b. Electronic Sources

The required data elements are available in electronic health records or other electronic sources. If the required data are not in electronic health records or existing electronic sources, a credible, near-term path to electronic collection is specified.

3b.1. **To what extent are the specified data elements available electronically in defined fields?** *(i.e., data elements that are needed to compute the performance measure score are in defined, computer-readable fields)*

ALL data elements are in defined fields in electronic claims

3b.2. **If ALL the data elements needed to compute the performance measure score are not from electronic sources, specify a credible, near-term path to electronic capture, OR provide a rationale for using other than electronic sources.**

3b.3. **If this is an eMeasure, provide a summary of the feasibility assessment in an attached file or make available at a measure-specific URL.**

Attachment:

3c. Data Collection Strategy

Demonstration that the data collection strategy (e.g., source, timing, frequency, sampling, patient confidentiality, costs associated with fees/licensing of proprietary measures) can be implemented (e.g., already in operational use, or testing demonstrates that it is ready to put into operational use). For eMeasures, a feasibility assessment addresses the data elements and measure logic and demonstrates the eMeasure can be implemented or feasibility concerns can be adequately addressed.

3c.1. **Describe what you have learned/modified as a result of testing and/or operational use of the measure regarding data collection, availability of data, missing data, timing and frequency of data collection, sampling, patient confidentiality, time and cost of data collection, other feasibility/implementation issues.**

IF a PRO-PM, consider implications for both individuals providing PROM data (patients, service recipients, respondents) and those whose performance is being measured.

As part of our general implementation of these measures and related analyses, we have worked through dozens of different and sometimes very large datasets. From Medicare to Medicaid to regional and national commercial carriers, as well as individual employers, the principal lesson learned is the heterogeneity of the data sets and the significant variability in fill rate of critical data elements. As a result, we have created highly specific recommendations for which data elements are required to ensure measure validity, the accuracy of those data elements, and their completeness in the dataset. When claims datasets are organized in the way we specify in the measure analysis, and contain the coding information required, the analysis of the measure and its results are highly reliable.

3c.2. **Describe any fees, licensing, or other requirements to use any aspect of the measure as specified** *(e.g., value/code set, risk model, programming code, algorithm)*.

The calculations of rates of potentially avoidable complications can be replicated by anyone that uses the measure specifications along with the metadata file that is available for free on our web site at http://www.hci3.org/ecre/xml-agreement.html.

We also plan on providing a limited automated analysis, at no cost, on our website.

4. Usability and Use

Extent to which potential audiences (e.g., consumers, purchasers, providers, policy makers) are using or could use performance results for both accountability and performance improvement to achieve the goal of high-quality, efficient healthcare for individuals or populations.

4a. Accountability and Transparency

Performance results are used in at least one accountability application within three years after initial endorsement and are publicly reported within six years after initial endorsement (or the data on performance results are available). If not in use at the time of initial endorsement, then a credible plan for implementation within the specified timeframes is provided.

4.1. Current and Planned Use

NQF-endorsed measures are expected to be used in at least one accountability application within 3 years and publicly reported within 6 years of initial endorsement in addition to performance improvement.

Planned	Current Use (for current use provide URL)
Public Reporting Professional Certification or Recognition Program Quality Improvement with Benchmarking (external benchmarking to multiple organizations)	Payment Program Blue Cross Blue Shield of North Carolina https://www.bcbsnc.com/ Blue Cross Blue Shield of New Jersey http://www.horizonblue.com/ Pennsylvania Employee Benefits Trust Fund https://www.pebtf.org/ Quality Improvement (Internal to the specific organization) Blue Cross Blue Shield of North Carolina https://www.bcbsnc.com/assets/providers/public/pdfs/specialty_methodology.pdf

4a.1. For each CURRENT use, checked above, provide:

- Name of program and sponsor
- Purpose
- Geographic area and number and percentage of accountable entities and patients included

Measures associated to potentially avoidable complications (PACs) are in use today with some private sector payers and gaining further acceptance among a wide variety of organizations across the health system (public and private payers, clinicians, consultants, all-payer claims database stewards, etc.) [1-8]. They are being used in various capacities in different pilot site implementations. To name a few:

•BCBSA (Blue Cross Blue Shield Association) – uses them for their Centers of Excellence (COE) programs: Blue Distinction
•BCBSNC (Blue Cross Blue Shield of North Carolina) – is using them for tiering providers

In addition, the PAC measures are incorporated by the following organizations in their bundled payment programs:

•BCBSSC – for CABG and PCI programs
•Horizon BCBSNJ– for CHF and CABG programs
•BCBSNC
•PEBTF in PA

http://www.ajmc.com/interviews/Lili-Brillstein-on-How-Bundled-Payments-Are-Tranforming-Healthcare

In these programs they look at PACs related to the measure for process improvement activities and for practice re-engineering.

We have created reports for rates of PACs for the following organizations:
-Vermont Payment Reform
-Maine Health Management Coalition
-WellPoint / Anthem CT
-NY State Medicaid
-CT Medicaid
-CO All-payer Claims Database, Center for Improving Value in Health Care

There are several companies that are leveraging these measures to create analytics and software for customers – these include HealthQx, Aver Informatics, McKesson, and TriZetto.

Below are some references that highlight our work with Potentially Avoidable Complications (PACs).

4a.2. If not currently publicly reported OR used in at least one other accountability application (e.g., payment program, certification, licensing) what are the reasons? (*e.g., Do policies or actions of the developer/steward or accountable entities restrict access to performance results or impede implementation?*)
N/A

4a.3. If not currently publicly reported OR used in at least one other accountability application, provide a credible plan for implementation within the expected timeframes -- any accountability application within 3 years and publicly reported within 6 years of initial endorsement. (*Credible plan includes the specific program, purpose, intended audience, and timeline for implementing the measure within the specified timeframes. A plan for accountability applications addresses mechanisms for data aggregation and reporting.*)
Measures associated with PACs are currently in use as described in the prior section. In addition, we are working with several not-for-profit and for-profit organizations to provide them with the algorithms needed to calculate rates of potentially avoidable complications. Some of these organizations include:

Fair Health – based in NY and whose mission is to increase transparency of provider cost and quality,

CastLight – based in CA and serving large employers. We currently provide CastLight with Bridges To Excellence recognitions and will work with them to augment provider transparency by using PAC measures,

MA APCD (Massachusetts All Payers Claims Database) Council – we currently have an agreement in place with the MA APCD Council to produce PAC measures on hospitals and physicians and report back to the council with tests of reliability and validity of the measures. The purpose is to authorize the publication of these measures,

Maryland Health Care Cost Commission – we have a two year agreement to produce measures of cost and quality for public dissemination.

4b. Improvement

Progress toward achieving the goal of high-quality, efficient healthcare for individuals or populations is demonstrated. If not in use for performance improvement at the time of initial endorsement, then a credible rationale describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.

4b.1. **Progress on Improvement. (Not required for initial endorsement unless available.)**
Performance results on this measure (current and over time) should be provided in 1b.2 and 1b.4. Discuss:

- **Progress (trends in performance results, number and percentage of people receiving high-quality healthcare)**
- **Geographic area and number and percentage of accountable entities and patients included**

We do not have any public information to share about the improvements in rates of potentially avoidable complications, as the implementation of these measures is too recent to provide valid comparisons. Further, some of the definitions of PACs have changed since the measures were initially endorsed, making comparisons even more difficult and unreliable.

Nevertheless, the variation in performance scores presented in Section 1b.2 indicates that there are differences between providers in their risk-adjusted PAC rates (higher scores equal worse performance). This suggests that real opportunities exist to identify lower performing providers and reduce the overall occurrence of PACs.

4b.2. **If no improvement was demonstrated, what are the reasons? If not in use for performance improvement at the time of initial endorsement, provide a credible rationale that describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.**
Performance results provide summary PACs rates by provider, which can be used by payers and providers in a number of ways to improve the quality of care.

From the payer perspective, payers can use this information to 1) create a high-value provider networks, 2) work with high-value providers to share best practices, 3) incentivize low-value providers to improve, 4) modify their insurance design to activate consumers to select the right care from the right providers at the right time.

From the provider perspective, providers can 1) view services and activity for their patients longitudinally across the entire care continuum, such as frequency of readmissions and ED visits and drill down on patients with high PAC rates, 2) review actionable drill down reports to identify the most frequent PACs across all patients to create care pathways and process improvement plans to impact the most frequent PACs.

4c. Unintended Consequences

The benefits of the performance measure in facilitating progress toward achieving high-quality, efficient healthcare for individuals or populations outweigh evidence of unintended negative consequences to individuals or populations (if such evidence exists).

4c.1. **Were any unintended negative consequences to individuals or populations identified during testing; OR has evidence of unintended negative consequences to individuals or populations been reported since implementation? If so, identify the negative unintended consequences and describe how benefits outweigh them or actions taken to mitigate them.**
No unintended consequences were reported, but there is the potential for:
1. Under-coding of PACs in the claim stream resulting in under-reporting the actual rate and/or providers gaming the measures
2. Payers calculating the measures even with inadequate sample sizes and using the results to penalize providers

The measure is designed for transparency efforts and to spur quality improvement. Detailed PAC reports can help providers identify areas of quality improvement. Even detailed reports of small samples of patients can be helpful for quality improvement purposes, but not for public reporting. To mitigate the potential for invalid provider comparisons, we specify in this submission the minimum sample size needed to ensure the reliability of a provider's score. Ultimately, there isn't any good way to prevent provider gaming of the measure by under-coding claims, however, under the current DRG payment methodology, many providers would be penalized by under-coding PACs since these codes often result in the assignment of more complicated DRGs.

5. Comparison to Related or Competing Measures

If a measure meets the above criteria and there are endorsed or new related measures (either the same measure focus or the same target population) or competing measures (both the same measure focus and the same target population), the measures are compared to address harmonization and/or selection of the best measure.

5. Relation to Other NQF-endorsed Measures

Are there related measures (conceptually, either same measure focus or target population) or competing measures (conceptually both the same measure focus and same target population)? If yes, list the NQF # and title of all related and/or competing measures.

Yes

5.1a. **List of related or competing measures (selected from NQF-endorsed measures)**

0141 : Patient Fall Rate
0202 : Falls with injury
0337 : Pressure Ulcer Rate (PDI 2)
0450 : Perioperative Pulmonary Embolism or Deep Vein Thrombosis Rate (PSI 12)
0695 : Hospital 30-Day Risk-Standardized Readmission Rates following Percutaneous Coronary Intervention (PCI)
0705 : Proportion of Patients Hospitalized with Stroke that have a Potentially Avoidable Complication (during the Index Stay or in the 30-day Post-Discharge Period)
0708 : Proportion of Patients Hospitalized with Pneumonia that have a Potentially Avoidable Complication (during the Index Stay or in the 30-day Post-Discharge Period)
0709 : Proportion of patients with a chronic condition that have a potentially avoidable complication during a calendar year.
1789 : Hospital-Wide All-Cause Unplanned Readmission Measure (HWR)

5.1b. **If related or competing measures are not NQF endorsed please indicate measure title and steward.**

-0531 Patient Safety for Selected Indicators (Composite Measure, endorsed) (AHRQ)
-CMS defined hospital acquired conditions (HACs) are a subset of our PACs. We have pain-stakingly matched the definitions to provide as much consistency as possible. http://www.cms.gov/Medicare/Quality-Initiatives-Patient-Assessment-Instruments/HospitalQualityInits/HospitalRHQDAPU.html

5a. Harmonization

The measure specifications are harmonized with related measures;
OR
The differences in specifications are justified

5a.1. **If this measure conceptually addresses EITHER the same measure focus OR the same target population as NQF-endorsed measure(s):**
Are the measure specifications completely harmonized?

No

5a.2. **If the measure specifications are not completely harmonized, identify the differences, rationale, and impact on interpretability and data collection burden.**

Some of the measures listed in the prior section are, fully harmonized with the submitted measure, in particular, 0705, 0708, and 0709. Other measures such as 0531, 0450, 0337, 0141, 0202 are in fact, subsets of our measure. However, there are some measures that are not harmonized, in particular the 30-day all-cause readmission measure and the Hospital wide all-cause readmission measure. While the submitted PAC measures include hospitalizations and readmissions that occur during the episode time window, the hospitalizations, by definition, have to be relevant to the index event. PACs include relevant readmissions, and are designed to enable accountability at the locus of provider control as well as some shared accountability between settings, centered around a patient, and for a specific medical episode of care. In that sense, they are consistent with the all-cause 30-day readmission rates, but represent a subset of those admissions. However, they do extend to the entire episode time window. As such, the PAC measures, as submitted, don't create added burden of reporting because the readmissions reported are simply a part of the broader 30-day all-cause readmission measures already endorsed by NQF. Because PAC measures are comprehensive, they include patient safety events that can occur during the stay, as well as adverse events, including readmissions, that can occur post-discharge. As a result, they provide facilities and physicians with an overall measure of avoidable complications for a specific medical episode. The data collection for all of the HCI3 measures is automated by a software package and is fully harmonized with

all other PAC measures. A single download automates creation of all reports related to each of the PAC measures.

5b. Competing Measures

The measure is superior to competing measures (e.g., is a more valid or efficient way to measure);
OR
Multiple measures are justified.

5b.1. **If this measure conceptually addresses both the same measure focus and the same target population as NQF-endorsed measure(s):**
Describe why this measure is superior to competing measures (e.g., a more valid or efficient way to measure quality); OR provide a rationale for the additive value of endorsing an additional measure. (Provide analyses when possible.)
PAC measures are composite measures representing "all-cause harms". They look at many "care defects" comprehensively. They are composed of several cross-cutting measures and together they paint a global picture of the provider's overall performance.

PACs may occur any time during the episode time window. Furthermore, the measure is constructed so that the occurrence of any number of PACs during a defined episode would only count as one occurrence. PACs look at readmissions, emergency room visits, adverse events due to errors of omission or commission. They look at complications that are due to patient safety failures, and also those directly related to the index condition. These are all a cause of significant waste and quality concerns. As such, the measure can provide clinicians with an overall and comprehensive view, in one measure, of all potentially avoidable complications for a patient and drive quality improvement efforts.

For clinicians and facilities increasingly engaged in value-based payment efforts and/or driving quality improvement for population health, the value of a PAC measure over a series of related, but more discrete measures, is that one can better determine if the sources of complications primarily stem from activities within the facility or outside the facility, and the specific nature of the complications that have a higher frequency of occurrence. While individual components of the PAC measure may have small frequencies and may be difficult to interpret with regards to provider performance or actionability, aggregating all the PACs into a comprehensive, composite measure provides the parsimony that is so desirable. For providers, it's far easier to construct a quality dashboard from a parsimonious set of measures, and that's what PAC measures offer.

Further, as a comprehensive outcome measures, PACs are also useful for public transparency of quality, as substantiated by the research from Judy Hibbard and colleagues previously cited in the "testing" section of this submission. As a comprehensive outcome measure, they are easier to explain to the average consumer. From a patient's point of view, any bad outcome has an impact on their health with respect to return to work, functional limitations and need for additional support. If a provider has a high PAC rate with regards to one component PAC but not the other PACs, the impact on the patient is still adverse. In selecting providers, individual component PAC scores would mean nothing to a patient, but aggregating it to a comprehensive quality score could be a measure of "all-cause" harms and easier to interpret and act on.

Appendix

A.1 Supplemental materials may be provided in an appendix. All supplemental materials (such as data collection instrument or methodology reports) should be organized in one file with a table of contents or bookmarks. If material pertains to a specific submission form number, that should be indicated. Requested information should be provided in the submission form and required attachments. There is no guarantee that supplemental materials will be reviewed.

Additional Information

Ad.1 **Workgroup/Expert Panel involved in measure development**

Provide a list of sponsoring organizations and workgroup/panel members' names and organizations. Describe the members' role in measure development.

From 2006 onwards, and under the auspices of various funding organizations, HCI3 has convened and managed, or helped to convene and manage, Clinical Working Groups to inform the development and refinement of the measures. For example, in 2011, 2012 and 2013, HCI3 worked collaboratively with the American Board of Medical Specialties and the American Medical Association's Physicians Consortium for Performance Improvement, under a federal contract, to convene and get input from various clinical experts on definitions of episodes of care and their sequelae, including avoidable complications.

Some of the clinical experts that have contributed to our work include:
-Dr. John Allen, American Gastroenterology Association (AGA)
-Dr. Morton Arnsdorf, Cardiologist, University of Chicago, IL
-Dr. Peter Bach, Memorial Sloan Kettering Cancer Center (MSKCC)
-Dr. Peter Basch, Primary Care, Medstar Health, DC
-Dr. Justin Beckelman, Radiation Oncology, University of Pennsylvania, PA
-Dr. Debra Bingham, Executive Director, California Maternal Quality Care Collaborative (CMQCC) at Stanford University, CA
-Dr. John Birkmeyer, American Society of Metabolic and Bariatric Surgery (ASMBS)
-Dr. Linda Bosserman, Wilshire Oncology Medical Group, CA
-Dr. Matthew Brengman, American Society of Metabolic and Bariatric Surgery (ASBMS)
-Dr. Joel Brill, American Gastroenterology Association (AGA)
-Dr. George Cautilli, Cautilli Orthopedic Surgical Specialists PC, Yardley, PA
-Dr. Ashwini Davison, Internist, Johns Hopkins Hospital, MD
-Dr. James Denneny, III, American Academy of Otolaryngology – Head and Neck Surgery (AAO-HNS)
-Dr. Chris Gallagher, American Society of Metabolic and Bariatric Surgery (ASMBS)
-Dr. Robert Haralson, III, American Academy of Orthopedic Surgeons (AAOS)
-Ms. Dawn Holcombe, Executive Director, Connecticut Oncology Association, CT
-Dr. Colin Howden, American Gastroenterology Association (AGA)
-Dr. John Knightly, American Association of Neurological Surgeons (AANS)
-Dr. Larry Kosinski, American Gastroenterology Association (AGA)
-Dr. Nalini Krishnan, Obstetrics & Gynecology, MN
-Dr. Kelly Kyanko, Internist, NYU School of Medicine, NY
-Dr. Tara Lagu, Internist & Infectious Disease, Baystate Medical Center, MA
-Dr. Robert Lee, Society of Thoracic Surgeons (STS)
-Dr. Alex Little, Society of Thoracic Surgeons (STS)
-Dr. Michael London, Orthopedic Surgeon, OMNI Orthopedics, OH
-Dr. Elliott Main, Obstetrics & Gynecology, California Pacific Medical Center, CA
-Dr. Constantine Mantz, 21st Century Oncology, FL
-Dr. Joseph Messer, Cardiologist, Rush University Medical Center, IL
-Dr. David Metz, American Gastroenterology Association (AGA)
-Dr. Ronald Nahass, Infectious Disease Care, NJ
-Dr. Ajay Nehra, Urologist, Rush University Medical Center, IL
-Dr. Francis Nichols, Society of Thoracic Surgeons (STS)
-Dr. Patrick O'Connor, Primary Care, HealthPartners, MN
-Dr. Sara Perkel, National Comprehensive Cancer Network, PA
-Dr. David Peura, American Gastroenterology Association (AGA)
-Dr. John Ratliff, American Association of Neurological Surgeons (AANS)
-Dr. Steven Schutzer, Connecticut Joint Replacement Institute, CT
-Dr. Leif Solberg, Primary Care, HealthPartners, MN
-Dr. Scott Sporer, Midwest Orthopedics at Rush, Chicago IL
-Dr. Bonnie Weiner, Cardiologist, Worcester Medical Center, MA
-Dr. Jonathan Weiner, Bariatric Surgery codes, Prof of Health Policy and Management, Johns Hopkins University, MD
-Dr. Janet Wright, Cardiologist, Northstate Cardiology Consultants, CA

Brief Measure Information

NQF #: 2752

De.2. **Measure Title:** Proportion of Patients undergoing Pacemaker / Defibrillator Implantation (PCMDFR) that have a Potentially Avoidable Complication (during the episode time window)

Co.1.1. **Measure Steward:** Health Care Incentives Improvement Institute Inc. (HCI3)

De.3. **Brief Description of Measure:** Percent of adult population aged 18 + years who had a pacemaker/defibrillator implantation (PCMDFR), are followed for at least 30-days, and have one or more potentially avoidable complications (PACs). PACs may occur during the index stay or during the 30-day post discharge period.

Please reference attached document labeled NQF_PCMDFR_all_codes_risk_adjustment_06.30.15.xls, in the tabs labeled PACs I-9 and PAC I-10 for a list of code definitions of PACs relevant to PCMDFR.

We define PACs as one of two types:

(1) Type 1 PACs - PACs directly related to the index condition: Patients are considered to have a PAC, if they receive services during the episode time window for any of the complications directly related to PCMDFR, such as for wound infection, hypotension, cardiac arrest etc.

(2) Type 2 PACs - PACs suggesting Patient Safety Failures: Patients are also considered to have a PAC, if they receive services during the episode time window for any of the complications related to patient safety failures such as for sepsis, infections, phlebitis, deep vein thrombosis, pressure sores etc.

All readmissions in a patient with PCMDFR are considered potentially avoidable and flagged as PACs.

PACs are counted as a dichotomous (yes/no) outcome. If a patient had one or more PACs, they get counted as a "yes" or a 1. The enclosed workbook labeled NQF_PCMDFR_all_codes_risk_adjustment_06.30.15.xls serves as an example. The tab labeled PAC overview gives the percent of PCMDFR episodes that have a PAC and the tab labeled "PAC drill down" gives the types of PACs and their frequencies in PCMDFR episodes within this dataset.

The information is based on a two-year claims database from a large regional commercial insurer. The database had over 3.2 million covered lives and over $25.9 billion in "allowed amounts" for claims costs. The database is an administrative claims database with medical as well as pharmacy claims.

1b.1. **Developer Rationale:** Measures associated to potentially avoidable complication (PAC) have been used as comprehensive outcomes measures since 2007 for several conditions and procedures (de Brantes 2010) (Joynt 2013) (James 2013). In 2011, following the NQF endorsement of these measures for certain acute medical conditions (AMI, Pneumonia and Stroke), and for chronic conditions, they were adopted for various purposes, including the creation of related measures (NQF – Measure #1550). Some commercial payers have used them as a means for tracking outcomes (Yong 2010) and for tiering providers for pay for performance programs (BCBSNC). In addition, some provider organizations have used them in quality improvement efforts by homing in on the detailed specifications of the measures to reveal opportunities for care improvement (CALPERS – link below). Identification of PACs has spurred provider innovation (Bundled Payment Summit 2015) for practice re-engineering, to create proactive care pathways, and to focus on areas of high variability (McVary 2010). Some employers are also using measures of avoidable complications as public measures of quality (Colorado Business Group on Health) given the research that demonstrated the potential efficacy of these measures to differentiate provider quality and cost (Hibbard 2012). In fact in a series of focus groups led by Judy Hibbard and colleagues, the researchers found that the very framing of potentially avoidable complications as an indicator of potential harm, is an effective way of communicating the quality of care. And when measures of PACs were presented in conjunction with price, consumers intuitively accepted the logical relationship between low PACs – fewer "defects" – and lower price.

Accountability for and measurement of PACs occurs at the practice, medical group, provider system or purchaser/payer level. PAC rates are calculated as absolute values. For example, a health plan would report that 40% of its plan members with hypertension incurred PACs in the study time window. The objective of the measure is to encourage the unit being measured to progressively reduce that amount over time. In addition, comparisons of PAC rates across plans or provider systems should be encouraged and publicly reported. An organization that uses the measure should be able to identify the leading causes of PACs and implement

improvements to existing processes that will decrease PACs. There are several tools available for provider systems and health plans to impact PAC rates. These include care coordination across care settings; post-discharge planning and patient follow- up, active care management, sharing medical record data between care settings and providers, total quality management within hospitals and active reduction of patient safety failures. Reducing PACs has the potential to significantly improve the overall level of quality.

Creating a single measure of accountability for physicians and hospitals tied to gaps in quality is likely to yield much improved outcomes for patients. A measure of accountability for health plans helps them review trends over time and work with physicians and hospitals to improve the ways in which they engage patients using more optimal care management and care coordination (Cassel 2014). In addition, PAC measures could be used as a surrogate for quality in a consumer transparency tool to differentiate providers with regards to their performance.

Moreover, since these measures are claims based, there is minimal added burden for collecting the data, and it also avoids potential gaming that may occur for other measures that require reporting information to registries. Although use of administrative claims data in identifying conditions and measuring provider quality has been questioned, there are several studies in literature that acknowledge validity of its use (Normand 2007) (Quan 2009). Until more readily available data are at hand, use of administrative data to measure provider performance has steadily increased (Miller 2001), (NQF Quality Positioning System). Interestingly, in the current fee for service system, services for most PACs are rewarded by continued payment (except the CMS defined "never events") and hence to our advantage, adverse events surface in billing data. Claims based PAC measures; therefore serve as an alternative method to track adverse outcomes that do occur (Leibson 2008).

S.4. **Numerator Statement:** Number of patients who underwent a pacemaker/defibrillator implantation (PCMDFR), are followed for at least 30-days, and have one or more potentially avoidable complications (PACs) during the episode time window.
S.7. **Denominator Statement:** Adult patients aged 18 years and above who underwent a Pacemaker/defibrillator implantation - PCMDFR) procedure and are followed for at least 30-days.
S.10. **Denominator Exclusions:** Denominator exclusions include exclusions of either "patients" or "claims" based on the following criteria:
1. "Patients" excluded are those that do not meet the enrollment criteria. If patient has an enrollment gap for any time period during the episode time window, it is considered as an enrollment gap
2. "Patients" are also excluded if the cost of the episode is an outlier at greater than 99th percentile or less than 1st percentile value for all episodes. This is another way to ensure that episodes are complete as well as they do not bring in random noise into the analysis due to inappropriate codes or services.
3. "Claims" are excluded from the PCMDFR measure if they are considered not relevant to PCMDFR care.

De.1. **Measure Type:** Composite, Outcome
S.23. **Data Source:** Administrative claims
S.26. **Level of Analysis:** Clinician : Individual, Clinician : Group/Practice, Clinician : Team, Facility, Integrated Delivery System
Is this an eMeasure? ☐ **Yes** ☒ **No** **If Yes, was it re-specified from a previously endorsed measure?** ☐ **Yes** ☐ **No**

IF this measure is included in a composite, NQF Composite#/title: n/a – 2751 is i an "any or none" composite measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient)any-or-none measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient)
Composite Measure Construction: n/a. The individual complications are considered measurable components

Is this a MAINTENANCE measure submission? ☐ **Yes** ☒ **No, this is a NEW measure submission.**
For MAINTENANCE, state the Original Endorsement Date: n/a **Most Recent Endorsement Date:** n/a

Preliminary Analysis

The preliminary analysis was developed in response to recommendations from NQF's Consensus Task Force and measurement stakeholders as a way to enhance and streamline the measures evaluation and voting processes. The preliminary analysis will help to guide the Standing Committee evaluation of each measure by summarizing the measure developer submission, guide measure evaluation discussion, and identify topic areas for additional input. **NQF staff would like to stress that the preliminary analysis is intended to be used as a guide to facilitate the Committee's discussion and evaluation.**

Criteria 1: Importance to Measure and Report

1a. Evidence

1a. Evidence. The evidence requirements for a health outcomes measure include providing rationale that supports the relationship of the health outcome to processes or structures of care. The guidance for evaluating clinical evidence asks if the there is a relationship between the measured health outcome and at least one clinical action is identified and if it is supported by the stated rationale. For a composite measure, the developer must discuss the reasoning for the

composite quality constructs, the rationale for constructing, & aggregation and weighting of measure components.

- This new risk-adjusted (by age, gender and clinical co-morbidities) outcomes composite measure assesses the proportion (rate) of adult patients undergoing Pacemaker / Defibrillator Implantation (PCMDFR) with *at least one* Potentially Avoidable Complications (PAC) for the measure time window.
- Based on NQF's criteria, this measure is considered an "any or none" composite measure that assesses if 1 or more PACs or "care defects" have occurred for the index episode. For this composite measure, the individual complications considered the measurable components. PACs are classified in two types: 1) related to PCMDFR, and 2) related to Patient Safety Failures. The2 PAC types are combined into a single "any or none" (bimodal "yes" or "no") PAC rate. PACs are considered unwarranted health outcomes that combine concepts from AHRQ PSIs, PQIs and the CMS HACs and episode-specific PACs into index episode all-cause patient harms rate.
- The developer links errors of commission/omission (poor safety practices) to unnecessary ER visits, hospitalizations, readmissions, and mortalities to increased PACs. The developer further states that PACs for PCMDFR patients should occur rarely in well-managed patients, and defines potential avoidable PCMDFR complications, that include (but are not limited to) line sepsis, infections, pocket hematomas, pneumothorax, perforations, and death.
- The evidence for Patient Safety Failure PACs is described to be within the influence of the measured entity, though the rationale for selecting some of the identified PACs is not clear (e.g., post procedural fever, oral bisphosphonates, hallucinations). The developer provides an extensive list of comorbidities as risk factor for increased PAC potential, though the severity is not captured in consistently within the claims data.
- In addition to linking processes of care to outcomes, the developer provides an extensive PAC literature review in sections 1a.2. and 1a.2.1. for PCMDFR, Patient Safety Failures & processes of care, as well as background information on the process for PAC development.
- The developer discusses the rationale for constructing, aggregation and equal weighting for the measure.

Questions for the Committee:

- *Does sufficient evidence exist connecting Patient Safety Failures to the PCMDFR index episode?*
- *Does sufficient evidence exist between the measured health outcome and at least one clinical action identified and supported by the stated rationale?*

1b. Gap in Care/Opportunity for Improvement and 1b. Disparities

1b. Performance Gap. The performance gap requirements include demonstrating quality problems and opportunity for improvement.

- PCMDFR PCA performance gap data are calculated from PROMETHEUS administrative claims data from April 1, 2012 through December 17, 2014, for 1,806 of 3,968 (45.5%) PCMDFR episodes (in 3,258,706 unique beneficiaries) and 22 of 380 (5.8%) facilities after excluding fewer than 10 attributable episodes due to unstable small samples.

Unadjusted PAC Rates:		**Risk-Standardized PAC Rates (RSPR):**	
Median (IQR):	46.8% (39.5%, 55.2%)	Median (IQR):	46.2% (36.8%, 54.0%)
Range:	20% - 64.3%	Range:	20.8% - 62.5%

- Descriptive data on the patient, facility and payer are not provided. The developer provides "Overview" and "Drill Down" PAC rates in the spreadsheet demonstrating gap, though PAC rates for individual complications are not provided.
- The developer does not provide data on disparities.

Questions for the Committee:

- *Is there a gap in care that warrants a national performance measure?*
- *If no disparities information is provided, are you aware of evidence that disparities exist in this area of healthcare?*
- *Should this measure be indicated as disparities sensitive?*

1c. Priority

1c. High Priority (previously "High Impact") requires measures to address national health goal/priority or a demonstrated high-impact aspect of care.

- *Beginning in 2015, priority is no longer an NQF measure evaluation criterion.*

Committee pre-evaluation comments

Criteria 1: Importance to Measure and Report (including 1a, 1b, 1c)

1. ***Committee's Overview Comments***:
   - There is clear evidence that measures that can minimize complications of pacemaker and ICD implants are important. However, I have major concerns about the measure as it is proposed.

1a. ***Committee's Comments on Evidence to Support Measure Focus:***

- It is not clear what would be considered a PAC or not. Where do they draw the line? What about HF? A stroke? An MI not related to the procedure? What about trauma related to MVA? Do ICD shocks count as well? What if the programming of the device is in line with the evidence why would we penalize clinicians for that?

1b. ***Committee's Comments on Performance Gap:***

- PCMDFR PCA performance gap data are calculated from PROMETHEUS administrative claims data from April 1, 2012 through December 17, 2014, for 1,806 of 3,968 (45.5%) PCMDFR episodes (in 3,258,706 unique beneficiaries) and 22 of 380 (5.8%) facilities after excluding fewer than 10 attributable episodes due to unstable small samples.
- Unadjusted PAC Rates:
  - Median (IQR): 46.8% (39.5%, 55.2%)
  - Range: 20% - 64.3%
  - Risk-Standardized PAC Rates (RSPR):
  - Median (IQR): 46.2% (36.8%, 54.0%)
  - Range: 20.8% - 62.5%
- Descriptive data on the patient, facility and payer are not provided. The developer provides "Overview" and "Drill Down" PAC rates in the spreadsheet demonstrating gap, though PAC rates for individual complications are not provided.
- The developer does not provide data on disparities.

1c. ***Committee's Comments on Composite Performance Measure:***

- Any or none measure.

Criteria 2: Scientific Acceptability of Measure Properties

2a. Reliability

2a1. Reliability Specifications

2a1. Specifications requires the measure, as specified, to produce consistent (reliable) and credible (valid) results about the quality of care when implemented.

- The measure assesses the rate of patients with 1 or more PAC(s) during index episodes. This new risk adjusted outcomes measure is specified for use at the individual clinician, group/practice, team, facility & integrated delivery system levels of analyses.
- The measure exclusively uses electronically available administrative claims data to calculation the measure score, and for this measure, better care equals lower scores.
- The developer describes non-patient-related PACs as controllable by facility processes without further analysis as other influencers that may contribute to PAC rates beyond the patient and facility (e.g., payer, access, suppliers, etc.).
- Patient- and claims-based exclusions are provided to promote the availability and consistency of claims data capture, including payer enrollment requirements, cost outliers of < 1% or > 99%, and claims not relevant to PCMDFR.
- Developers provide administrative claims codes for PCMDFR & PAC (PCMDFR - & Patient Safety Failure-related) triggers, and describe a 7 day look back and 30 days after the PCMDFR triggered claims data. The developer should

provide context for the use of claims data prior to the PCMDFR in relation to triggering index episodes and/or PACs.

- A calculation algorithm is provided, as well as ICD-9 & ICD-10 codes, though ICD-10 descriptions & an ICD-9 to ICD-10 crosswalk methodology are not provided.
- A conceptual risk model and statistical method using logistic regression model for determining the probability of a patient incurring a PAC are provided. After adjusting for patient-related factors, the developers state the remaining PAC variance is due to factors potentially controlled by the facility during and after hospitalization. "Predicted" coefficients from the risk adjustment models are summed to give predicted probabilities of PAC occurrence.

Questions for the Committee:

- *Are all the data elements clearly defined? Are all appropriate codes included?*
- *Is the logic or calculation algorithm clear?*
- *Is it likely this measure can be consistently implemented?*

2a2. Reliability Testing Testing attachment

2a2. Reliability testing demonstrates if the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise enough to distinguish differences in performance across facilities.

- The developer tested reliability at the performance measure score, and used a beta-binomial model and a signal-to-noise analysis, which is appropriate for this type of measure, to differentiate the true difference between measured entities (the signal) to random measurement error (the noise). A value of 0 indicates that all variation is due to measurement error and a value of 1 indicates that all variation is due to real differences in between *facility* performance. A value of 0.7 is often regarded as a minimum acceptable reliability value, and the developer also states values above 0.9 are considered sufficient to see differences between pairs of physicians.
- The measure is specified for patients ≥ 18 years that underwent PCMDFR, though the testing sample includes patients 18 through 64 years.
- The measure is specified for use with individual clinician, group/practice, team, facility & integrated delivery system levels of analyses, though testing is provided for facilities. NQF's measure evaluation criterion requires testing for all measure specification levels.
- Facilities with < 10 PCMDFR episodes were excluded from reliability testing, though the measure is specified for patient without episode restrictions. A sample of 380 facilities was initially included in the data set, though facilities with less than 10 PCMDFR episodes were excluded, allowing for 22 (5.8%) remaining facilities. There were 1,806 episodes of PCMDFR with a mean age of 54.1 (18-64 years) with 31% being female.
- Patient with missing gender were excluded from the denominator, and no other missing data was identified.
- The developer states, "Minimum sample size requirements for PAC measures are a function of the reliability testing of the measures on every dataset on which the measures are applied. Our research suggests that minimum sample sizes to achieve high degrees of reliability in the measures are a function of the dataset analyzed, and as such may vary from dataset to dataset. One should not infer that a minimum sample size achieved in one dataset will apply to another." The developer also states that very high sample sizes are to achieve any meaningful and reliable comparisons.
- In section 2a2, the developer states, "The beta-binomial failed to produce statistically significant parameters. We were therefore unable to calculate facility reliability scores. We were unable to report reliability scores, suggesting that statistically the measure may not adequately differentiate between facilities in the current database tested."
- Due to the original reliability testing results, an ad hoc commercial data set demonstrating "providers with sample sizes as low as 22 patients, had a reliability >0.7", though specific results are not provided (details are provided in the Ad Hoc Pacemaker Defibrillator Reliability Analysis spreadsheet in SharePoint).
- A patient may have more than one condition-specific concurrent episode with claims applied to both episodes. If an inpatient claim corresponds to a procedure index episode and to a condition index episode, the claim would be assigned to the procedure index episode, rather than the condition index episode (e.g., for a claim that corresponds to both index episodes of CAD & CABG, the claim would be assigned to CABG).
- Patient with missing gender were excluded from the denominator, and no other missing data was identified.
- The developer provides an additional supplementary fact sheet related to PAC development & testing (available for

review on SharePoint).

Questions for the Committee:

- *Reliability testing was attempted only for those facilities with at least 10 episodes. Can differences in performance be identified for facilities with fewer than 10 or 22 episodes? For patients ≥ 65 years?*
- *Should the measure be specified to include only those facilities with at least 10 episodes?*
- *Is the test sample adequate to generalize for widespread implementation?*
- *Do the results demonstrate sufficient reliability so that differences in performance can be identified?*

2b. Validity

2b1. Validity: Specifications

2b1. Validity Specifications. This section should determine if the measure specifications are consistent with the evidence.

- Because this is an outcome measure, the rationale that is presented for subcriterion 1a does not necessarily have to address all of the variables used to calculate the measure.
- The measure uses a statistical risk model with 170 risk factors and episode-specific subtypes/severity markers including age, gender and clinical comorbidities, on at least 10 claims to determine "stable" covariates and assess comorbidity or procedure impact on the PAC. All covariates must be present prior to an episode trigger. No formal covariate analysis was conducted to select risk factors beyond the minimum of 10 claims threshold. The developer describes the heterogeneity of the provided data sets as crucial to ensure measure validity, and the accuracy and completeness of the data sets.
- The developers did not provide disparities data, an exploration of a conceptual relation to SDS, or SDS factors in the risk model.

Question for the Committee:

- *Are the specifications consistent with the evidence?*
- *Are these variables available and generally accessible for the measured patient population?*

2b2. Validity testing

2b2. Validity Testing should demonstrate the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality.

- The developer conducted systematic assessment of face validity for the performance measure score for validity testing in numerous ways, including the use of monthly multi-specialty clinical working groups, and other tests of face validity, along with focus groups, face validity comparisons of the measure to other national accountability measures, as well as additional literature for the measure & PAC development process.
- No empiric results are provided for the face validity tests described above.

Questions for the Committee:

- *Is the test sample adequate to generalize for widespread implementation?*
- *Do the results demonstrate sufficient validity so that conclusions about quality can be made?*
- *Do you agree that the score from this measure as specified is an indicator of quality?*
- *Is there evidence of a systematic assessment of expert opinion beyond those involved in developing the measure?*

2b3-2b7. Threats to Validity

2b3. Exclusions:

- The developer describes patient- (demographic, enrollment or low/high claims cost) and claims-based (due to missing or non-relevant data) exclusions for the measure. They further state nearly half of the original population of PCMDFR

patients was removed from the denominator with applied exclusions.

- A significant number of episodes were eliminated from the measure due to exclusion criteria, permitting 1,806 of 3,968 (45.5%) PCMDFR episodes (in 3,258,706 unique beneficiaries) and 22 of 380 (5.8%) facilities for analysis.

Questions for the Committee:

- *Are high cost outliers (> 99%) exclusions an opportunity to identify PACs?*
- *Does the high number of exclusions restrict the measure use?*
- *Are the exclusions consistent with the evidence?*
- *Are any patients or patient groups inappropriately excluded from the measure?*
- *Are the exclusions/exceptions of sufficient frequency and variation across facilities to be needed (and outweigh the data collection burden)?*

2b4. Risk adjustment:

- The risk model (detailed in the accompanied spreadsheet) includes 170 factors and subtypes including age, gender, 12-month enrollment markers, co-morbidities, and episode severity markers.
- No SDS factors beyond age and gender were included in the risk-adjustment approach. The developers note that race was not available for analysis, and no description of the of the conceptual relationships between patient sociodemographic factors, patient clinical factors, quality of care, and the outcomes (PAC rates) were provided, nor do they discuss the availability of SDS variables.
- Logistic regression was used to model the probability of at least one PAC during an episode. The reasoning for no additional modeling performed is described.
- The performance of the model was determined with a split sample method by estimating the model coefficients using a development dataset (80% of the sample) and applying those coefficients to a validation dataset (20% of the sample). C-statistics for the development and validation samples with c-statistic results of 0.740, for the test sample only. C-statistics measures the extent of a statistical model to discriminate between a patient with and without PAC, with an ability to predict if a PAC is or is not present about 60% of the time. A c-statistic of 0.50 indicates the model is no better than random prediction, implying that the patient risk factors do not predict variation in the outcome; conversely, a c-statistic of 1.0 indicates perfect prediction, implying patients' outcomes can be predicted completely by their risk factors, and physicians and hospitals play little role in patients' outcomes. Models with c-statistic values of at least 0.7 are considered good and those above 0.8 are considered strong.
- Both Hosmer-Lemeshow Goodness-of-Fit statistics and risk-decide plots were provided to indicate model fit. Results from the Hosmer-Lemeshow test suggest that the fit is not good; however, this test is sensitive to the number of groupings and sample sizes. Results from the risk decile plot indicate that the predicted PAC rates are similar to the observed PAC rates across all deciles of risk. The developer states the model demonstrates strong predictive power.

Questions for the Committee:

- *Is the Committee aware of conceptual relationship(s) between additional patient-level SDS factors, patient clinical factors, quality of care, and PACs (other than gender and age)? If so, what data might be available to allow an empirical analysis of these relationships?*
- *Is an appropriate risk-adjustment strategy included in the measure?*
- *Are the candidate and final variables included in the risk adjustment model adequately described for the measure to be implemented?*
- *Are all of the risk adjustment variables present at the start of care? If not, describe the rationale provided.*

2b5. Meaningful difference:

- The developer presents PAC rates across facilities and also facilities adjusting for differences in patient severity in a ratio of observed to expected attributable episodes to PACS accounting for patient severity, and calculates estimates from the risk model, for risk-standardized PAC rates for the facility.
- The table below provides PAC rates per provider. The developer should clarify PACs in the table represent individual providers or facilities.

Summary of Unadjusted and Adjusted Performance Scores Across Facilities:

PAC Rates	Minimum # Episodes Per Provider	
	>=10	>=25
# Providers	22	16
Unadjusted		
Median (IQR)	47% (40%, 55%)	46% (35%, 55%)
Range	20% - 64%	26% - 64%
Adjusted (RSPR)*		
Median (IQR)	46% (37%, 54%)	46% (35%, 55%)
Range	21% - 63%	25% - 63%

***RSPR = Risk Standardized PAC Rate**

Please refer to the NQF_ PCMDFR _all_codes_risk_adjustment_06.30.15.xls workbook under the "ProviderAttribution Reliability" tab to see specific results for each provider.

Question for the Committee:

- *Does this measure identify meaningful differences about quality?*

2b6. Comparability of data sources/methods:

- As there is only one data source used for measure calculation (administrative claims), comparability of data sources or methods is not applicable.

2b7. Missing Data

- No formal analysis of missing data is provided. As the measure assesses the rate of patients with PACs, rather than the rate of PACs per index episode, the total number of PACs is not included in the PAC rate.
- Patient with missing gender were excluded from the denominator, and no other missing data was identified.
- The developers state the under-coding of claims is unavoidable in the current DRG payment structure which could lead to under capture or missing PACs.

2d. Empirical Analysis to Support Composite Construction

- As an "any or none" composite, the individual complications are considered measurable components of the composite. Frequency and distribution statistics are provided in the PAC Overview and PAC Drill Down tabs in the measure spreadsheet, which detail PAC types and subtypes. The identification of individual PACs are not provided (e.g., sepsis, unattended falls, DVT).
- PACs are counted as a dichotomous (yes/no) outcome. If a patient had one or more PACs, they get counted as a "yes" or a 1. Since our premise is that all PACs are potentially avoidable, we adopted the approach to count all PACs and give them equal weights. The overall composite score results in the quality construct that could be measured and interpreted.
- The developer states that no formal analysis was performed on missing data. For details, see 2b7 above.

Committee pre-evaluation comments

Criteria 2: Scientific Acceptability of Measure Properties (including all 2a, 2b, and 2d)

2a1. &2b1.: ***Committee's Comments on Reliability-Specifications:***

- Under exclusions: What about CRT? What about device replacements or procedures only involving leads etc.. Otherwise, ok.

2a2.: ***Committee's Comments on Reliability-Testing:***

- The sponsor was not successful in proving the following: The measure is specified for use with individual clinician, group/practice, team, facility & integrated delivery system levels of analyses, though testing is provided for facilities. NQF's measure evaluation criterion requires testing for all measure specification levels.
- The following is concerning: "The beta-binomial failed to produce statistically significant parameters. We were therefore unable to calculate facility reliability scores. We were unable to report reliability scores, suggesting that statistically the measure may not adequately differentiate between facilities in the current database tested."
- I am not sure I understand this: Due to the original reliability testing results, an ad hoc commercial data set

demonstrating "providers with sample sizes as low as 22 patients, had a reliability >0.7", though specific results are not provided.

2b1.: ***Committee's Comments on Validity-Specifications***:

- Not Applicable

2b2.: ***Committee's Comments on Validity-Testing:***

- I am worried that one would have to adjust for 170 factors. Why that many? How were these chosen? May did not appear to be relevant. Also, with the need to adjsut for 170 factors, is the measure even practical or feasible to use?
- No empiric results are provided for the face validity tests described above.

2b3-7.: ***Committee's Comments on Threats to Validity:***

- The developer describes patient- (demographic, enrollment or low/high claims cost) and claims-based (due to missing or non-relevant data) exclusions for the measure. They further state nearly half of the original population of PCMDFR patients was removed from the denominator with applied exclusions.
- A significant number of episodes were eliminated from the measure due to exclusion criteria, permitting 1,806 of 3,968 (45.5%) PCMDFR episodes (in 3,258,706 unique beneficiaries) and 22 of 380 (5.8%) facilities for analysis. These are concerning.

2d.: ***Committee's Comments on Composite Performance Measure:***

- Not Applicable

Criterion 3. Feasibility

3. Feasibility is the extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

- All measure elements are readily available in electronic sources via administrative claims data, and coded by someone other than the person obtaining the original information (e.g., DRG, ICD-9 codes on claims).
- The developer provides an excel spreadsheet attachment including diagnoses, visits, hospitalizations, post-acute facility stays, procedures, laboratory tests and procedures/surgeries, for PCMDFR & PAC triggers, and describe the time window for measuring PAC triggers as a 7 day look back and 30 days after undergoing a PCMDFR, as well as a decision tree for measure calculation and implementation.
- The measure specifications, metadata and calculation algorithms are available free of charge on the developer's website. Limited analytics are planned at no cost to the end user.
- This is not an eMeasure.

Questions for the Committee:

- *Are the required data elements routinely generated and used during care delivery?*
- *Are the required data elements available in electronic form, e.g., EHR or other electronic sources?*
- *Is the data collection strategy ready to be put into operational use?*

Committee pre-evaluation comments

Criteria 3: Feasibility

3.: ***Committee's Comments on Feasibility:***

- I am not sure

Criterion 4: Usability and Use

4. Usability and Use evaluate the extent to which audiences (e.g., consumers, purchasers, providers, policymakers) use or could use performance results for both accountability and performance improvement activities.

- This is a newly developed claims measure is current used in accountability programs for payers, states, and planned for public reporting, professional certification or recognition programs, and external quality improvement for benchmarking purposes.
- The developer states that PAC measures provide a foundation for the relationship between healthcare quality and cost and assist in the exploration of practice reengineering and alternative payment models, act as indicators of potential harm, and is spurring the development of private-based analytics software for further outcomes exploration. No public improvement rates are available due to recent implementation and variation in PAC definitions have also modified, though the provided PROMETHEUS data suggest wide variation in performance and improvement opportunities.
- The developer found no noted unintended consequences, though they state the measure is intended for transparency and QI activities only. They also state the under-coding of claims is unavoidable in the current DRG payment structure could be an unintended consequences of the measure, and payers calculating the measures even with inadequate sample sizes and using the results to penalize providers could lead to invalid provider comparisons.
- If the measure was theoretically to be used for accountability purposes to "ding" the measured entity as defined in the level of analysis, further exploration of PAC antecedents and the measured entity is warranted, especially with lower volume PCMDFR facilities. In the original testing sample of 380 facilities, when facilities with fewer than 10 PCMDFR episodes were eliminated from analysis due to less reliability estimates with small numbers, 22 (5.8%) remained for analysis.

***Questions for the Committee**:*

- *Is the measure publicly reported?*
- *How can the performance results be used to further the goal of high-quality, efficient healthcare?*
- *Should PAC measures also include the clinician: group in the analysis or include population-level only entities?*
- *Do the benefits of the measure outweigh any potential unintended consequences?*

Committee pre-evaluation comments

Criteria 4: Usability and Use

4.: ***Committee's Comments on Usability and Use:***

- I am not convinced.

Criterion 5: Related and Competing Measures

5.1a. List of related or competing measures (selected from NQF-endorsed measures)

0141 : Patient Fall Rate
0202 : Falls with injury
0337 : Pressure Ulcer Rate (PDI 2)
0450 : Perioperative Pulmonary Embolism or Deep Vein Thrombosis Rate (PSI 12)
0705 : Proportion of Patients Hospitalized with Stroke that have a Potentially Avoidable Complication (during the Index Stay or in the 30-day Post-Discharge Period)
0708 : Proportion of Patients Hospitalized with Pneumonia that have a Potentially Avoidable Complication (during the Index Stay or in the 30-day Post-Discharge Period)
0709 : Proportion of patients with a chronic condition that have a potentially avoidable complication during a calendar year.
1789 : Hospital-Wide All-Cause Unplanned Readmission Measure (HWR)

5.1b. If related or competing measures are not NQF endorsed please indicate measure title and steward.

-0531 Patient Safety for Selected Indicators (Composite Measure, endorsed) (AHRQ)
-CMS defined hospital acquired conditions (HACs) are a subset of our PACs. We have pain-stakingly matched the definitions to provide as much consistency as possible. http://www.cms.gov/Medicare/Quality-Initiatives-Patient-Assessment-Instruments/HospitalQualityInits/HospitalRHQDAPU.html

Pre-meeting public and member comments

-

NATIONAL QUALITY FORUM—Evidence (subcriterion 1a)

Measure Number (*if previously endorsed*)**:** 2752

Measure Title: Proportion of Patients undergoing Pacemaker / Defibrillator Implantation (PCMDFR) that have a Potentially Avoidable Complication (during the episode time window)

IF the measure is a component in a composite performance measure, provide the title of the Composite Measure here: Click here to enter composite measure #/ title

Date of Submission: 6/30/2015

Instructions

- *For composite performance measures:*
  - *A separate evidence form is required for each component measure unless several components were studied together.*
  - *If a component measure is submitted as an individual performance measure, attach the evidence form to the individual measure submission.*
- Respond to all questions as instructed with answers immediately following the question. All information needed to demonstrate meeting the evidence subcriterion (1a) must be in this form. An appendix of *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 10 pages (*incudes questions/instructions*; minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the evidence for this measure meets NQF's evaluation criteria.

. Evidence to Support the Measure Focus

The measure focus is evidence-based, demonstrated as follows:

- Health outcome: [3] a rationale supports the relationship of the health outcome to processes or structures of care. Applies to patient-reported outcomes (PRO), including health-related quality of life/functional status, symptom/symptom burden, experience with care, health-related behavior.
- Intermediate clinical outcome: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured intermediate clinical outcome leads to a desired health outcome.
- Process: [5] a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured process leads to a desired health outcome.
- Structure: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured structure leads to a desired health outcome.

- Efficiency: [6] evidence not required for the resource use component.

Notes

3. Generally, rare event outcomes do not provide adequate information for improvement or discrimination; however, serious reportable events that are compared to zero are appropriate outcomes for public reporting and quality improvement.

4. The preferred systems for grading the evidence are the U.S. Preventive Services Task Force (USPSTF) grading definitions and methods, or Grading of Recommendations, Assessment, Development and Evaluation (GRADE) guidelines.

5. Clinical care processes typically include multiple steps: assess → identify problem/potential problem → choose/plan intervention (with patient input) → provide intervention → evaluate impact on health status. If the measure focus is one step in such a multistep process, the step with the strongest evidence for the link to the desired outcome should be selected as the focus of measurement. Note: A measure focused only on collecting PROM data is not a PRO-PM.

6. Measures of efficiency combine the concepts of resource use and quality (see NQF's Measurement Framework: Evaluating Efficiency Across Episodes of Care; AQA Principles of Efficiency Measures).

1a.1.This is a measure of: (*should be consistent with type of measure entered in De.1*)

Outcome

☒ Health outcome: Potentially Avoidable Complications

☐ Patient-reported outcome (PRO): Click here to name the PRO

PROs include HRQoL/functional status, symptom/symptom burden, experience with care, health-related behaviors

☐ Intermediate clinical outcome (*e.g., lab value*): Click here to name the intermediate outcome

☐ Process: Click here to name the process

☐ Structure: Click here to name the structure

☐ Other: Click here to name what is being measured

HEALTH OUTCOME/PRO PERFORMANCE MEASURE *If not a health outcome or PRO, skip to 1a.3*

1a.2. Briefly state or diagram the path between the health outcome (or PRO) and the healthcare structures, processes, interventions, or services that influence it.

With the expanded indications for Pacemaker / Defibrillator (PCMDFR) use, improved technology and increasing number of patients with cardiac diseases, the use of PCMDFR's has increased exponentially (van Rees 2011) (Greenspon 2012). Dedicated quality improvement efforts to enhance patient safety, and reduce procedural complications are required to be in place, and could pay for themselves with better patient outcomes and reduced costs (Reynolds 2006). PCMDFR complications could be reduced by a combination of optimal medical treatment as well as adoption of adequate implantation techniques for these devices (van Rees 2011). Optimal placement requires a clinical center, hosting a team of qualified and experienced cardiologists, nurses and technicians. The teams' experience, and the volume of pacemakers implanted in the

center, plays a role in reducing post-implantation complications. Studies have shown low volume centers (<750 procedures per annum) to have 50-100% higher risk of any complication compared to high volume centers (Kirkfeldt 2013).

Potentially avoidable complications (PACs) are the health outcomes that this measure addresses. PACs are both directly and indirectly related to healthcare services provided (or not provided) for a condition or procedure (de Brantes 2010). PACs may occur due to errors in omission or commission. Errors of omission in a patient undergoing a pacemaker / defibrillator implantation could be due to failure of hospitals and / or physicians to establish or implement patient safety protocols when inserting pacemaker leads or the defibrillator assembly leading to line sepsis, infections etc. (Pronovost 2010). In addition, errors of commission could be due to improper placement of leads resulting in pneumothorax, perforation during PCMDFR lead placement or lead dislodgement as a late complication (van Rees 2011). Pocket hematomas, if not diagnosed early could lead to a 15-fold increase in wound infections (Klug 2007). Lack of operator experience, lack of care coordination, poor discharge planning and poor arrangements of patient follow-up could lead to unnecessary ER visits, readmissions and gaps in care leading to increased morbidity and the need for lead replacement. Cumulative incidence of inappropriate shocks can increase to 18% and results in an increased all cause mortality (van Rees 2011). Readmissions are common after inappropriate shocks for reasons varying from battery failure, addition of antiarrhythmic medications, treatment of associated MI, to treatment of discomfort and psychological support for anxiety (Beyerbach 2014). Minimizing inappropriate defibrillator shocks is therefore of paramount importance and requires a multifactorial approach including, appropriate patient selection, medical care, counseling, choosing the right device and appropriate programming to reduce shocks (Koneru 2011). Up to 35% of patients could develop anxiety disorders following implantation and need appropriate psychosocial support (Kamphuis 2003). All these adverse events are aggregated together in the PAC measure to study the overall rate of PACs in the PCMDFR population.

Adult patient undergoing a pacemaker or defibrillator implantation admitted to a hospital or an outpatient facility

↓

Hospital/physician fails to carry out safe practices (errors in commission/omission)

↓

Patient suffers complication stemming from hospital/physician potentially avoidable error

↓

Patient remains in hospital for treatment of PAC

OR

Patient readmitted to hospital with 1+ Potentially avoidable complication

Well-managed patients receieving a pacemaker or defibrillator should rarely incur a potentially avoidable complication such as an emergency room visit post-discharge, and readmissions related to PCMDFR should occur only in the rarest of circumstances.

The enclosed workbook entitled NQF_PCMDFR_all_codes_risk_adjustment 06.30.15.xls lists the types of PACs and their frequency as calculated in a large regional database (see tab PAC overview). Over 47% of PCMDFR episodes had a PAC. Of these, over 37% were incurred for direct complications of PCMDFR, such as malfunction / complications of the device, or lung complications from line insertion (see tab PAC Drill Down Graph). Although the preventable readmissions in the PCMDFR population were low, at only 3.8%, approximately 20% of patients with PCMDFR had PACs related to patient centered care failures such as respiratory insufficiency and poor control of diabetes, many of them being managed in an outpatient setting in physician offices. As a result 42% of episodes had a PAC indicator on the professional claims.

While PACs may not be eliminated completely, identifying the magnitude of PACs and knowledge of the cause for the most frequent or the most expensive PACs could place an emphasis in reducing them and as a consequence improving patient outcomes. The ability to clearly identify the type and frequency of each PAC creates a highly actionable measure for all providers that are managing or co-managing the patient, as well as for the health plan with whom the patient is a member.

1a.2.1. State the rationale supporting the relationship between the health outcome (or PRO) to at least one healthcare structure, process, intervention, or service (*i.e., influence on outcome/PRO*).

Note: For health outcome/PRO performance measures, no further information is required; however, you may provide evidence for any of the structures, processes, interventions, or service identified above.

Rationale: There exists a continuing need for reduction of the clinical and economic burden of PAC's due to PCMDFR's. PCMDFR use is associated with complications at all stages of device use, starting from in-hospital stay to post discharge. Associated comorbidities, type of device used as well as physician volumes further influence the complication rates. Various studies have shown that the commonest complications like lead displacement, pneumothorax, infection and perforation are all PAC's and are influenced by physician experience and training. Complex lead placements are usually performed by more experienced consultants

and consequently had lower displacement rates (Bond 2012). Implantations performed in an emergency or out-of-hours settings are also associated with higher complication risks (Kirkfeldt 2013).

Shocks from ICD's though life saving in patients paradoxically can also cause much of the morbidity associated with their use and reduce quality of life. Cumulative incidence of inappropriate shocks can increase to 18% and results in an increased all cause mortality (van Rees 2011). Readmissions are common after inappropriate shocks for reasons varying from battery failure, addition of antiarrhythmic medications, treatment of associated MI, to treatment of discomfort and psychological support for anxiety (Beyerbach 2014). Minimizing inappropriate ICD shocks is therefore of paramount importance and requires a multifactorial approach including, appropriate patient selection, medical care, counseling, choosing the right device and appropriate programming to reduce shocks (Koneru 2011). Up to 35% of patients can develop anxiety disorders following implantation and need appropriate psychosocial support (Kamphuis 2003). Appropriate programming could minimize unnecessary shocks in patients receiving an implantable pacemaker / defibrillator (Koneru 2011), in turn reducing unnecessary anxiety disorders in these patients (Kamphuis 2003).

Mariana Parahuleva, in her extensive review of PCMDFR complications published as a book chapter states that, identification of factors contributing to complications may permit identification of high-risk individuals that warrant incremental monitoring and therapy to attenuate risk (Parahuleva 2011). Centers should strive for significant reductions in frequency of complications related to pacemaker/defibrillators through adopting and incorporating technological developments, improved operator competence and patient education.

PAC measures in the setting of pacemaker / defibrillator (PCMDFR) implantation look at all-cause harms, such as the ones highlighted above, arising from poor management of a patient receiving a PCMDFR.

Note: For health outcome/PRO performance measures, no further information is required; however, you may provide evidence for any of the structures, processes, interventions, or service identified above.

INTERMEDIATE OUTCOME, PROCESS, OR STRUCTURE PERFORMANCE MEASURE

1a.3. Briefly state or diagram the path between structure, process, intermediate outcome, and health outcomes. Include all the steps between the measure focus and the health outcome.

1a.3.1. What is the source of the systematic review of the body of evidence that supports the performance measure?

☒ Clinical Practice Guideline recommendation – ***complete sections 1a.4, and 1a.7***

☐ US Preventive Services Task Force Recommendation – ***complete sections 1a.5 and 1a.7***

☐ Other systematic review and grading of the body of evidence (*e.g., Cochrane Collaboration, AHRQ Evidence Practice Center*) – ***complete sections 1a.6 and 1a.7***

☐ Other – ***complete section 1a.8***

Please complete the sections indicated above for the source of evidence. You may skip the sections that do not apply.

1a.4. CLINICAL PRACTICE GUIDELINE RECOMMENDATION

1a.4.1. Guideline citation (*including date*) and **URL for guideline** (*if available online*):

1a.4.2. Identify guideline recommendation number and/or page number and **quote verbatim, the specific guideline recommendation**.

1a.4.3. Grade assigned to the quoted recommendation with definition of the grade:

1a.4.4. Provide all other grades and associated definitions for recommendations in the grading system.
(*Note: If separate grades for the strength of the evidence, report them in section 1a.7.*)

1a.4.5. Citation and URL for methodology for grading recommendations (*if different from 1a.4.1*)**:**

1a.4.6. If guideline is evidence-based (rather than expert opinion), are the details of the quantity, quality, and consistency of the body of evidence available (e.g., evidence tables)?

☐ Yes → ***complete section 1a.7***

☐ No → ***report on another systematic review of the evidence in sections 1a.6 and 1a.7; if another review does not exist, provide what is known from the guideline review of evidence in 1a.7***

1a.5. UNITED STATES PREVENTIVE SERVICES TASK FORCE RECOMMENDATION

1a.5.1. Recommendation citation (*including date*) and **URL for recommendation** (*if available online*):

1a.5.2. Identify recommendation number and/or page number and **quote verbatim, the specific recommendation**.

1a.5.3. Grade assigned to the quoted recommendation with definition of the grade:

1a.5.4. Provide all other grades and associated definitions for recommendations in the grading system.
(*Note: the grading system for the evidence should be reported in section 1a.7.*)

1a.5.5. Citation and URL for methodology for grading recommendations (*if different from 1a.5.1*)**:**

Complete section 1a.7

1a.6. OTHER SYSTEMATIC REVIEW OF THE BODY OF EVIDENCE

1a.6.1. Citation (*including date*) and **URL** (*if available online*):

1a.6.2. Citation and URL for methodology for evidence review and grading (*if different from 1a.6.1*)**:**

Complete section 1a.7

1a.7. FINDINGS FROM SYSTEMATIC REVIEW OF BODY OF THE EVIDENCE SUPPORTING THE MEASURE

If more than one systematic review of the evidence is identified above, you may choose to summarize the one (or more) for which the best information is available to provide a summary of the quantity, quality, and consistency of the body of evidence. Be sure to identify which review is the basis of the responses in this section and if more than one, provide a separate response for each review.

1a.7.1. What was the specific structure, treatment, intervention, service, or intermediate outcome addressed in the evidence review?

1a.7.2. Grade assigned for the quality of the quoted evidence with definition of the grade:

1a.7.3. Provide all other grades and associated definitions for strength of the evidence in the grading system.

1a.7.4. What is the time period covered by the body of evidence? (*provide the date range, e.g., 1990-2010*).
Date range: Click here to enter date range

QUANTITY AND QUALITY OF BODY OF EVIDENCE

1a.7.5. How many and what type of study designs are included in the body of evidence? (*e.g., 3 randomized controlled trials and 1 observational study*)

1a.7.6. What is the overall quality of evidence across studies in the body of evidence? (*discuss the certainty or confidence in the estimates of effect particularly in relation to study factors such as design flaws, imprecision due to small numbers, indirectness of studies to the measure focus or target population*)

ESTIMATES OF BENEFIT AND CONSISTENCY ACROSS STUDIES IN BODY OF EVIDENCE

1a.7.7. What are the estimates of benefit—magnitude and direction of effect on outcome(s) <u>across studies</u> in the body of evidence? (*e.g., ranges of percentages or odds ratios for improvement/ decline across studies, results of meta-analysis, and statistical significance*)

1a.7.8. What harms were studied and how do they affect the net benefit (benefits over harms)?

N/A

UPDATE TO THE SYSTEMATIC REVIEW(S) OF THE BODY OF EVIDENCE

1a.7.9. If new studies have been conducted since the systematic review of the body of evidence, provide for <u>each</u> new study: 1) citation, 2) description, 3) results, 4) impact on conclusions of systematic review.

1a.8 OTHER SOURCE OF EVIDENCE

If source of evidence is NOT from a clinical practice guideline, USPSTF, or systematic review, please describe the evidence on which you are basing the performance measure.

1a.8.1 What process was used to identify the evidence?

1a.8.2. Provide the citation and summary for each piece of evidence.

1. Evidence, Performance Gap, Priority – Importance to Measure and Report
Extent to which the specific measure focus is evidence-based, important to making significant gains in healthcare quality, and improving health outcomes for a specific high-priority (high-impact) aspect of healthcare where there is variation in or overall less-than-optimal performance. ***Measures must be judged to meet all subcriteria to pass this criterion and be evaluated against the remaining criteria.***
1a. Evidence to Support the Measure Focus – See attached Evidence Submission Form 2752_PCMDFR_Evidence_Attachment_HCI3.docx
1b. Performance Gap Demonstration of quality problems and opportunity for improvement, i.e., data demonstrating: • considerable variation, or overall less-than-optimal performance, in the quality of care across providers; and/or • disparities in care across population groups. 1b.1. **Briefly explain the rationale for this measure** *(e.g., the benefits or improvements in quality envisioned by use of this measure)* Measures associated to potentially avoidable complication (PAC) have been used as comprehensive outcomes measures since 2007 for several conditions and procedures (de Brantes 2010) (Joynt 2013) (James 2013). In 2011, following the NQF endorsement of these measures for certain acute medical conditions (AMI, Pneumonia and Stroke), and for chronic conditions, they were adopted for various purposes, including the creation of related measures (NQF – Measure #1550). Some commercial payers have used them as a means for tracking outcomes (Yong 2010) and for tiering providers for pay for performance programs (BCBSNC). In addition, some provider organizations have used them in quality improvement efforts by homing in on the detailed specifications of the measures to reveal opportunities for care improvement (CALPERS – link below). Identification of PACs has spurred provider innovation (Bundled Payment Summit 2015) for practice re-engineering, to create proactive care pathways, and to focus on areas of high variability

(McVary 2010). Some employers are also using measures of avoidable complications as public measures of quality (Colorado Business Group on Health) given the research that demonstrated the potential efficacy of these measures to differentiate provider quality and cost (Hibbard 2012). In fact in a series of focus groups led by Judy Hibbard and colleagues, the researchers found that the very framing of potentially avoidable complications as an indicator of potential harm, is an effective way of communicating the quality of care. And when measures of PACs were presented in conjunction with price, consumers intuitively accepted the logical relationship between low PACs – fewer "defects" – and lower price.

Accountability for and measurement of PACs occurs at the practice, medical group, provider system or purchaser/payer level. PAC rates are calculated as absolute values. For example, a health plan would report that 40% of its plan members with hypertension incurred PACs in the study time window. The objective of the measure is to encourage the unit being measured to progressively reduce that amount over time. In addition, comparisons of PAC rates across plans or provider systems should be encouraged and publicly reported. An organization that uses the measure should be able to identify the leading causes of PACs and implement improvements to existing processes that will decrease PACs. There are several tools available for provider systems and health plans to impact PAC rates. These include care coordination across care settings; post-discharge planning and patient follow- up, active care management, sharing medical record data between care settings and providers, total quality management within hospitals and active reduction of patient safety failures. Reducing PACs has the potential to significantly improve the overall level of quality.

Creating a single measure of accountability for physicians and hospitals tied to gaps in quality is likely to yield much improved outcomes for patients. A measure of accountability for health plans helps them review trends over time and work with physicians and hospitals to improve the ways in which they engage patients using more optimal care management and care coordination (Cassel 2014). In addition, PAC measures could be used as a surrogate for quality in a consumer transparency tool to differentiate providers with regards to their performance.

Moreover, since these measures are claims based, there is minimal added burden for collecting the data, and it also avoids potential gaming that may occur for other measures that require reporting information to registries. Although use of administrative claims data in identifying conditions and measuring provider quality has been questioned, there are several studies in literature that acknowledge validity of its use (Normand 2007) (Quan 2009). Until more readily available data are at hand, use of administrative data to measure provider performance has steadily increased (Miller 2001), (NQF Quality Positioning System). Interestingly, in the current fee for service system, services for most PACs are rewarded by continued payment (except the CMS defined "never events") and hence to our advantage, adverse events surface in billing data. Claims based PAC measures; therefore serve as an alternative method to track adverse outcomes that do occur (Leibson 2008).

1b.2. Provide performance scores on the measure as specified (current and over time) at the specified level of analysis. *(This is required for endorsement maintenance. Include mean, std dev, min, max, interquartile range, scores by decile. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities included). This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*

The data included two years of administrative claims covering the period April 1, 2012 through December 17, 2014. There were a total 1,806 episodes of PCMDFR.

Because facilities with small volumes may provide unreliable estimates, we excluded any with fewer than 10 attributed episodes prior to the calculations. After this exclusion 22 (out of 380) facilities remained. Performance scores for these facilities are summarized in the following table:

Unadjusted PAC Rates:
- Median (IQR): 46.8% (39.5%, 55.2%)
- Range: 20% - 64.3%

Risk-Standardized PAC Rates (RSPR):
- Median (IQR): 46.2% (36.8%, 54.0%)
- Range: 20.8% - 62.5%

Please refer to the NQF_PCMDFR_all_codes_risk_adjustment 06.30.15.xls workbook under the “ProviderAttribution Reliability” tab to see specific results for each facility.

1b.3. If no or limited performance data on the measure as specified is reported in 1b2, then provide a summary of data from the literature that indicates opportunity for improvement or overall less than optimal performance on the specific focus of measurement.

Physician level of training and level of specialty certification have been shown to affect the risk of adverse events associated with ICD implant. An ICD Registry analysis found that physicians who implant more ICDs have lower rates of procedural complications and in hospital mortality (Krahn 2011) (Poole 2010).

A study analyzing data from the REPLACE registry reported a 4.0% complication rate in 1031 patients undergoing generator replacement and 15.3% in 713 patients with replacement and a lead addition. The REPLACE registry reported that ICDs were associated with a greater risk of complications (Poole 2010). Van Rees et al., who conducted a systematic review of major RCT's, concluded that both thoracotomy and non-thoracotomy ICD's had significantly higher in-hospital mortality and higher complication rates (Poole 2010). Mariana Parahuleva, in her extensive review of PCMDFR complications published as a book chapter states that, identification of factors contributing to complications may permit identification of high-risk individuals that warrant incremental monitoring and therapy to attenuate risk (Parahuleva 2011).

While PACs may not be completely eliminated, identifying their magnitude and understanding their causality, in particular for the most frequent or the most expensive, could lead to improving patient outcomes.

1b.4. **Provide disparities data from the measure as specified (current and over time) by population group, e.g., by race/ethnicity, gender, age, insurance status, socioeconomic status, and/or disability.** *(This is required for endorsement maintenance. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities include.) This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*
Not applicable

1b.5. **If no or limited data on disparities from the measure as specified is reported in 1b4, then provide a summary of data from the literature that addresses disparities in care on the specific focus of measurement. Include citations.**
Not applicable

1c. High Priority (previously referred to as High Impact)

The measure addresses:

- a specific national health goal/priority identified by DHHS or the National Priorities Partnership convened by NQF; OR
- a demonstrated high-priority (high-impact) aspect of healthcare (e.g., affects large numbers of patients and/or has a substantial impact for a smaller population; leading cause of morbidity/mortality; high resource use (current and/or future); severity of illness; and severity of patient/societal consequences of poor quality).

1c.1. **Demonstrated high priority aspect of healthcare**
Affects large numbers, A leading cause of morbidity/mortality, Frequently performed procedure, High resource use, Patient/societal consequences of poor quality, Severity of illness

1c.2. **If Other:**

1c.3. **Provide epidemiologic or resource use data that demonstrates the measure addresses a high priority aspect of healthcare. List citations in 1c.4.**
The use of pacemakers / defibrillators (PCMDFR) has increased exponentially by a combination of increasing number of patients with cardiac disease, expanding indications of device use and improved technology (van Rees 2011) (Greenspon 2012). Publication of the second Multicenter Automated Defibrillator Implantation Trial (MADIT II) trial resulted in the Centers for Medicare and Medicaid Services (CMS) coverage of ICDs (implantable cardioverter defibrillator) for patients meeting the MADIT II inclusion and exclusion criteria (Reynolds 2003). There was a 55.6% increase in the use of PCMDFR's in the 17 years from1993 to 2009, with 2.9 million patients receiving permanent pacemakers. The economic impact of these devices is significant with hospital charges for ICD's increasing by 45.3% during the same period (Greenspon 2012).

PCMDFR use is associated with complications at all stages of device use, starting from implantation, in-hospital stay to post discharge (Bond 2012). Patients with any complication, compared with those with none, generated $7251 in increased hospital costs and 3.4

days in increased LOS after adjustment for baseline characteristics (Reynolds 2006). In a large study analyzing more than 30,000 Medicare beneficiaries undergoing PCMDFR implantations, 10.8% experienced one or more complications prior to discharge. The occurrence of a complication increased adjusted hospital costs by almost 20% with an incremental cost of complications exceeding $78million per 100,000 implanted defibrillators (Reynolds 2006).

In order to analyze and report ICD procedural complications, the CMS created the Medicare ICD registry in 2005, now maintained by the American college of Cardiology (ACC NCDR ICD Registry). An analysis of more than 350,000 ICD implantations included in the National Cardiovascular Data Registry–ICD Registry revealed 3.1% of patients experienced in hospital adverse events, 1.2% experienced major adverse events, and 0.4% died. Adverse events were lower (1.9%) with single-chamber ICD implants than with dual-chamber ICD implants (2.9%) or with biventricular ICD implants (4.1%). Specific adverse event rates included lead dislodgement (1%), hematoma (0.9%), pneumothorax (0.4%), and cardiac arrest (0.3%)(Freeman 2012).

Associated comorbidities, type of device used as well as physician volumes further influence the complication rates. Physician level of training and level of specialty certification have been shown to affect the risk of adverse events associated with ICD implant. Various studies have shown that the commonest complications like lead displacement, pneumothorax, infection and perforation are all PAC's and are influenced by physician experience and training (Bond 2012) (Reynolds 2006) (Grimm 2006) (Eberhardt 2005) (Parsonette 1998) (Johansen 2011). An ICD Registry analysis also confirmed this finding (Krahn 2011) (Poole 2010).

With the rise in use of pacemakers / defibrillators (PCMDFR) and the significant number of avoidable complications (Kirkfeldt 2013) (Koneru 2011) (Beyerbach 2014) that are under the provider's control, PAC measures in the pacemaker / defibrillator population is a high priority aspect of health care. The PAC measures look for all-cause harms in patients receiving these devices.

1d. Composite Quality Construct and Rationale

1d.1. **A composite performance measure is a combination of two or more component measures, each of which individually reflects quality of care, into a single performance measure with a single score.**

For purposes of NQF measure submission, evaluation, and endorsement, the following will be considered composites:

- Measures with two or more individual performance measure scores combined into one score for an accountable entity.
- Measures with two or more individual component measures assessed separately for each patient and then aggregated into one score for an accountable entity:
  - all-or-none measures (e.g., all essential care processes received, or outcomes experienced, by each patient); or
  - any-or-none measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient).

1d.1. Please identify the composite measure construction: any-or-none measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient)

1d.2. **Describe the quality construct, including:**

- the overall area of quality
- included component measures and
- the relationship of the component measures to the overall composite and to each other.

The PAC measures, as we define them, look at many "care defects" comprehensively. They are composed of several cross-cutting measures and together they paint a global picture of the provider's overall performance.

We classify PACs into two types: Type 1 PACs are directly related to the index condition and are often controlled by the servicing provider; Type 2 PACs, on the other hand result from patient safety failures and could be reduced by better systems and better processes in care. Both types of PACs could occur in any setting and so could be identified through any type of claims coming in the administrative dataset, including in-patient, out-patient, or professional claims. PACs may occur any time during the episode time window. PACs are counted as a dichotomous (yes/no) outcome. If a patient had one or more PACs, they get counted as a "yes" or a 1.

The PAC measure definitions encompass several other measures that are accepted as being valid complications of care and are widely used throughout the country. These include CMS defined Hospital Acquired Conditions (HACs), Hospital Inpatient Quality Reporting measures, Avoidable Readmissions, AHRQ defined patient safety indicators (PSIs), NQF endorsed patient safety measures

such as patient fall rates, pressure ulcer rates, and peri-operative pulmonary embolism or deep vein thrombosis rates.

All defined PACs, irrespective of their type, or site of occurrence, are aggregated to create an overall comprehensive, composite measure. They all have equal weighting, since they are measured simply by the frequency of their occurrence.

1d.3. **Describe the rationale for constructing a composite measure, including how the composite provides a distinctive or additive value over the component measures individually.**
Each individual PAC, when measured in isolation, provides a very limited picture of the performance of the provider(s) who are managing or co-managing the care of the patient. However, looking at all the PACs that may occur individually or concurrently in a patient with a given episode provides a comprehensive picture of the care received by the patient for that particular condition or illness.

Additionally, the frequency of occurrence of individual PACs may be so low that it may require very high sample sizes from individual providers to achieve any meaningful and reliable comparisons. But aggregating all the PACs into a single quality metric creates meaningful scores that can be compared across providers even with relatively smaller sample sizes.

Additionally, a comprehensive measure is easier to explain to the average consumer. From a patient's point of view, any bad outcome has an impact on their health with respect to return to work, functional limitations and need for additional support. If a provider has a high PAC rate with regards to one component PAC but not the other PACs, the impact on the patient is still adverse. In selecting providers, individual component PAC scores would mean nothing to a patient, but aggregating it to a comprehensive quality score could be a measure of "all-cause" harms and easier to interpret and act on.

1d.4. **Describe how the aggregation and weighting of the component measures are consistent with the stated quality construct and rationale.**
In constructing the comprehensive composite PAC measure, each component PAC, as clinically defined by the subject matter experts, was given the same weight so that arbitrary weights may not bias the results. Furthermore, the measure is constructed so that the occurrence of any number of PACs during a defined episode would only count as one occurrence. As such, the patient is the ultimate unit of measurement and if the patient incurred any PAC during the episode, then that counts against the numerator.

Since the emphasis of the PAC measure was to simply identify the occurrence of PACs in any setting, aggregation of the PAC counts to create a comprehensive quality score with equal weights has been met with overall support from the clinical working groups as well as from the implementation sites.

2. Reliability and Validity—Scientific Acceptability of Measure Properties

Extent to which the measure, as specified, produces consistent (reliable) and credible (valid) results about the quality of care when implemented. ***Measures must be judged to meet the subcriteria for both reliability and validity to pass this criterion and be evaluated against the remaining criteria.***

2a.1. Specifications The measure is well defined and precisely specified so it can be implemented consistently within and across organizations and allows for comparability. eMeasures should be specified in the Health Quality Measures Format (HQMF) and the Quality Data Model (QDM).

De.5. **Subject/Topic Area** *(check all the areas that apply):*
Cardiovascular

De.6. **Cross Cutting Areas** *(check all the areas that apply):*
Care Coordination, Care Coordination : Readmissions, Safety, Safety : Complications, Safety : Healthcare Associated Infections, Safety : Medication Safety, Safety : Readmissions, Safety : Venous Thromboembolism

S.1. **Measure-specific Web Page** *(Provide a URL link to a web page specific for this measure that contains current detailed specifications including code lists, risk model details, and supplemental materials. Do not enter a URL linking to a home page or to general information.)*
http://www.hci3.org/ecr_descriptions/ecr_description.php?version=5.2.006&name=PCMDFR&submit=Submit

S.2a. **If this is an eMeasure**, HQMF specifications must be attached. Attach the zipped output from the eMeasure authoring tool (MAT) - if the MAT was not used, contact staff. (Use the specification fields in this online form for the plain-language description of the specifications)
This is not an eMeasure **Attachment:**

S.2b. **Data Dictionary, Code Table, or Value Sets** *(and risk model codes and coefficients when applicable) must be attached. (Excel or csv file in the suggested format preferred - if not, contact staff)*
Attachment **Attachment:** NQF_PCMDFR_all_codes_risk_adjustment_06.30.15-635719851913348171.xlsx

S.3. **For endorsement maintenance**, please briefly describe any changes to the measure specifications since last endorsement date and explain the reasons.
Not applicable

S.4. **Numerator Statement** *(Brief, narrative description of the measure focus or what is being measured about the target population, i.e., cases from the target population with the target process, condition, event, or outcome)*
IF an OUTCOME MEASURE, state the outcome being measured. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
Number of patients who underwent a pacemaker/defibrillator implantation (PCMDFR), are followed for at least 30-days, and have one or more potentially avoidable complications (PACs) during the episode time window.

S.5. **Time Period for Data** *(What is the time period in which data will be aggregated for the measure, e.g., 12 mo, 3 years, look back to August for flu vaccination? Note if there are different time periods for the numerator and denominator.)*
The time window includes a 7-day look-back period and a 30-day look-forward period from the PCMDFR trigger claim.

S.6. **Numerator Details** *(All information required to identify and calculate the cases from the target population with the target process, condition, event, or outcome such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
IF an OUTCOME MEASURE, describe how the observed outcome is identified/counted. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
Patients that have triggered a PCMDFR episode, are followed for at least 30-days, and are identified as having services for potentially avoidable complications (PACs). PACs may occur during the index stay or during the 30-day post discharge period. The enclosed excel workbook entitled NQF_PCMDFR_all_codes_risk_adjustment_06.30.15 gives the detailed codes for PACs in the tabs entitled PACs I-9 and PACs I-10.

Services for PACs are identified as follows:
a. Any Index stay that has a PAC diagnosis code in any position except in the PRIMARY (principal) position is considered as having a potentially avoidable complication
b. Any readmission to an acute care facility 2 days or later after discharge but within 30-days post-discharge, that is relevant to PCMDFR
c. Any admission to a post-acute care facility, that is relevant to PCMDFR and has a PAC code in any position on the claim
d. Any other service (professional, outpatient facility, ancillary) that is relevant to PCMDFR and has a PAC code in any position on the claim

S.7. **Denominator Statement** *(Brief, narrative description of the target population being measured)*
Adult patients aged 18 years and above who underwent a Pacemaker/defibrillator implantation - PCMDFR) procedure and are followed for at least 30-days.

S.8. **Target Population Category** *(Check all the populations for which the measure is specified and tested if any):*
Populations at Risk, Populations at Risk : Dual eligible beneficiaries, Populations at Risk : Individuals with multiple chronic conditions, Populations at Risk : Veterans, Senior Care

S.9. **Denominator Details** *(All information required to identify and calculate the target population/denominator such as definitions, specific data collection items/responses , code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
Please refer to the enclosed excel workbook entitled
NQF_PCMDFR_all_codes_risk_adjustment 06.30.15

The target population is identified using the following criteria:
1. Using administrative claims database, patients undergoing PCMDFR are identified using one of the following criteria:
 a. Patients with a procedure code of PCMDFR in any position on an in-hospital stay claim with a qualifying diagnosis code relevant to the PCMDFR procedure.
 b. Patients with a procedure trigger code of PCMDFR in any position on an outpatient facility claim with a qualifying diagnosis code relevant to the PCMDFR procedure.
 c. Patients having a professional service carrying a trigger code of PCMDFR in any position.
The trigger codes for PCMDFR and the qualifying diagnosis codes are provided in the tab called "Triggers I-9" or "Triggers I-10".

2. The patient should have continuous enrollment for the entire time window with no enrollment gap, with the entity providing the data (so we can ensure that the database has captured most of the claims for the patient during the episode time window).
3. The patient should have a complete episode time window in the claims data – so the end date of the episode should not be past the database claims end date.
4. Patient should be at least 18 years of age
5. Patients that have a trigger code on a professional claim and have no associated facility bill are considered as having an orphan (incomplete) episode and are dropped from analysis.

Once the episode is triggered all relevant claims are assigned to the episode. Relevant claims could be inpatient facility claims, outpatient facility claims, professional services, laboratory services, imaging services, ancillary claims, home health, durable medical equipment as well as pharmacy claims across the entire continuum of care centered around the patient's episode of care. Relevant claims are identified as those that have a diagnosis code that matches the codes in the typical Dx codes tabs (Typical Dx I-9 or Typical Dx I-10), or in the PAC Dx codes tab (PACs I-9 or PACs I-10) AND a procedure code as identified in the Relevant Procedures I-9 & I-10 tab in the enclosed workbook. Relevant readmissions and relevant admissions to post-acute care facilities are also included in the denominator.

S.10. **Denominator Exclusions** *(Brief narrative description of exclusions from the target population)*
Denominator exclusions include exclusions of either "patients" or "claims" based on the following criteria:
1. "Patients" excluded are those that do not meet the enrollment criteria. If patient has an enrollment gap for any time period during the episode time window, it is considered as an enrollment gap
2. "Patients" are also excluded if the cost of the episode is an outlier at greater than 99th percentile or less than 1st percentile value for all episodes. This is another way to ensure that episodes are complete as well as they do not bring in random noise into the analysis due to inappropriate codes or services.
3. "Claims" are excluded from the PCMDFR measure if they are considered not relevant to PCMDFR care.

S.11. **Denominator Exclusion Details** *(All information required to identify and calculate exclusions from the denominator such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
Denominator exclusions include exclusions of "patients" as well as "claims" not relevant to PCMDFR care. Please refer to the enclosed excel workbook entitled (NQF_PCMDFR_all_codes_risk_adjustment 06.30.15.xls)

1. "Patients" are excluded from the measure if they meet one of the following criteria:
 a. If age is < 18 years
 b. If gender is missing
 c. If they do not have continuous enrollment for the entire time window with a maximum of 30 day enrollment gap with the entity providing the data (this helps determine if the database has captured most of the claims for the patient in the time window).
 d. If the episode time window extends beyond the dataset end date (this helps eliminate incomplete episodes).
 e. The episode cost is an outlier (less than 1st percentile or greater than 99th percentile value for all episodes of the same type). This eliminates extreme variation that may result from random outlier events.

2. "Claims" are excluded from the measure based on the following criteria:
 a. If none of the diagnosis codes on the claim are on the list of relevant diagnosis codes (either typical Dx or PAC Dx) for PCMDFR.
 b. If none of the procedure / CPT codes on the claim are on the list of relevant procedure codes for PCMDFR.

S.12. **Stratification Details/Variables** *(All information required to stratify the measure results including the stratification variables, definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format with at S.2b)*
None

S.13. Risk Adjustment Type (Select type. Provide specifications for risk stratification in S.12 and for statistical model in S.14-15)
Statistical risk model
If other:

S.14. Identify the statistical risk model method and variables *(Name the statistical method - e.g., logistic regression and list all the risk factor variables. Note - risk model development and testing should be addressed with measure testing under Scientific Acceptability)*
Conceptual Model
Variations in outcomes across populations may be due to patient-related factors or due to provider-controlled factors. When we adjust for patient-related factors, the remaining variance in PACs are due to factors that could be controlled by all providers that are managing or co-managing the patient, both during and after hospitalization.

Statistical Method:
Logistic Regression model to determine the probability of a patient incurring a PAC
Demographic variables, comorbid conditions, as well as clinical severity indicators are fed as independent risk factors into the model. Risk Factors are collected historically. Subtype information is collected from the index claim and any look-back period, if relevant. Subtypes are clinical severity indicators suggesting severity of the episode itself, for example, diagnosis of cardiomyopathy in a PCMDFR patient. For each patient the "predicted" coefficients from the risk adjustment models are summed to give the predicted probabilities of the occurrence of a PAC.

Risk Factors :(Please refer to the enclosed excel workbook entitled (NQF_PCMDFR_all_codes_risk_adjustment 06.30.15.xls). The risk factors along with their codes are listed in the tabs called "All Risk Factors I-9" and "All Risk Factors I-10" and also listed below:

AGE CONTINUOUS VARIABLE
GENDER FEMALE = 1 (MALE IS REFERENCE = 0)

Risk Factor #	Risk Factor Name
RF0101	Anoxic Brain Damage, persistent vegetative state
RF0102	Delirium, Meningitis, Encephalitis
RF0103	Previous Stroke, Paralysis
RF0104	Cerebral Palsy and Other Paralytic Syndromes

The prevalence of the risk factors in our reference dataset are listed in the enclosed workbook entitled NQF_PCMDFR_all_codes_risk_adjustment 06.30.15.xls – see tab "Risk Factor Prevalence". The output of the regression model are given in the same workbook in the tab "Risk Model'.

S.15. **Detailed risk model specifications** *(must be in attached data dictionary/code list Excel or csv file. Also indicate if available at measure-specific URL identified in S.1.)*
Note: Risk model details (including coefficients, equations, codes with descriptors, definitions), should be provided on a separate worksheet in the suggested format in the Excel or csv file with data dictionary/code lists at S.2b.
Available in attached Excel or csv file at S.2b

S.15a. **Detailed risk model specifications** (*if not provided in excel or csv file at S.2b*)

S.16. **Type of score:**
Rate/proportion
If other:

S.17. **Interpretation of Score** *(Classifies interpretation of score according to whether better quality is associated with a higher score, a lower score, a score falling within a defined interval, or a passing score)*
Better quality = Lower score

S.18. **Calculation Algorithm/Measure Logic** *(Describe the calculation of the measure score as an ordered sequence of steps including identifying the target population; exclusions; cases meeting the target process, condition, event, or outcome; aggregating data; risk adjustment; etc.)*
Please refer to the enclosed excel workbook entitled (NQF_PCMDFR_all_codes_risk_adjustment 06.30.15.xls).

Assembling the Denominator:

Using administrative claims database, patients undergoing a PCMDFR are identified using one of the following criteria: 1) Patients with a procedure code of PCMDFR in any position on an in-patient of an out-patient facility claim with a qualifying diagnosis code relevant to the PCMDFR procedure, 2) Patients having a professional service carrying a trigger code of PCMDFR in any position. The trigger codes for PCMDFR are provided in the tab called "Triggers I-9" or "Triggers I-10".

Patients are retained if they are 18 years of age or more, do not have a missing gender, have a complete episode time window in the database, have a maximum of 30-dayno enrollment gap for the entire episode time window, and have no outlier episode costs. All relevant professional, laboratory, imaging, ancillary and other claims that are incurred during the episode time window are included as part of the episode. Claims are considered relevant to PCMDFR care if they have one of the diagnosis codes, as listed on the tab entitled Triggers I-9, Triggers 1-10, PACs I-9, PACs I-10, Typical Dx I-9, or Typical Dx I-10 in any position on the claim AND a procedure code as identified in the Relevant Procedures I-9 & I-10 tab in the enclosed workbook. Relevant readmissions and relevant admissions to post-acute care facilities are also included in the denominator. All relevant pharmacy claims carrying codes that match the ingredients listed in the Pharmacy tab of the enclosed workbook are also included as part of the episode.

If a patient has more than one concurrent episode, and the claim is relevant to both episodes, the claim could get multi-assigned, except in the case of procedural episodes that get carved out with respect to the index stay. So if an inpatient stay claim carried a procedure code that matched the trigger procedure code for PCMDFR but they also had a qualifying diagnosis code for CAD (coronary artery disease), the stay claim would trigger both episodes concurrently, but get uniquely assigned to PCMDFR and not be counted with CAD.

Once all the episodes are assembled, episodes that match the exclusion criteria, such as those with outlier costs, are flagged (those with total episode costs less than 1st percentile or greater than 99th percentile), and excluded from the final analysis.

Assembling the Numerator:

For every episode included in the denominator, services are flagged as having a PAC (potentially avoidable complication) based on the criteria listed below:

Any Index stay that has a PAC diagnosis code in any position except in the PRIMARY (principal) position is considered as having a potentially avoidable complication

Any readmission to an acute care facility 2 days or later after discharge but within 30-days post-discharge, that is relevant to PCMDFR

Any admission to a post-acute care facility, that is relevant to PCMDFR and has a PAC code in any position on the claim

Any other service (professional, outpatient facility, laboratory, imaging, ancillary) that is relevant to PCMDFR and has a PAC code in any position on the claim

Relevant claims that do not have any PAC codes, and do not qualify as a PAC based on the criteria outlined above, are listed as typical claims. All included relevant pharmacy services are flagged as typical. Patients that have even a single PAC claim are counted as part of the numerator.

Calculating the measure:

Proportion of PCMDFR patients that have PACs, is simply the ratio of patients with PACs within the PCMDFR population and is called the PAC rate as shown in the equation below:

PAC rate = Patients with PCMDFR that have at least one PAC claim / Total number of PCMDFR patients

A flow chart demonstrating the series of steps and the counts of patients at each step is shown in tab entitled Decision Tree of the enclosed workbook called NQF_PCMDFR_all_codes_risk_adjustment 06.30.15.xls

Drill Down Calculations:

Further analysis from this construct helps create actionable reports.

For example as shown in the tab labeled PAC overview, not only do we have the PAC rate for a population, we can break them down by the PAC type – type 1 being directly related to PCMDFR and so actionable by the servicing physician, while type 2 PACs are related to patient safety failures and can be improved by process improvement. Additionally, analyzing what portion of the PACs occur during the index stay, vs. in the post-discharge period and how many are due to readmissions helps focus strategies in reducing them.

Risk Adjustment:

Once we have the observed PAC rates, we risk-adjust them for patient factors such as patient demographics, comorbidities collected historically, and for severity of illness or procedure using subtypes collected from the index stay and / or look-back period. This

helps adjust for factors outside the providers control and levels the playing field for provider performance comparisons.

Unit of Analysis:
The unit of analysis is the individual episode.

Dependent Variable:
The dependent variable is a dichotomous variable indicating whether an episode had one or more claims assigned as a PAC (=1) or not (=0).

Independent Variables:
A number of patient-related "risk factors" or covariates are included in the models:

Patient demographics: age, gender, and an indicator of whether a member has enrolled within the previous 6 months. This latter risk factor is intended to account for the patient's lack of claims history, which limits the number of potential comorbidities that can be identified.

Comorbidities: These are conditions or events that occurred prior to the start of the episode that can have a potential impact on the patient's risk of having a PAC. The risk factors are 170 disease indicators (0/1) identified through the presence of ICD diagnosis codes on individual medical claims and collected from the historical claims data before the start of an episode. These are universally applied across all episodes. Please see the tab labeled "All Risk Factors I-9" and "All Risk Factors I-10" for a list of risk factors and their corresponding codes in the enclosed workbook called NQF_PCMDFR_all_codes_risk_adjustment 06.30.15.xls

Episode Subtypes or Severity Markers: These are markers that distinguish an episode as being more severe than another. They indicate either specific patient comorbidities that are known to make the procedure or condition more difficult to treat (e.g., obesity) or severity of the illness itself (e.g., unstable anginacardiomyopathy). Please see the tab labeled "Subtypes I-9" and "Subtypes I-10" for a list of subtypes and their corresponding codes in the enclosed workbook called NQF_PCMDFR_all_codes_risk_adjustment 06.30.15.xls

As mentioned previously, to avoid creating perverse incentives all comorbidities and subtypes are identified prior to or at the very start of the episode. None are identified during the episode period.

Statistical Methods
We use logistic regression to model the probability of at least one PAC occurring during the episode. Only comorbidities and subtypes are included in the models as covariates if they are present in at least 10 episodes to prevent unstable coefficients. No further model building is conducted after the initial models are built. This reflects a desire to explain as much variation in the probability of having a PAC as possible, but it does not make it a priority that all covariates in the model be individually significant or even uncorrelated with each other. Accordingly, the model uses a very large group of covariates. This modeling approach allows for fewer potentially artificial constraints around the definitions of what constitutes severity of a episode condition, and lets each regression model determine for itself which of the factors are more significant for a specific episode. Non-significant covariates in episode models can not overly influence predicted outcomes, nor is much harm realized, if a group of correlated covariates work together to explain variation rather than having the variation explained by a single best factor.

When more than one line of business is included in the data, separate models are calculated for each sample (i.e., commercial, Medicaid etc.).

Provider Attribution and calculating PAC rates by provider:

Once episodes are constructed they are attributed to providers based on one of the various attribution rules. For PCMDFR, episodes are attributed to the facility where the episode triggered, or, if the episode is triggered off a professional claim, it is attributed to the first facility claim that overlaps the professional trigger claim date.episodes are attributed to the facility where the episode triggered, or, if the episode is triggered off a professional claim, the facility listed on the first facility claim that occurs during the episode.

Using the logistic regression technique described above, a model is developed that gives estimates for each risk factor and subtype for the patients in the population analyzed. These estimates are used to develop patient-level probabilities for the occurrence of PACs. The patient-level probability estimates are summed to construct aggregated measures (e.g., facility/provider-level). This method is similar to the methods employed by the Centers for Medicare and Medicaid Services (CMS) and endorsed by the National Quality Forum (NQF) to construct similar facility- and practice-level measures (i.e., mortality, readmissions, etc.):
1. For each provider, the number of actual observed occurrences of the outcome is summed across all attributed patients with that episode, to give the observed PAC rates for the provider.
2. Similarly adjusted probabilities from the risk adjustment models are summed across all attributed patients to give expected PACs

for the provider.
3. The observed sum is then divided by the summed probabilities (O/E). This number yields whether the provider or facility had more PACs than expected (ratio>1), as expected (ratio=1), or less than expected (ratio<1). This calculation yields a practice-level unstandardized performance ratio.
4. To facilitate accurate comparisons of rates across units of analysis, this ratio is then standardized to the community rate using the indirect method. Specifically, the provider-level rate is multiplied by the expected community rate, calculated as the sum of adjusted probabilities for every individual in the sample across all providers in the analysis. This measure, known as the standardized rate, represents what the unit's risk-adjusted rate would be for the outcome of interest if its patient population was reflective of the of the overall community.

The formula for this calculation is as follows:

Adj Outcome_j={(SUM Observed_ij)/(SUM Prob_ij)} × {(SUM Prob_i) / (# of episodes)}
Where individual is attributed to unit of analysis j (e.g., practice, provider, etc.)

Minimum sample size requirements for PAC measures are a function of the reliability testing of the measures on every dataset on which the measures are applied. Our research suggests that minimum sample sizes to achieve high degrees of reliability in the measures are a function of the dataset analyzed, and as such may vary from dataset to dataset. One should not infer that a minimum sample size achieved in one dataset will apply to another.

S.19. **Calculation Algorithm/Measure Logic Diagram URL or Attachment** *(You also may provide a diagram of the Calculation Algorithm/Measure Logic described above at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
Available in attached appendix at A.1

S.20. **Sampling** *(If measure is based on a sample, provide instructions for obtaining the sample and guidance on minimum sample size.)*
IF a PRO-PM, identify whether (and how) proxy responses are allowed.
Not applicable

S.21. **Survey/Patient-reported data** *(If measure is based on a survey, provide instructions for conducting the survey and guidance on minimum response rate.)*
IF a PRO-PM, specify calculation of response rates to be reported with performance measure results.
Not applicable

S.22. **Missing data** (specify how missing data are handled, e.g., imputation, delete case.)
Required for Composites and PRO-PMs.
If patient related data is missing, the case is deleted from both the numerator and the denominator

S.23. **Data Source** *(Check ONLY the sources for which the measure is SPECIFIED AND TESTED).*
If other, please describe in S.24.
Administrative claims

S.24. **Data Source or Collection Instrument** *(Identify the specific data source/data collection instrument e.g. name of database, clinical registry, collection instrument, etc.)*
IF a PRO-PM, identify the specific PROM(s); and standard methods, modes, and languages of administration.
The information is based on a two-year claims database from a large regional commercial insurer. The database has over 3.2 million covered lives and $25.9 billion in "allowed amounts" for claims costs. The database is an administrative claims database with medical as well as pharmacy claims.

The methodology can be used on any claims database with at least two years of data and a minimum of 150 patients with the index condition or hospitalization. Having pharmacy data adds to the richness of the risk-adjustment models.
The calculations of rates of potentially avoidable complications can be replicated by anyone that uses the measure specifications along with the metadata file that is available for free on our web site at http://www.hci3.org/ecre/xml-agreement.html.
We also plan on providing a limited automated analysis, at no cost, on our website.
The methodology has been tested on databases of several health plans as well as on a few employer databases.

No data collection instrument was used.

S.25. **Data Source or Collection Instrument** *(available at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
No data collection instrument provided

S.26. **Level of Analysis** *(Check ONLY the levels of analysis for which the measure is SPECIFIED AND TESTED)*
Clinician : Group/Practice, Clinician : Team, Facility, Health Plan, Population : National, Population : Regional, Population : State

S.27. **Care Setting** *(Check ONLY the settings for which the measure is SPECIFIED AND TESTED)*
Ambulatory Care : Ambulatory Surgery Center (ASC), Hospital/Acute Care Facility, Other
If other: Across the care continuum

S.28. **COMPOSITE Performance Measure** - Additional Specifications *(Use this section as needed for aggregation and weighting rules, or calculation of individual performance measures if not individually endorsed.)* The individual complications are considered measurable components. Separate specifications are not required for this measure.

2a. Reliability – See attached Measure Testing Submission Form
2b. Validity – See attached Measure Testing Submission Form
2752_PCMDFR_Testing_Reliability_Validity_HCI3.docx

NATIONAL QUALITY FORUM—Measure Testing (subcriteria 2a2, 2b2-2b7)

Composite Measure Title: 2752
Measure Title: Proportion of Patients undergoing Pacemaker / Defibrillator Implantation (PCMDFR) that have a Potentially Avoidable Complication (during the episode time window)
Date of Submission: 06/30/15
Composite Construction:
☐Two or more individual performance measure scores combined into one score
☐ All-or-none measures (e.g., all essential care processes received or outcomes experienced by each patient)
☐ Any-or-none measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient)

Instructions

- Measures must be tested for all the data sources and levels of analyses that are specified. ***If there is more than one set of data specifications or more than one level of analysis, contact NQF staff*** about how to present all the testing information in one form.
- **For all measures, sections 1, 2a2, 2b2, 2b3, and 2b5 must be completed.**
- **For outcome and resource use measures**, section **2b4** also must be completed.
- If specified for **multiple data sources/sets of specifications** (e.g., claims and EHRs), section **2b6** also must be completed.
- Respond to all questions as instructed with answers immediately following the question. All information on testing to demonstrate meeting the subcriteria for reliability (2a2) and validity (2b2-2b6) must be in this form. An appendix for *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 20 pages (*including questions/instructions;* minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the testing results for this measure meet NQF's evaluation criteria for testing.

2a2. Reliability testing [10] demonstrates the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise. For **PRO-PMs and composite performance measures**, reliability should be demonstrated for the computed performance score.

2b2. Validity testing [11] demonstrates that the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality. For **PRO-PMs and composite performance measures**, validity should be demonstrated for the computed performance score.

2b3. Exclusions are supported by the clinical evidence; otherwise, they are supported by evidence of sufficient frequency of occurrence so that results are distorted without the exclusion; [12]
AND
If patient preference (e.g., informed decisionmaking) is a basis for exclusion, there must be evidence that the exclusion impacts performance on the measure; in such cases, the measure must be specified so that the information about patient preference and the effect on the measure is transparent (e.g., numerator category computed separately, denominator exclusion category computed separately). [13]

2b4. For outcome measures and other measures when indicated (e.g., resource use):

- **an evidence-based risk-adjustment strategy** (e.g., risk models, risk stratification) is specified; is based on patient factors that influence the measured outcome (but not factors related to disparities in care or the quality of care) and are present at start of care; [14,15] and has demonstrated adequate discrimination and calibration

OR

- rationale/data support no risk adjustment/ stratification.

2b5. Data analysis of computed measure scores demonstrates that methods for scoring and analysis of the specified measure allow for **identification of statistically significant and practically/clinically meaningful** [16] **differences in performance**;
OR
there is evidence of overall less-than-optimal performance.

2b6. If multiple data sources/methods are specified, there is demonstration they produce comparable results.

2b7. For **eMeasures, composites, and PRO-PMs** (or other measures susceptible to missing data), analyses identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias.

Notes
10. Reliability testing applies to both the data elements and computed measure score. Examples of reliability testing for data elements include, but are not limited to: inter-rater/abstractor or intra-rater/abstractor studies; internal consistency for multi-item scales; test-retest for survey items. Reliability testing of the

measure score addresses precision of measurement (e.g., signal-to-noise).
11. Validity testing applies to both the data elements and computed measure score. Validity testing of data elements typically analyzes agreement with another authoritative source of the same information. Examples of validity testing of the measure score include, but are not limited to: testing hypotheses that the measures scores indicate quality of care, e.g., measure scores are different for groups known to have differences in quality assessed by another valid quality measure or method; correlation of measure scores with another valid indicator of quality for the specific topic; or relationship to conceptually related measures (e.g., scores on process measures to scores on outcome measures). Face validity of the measure score as a quality indicator may be adequate if accomplished through a systematic and transparent process, by identified experts, and explicitly addresses whether performance scores resulting from the measure as specified can be used to distinguish good from poor quality.
12. Examples of evidence that an exclusion distorts measure results include, but are not limited to: frequency of occurrence, variability of exclusions across providers, and sensitivity analyses with and without the exclusion.
13. Patient preference is not a clinical exception to eligibility and can be influenced by provider interventions.
14. Risk factors that influence outcomes should not be specified as exclusions.
15. Risk models should not obscure disparities in care for populations by including factors that are associated with differences/inequalities in care, such as race, socioeconomic status, or gender (e.g., poorer treatment outcomes of African American men with prostate cancer or inequalities in treatment for CVD risk factors between men and women). It is preferable to stratify measures by race and socioeconomic status rather than to adjust out the differences.
16. With large enough sample sizes, small differences that are statistically significant may or may not be practically or clinically meaningful. The substantive question may be, for example, whether a statistically significant difference of one percentage point in the percentage of patients who received smoking cessation counseling (e.g., 74 percent v. 75 percent) is clinically meaningful; or whether a statistically significant difference of $25 in cost for an episode of care (e.g., $5,000 v. $5,025) is practically meaningful. Measures with overall less-than-optimal performance may not demonstrate much variability across providers.

1. DATA/SAMPLE USED FOR ALL TESTING OF THIS MEASURE
Often the same data are used for all aspects of measure testing. In an effort to eliminate duplication, the first five questions apply to all measure testing. If there are differences by aspect of testing,(e.g., reliability vs. validity) be sure to indicate the specific differences in question 1.7.

1.1. What type of data was used for testing? (*Check all the sources of data identified in the measure specifications and data used for testing the measure*. *Testing must be provided for all the sources of data specified and intended for measure implementation.* ***If different data sources are used for the numerator and denominator, indicate N [numerator] or D [denominator] after the checkbox.***)

Measure Specified to Use Data From: (***must be consistent with data sources entered in S.23***)	**Measure Tested with Data From:**
☐ abstracted from paper record	☐ abstracted from paper record
☐ administrative claims	☐ administrative claims
☐ clinical database/registry	☐ clinical database/registry
☐ abstracted from electronic health record	☐ abstracted from electronic health record
☐ eMeasure (HQMF) implemented in EHRs	☐ eMeasure (HQMF) implemented in EHRs
☐ other: Click here to describe	☐ other: Click here to describe

1.2. If an existing dataset was used, identify the specific dataset (*the dataset used for testing must be consistent with the measure specifications for target population and healthcare entities being measured; e.g., Medicare Part A claims, Medicaid claims, other commercial insurance, nursing home MDS, home health OASIS, clinical registry*).

The information is based on a two-year administrative claims database from a large regional commercial insurer. The database contains medical and pharmacy claims on over 3.2 million covered lives and more than $25.9 billion in "allowed amounts" for costs.

1.3. What are the dates of the data used in testing? April 1, 2012 – December 17, 2014

1.4. What levels of analysis were tested? (*testing must be provided for <u>all</u> the levels specified and intended for measure implementation, e.g., individual clinician, hospital, health plan*)

Measure Specified to Measure Performance of: (*must be consistent with levels entered in item S.26*)	**Measure Tested at Level of:**
☐ individual clinician	☐ individual clinician
☐ group/practice	☐ group/practice
☐ hospital/facility/agency	☐ hospital/facility/agency
☐ health plan	☐ health plan
☐ other: Integrated Delivery System	☐ other:

1.5. How many and which <u>measured entities</u> were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of measured entities included in the analysis (e.g., size, location, type); if a sample was used, describe how entities were selected for inclusion in the sample*)

There were a total of 380 facilities in the data set. Because providers or facilities with small volumes may provide unreliable estimates, we excluded any with fewer than 10 attributed episodes prior to the reliability calculations. After this exclusion, there were 22 facilities left.

1.6. How many and which <u>patients</u> were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of patients included in the analysis (e.g., age, sex, race, diagnosis); if a sample was used, describe how patients were selected for inclusion in the sample*)

After exclusions (see 2b.3.1 below), there were a total of 1,806 episodes of PCMDFR were included in the testing and analysis. Patients in these episodes were, on average, 54.1 years of age (range 18-64) and 31% were female. We did not have race information on these patients. All patients for this analysis had a trigger inpatient claim of PCMDFR as identified in our code tables.

1.7. If there are differences in the data or sample used for different aspects of testing (e.g., reliability, validity, exclusions, risk adjustment), identify how the data or sample are different for each aspect of testing reported below.

For the reliability analysis, we restricted the data to only facilities with at least 10 attributed episodes. For risk adjustment, all episodes were used in the analysis, regardless of the facility to which they were attributed.

1.8 What were the patient-level sociodemographic (SDS) variables that were available and analyzed in the data or sample used? For example, patient-reported data (e.g., income, education, language), proxy variables when SDS data are not collected from each patient (e.g. census tract), or patient community characteristics (e.g. percent vacant housing, crime rate).
None of the analyses included SDS variables.

_____

2a2. RELIABILITY TESTING
***Note**: If accuracy/correctness (validity) of data elements was empirically tested, separate reliability testing of data elements is not required – in 2a2.1 check critical data elements; in 2a2.2 enter "see section 2b2 for validity testing of data elements"; and skip 2a2.3 and 2a2.4.*

2a2.1. What level of reliability testing was conducted? (*may be one or both levels*)
☐ **Critical data elements used in the measure** (*e.g., inter-abstractor reliability; data element reliability must address ALL critical data elements*)
☐ **Performance measure score** (e.g., *signal-to-noise analysis*)

2a2.2. For each level checked above, describe the method of reliability testing and what it tests (*describe the steps—do not just name a method; what type of error does it test; what statistical analysis was used*)

We assessed the reliability of the measure to demonstrate that it sufficiently differentiates performance between providers using the beta-binomial method, which is applicable to measures of this type. Reliability is a measure that distinguishes the signal (the extent of performance variation between entities that is due to true differences in performance) from statistical noise. Our approach follows directly from the methods outlined in the technical report "The Reliability of Provider Profiling: A Tutorial" by J.L. Adams.

Reference:

Adams JL. The Reliability of Provider Profiling: A Tutorial. Rand Corporation. http://www.rand.org/pubs/technical_reports/TR653.html.

2a2.3. For each level of testing checked above, what were the statistical results from reliability testing? (e.*g., percent agreement and kappa for the critical data elements; distribution of reliability statistics from a signal-to-noise analysis*)

The beta-binomial failed to produce statistically significant parameters. Therefore the reliability scores calculated show low reliability and we will be unable to differentiate provider performance in this dataset. For detailed calculations, refer to the workbook entitled, NQF_PCMDRF_all_codes_risk_adjustment_06.30.15.xls, under the "ProviderAttribution Reliability" tab to see provider-specific results.

As an ad hoc analysis, we tested the measure in another commercial dataset, and found decent reliability scores and providers with sample sizes as low as 22 patients, had a reliability >0.7. Results of this analysis are also displayed in the enclosed workbook entitled, NQF_PCMDRF_all_codes_risk_adjustment_06.30.15.xls, under the "ProviderAttribution Reliability" tab.
.

2a2.4 What is your interpretation of the results in terms of demonstrating reliability? (i.*e., what do the results mean and what are the norms for the test conducted?*)

Reliability scores can vary from 0.0 to 1.0, with a score of zero indicating that all variation is attributable to measurement error (noise, or variation across patients within providers) whereas a reliability of 1.0 implies that all variation is caused by real difference in performance across accountable entities.

There is not a clear cut-off for minimum reliability level. Values above 0.7, however, are considered sufficient to see differences between some physicians and the mean, and values above 0.9 are considered sufficient to see differences between pairs of physicians (see Adams, 2009 cited above).

In this dataset, based on our analysis, we were unable to report adequate reliability scores, suggesting that statistically the measure may not adequately differentiate performance between facilities.

Minimum sample size requirements for PAC measures are a function of the reliability testing of the measures on every dataset on which the measures are applied. Our research suggests that minimum sample sizes to achieve high degrees of reliability in the measures are a function of the dataset analyzed, and as such may vary from dataset to dataset. One should not infer that a minimum sample size achieved in one dataset would apply to another.

_____

2b2. VALIDITY TESTING

2b2.1. What level of validity testing was conducted? (*may be one or both levels*)

☐ **Critical data elements** (*data element validity must address ALL critical data elements*)

☐ **Performance measure score**

☐ **Empirical validity testing**

☐ **Systematic assessment of face validity of performance measure score as an indicator** of quality or resource use (*i.e., is an accurate reflection of performance on quality or resource use and can distinguish good from poor performance*)

2b2.2. For each level of testing checked above, describe the method of validity testing and what it tests (*describe the steps—do not just name a method; what was tested, e.g., accuracy of data elements compared to authoritative source, relationship to another measure as expected; what statistical analysis was used)*

Content validity was built into the development of the definitions of potentially avoidable complications (PACs). This involved working with clinicians who are experts in their respective fields and specific to the episodes for which PACs are being measured. In particular, the clinical experts focused on whether or not a potentially avoidable complication can be deemed as such for a specific episode of care, and help defined and review all of the diagnosis and procedure codes for each PAC. The enclosed link lists clinicians who have participated in the various Clinical Working Groups (http://www.hci3.org/content/clinical-working-group-contributors). Some of the clinical experts have also participated in monthly webinars that highlight the clinical aspects of these measures (http://www.hci3.org/content/using-ecrs-providers).

In addition, we illustrate that our measure has face validity in several ways.

Beyond the up front work performed by clinical experts, the validity of the measure has also been tested in various real world settings. For example, we have presented results of claims data analyses that reveal the frequency and costs of PACs to physicians in several different healthcare systems involved in our pilot site implementations, as well as to medical directors from the employer coalitions and the health plans that provided the dataset to run the analyses. Some of these implementations include the Pennsylvania Employee Benefits Trust Fund and local provider groups and hospital, Horizon Blue Cross Blue Shield of NJ and many

physicians and health systems.

In addition, we have performed dozens of analyses of very large claims data sets and reported results of rates and costs of PACs to policy makers, health plan leaders and physician leaders from different states. These include:

- Vermont Payment Reform Commission
- Maine Health Management Coalition
- WellPoint / Anthem CT
- NY State Medicaid
- CT Medicaid
- CO All-payer Claims Database, Center for Improving Value in Health Care

These analyses and their results have influenced, and continue to influence, the development of various public reporting, payment reform and delivery system reform efforts. To-date, we have never experienced either wholesale or partial rejection of the results of analyses showing rates of PACs, which demonstrates the level of acceptability – face validity – of the measures from the payer, policymaker, employer and payer communities.

As importantly, measures of potentially avoidable complications have face-validity with consumers. In a series of focus groups, Judy Hibbard and colleagues[1] examined the impact of presenting information about price and quality of certain providers in influencing the decisions of consumers. They tested the validity of PACs as a discriminator of quality, as well as other measures of quality, and used the dollar symbol to illustrate the level of price, much like is done for restaurant reviews. When the PAC measure was used, respondents selected the providers with the lowest PAC rates with a high level of confidence in choice, and used it as a surrogate for a strong quality signal. To the contrary, when more standard measures of quality were used, consumers tended to ignore them and use price as a surrogate for quality. As such, what the researchers found is that the very framing of potentially avoidable complications as an indicator of potential harm, is an effective way of communicating the quality of care. And when measures of PACs were presented in conjunction with price, consumers intuitively accepted the logical relationship between low PACs – fewer "defects" – and lower price.

Finally, our measure definitions encompass several other measures that are accepted as being valid complications of care and are widely used throughout the country. These include CMS defined Hospital Acquired Conditions (HACs)[2], Hospital Inpatient Quality Reporting measures [3], Avoidable Readmissions [4,5], AHRQ defined patient safety indicators (PSIs) [6], NQF endorsed patient safety measures such as patient fall rates, pressure ulcer rates, and peri-operative pulmonary embolism or deep vein thrombosis rates [7].

2b2.3. What were the statistical results from validity testing? (*e.g., correlation; t-test*)
Not applicable.

2b2.4. What is your interpretation of the results in terms of demonstrating validity? (i.*e., what do the results mean and what are the norms for the test conducted?*)

Given the significant clinical input that went into developing the measure, the widespread use and acceptance the measure has gained among a wide variety of individuals and organizations across the health system (public and private payers, clinicians, consultants, patients, etc.) [1-13], and the parallels between this measure and other measures that are in widespread use, this demonstrates that the measure has strong face validity.

2b3. EXCLUSIONS ANALYSIS

NA ☐ no exclusions — *skip to section 2b4*

2b3.1. Describe the method of testing exclusions and what it tests (*describe the steps—do not just name a method; what was tested, e.g., whether exclusions affect overall performance scores; what statistical analysis was used*)

No formal exclusion testing was done since no real exclusions were done. The only patients excluded were the ones that had incomplete or missing data and those that would not have given a homogenous population such as outliers.

Exclusions included exclusions of "patients" as well as "claims" not relevant to PCMDFR care. Please refer to the enclosed excel workbook entitled (NQF_PCMDFR_all_codes_risk_adjustment_06.30.15.xls)

1. "Patients" are excluded from the measure if they meet one of the following criteria:
   a. If age is < 18 years
   b. If gender is missing
   c. If they do not have continuous enrollment for the entire time window with a maximum of 30 day enrollment gap with the entity providing the data (this helps determine if the database has captured most of the claims for the patient in the time window).
   d. If the episode time window extends beyond the dataset end date (this helps eliminate incomplete episodes).
   e. The episode cost is an outlier (less than 1st percentile or greater than 99th percentile value for all episodes of the same type). This eliminates extreme variation that may result from random outlier events.

2. "Claims" are excluded from the measure based on the following criteria:

a. If none of the diagnosis codes on the claim are on the list of relevant diagnosis codes (either typical Dx or PAC Dx) for PCMDFR.
b. If none of the procedure / CPT codes on the claim are on the list of relevant procedure codes for PCMDFR.

2b3.2. What were the statistical results from testing exclusions? (*include overall number and percentage of individuals excluded, frequency distribution of exclusions across measured entities, and impact on performance measure scores*)

We started with a total PCMDFR population of 3,968 episodes. After all the exclusions were applied, the remaining PCMDFR population included in the analysis consisted of 1,806 episodes. As mentioned above, no real exclusions were done. The only patients excluded were the ones that had incomplete or missing data and those that would not have given a homogenous population such as outliers. As such, no formal exclusion testing was done.

2b3.3. What is your interpretation of the results in terms of demonstrating that exclusions are needed to prevent unfair distortion of performance results? (*i.e., the value outweighs the burden of increased data collection and analysis. Note: **If patient preference is an exclusion**, the measure must be specified so that the effect on the performance score is transparent, e.g., scores with and without exclusion*)

No formal analysis was done on the impact of exclusions on performance scores.

Descriptive Explanation:

Exclusions of patients were for the following reasons. Some are for comparative purposes and some for medical reasons.

(a) Comparative Purposes:
We excluded patients that did not have complete enrollment for the entire episode time window. This was done to ensure that the database had complete information on patients to be able to create the entire episode. Including patients with only a partial episode window could distort the measure by artificially reducing the actual count of patients with PACs.

(b) Medical Reasons:
Patients with outlier costs (less than 1st percentile value or greater than 99th percentile) were considered to be different from the general pool, and excluded from both the numerator and the denominator. This is another way to ensure that episodes are complete (because incomplete episodes may have very low costs), and do not bring in random noise into the analysis due to inappropriate codes or services (high outliers).

2b4. RISK ADJUSTMENT/STRATIFICATION FOR OUTCOME OR RESOURCE USE MEASURES
If not an intermediate or health outcome, or PRO-PM, or resource use measure, skip to section 2b5.

2b4.1./S13 What method of controlling for differences in case mix is used?
☐ **No risk adjustment or stratification**
☐ **Statistical risk model** with 170 potential risk factors and episode specific subtypes
☐ **Stratification by** Click here to enter number of categories **risk categories**

☐ **Other,** Click here to enter description

2b4.1.2. If an outcome or resource use measure is not risk adjusted or stratified, provide rationale and analyses to demonstrate that controlling for differences in patient characteristics (case mix) is not needed to achieve fair comparisons across measured entities.

2b4.2/S14. Identify the statistical risk model variables (Name the statistical method – e.g., logistic regression and list all the risk factor variables.
A number of patient-related "risk factors" or covariates are included in the models:

Patient demographics: age, gender, and an indicator of whether a member has enrolled within the previous 6 months. This latter risk factor is intended to account for the patient's lack of claims history, which limits the number of potential comorbidities that can be identified.

Comorbidities: These are conditions or events that occurred prior to the start of the episode that can have a potential impact on the patient's risk of having a PAC. The risk factors are 170 disease indicators (0/1) identified through the presence of ICD diagnosis codes on individual medical claims and collected from the historical claims data before the start of an episode. These are universally applied across all episodes. Please see the tab labeled "All Risk Factors I-9" and "All Risk Factors I-10" for a list of risk factors and their corresponding codes in the enclosed workbook called NQF_PCMDFR_all_codes_risk_adjustment_06.30.15.xls. This list was selected based on input from clinical experts in clinical working groups.

Episode Subtypes or Severity Markers: These are markers that distinguish an episode as being more severe than another. They indicate either specific patient comorbidities that are known to make the procedure or condition more difficult to treat (e.g., obesity) or severity of the illness itself (e.g., cardiomyopathy). Subtypes are specific to each unique episode and are included in the models only if they are present at the start of the episode. Please see the tab labeled "Subtypes I-9" and "Subtypes I-10" for a list of subtypes and their corresponding codes in the enclosed workbook called NQF_PCMDFR_all_codes_risk_adjustment_06.30.15.xls. This list was selected based on input from clinical experts in clinical working groups.

Candidate comorbidities and subtypes were included in the models as covariates if they were present in at least 10 episodes to prevent unstable coefficients.

2b4.2.1/S15. Detailed risk model specifications including coefficients, equations, codes with descriptors, definitions(may be attached in an Excel or cvs file)

All Risk Factors with their coefficients are detailed in the enclosed workbook called NQF_PCMDFR_all_codes_risk_adjustment_06.30.15.xls – Please reference the tabs titled Risk Factor Prevalence and Risk Model.

2b4.3. Describe the conceptual/clinical and statistical methods and criteria used to select patient factors (clinical factors or sociodemographic factors) used in the statistical risk model or for stratification by risk(*e.g., potential factors identified in the literature and/or expert panel; regression analysis; statistical significance of p<0.10; correlation of x or higher; patient factors should be present at the start of care*)

Risk factors are comorbidity indicators collected from historical claims before the start of an episode. These are universally applied across all episodes. This list was selected based on input from clinical experts in clinical working groups. In addition, the Clinical Working Groups identified episode specific severity markers that were called episode subtypes and they help distinguish an episode as being more severe than another.

All risk factors and subtypes must be present prior to, or at the start of the episode and are identified using diagnosis codes in the patient's historical claims.

To be included in the risk adjustment models, any risk factor or subtype must be present in at least 10 episodes. Beyond this no further model building was conducted to add or remove risk factors or subtypes from the model after it was initially run. This reflects a desire to explain as much variation in the probability of having a PAC as possible, but does not make it a priority that all covariates be individually significant or even uncorrelated with each other. Accordingly, the model uses a very large group of covariates. This modeling approach allows for fewer potentially artificial constraints around the definitions of what constitutes severity, and lets the model determine for itself which of the factors are more significant. Non-significant covariates cannot overly influence the predicted outcomes, nor is much harm realized, if a group of correlated covariates work together to explain variation rather than having the variation explained by a single best factor.

2b4.4a. What were the statistical results of the analyses used to select risk factors?

As explained above, no formal analysis was conducted to select risk factors. In fact, all potential risk factors and subtypes with a count of at least 10 episodes were retained to serve as predictors. The goal was to achieve a more complete explanatory model rather than achieve parsimony.

Please reference the tabs titled Risk Model in the NQF_PCMDFR_all_codes_risk_adjustment_06.30.15.xls workbook to see the list of risk factors that met the selection criteria.

2b4.4b. Describe the analyses and interpretation resulting in the decision to select SDS factors (e.g. prevalence of the factor across measured entities, empirical association with the outcome, contribution of unique variation in the outcome, assessment of between-unit effects and within-unit effects)

Not Applicable since our analysis did include SDS variables

2b4.5. Describe the method of testing/analysis used to develop and validate the adequacy of the statistical model or stratification approach (*describe the steps—do not just name a method; what statistical analysis was used*)

Model Development Approach

We used logistic regression to model the probability of at least one PAC occurring during the episode. The model included all covariates that were identified through the process above. No further model building was conducted after the initial model was run. This reflects a desire to explain as much variation in the probability of having a PAC as possible, but does not make it a priority that all covariates be individually significant or even uncorrelated with each other. Accordingly, the model uses a very large group of covariates. This modeling approach allows for fewer potentially artificial constraints around the definitions of what constitutes severity, and lets the model determine for itself which of the factors are more significant. Non-significant covariates can not overly influence the predicted outcomes, nor is much harm realized, if a group of correlated covariates work together to explain variation rather than having the variation explained by a single best factor.

For a more complete description of the risk adjustment approach, please see the document entitled, "PACs and Severity Adjustment Fact Sheet" that accompanies this submission.

Approach to Model Testing and Validation

To determine the validity and performance of the model, we used the split sample method to divide the patient sample randomly into: 1) the model building data set (80% of the sample) and 2) the test data set (20% of sample. The model was built using logistic regression on the first data set and then the coefficients from the development model were tested in the second dataset. Area under the curve (AUC) and the c-statistic were used to compare the predictive ability of the model in each of the data sets. Hosmer-Lemeshow Goodness-of-Fit tests and comparisons of observed to expected probabilities across risk deciles were further examined to assess the model's overall predictive accuracy.

Provide the statistical results from testing the approach to controlling for differences in patient characteristics (case mix) below.
If stratified, skip to 2b4.9

2b4.6. Statistical Risk Model Discrimination Statistics (*e.g., c-statistic, R-squared*)**:**

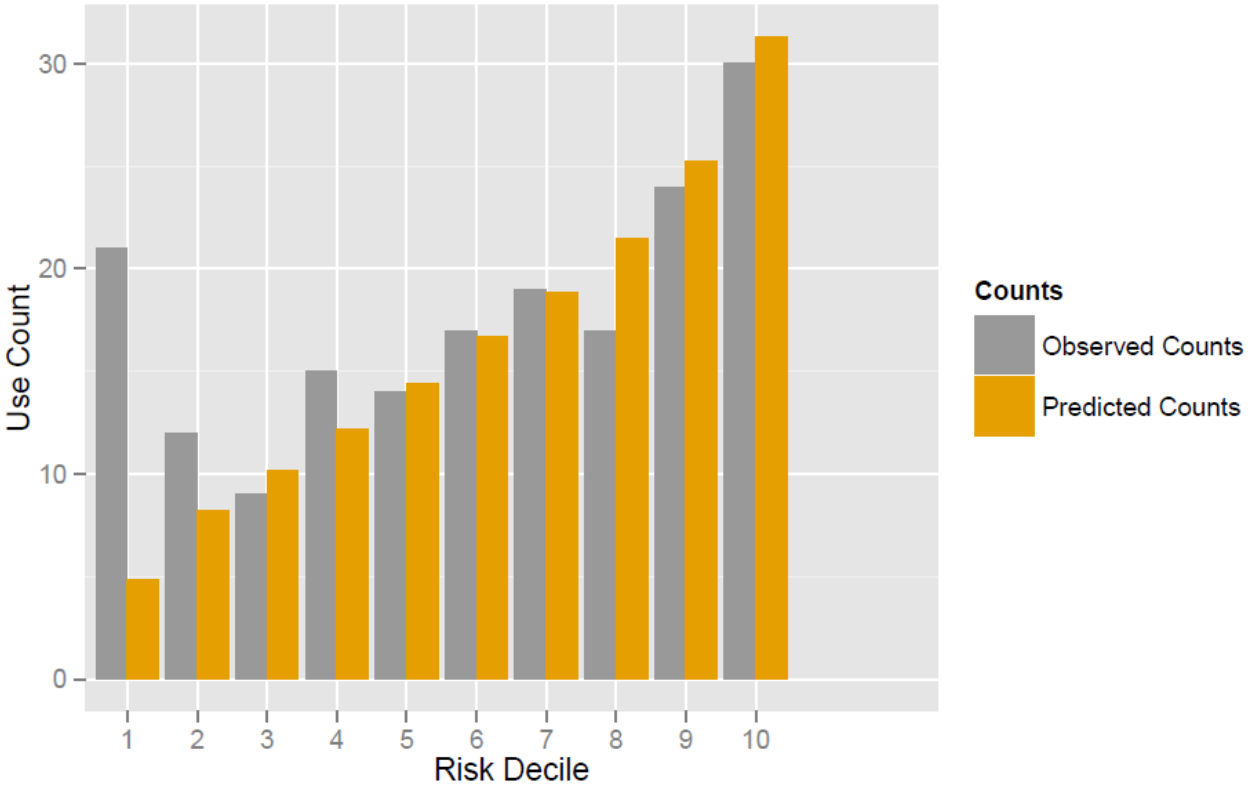
Sample	Accuracy (%)*	AUC
Test	66.8%	0.740
Validation	60.2%	0.624

*Episodes with predicted probabilities <50% were classified as having a predicted 0 (not having a PAC). Episodes with predicted probabilities >50% were classified as having a predicted 1 (having a PAC)

2b4.7. Statistical Risk Model Calibration Statistics (*e.g., Hosmer-Lemeshow statistic*):

Sample	Chi Square	Degrees of Freedom	p-value
Test	6.1	8	0.6338
Validation	68.7	8	<0.0001

2b4.8. Statistical Risk Model Calibration – Risk decile plots or calibration curves:



2b4.9. Results of Risk Stratification Analysis:
Not applicable

2b4.10. What is your interpretation of the results in terms of demonstrating adequacy of controlling for differences in patient characteristics (case mix)? (i*.e., what do the results mean and what are the norms for the test conducted*)

The C statistic is a measure of the extent to which a statistical model is able to discriminate between a patient with and without an outcome. The c-statistic ranges from 0.5 to 1.0. A c-statistic of 0.50 indicates the model is no better than random prediction, implying that the patient risk factors do not predict variation in the outcome; conversely, a c-statistic of 1.0 indicates perfect prediction, implying patients' outcomes can be predicted completely by their risk factors, and physicians and hospitals play little role in patients' outcomes. Models with c-statistic values of at least 0.7 are considered good and those above 0.8 are considered strong [1]. The purpose of the model is to adjust for patient-related factors. The remaining unexplained differences in PAC rates are due to factors that could be controlled by all providers that are managing or co-managing the patient, during the entire episode time window.

The results above indicate that the C-statistic for the risk model on the testing sample (0.740) is above the level at which the model is considered to have good discriminatory power. And while the c-statistic for the testing sample was somewhat low, the model still predicted the outcome correctly 60% of the time, better than would be expected if the outcome were chosen at random (i.e., 50%). Moreover, the H-L test was not significant for the testing sample, meaning that the model was a good fit for the data. Finally, the decile plot shows that, with the exception of the first decile, the model predicts PACs somewhat similarly to observed PACs.

Overall, the results demonstrate that the model has sufficient predictive power.

2b5. IDENTIFICATION OF STATISTICALLY SIGNIFICANT & MEANINGFUL DIFFERENCES IN PERFORMANCE

2b5.1. Describe the method for determining if statistically significant and clinically/practically meaningful differences in performance measure scores among the measured entities can be identified (*describe the steps—do not just name a method; what statistical analysis was used? Do not just repeat the information provided related to performance gap in 1b)*

To directly compare PAC rates across providers or facilities while also appropriately accounting for differences in patient severity, we calculated a risk-standardized PAC rate for each provider. This method is similar to calculations used by others for reporting outcomes measures [1]. For each provider or facility, the ratio of observed attributed episodes with PACs to the expected number of attributed episodes with PACs given the patient's risk factor and estimated from the risk-adjustment model was calculated. This number yielded whether the provider or facility had more PACs than expected (ratio>1), as expected (ratio=1), or less than expected (ratio<1). We then multiplied this ratio by the overall expected PAC rate across all providers or facilities to obtain the risk-standardized PAC rate for the provider or facility. This measure represents what a facility's PAC rate would be if its patient population was reflective of the overall population.

Because facilities with small volumes may provide unreliable estimates, we excluded any with fewer than 10 attributed episodes prior to the calculations. Comparison of risk-adjusted PAC rates gives a measure of the provider's relative performance. Our analysis compared risk-standardized PAC rates across facilities. We analyzed various descriptive statistics including the range in PAC rates, medians, interquartile range, etc.

Reference:

[1] See, for example: NQF#1550: Hospital-level risk-standardized complication rate (RSCR) following elective primary total hip arthroplasty (THA) and / or total knee arthroplasty (TKA). Online version: http://bit.ly/1BWQTRt

2b5.2. What were the statistical results from testing the ability to identify statistically significant and/or clinically/practically meaningful differences in performance measure scores across measured entities? (e.g., *number and percentage of entities with scores that were statistically significantly different from mean or some benchmark, different from expected; how was meaningful difference defined*)

PAC Rates	Minimum # Episodes Per Provider	
	>=10	>=25
# Providers	22	16

Unadjusted		
Median (IQR)	47% (40%, 55%)	46% (35%, 55%)
Range	20% - 64%	26% - 64%
Adjusted (RSPR)*		
Median (IQR)	46% (37%, 54%)	46% (35%, 55%)
Range	21% - 63%	25% - 63%

***RSPR = Risk Standardized PAC Rate**

Please refer to the NQF_PCMDFR_all_codes_risk_adjustment_06.30.15.xls workbook under the "ProviderAttribution Reliability" tab to see specific results for each facility.

2b5.3. What is your interpretation of the results in terms of demonstrating the ability to identify statistically significant and/or clinically/practically meaningful differences in performance across measured entities? (i*.e., what do the results mean in terms of statistical and meaningful differences?*)

While there was some variation among facilities in the adjusted rates, these should be considered in the context of the reliability analysis above showing that measure may not sufficiently differentiate performance differences between facilities.

Minimum sample size requirements for PAC measures are a function of the reliability testing of the measures on every dataset on which the measures are applied. Our research suggests that minimum sample sizes to achieve high degrees of reliability in the measures are a function of the dataset analyzed, and as such may vary from dataset to dataset. One should not infer that a minimum sample size achieved in one dataset would apply to another.

2b6. COMPARABILITY OF PERFORMANCE SCORES WHEN MORE THAN ONE SET OF SPECIFICATIONS
***If only one set of specifications, this section can be skipped*.**

Note: *This criterion is directed to measures with more than one set of specifications/instructions (e.g., one set of specifications for how to identify and compute the measure from medical record abstraction and a different set of specifications for claims or eMeasures). It does not apply to measures that use more than one source of data in one set of specifications/instructions (e.g., claims data to identify the denominator and medical record abstraction for the numerator).* ***Comparability is not required when comparing performance scores with and without SDS factors in the risk adjustment model. However, if comparability is not demonstrated for measures with more than one set of specifications/instructions, the different specifications (e.g., for medical records vs. claims) should be submitted as separate measures.***

2b6.1. Describe the method of testing conducted to demonstrate comparability of performance scores for the same entities across the different data sources/specifications (*describe the steps—do not just name a method; what statistical analysis was used*)

Not applicable

2b6.2. What were the statistical results from testing comparability of performance scores for the same entities when using different data sources/specifications? (*e.g., correlation, rank order*)

Not performed

2b6.3. What is your interpretation of the results in terms of demonstrating comparability of performance measure scores for the same entities across the different data sources/specifications? (i.*e., what do the results mean and what are the norms for the test conducted*)

Not applicable

2b7. MISSING DATA ANALYSIS AND MINIMIZING BIAS

2b7.1. Describe the method of testing conducted to identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias (*describe the steps—do not just name a method; what statistical analysis was used*)

If patient related data is missing, the entire patient is excluded from the numerator as well as the denominator.

Within our measure constructs, presence of potentially avoidable complications are identified from administrative claims data. Furthermore, the measure is constructed so that the occurrence of any number of PACs during a defined episode would only count as one occurrence.

According to our measure definition, in constructing the measure it is possible for a provider to have only one or some types of PACs and not others. Alternatively, the provider may have all PAC types occur for their patients. The measure only considers whether any PAC occurred regardless of the type, and all PAC types are weighted equally, therefore we believe, there is no potential for the absence of specific PAC types to bias performance scores for individual providers.

For these reasons, no formal analyses were done on missing data.

2b7.2. What is the overall frequency of missing data, the distribution of missing data across providers, and the results from testing related to missing data? (*e.g., results of sensitivity analysis of the effect of various rules for missing data/nonresponse; if no empirical sensitivity analysis, identify the approaches for handling missing data that were considered and pros and cons of each*)
Not applicable

2b7.3. What is your interpretation of the results in terms of demonstrating that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias**?** (i.*e., what do the results mean in terms of supporting the selected approach for missing data and what are the norms for the test conducted; if no empirical analysis, provide rationale for the selected approach for missing data*)

2d. EMPIRICAL ANALYSIS TO SUPPORT COMPOSITE CONSTRUCTION APPROACH
Note: *If empirical analyses do not provide adequate results—or are not conducted—justification must be provided and accepted in order to meet the must-pass criterion of Scientific Acceptability of Measure Properties. Each of the following questions has instructions if there is no empirical analysis.*

2d1. Empirical analysis demonstrating that the component measures fit the quality construct, add value to the overall composite, and achieve the object of parsimony to the extent possible.

The PAC measures, as we define them, look at many "care defects" comprehensively. They are composed of several cross-cutting measures and together they paint a global picture of the provider's overall performance.

PACs may occur any time during the episode time window. PACs are counted as a dichotomous (yes/no) outcome. If a patient had one or more PACs, they get counted as a "yes" or a 1. The enclosed workbook entitled NQF_PCMDFR_all_codes_risk_adjustment_06.30.15.xls provides outputs from empirical analysis. The tab labeled "PAC overview" demonstrates percentage of episodes that had at least one PAC, and provides the breakdown of PACs: 1) by the type of PAC whether directly related to index condition or due to patient safety failures; 2) the setting of the PAC, whether seen in the in-patient setting, out-patient facility or during professional visits; and 3) preventable hospitalizations.

The "PAC Drill Down Graph" provides further detail on each component of the PAC and their frequency. As can be seen by the individual counts and the graph, while each individual PAC may have such small occurrences that no meaningful comparisons in provider performances could be made; together, they add value to provide a comprehensive picture that result in meaningful numbers. The aggregation of PACs to a comprehensive, composite measure, in itself provides the parsimony that is so desirable.

2d1.1 Describe the method used (*describe the steps—do not just name a method; what statistical analysis was used; if no empirical analysis, provide justification)*

All PACs, as clinically defined by the subject matter experts were used with equal weighting. Since the emphasis of the PAC measure is to identify the occurrence of PACs in any setting, a simple and straightforward approach was adopted.

2d1.2. What were the statistical results obtained from the analysis of the components? (e.g., *correlations, contribution of each component to the composite score, etc*.; *if no empirical analysis, identify the components that were considered and the pros and cons of each*)

No formal analysis was performed.

2d1.3. What is your interpretation of the results in terms of demonstrating that the components included in the composite are consistent with the described quality construct and add value to the overall composite? (i.*e., what do the results mean in terms of supporting inclusion of the components; if no empirical analysis, provide rationale for the components that were selected)*

Since our premise is that all PACs are potentially avoidable, we adopted the approach to count all PACs and give them equal weights. The overall composite score results in the quality construct that could be measured and interpreted.

2d2. Empirical analysis demonstrating that the aggregations and weighting rules are consistent with the quality construct and achieve the objective of simplicity to the extent possible

2d2.1 Describe the method used (*describe the steps—do not just name a method; what statistical analysis was used; if no empirical analysis, provide justification)*

Within our measure constructs, presence of potentially avoidable complications are identified from administrative claims data. Additionally, if a patient had one or more PACs, it is simply counted as a 1, i.e., flagged as having a PAC. The measure only considers whether any PAC occurred regardless of the type, or the site, and all PAC types are weighted equally. Therefore, no formal analysis of individual components was performed.

2d2.2. What were the statistical results obtained from the analysis of the aggregation and weighting rules? (e.g., *results of sensitivity analysis of effect of different aggregations and/or weighting rules; if no empirical analysis, identify the aggregation and weighting rules that were considered and the pros and cons of each*)

We chose not to weight the components of the measure.

Considerations were given to the fact that preventable hospitalizations may be given more weight, than PACs identified in a doctor's office. Similarly PACs in an in-patient setting may have more serious implications on a patient's ultimate outcome, than PACs occurring in an outpatient setting. Additionally, preventable hospitalizations as well as index hospitalizations, each with longer lengths of stay, may have serious PACs. But how do we weigh these effects? An alternative model was considered, where cost could be considered as a surrogate for the weights. Higher cost PACs could imply more serious PACs. However, differences in costs could be driven by many issues other than the PAC itself, such as unit price of the service, method of reimbursements, contracting arrangements etc.

Furthermore, in-patient facility billing does not allow for the distinction of PAC related costs from other costs within the stay. We would fail to capture PAC related costs within the stay and potentially underweight those. As a result, the decision was made to avoid weighting and keep the measure as a straightforward count.

2d2.3. What is your interpretation of the results in terms of demonstrating the aggregation and weighting rules are consistent with the described quality construct? (i*.e., what do the results mean in terms of supporting the selected rules for aggregation and weighting; if no empirical analysis, provide rationale for the selected rules for aggregation and weighting*)

Measuring all providers with the same yardstick will provide consistent results and reasonable comparisons over time. If the goal is to reduce PACs, then the PAC measure as was constructed with the help of various experts in the field would provide reasonable comparisons. A word of caution however pertains to the sample size of the provider panel before making any reasonable conclusions.

Minimum sample size requirements for PAC measures are a function of the reliability testing of the measures on every dataset on which the measures are applied. Our research suggests that minimum sample sizes to achieve high degrees of reliability in the measures are a function of the dataset analyzed, and as such may vary from dataset to dataset. One should not infer that a minimum sample size achieved for high reliability in one dataset would apply to another.

2d3. Empirical analysis demonstrating that the approach for handling missing data minimizes bias (*i.e., achieves scores that are an accurate reflection of quality*)**.**

Note: *Applies to the overall composite measure; the focus is on missing data rather than exclusions, which are considered in 2b3.*

Please refer to section 2b7

2d3.1. What is the overall frequency of missing data and the distribution of missing data across providers?

2d3.2. Describe the method used to compare approaches for handling missing data (*describe the steps—do not just name a method; what statistical analysis was used; if no empirical analysis, provide justification)*

2d3.3. What were the statistical results obtained from the analysis of missing data? (e.g., *results of sensitivity analysis of effect of various rules for missing data; if no empirical analysis, identify the approaches for handling missing data that were considered and pros and cons of each*)

2d3.4. What is your interpretation of the results in terms of demonstrating that the approach used for missing data minimizes bias? (i.*e., what do the results mean in terms of supporting the selected approach for missing data; if no empirical analysis, provide rationale for the selected approach for missing data*)

3. Feasibility

Extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

3a. Byproduct of Care Processes

For clinical measures, the required data elements are routinely generated and used during care delivery (e.g., blood pressure, lab test, diagnosis, medication order).

3a.1. **Data Elements Generated as Byproduct of Care Processes.**

Coded by someone other than person obtaining original information (e.g., DRG, ICD-9 codes on claims)

If other:

3b. Electronic Sources

The required data elements are available in electronic health records or other electronic sources. If the required data are not in electronic health records or existing electronic sources, a credible, near-term path to electronic collection is specified.

3b.1. **To what extent are the specified data elements available electronically in defined fields?** *(i.e., data elements that are needed to compute the performance measure score are in defined, computer-readable fields)*

ALL data elements are in defined fields in electronic claims

3b.2. **If ALL the data elements needed to compute the performance measure score are not from electronic sources, specify a credible, near-term path to electronic capture, OR provide a rationale for using other than electronic sources.**

3b.3. **If this is an eMeasure, provide a summary of the feasibility assessment in an attached file or make available at a measure-specific URL.**

Attachment:

3c. Data Collection Strategy

Demonstration that the data collection strategy (e.g., source, timing, frequency, sampling, patient confidentiality, costs associated with fees/licensing of proprietary measures) can be implemented (e.g., already in operational use, or testing demonstrates that it is ready to put into operational use). For eMeasures, a feasibility assessment addresses the data elements and measure logic and demonstrates the eMeasure can be implemented or feasibility concerns can be adequately addressed.

3c.1. **Describe what you have learned/modified as a result of testing and/or operational use of the measure regarding data collection, availability of data, missing data, timing and frequency of data collection, sampling, patient confidentiality, time and cost of data collection, other feasibility/implementation issues.**

IF a PRO-PM, consider implications for both individuals providing PROM data (patients, service recipients, respondents) and those whose performance is being measured.

As part of our general implementation of these measures and related analyses, we have worked through dozens of different and sometimes very large datasets. From Medicare to Medicaid to regional and national commercial carriers, as well as individual employers, the principal lesson learned is the heterogeneity of the data sets and the significant variability in fill rate of critical data elements. As a result, we have created highly specific recommendations for which data elements are required to ensure measure validity, the accuracy of those data elements, and their completeness in the dataset. When claims datasets are organized in the way we specify in the measure analysis, and contain the coding information required, the analysis of the measure and its results are highly reliable.

3c.2. **Describe any fees, licensing, or other requirements to use any aspect of the measure as specified** *(e.g., value/code set, risk model, programming code, algorithm)*.

The calculations of rates of potentially avoidable complications can be replicated by anyone that uses the measure specifications along with the metadata file that is available for free on our web site at http://www.hci3.org/ecre/xml-agreement.html.

We also plan on providing a limited automated analysis, at no cost, on our website.

4. Usability and Use

Extent to which potential audiences (e.g., consumers, purchasers, providers, policy makers) are using or could use performance results for both accountability and performance improvement to achieve the goal of high-quality, efficient healthcare for individuals or populations.

4a. Accountability and Transparency

Performance results are used in at least one accountability application within three years after initial endorsement and are publicly reported within six years after initial endorsement (or the data on performance results are available). If not in use at the time of initial endorsement, then a credible plan for implementation within the specified timeframes is provided.

4.1. Current and Planned Use

NQF-endorsed measures are expected to be used in at least one accountability application within 3 years and publicly reported within 6 years of initial endorsement in addition to performance improvement.

Planned	Current Use (for current use provide URL)
Public Reporting Regulatory and Accreditation Programs Professional Certification or Recognition Program	Public Health/Disease Surveillance Blue Cross Blue Shield of North Carolina https://www.bcbsnc.com/ Blue Cross Blue Shield of New Jersey http://www.horizonblue.com/ Pennsylvania Employee Benefits Trust Fund https://www.pebtf.org/ Quality Improvement with Benchmarking (external benchmarking to multiple organizations) Blue Cross Blue Shield of North Carolina https://www.bcbsnc.com/assets/providers/public/pdfs/specialty_methodology.pdf

4a.1. For each CURRENT use, checked above, provide:

- Name of program and sponsor
- Purpose
- Geographic area and number and percentage of accountable entities and patients included

Measures associated to potentially avoidable complications (PACs) are in use today with some private sector payers and gaining further acceptance among a wide variety of organizations across the health system (public and private payers, clinicians, consultants, all-payer claims database stewards, etc.) [1-8]. They are being used in various capacities in different pilot site implementations. To name a few:

•BCBSA (Blue Cross Blue Shield Association) – uses them for their Centers of Excellence (COE) programs: Blue Distinction
•BCBSNC (Blue Cross Blue Shield of North Carolina) – is using them for tiering providers

In addition, the PAC measures are incorporated by the following organizations in their bundled payment programs:

•BCBSSC – for CABG and PCI programs
•Horizon BCBSNJ– for CHF and CABG programs
•BCBSNC
•PEBTF in PA

http://www.ajmc.com/interviews/Lili-Brillstein-on-How-Bundled-Payments-Are-Tranforming-Healthcare

In these programs they look at PACs related to the measure for process improvement activities and for practice re-engineering.

We have created reports for rates of PACs for the following organizations:
-Vermont Payment Reform
-Maine Health Management Coalition
-WellPoint / Anthem CT
-NY State Medicaid
-CT Medicaid
-CO All-payer Claims Database, Center for Improving Value in Health Care

There are several companies that are leveraging these measures to create analytics and software for customers – these include HealthQx, Aver Informatics, McKesson, and TriZetto.

Below are some references that highlight our work with Potentially Avoidable Complications (PACs).

4a.2. If not currently publicly reported OR used in at least one other accountability application (e.g., payment program, certification, licensing) what are the reasons? (*e.g., Do policies or actions of the developer/steward or accountable entities restrict access to performance results or impede implementation?*)
N/A

4a.3. If not currently publicly reported OR used in at least one other accountability application, provide a credible plan for implementation within the expected timeframes -- any accountability application within 3 years and publicly reported within 6 years of initial endorsement. (*Credible plan includes the specific program, purpose, intended audience, and timeline for implementing the measure within the specified timeframes. A plan for accountability applications addresses mechanisms for data aggregation and reporting.*)
Measures associated with PACs are currently in use as described in the prior section. In addition, we are working with several not-for-profit and for-profit organizations to provide them with the algorithms needed to calculate rates of potentially avoidable complications. Some of these organizations include:

Fair Health – based in NY and whose mission is to increase transparency of provider cost and quality,

CastLight – based in CA and serving large employers. We currently provide CastLight with Bridges To Excellence recognitions and will work with them to augment provider transparency by using PAC measures,

MA APCD (Massachusetts All Payers Claims Database) Council – we currently have an agreement in place with the MA APCD Council to produce PAC measures on hospitals and physicians and report back to the council with tests of reliability and validity of the measures. The purpose is to authorize the publication of these measures,
Maryland Health Care Cost Commission – we have a two year agreement to produce measures of cost and quality for public

dissemination.

4b. Improvement

Progress toward achieving the goal of high-quality, efficient healthcare for individuals or populations is demonstrated. If not in use for performance improvement at the time of initial endorsement, then a credible rationale describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.

4b.1. **Progress on Improvement. (Not required for initial endorsement unless available.)**
Performance results on this measure (current and over time) should be provided in 1b.2 and 1b.4. Discuss:

- **Progress (trends in performance results, number and percentage of people receiving high-quality healthcare)**
- **Geographic area and number and percentage of accountable entities and patients included**

We do not have any public information to share about the improvements in rates of potentially avoidable complications, as the implementation of these measures is too recent to provide valid comparisons. Further, some of the definitions of PACs have changed since the measures were initially endorsed, making comparisons even more difficult and unreliable.

Nevertheless, the variation in performance scores presented in Section 1b.2 indicates that there are differences between providers in their risk-adjusted PAC rates (higher scores equal worse performance). This suggests that real opportunities exist to identify lower performing providers and reduce the overall occurrence of PACs.

4b.2. **If no improvement was demonstrated, what are the reasons? If not in use for performance improvement at the time of initial endorsement, provide a credible rationale that describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.**
Performance results provide summary PACs rates by provider, which can be used by payers and providers in a number of ways to improve the quality of care.

From the payer perspective, payers can use this information to 1) create a high-value provider networks, 2) work with high-value providers to share best practices, 3) incentivize low-value providers to improve, 4) modify their insurance design to activate consumers to select the right care from the right providers at the right time.

From the provider perspective, providers can 1) view services and activity for their patients longitudinally across the entire care continuum, such as frequency of readmissions and ED visits and drill down on patients with high PAC rates, 2) review actionable drill down reports to identify the most frequent PACs across all patients to create care pathways and process improvement plans to impact the most frequent PACs.

4c. Unintended Consequences

The benefits of the performance measure in facilitating progress toward achieving high-quality, efficient healthcare for individuals or populations outweigh evidence of unintended negative consequences to individuals or populations (if such evidence exists).

4c.1. **Were any unintended negative consequences to individuals or populations identified during testing; OR has evidence of unintended negative consequences to individuals or populations been reported since implementation? If so, identify the negative unintended consequences and describe how benefits outweigh them or actions taken to mitigate them.**
No unintended consequences were reported, but there is the potential for:
1. Under-coding of PACs in the claim stream resulting in under-reporting the actual rate and/or providers gaming the measures
2. Payers calculating the measures even with inadequate sample sizes and using the results to penalize providers

The measure is designed for transparency efforts and to spur quality improvement. Detailed PAC reports can help providers identify areas of quality improvement. Even detailed reports of small samples of patients can be helpful for quality improvement purposes, but not for public reporting. To mitigate the potential for invalid provider comparisons, we specify in this submission the minimum sample size needed to ensure the reliability of a provider's score. Ultimately, there isn't any good way to prevent provider gaming of the measure by under-coding claims, however, under the current DRG payment methodology, many providers would be penalized by under-coding PACs since these codes often result in the assignment of more complicated DRGs.

5. Comparison to Related or Competing Measures

If a measure meets the above criteria and there are endorsed or new related measures (either the same measure focus or the same

target population) or competing measures (both the same measure focus and the same target population), the measures are compared to address harmonization and/or selection of the best measure.

5. Relation to Other NQF-endorsed Measures

Are there related measures (conceptually, either same measure focus or target population) or competing measures (conceptually both the same measure focus and same target population)? If yes, list the NQF # and title of all related and/or competing measures.

Yes

5.1a. List of related or competing measures (selected from NQF-endorsed measures)

0141 : Patient Fall Rate
0202 : Falls with injury
0337 : Pressure Ulcer Rate (PDI 2)
0450 : Perioperative Pulmonary Embolism or Deep Vein Thrombosis Rate (PSI 12)
0705 : Proportion of Patients Hospitalized with Stroke that have a Potentially Avoidable Complication (during the Index Stay or in the 30-day Post-Discharge Period)
0708 : Proportion of Patients Hospitalized with Pneumonia that have a Potentially Avoidable Complication (during the Index Stay or in the 30-day Post-Discharge Period)
0709 : Proportion of patients with a chronic condition that have a potentially avoidable complication during a calendar year.
1789 : Hospital-Wide All-Cause Unplanned Readmission Measure (HWR)

5.1b. If related or competing measures are not NQF endorsed please indicate measure title and steward.

-0531 Patient Safety for Selected Indicators (Composite Measure, endorsed) (AHRQ)
-CMS defined hospital acquired conditions (HACs) are a subset of our PACs. We have pain-stakingly matched the definitions to provide as much consistency as possible. http://www.cms.gov/Medicare/Quality-Initiatives-Patient-Assessment-Instruments/HospitalQualityInits/HospitalRHQDAPU.html

5a. Harmonization

The measure specifications are harmonized with related measures;
OR
The differences in specifications are justified

5a.1. If this measure conceptually addresses EITHER the same measure focus OR the same target population as NQF-endorsed measure(s):
Are the measure specifications completely harmonized?

No

5a.2. If the measure specifications are not completely harmonized, identify the differences, rationale, and impact on interpretability and data collection burden.

Several of the measures listed in the prior section are, in fact, fully harmonized with the submitted measures. In particular, 0705, 0708, 0709, 0531, 0450, 2503, 0337, 0141, 0202. However, there are some that are not, in particular the 30-day all-cause readmission measures. While the submitted PAC measures include readmissions that occur within 30 days of discharge, the readmissions, by definition, are related to the index hospitalization and not any hospitalization. While 30-day all-cause readmissions might make sense in a Medicare population, it is not self-evident that they do for commercial or Medicaid populations. However, that said, our data suggest that there are, in fact, very few readmissions within 30 days post discharge that aren't relevant to the index hospitalization. It is worth noting that there is some mounting controversy about the 30 day all cause readmission measures and some data suggest that these measures might have simply pushed out certain readmissions to 31 or more days post discharge. Irrespective of these points, PACs include readmissions and are designed to enable accountability at the locus of provider control as well as some shared accountability between settings, centered around a patient, and for a specific medical episode of care. In that sense, they are consistent with the all-cause 30-day readmission rates, but represent a subset of those admissions. As such, the PAC measures, as submitted, don't create added burden of reporting because the readmissions reported are simply a part of the broader 30-day all-cause readmission measures already endorsed by NQF. Because PAC measures are comprehensive, they include patient safety events that can occur during the stay, as well as adverse events, including readmissions, that can occur post-discharge. As a result, they provide facilities and physicians with an overall measure of avoidable complications for a specific medical episode. The data collection for all of the BTE measures is automated by a software package and is fully harmonized with all other PAC measures. A single download automates creation of all reports related to each of the PAC measures.

5b. Competing Measures

The measure is superior to competing measures (e.g., is a more valid or efficient way to measure);

OR
Multiple measures are justified.

5b.1. **If this measure conceptually addresses both the same measure focus and the same target population as NQF-endorsed measure(s):**
Describe why this measure is superior to competing measures (e.g., a more valid or efficient way to measure quality); OR provide a rationale for the additive value of endorsing an additional measure. (Provide analyses when possible.)
The PAC measure is a comprehensive measure representing "all-cause harms". It looks at all potentially avoidable complications in patients hospitalized with AMI during the stay or for 30-days post-discharge. It looks at readmissions, emergency room visits, adverse events due to errors of omission or commission. It looks at complications that are due to patient safety failures, and also those directly related to the index condition. These are a cause of significant waste and quality concerns for patients with an AMI episode. As such, the measure can provide clinicians with an overall and comprehensive view, in one measure, of all potentially avoidable complications for a patient and drive quality improvement efforts.

For clinicians and facilities increasingly engaged in value-based payment efforts and/or driving quality improvement for population health, the value of a PAC measure over a series of related, but more discrete measures, is that one can better determine if the sources of complications primarily stem from activities within the facility or outside the facility, and the specific nature of the complications that have a higher frequency of occurrence. For providers, it's far easier to construct a quality dashboard from a parsimonious set of measures, and that's what PAC measures offer.

Further, as a comprehensive outcome measures, PACs are also useful for public transparency of quality, as substantiated by the research from Judy Hibbard and colleagues previously cited in the "testing" section of this submission. As a comprehensive outcome measure, they are easier to explain to the average consumer. From a patient's point of view, any bad outcome has an impact on their health with respect to return to work, functional limitations and need for additional support. If a provider has a high PAC rate with regards to one component PAC but not the other PACs, the impact on the patient is still adverse. In selecting providers, individual component PAC scores would mean nothing to a patient, but aggregating it to a comprehensive quality score could be a measure of "all-cause" harms and easier to interpret and act on.

Appendix

A.1 Supplemental materials may be provided in an appendix. All supplemental materials (such as data collection instrument or methodology reports) should be organized in one file with a table of contents or bookmarks. If material pertains to a specific submission form number, that should be indicated. Requested information should be provided in the submission form and required attachments. There is no guarantee that supplemental materials will be reviewed.

Additional Information

Ad.1 **Workgroup/Expert Panel involved in measure development**
Provide a list of sponsoring organizations and workgroup/panel members' names and organizations. Describe the members' role in measure development.
From 2006 onwards, and under the auspices of various funding organizations, HCI3 has convened and managed, or helped to convene and manage, Clinical Working Groups to inform the development and refinement of the measures. For example, in 2011, 2012 and 2013, HCI3 worked collaboratively with the American Board of Medical Specialties and the American Medical Association's Physicians Consortium for Performance Improvement, under a federal contract, to convene and get input from various clinical experts on definitions of episodes of care and their sequelae, including avoidable complications.

Some of the clinical experts that have contributed to our work include:
-Dr. John Allen, American Gastroenterology Association (AGA)

-Dr. Morton Arnsdorf, Cardiologist, University of Chicago, IL
-Dr. Peter Bach, Memorial Sloan Kettering Cancer Center (MSKCC)
-Dr. Peter Basch, Primary Care, Medstar Health, DC
-Dr. Justin Beckelman, Radiation Oncology, University of Pennsylvania, PA
-Dr. Debra Bingham, Executive Director, California Maternal Quality Care Collaborative (CMQCC) at Stanford University, CA
-Dr. John Birkmeyer, American Society of Metabolic and Bariatric Surgery (ASMBS)
-Dr. Linda Bosserman, Wilshire Oncology Medical Group, CA
-Dr. Matthew Brengman, American Society of Metabolic and Bariatric Surgery (ASBMS)
-Dr. Joel Brill, American Gastroenterology Association (AGA)
-Dr. George Cautilli, Cautilli Orthopedic Surgical Specialists PC, Yardley, PA
-Dr. Ashwini Davison, Internist, Johns Hopkins Hospital, MD
-Dr. James Denneny, III, American Academy of Otolaryngology – Head and Neck Surgery (AAO-HNS)
-Dr. Chris Gallagher, American Society of Metabolic and Bariatric Surgery (ASMBS)
-Dr. Robert Haralson, III, American Academy of Orthopedic Surgeons (AAOS)
-Ms. Dawn Holcombe, Executive Director, Connecticut Oncology Association, CT
-Dr. Colin Howden, American Gastroenterology Association (AGA)
-Dr. John Knightly, American Association of Neurological Surgeons (AANS)
-Dr. Larry Kosinski, American Gastroenterology Association (AGA)
-Dr. Nalini Krishnan, Obstetrics & Gynecology, MN
-Dr. Kelly Kyanko, Internist, NYU School of Medicine, NY
-Dr. Tara Lagu, Internist & Infectious Disease, Baystate Medical Center, MA
-Dr. Robert Lee, Society of Thoracic Surgeons (STS)
-Dr. Alex Little, Society of Thoracic Surgeons (STS)
-Dr. Michael London, Orthopedic Surgeon, OMNI Orthopedics, OH
-Dr. Elliott Main, Obstetrics & Gynecology, California Pacific Medical Center, CA
-Dr. Constantine Mantz, 21st Century Oncology, FL
-Dr. Joseph Messer, Cardiologist, Rush University Medical Center, IL
-Dr. David Metz, American Gastroenterology Association (AGA)
-Dr. Ronald Nahass, Infectious Disease Care, NJ
-Dr. Ajay Nehra, Urologist, Rush University Medical Center, IL
-Dr. Francis Nichols, Society of Thoracic Surgeons (STS)
-Dr. Patrick O'Connor, Primary Care, HealthPartners, MN
-Dr. Sara Perkel, National Comprehensive Cancer Network, PA
-Dr. David Peura, American Gastroenterology Association (AGA)
-Dr. John Ratliff, American Association of Neurological Surgeons (AANS)
-Dr. Steven Schutzer, Connecticut Joint Replacement Institute, CT
-Dr. Leif Solberg, Primary Care, HealthPartners, MN
-Dr. Scott Sporer, Midwest Orthopedics at Rush, Chicago IL
-Dr. Bonnie Weiner, Cardiologist, Worcester Medical Center, MA
-Dr. Jonathan Weiner, Bariatric Surgery codes, Prof of Health Policy and Management, Johns Hopkins University, MD
-Dr. Janet Wright, Cardiologist, Northstate Cardiology Consultants, CA

MEASURE WORKSHEET

This document summarizes the evaluation of the measure as it progresses through NQF's Consensus Development Process (CDP). The information submitted by measure developers/stewards is included after the Brief Measure Information, Preliminary Analysis, and Pre-meeting Public and Member Comments sections.

To navigate the links in the worksheet: Ctrl + click link to go to the link; ALT + LEFT ARROW to return

Brief Measure Information

NQF #: 2763
De.2. **Measure Title:** Ischemic Vascular Disease Care: All or None Outcome Measure-Optimal Control
Co.1.1. **Measure Steward:** Wisconsin Collaborative for Healthcare Quality
De.3. **Brief Description of Measure:** The percentage of patients age 18 through 75 with one of the following conditions:
1) Two diagnoses related visits with Coronary Artery Disease (CAD) or a CAD risk-equivalent condition, or
2) Acute Coronary Event consisting of an acute myocardial infarction (AMI), coronary artery bypass graft (CABG), or percutaneous coronary intervention (PCI) from a hospital visit, who had each of the following during the one year measurement year:

•Documentation in the medical record of daily Aspirin or daily other antiplatelet medication usage, unless contraindicated.
•Most recent Blood pressure controlled to a level of less than 140/90 mm Hg
•Most recent Tobacco Status is Tobacco-Free
•Documentation in the medical record of Statin Use
•All or None Outcome Measure (Optimal Control) composite of BP <140/90, Tobacco Non-User, Daily Aspirin or Other Antiplatelet and Statin Use.

Patients are classified uniquely to one of the three condition subgroups in the order of Coronary Artery Disease, Coronary Artery Disease Risk-Equivalent condition, or Acute Coronary Event.
1d.3. **Developer Rationale:** Also indicated in 1d.2 above, this method was chosen because of the benefits it provides to both the patient and the practitioner. First, this methodology more closely reflects the interests and likely desires of the patient. With the data collected in a composite score, patients can easily look and see how their provider group is performing on these criteria rather than trying to make sense of multiple scores on individual measures. Second, this method represents a systems perspective emphasizing the importance of optimal care through a patient's entire healthcare experience. Third, this method gives a more sensitive scale for improvement. Whether reported at the organization, clinic site or provider level, for those scoring high marks on individual measures, the All-or-None measure will give room for benchmarks and additional improvements to be made.

Support for All-or-None measurement referenced by Nolan T, Berwick DM. All-or-None Measurement Raises the Bar on Performance. JAMA. 2006 Mar 8;295(10):1168-70.

S.4. **Numerator Statement:** All-or-None Outcome Measure (Optimal Control) - Using the IVD denominator optimal results include:
- Most recent blood pressure measurement is less than 140/90 mm Hg

And
- Most recent tobacco status is Tobacco Free

NOTE: If there is No Documentation of Tobacco Status the patient is not compliant for this measure.
And
- Daily Aspirin or Other Antiplatelet Unless Contraindicated

And
- Statin Use

S.7. **Denominator Statement:** Patients with CAD or a CAD Risk-Equivalent Condition 18-75 years of age and alive as of the last day of the MP.
S.10. **Denominator Exclusions:** There are no denominator exclusions

De.1. **Measure Type:** Composite
S.23. **Data Source:** Administrative claims, Electronic Clinical Data, Electronic Clinical Data : Electronic Health Record, Electronic Clinical Data : Registry

S.26. **Level of Analysis:** Clinician : Group/Practice
Is this an eMeasure? ☐ **Yes** ☒ **No** **If Yes, was it re-specified from a previously endorsed measure?** ☐ **Yes** ☐ **No**

Is this a MAINTENANCE measure submission? ☐ **Yes** ☒ **No, this is a NEW measure submission.**
For MAINTENANCE, state the Original Endorsement Date: n/a **Most Recent Endorsement Date:** n/a
Previous Measure Evaluation: n/a

IF this measure is included in a composite, NQF Composite#/title: n/a – 2763 is the composite measure.
1d.1. **Composite Measure Construction:** two or more individual performance measure scores combined into one score
Component Measures (if endorsed or submitted for endorsement): n/a
The *non-endorsed* component measures for this composite measure included:

1. Most recent blood pressure measurement is less than 140/90 mm Hg
2. Most recent tobacco status is Tobacco Free
3. Daily Aspirin or Other Antiplatelet Unless Contraindicated
4. Statin Use

Preliminary Analysis

The preliminary analysis was developed in response to recommendations from NQF's Consensus Task Force and measurement stakeholders as a way to enhance and streamline the measures evaluation and voting processes. The preliminary analysis will help to guide the Standing Committee evaluation of each measure by summarizing the measure developer submission, guide measure evaluation discussion, and identify topic areas for additional input. **NQF staff would like to stress that the preliminary analysis is intended to be used as a guide to facilitate the Committee's discussion and evaluation.**

Criteria 1: Importance to Measure and Report

1a. Evidence

1a. Evidence.

NQF considers each of the components in this composite to be an **intermediate clinical outcome**. The evidence for intermediate clinical outcomes measures should include a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence that the measured intermediate clinical outcome leads to a desired health outcome.

- This measure is a composite of intermediate outcomes intended to assess whether patients with Ischemic Vascular Disease (IVD) are receiving optimal care.
- The evidence for intermediate clinical outcomes measures should include a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence that the measured intermediate clinical outcome leads to a desired health outcome.
- The components of this measure are:
    - Most recent blood pressure measurement is less than 140/90 mm Hg
    - Most recent tobacco status is Tobacco Free
    - Daily Aspirin or Other Antiplatelet Unless Contraindicated
    - Statin Use
- NQF criteria indicate that each component in a composite must meet the evidence subcriterion to justify its inclusion in the composite; as per NQF guidance, evidence is presented separately for each component in this measure.
- Evidence for **Aspirin/Antiplatelet Therapy**
    - Regarding the link between this intermediate outcome and patient health outcomes, the developer notes that for patients on daily aspirin or other antiplatelet, risk of further cardiovascular complications is reduced.
    - The evidence for this component is derived from the AHA/ACC Guidelines for Preventing Heart Attack and Death in Patients with Atherosclerotic Cardiovascular Disease: 2011 Update
    - The specific guideline recommendation is as follows:
        - Goal: Aspirin 75–162 mg daily is recommended in all patients with coronary artery disease

unless contraindicated
    - This is a **Class I** recommendation (defined as a condition for which there is evidence and/or general agreement that a given procedure or treatment is useful and effective) with **level of evidence A** (defined as a recommendation based on evidence from multiple randomized trials or meta-analyses).
    - These are, respectively, the highest recommendation class and level of evidence available under the ACC/AHA grading system.
    - This recommendation is based on multiple clinical trials or meta-analyses covering multiple populations over the timespan of 2006-2011.
    - With respect to the quality, quantity, and consistency of the evidence, the developer states that there is a growing body of evidence confirming that, in patients with atherosclerotic vascular disease, comprehensive risk factor management reduces risk as assessed by a variety of outcomes, and that aspirin/antiplatelet therapy has been shown to be effective in secondary prevention of further cardiovascular risk.
    - The developer does not explicitly address the consistency across studies in the body of evidence or the estimated magnitude of effect related to aspirin/antiplatelet therapy in IVD patients.
- Evidence for **Blood Pressure Control**
    - Regarding the link between this intermediate outcome and patient health outcomes, the developer notes that blood pressure should be kept below 140mmHg systolic and 90mmHg diastolic to prevent further cardiovascular risk.
    - The evidence for this component is derived from the AHA/ACC Guidelines for Preventing Heart Attack and Death in Patients with Atherosclerotic Cardiovascular Disease: 2011 Update
    - The specific guideline recommendation is as follows:
        - Blood Pressure Goal: <140/90 mm Hg
    - This is a **Class I** recommendation (defined as a condition for which there is evidence and/or general agreement that a given procedure or treatment is useful and effective) with **level of evidence A** (defined as a recommendation based on evidence from multiple randomized trials or meta-analyses).
    - These are, respectively, the highest recommendation class and level of evidence available under the ACC/AHA grading system.
    - This recommendation is based on multiple clinical trials or meta-analyses covering multiple populations over the timespan of 2006-2011.
    - With respect to the quality, quantity, and consistency of the evidence, the developer states that there is a growing body of evidence confirming that in patients with atherosclerotic vascular disease, comprehensive risk factor management reduces risk as assessed by a variety of outcomes, that a BP of <140/90 has been shown to prevent further cardiovascular risk, and that BP results equal to or above 140/90 should be treated, as tolerated, with blood pressure medication to achieve goal blood pressure.
    - The developer does not explicitly address the consistency across studies in the body of evidence or the estimated magnitude of effect related to maintenance of blood pressure levels below 140/90 mm Hg.
- Evidence for **Tobacco Status**
    - As evidence for this component, the developer cites a 2008 clinical practice guideline from the U.S. Department of Health And Human Services – Public Health Service.
    - The developer discusses findings from the guideline suggesting that tobacco use accounts for more than 435,000 deaths each year in the United States, noting that smoking is a known cause of multiple serious diseases and other harmful consequences.
    - The developer also notes the costs of tobacco use to society, including smoking-attributable direct medical expenses and lost productivity.
    - In addition, the developer suggests that clinicians and health care systems often fail to treat tobacco use consistently and correctly, noting that as of 2005, only 70 percent of smokers reported having received some counseling to quit, and that among current smokers who attempted to stop for at least 1 day in the past year, only 21.7 percent used cessation medication.
    - The developer suggests that there is evidence that tobacco use interventions, if delivered in a timely and effective manner, can rapidly reduce the risk of suffering from smoking-related disease.
    - Although not included by the developer, the USPSTF has made the following grade A, high certainty

recommendation for all adults: *The USPSTF recommends that clinicians ask all adults about tobacco use and provide tobacco cessation interventions for those who use tobacco products*. This USPSTF guideline goes on to note that counseling and pharmaceutical interventions increase cessation rates that and that "The USPSTF found convincing evidence that smoking cessation decreases the risk for heart disease, stroke, and lung disease."

- Evidence for **Statin Use**
  - Regarding the link between this intermediate outcome and patient health outcomes, the developer notes that for those patients on appropriate statin medication, risk of further cardiovascular complications is reduced.
  - The evidence for this component measure is derived from the 2013 ACC/AHA Guideline on the Treatment of Blood Cholesterol to Reduce Atherosclerotic Cardiovascular Risk in Adults.
  - The specific guideline recommendation is as follows:
    - Goal: High-intensity statin therapy should be initiated or continued as first-line therapy in women and men ≤75 years of age who have clinical ASCVD, unless contraindicated.
  - This recommendation has an NHLBI grade of A (Strong), meaning there is high certainty based on evidence that the net benefit is substantial.
  - Within the ACC/AHA grading system, this is a **Class I** recommendation (defined as a condition for which there is evidence and/or general agreement that a given procedure or treatment is useful and effective) with **level of evidence A** (defined as a recommendation based on evidence from multiple randomized trials or meta-analyses).
  - The developer notes that the evidence supporting this guideline recommendation is derived from five randomized controlled trials (RCTs), as well as systematic reviews and meta-analyses of RCTs.
  - The developer suggests that the findings of the systematic evidence review support the use of statins to prevent both nonfatal and fatal atherosclerotic cardiovascular disease (ASCVD) events, noting that the review found a high level of evidence indicating that statins reduce total mortality in individuals with a history of prior ASCVD events, and moderate evidence that statins reduce total mortality in individuals who have no prior history of ASCVD events but are at increased ASCVD risk.
  - The developer provides a table listing the effects of high-, moderate-, and low-intensity statin therapy on LDL cholesterol levels.

Questions for the Committee:

- *Is the evidence directly applicable to the intermediate outcomes being measured?*
- *Are these intermediate outcomes proximal and closely related to desired outcomes?*

1b. Gap in Care/Opportunity for Improvement and 1b. Disparities

1b. Performance Gap. The performance gap requirements include demonstrating quality problems and opportunity for improvement.

- The developer presents 2014 performance data for 121 clinics, covering a total of 42,290 patients.
- Average clinic performance on the measure was .5862 (meaning that on average, clinics achieved all four goals for approximately 59 percent of eligible patients).
- Scores ranged from a minimum of .379 to a maximum of .750, with the 10th percentile at .485 and the 90th percentile at .672.
- The developer notes that this measure is not currently reported with disparities data, but that some data related to sociodemographic factors (e.g., race/ethnicity data, payer data, gender, and age) are collected and could potentially be incorporated in the future.

Questions for the Committee:

- *Do the data provided by the developer demonstrate a gap in care that warrants a national performance measure?*
- *Are you aware of evidence that disparities exist in this area of healthcare?*
- *Should this measure be indicated as disparities sensitive?*

1c. Priority

1c. High Priority (previously "High Impact") requires measures to address national health goal/priority or a demonstrated high-impact aspect of care.

- *Beginning in 2015, priority is no longer an NQF measure evaluation criterion.*

1d. Composite - Quality Construct and Rationale

1c. Composite Quality Construct and Rationale. The quality construct and rationale should be explicitly articulated and logical; a description of how the aggregation and weighting of the components is consistent with the quality construct and rationale also should be explicitly articulated and logical.

- This is an 'all-or-none' composite measure, meaning if a provider does not satisfy all four components (or 'goals') for a given patient, that patient will not be counted in the composite numerator, reducing the provider's performance score accordingly.
- The quality construct for the composite is 'optimal IVD care' – using multiple dimensions of performance, the measure assesses whether patients with Ischemic Vascular Disease (IVD) are receiving optimal care.
- The developer suggests that this methodology reflects the interests and likely desires of patients—with the data collected in a single score, patients can easily look and see how their provider group is performing on these criteria rather than trying to make sense of multiple scores on individual measures.
- The developer also notes that this method represents a systems perspective, emphasizing the importance of optimal care through a patient´s entire healthcare experience.
- Finally, the developer suggests that this method provides a more sensitive instrument for assessing provider performance.

Questions for the Committee:

- *Are the quality construct and rationale for the composite explicitly stated and logical?*
- *Is the method for* aggregation and weighting of the components explicitly stated and logical?

Committee pre-evaluation comments

Criteria 1: Importance to Measure and Report (including 1a, 1b, 1c)

1. ***Committee's Overview Comments***:
   - Very strong!

1a. ***Committee's Comments on Evidence to Support Measure Focus:***

- Very strong!

1b. ***Committee's Comments on Performance Gap:***

- The developer presents 2014 performance data for 121 clinics, covering a total of 42,290 patients.
  - Average clinic performance on the measure was .5862 (meaning that on average, clinics achieved all four goals for approximately 59 percent of eligible patients).
  - Scores ranged from a minimum of .379 to a maximum of .750, with the 10th percentile at .485 and the 90th percentile at .672.
  - The developer notes that this measure is not currently reported with disparities data, but that some data related to sociodemographic factors (e.g., race/ethnicity data, payer data, gender, and age) are collected and could potentially be incorporated in the future.

1c. ***Committee's Comments on Composite Performance Measure:***

- I am worried about the following: Most recent Tobacco Status is Tobacco-Free. Health care providers have little control over this.
- They need to modify this: Documentation in the medical record of Statin Use to Documentation in the medical record of Statin Use in the absence of contraindications.

Criteria 2: Scientific Acceptability of Measure Properties

2a. Reliability

2a1. Reliability Specifications

2a1. Specifications requires the measure, as specified, to produce consistent (reliable) and credible (valid) results about the quality of care when implemented.

- This measure is a composite of intermediate outcomes intended to assess whether patients with Ischemic Vascular Disease (IVD) are receiving optimal care.
- The denominator population includes patients with CAD or a CAD Risk-Equivalent Condition 18-75 years of age and alive as of the last day of the measurement period.
- Only patients whose care is currently being managed within the measured entity (i.e., physician group) are included in the denominator. The developers have provided the decision logic by which these determinations are made in their submission materials, and have included CPT and HCPS codes by which office visits are identified in their code list.
- The numerator population includes denominator-eligible patients who have met each of the four intermediate outcomes that are part of this composite.
- ICD-9, ICD-10, CPT, CPT-II, and HCPS diagnosis codes used to identify the numerator and denominator populations are specified in an Excel spreadsheet included as part of the measure submission.
- For the **statin use** and **aspirin/anti-platelet** components, the developer has provided lists of specific medications that satisfy the measure's requirements.
- The measure can be reported through an all-electronic data collection method, manual review using a random-sample method (for which the developer provides an online calculator to determine appropriate sample size), or a hybrid method using administrative claims review and manual review of records where information cannot be obtained through administrative data.
- When possible, data is collected in an all-electronic format and is all-inclusive. Where there is missing data, a patient-level validation and verification process is used.
- This measure is not risk-adjusted.

Questions for the Committee:

- *Are all the data elements clearly defined? Are all appropriate codes included?*
- *Is the calculation algorithm clear?*
- *Is it likely this measure can be consistently implemented?*

2a2. Reliability Testing Testing attachment

2a2. Reliability testing demonstrates if the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise enough to distinguish differences in performance across providers.

- Testing data is derived from 17 group practice members of the Wisconsin Collaborative for Healthcare Quality (WCHQ).
- 15 groups reported all electronically (Total Population) and 2 groups reported using the random sample methodology.
- Testing included data from 121 clinic sites covering 50,758 patients.
- Reliability testing was performed at the measure score level.
- The developer conducted a signal-to-noise analysis of the measure score, which tests reliability by estimating the extent to which variation in scoring is caused by real differences in performance ('signal' – represented here as an estimate of provider-to-provider variance) as opposed to measurement error ('noise' – here represented as an estimate of provider-specific variance).
- Scores of signal-to-noise reliability analyses generally range from 0.0 to 1.0, with a score of zero indicating that all variation is due to measurement error and a score of 1.0 indicating that all variation is attributable to real differences across measured entities.
- Across the 121 measured clinics, average reliability was found to be **0.7817**.
- The developer states that a reliability score of greater than 0.70 is generally accepted to be sufficient for determining performance differences between groups.

Questions for the Committee:

- *Is the test sample adequate to generalize for widespread implementation?*
- *Do the results demonstrate sufficient reliability so that differences in performance can be identified?*

2b. Validity

2b1. Validity: Specifications

2b1. Validity Specifications. This section should determine if the measure specifications are consistent with the evidence.

- This measure is specified to determine whether patients with IVD achieved all four of the following goals:
  - Most recent blood pressure measurement is less than 140/90 mm Hg
    - Blood pressure levels are extracted directly from the patient record. If no Blood Pressure is recorded during the Measurement Period, the patient is assumed to be "not controlled."
  - Most recent tobacco status is Tobacco Free
    - Patients are asked about their tobacco status; ICD-9, CPT, HCPCS and CPT-II Codes indicating tobacco use status may also be used.
  - Daily Aspirin or Other Antiplatelet Unless Contraindicated
    - Compliance with this goal is achieved if there is either (1) documentation of an active prescription for daily Aspirin; or (2) documentation on the patient's medication list of active daily usage of Aspirin.
  - Active use of a statin unless contraindicated
    - Compliance with this goal is achieved if there is either (1) documentation of an active prescription for a statin; or (2) documentation on the patient's medication list of active usage of a statin
- The evidence presented by the developer supports:
  - Maintenance of blood pressure below 140/90 mm Hg
  - Smoking cessation in all adults
  - Aspirin 75–162 mg daily in all patients with coronary artery disease unless contraindicated
  - High-intensity statin therapy in women and men ≤75 years of age who have clinical ASCVD, unless contraindicated
- This measure is not risk-adjusted. The developer did not consider whether there was a conceptual basis for adjusting this measure for sociodemographic (SDS) factors or clinical factors.

Question for the Committee:

- *Are the specifications consistent with the evidence?*
- *Is there a conceptual basis for risk adjustment (clinical or SDS factors) of this measure?*

2b2. Validity testing

2b2. Validity Testing should demonstrate the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality.

- The developer has assessed this measure for data element validity using the following process:
  - The measure numerator for each reporting entity is subject to validation once every three years, on a schedule based on random selection.
  - Results that vary greatly between reporting periods or that appear significantly higher or lower than the mean are subject to validation.
  - In their first year reporting data, measured entities are validated for all measure elements (denominator and numerator).
  - Upon the release of a new measure, all reporting entities are validated for each measure element (denominator and numerator).
- The developer also conducts mapping exercises to ensure certain data elements are meeting standards and that care is being attributed to the correct providers.

- The developer notes that measure results reported through the WCHQ data repository are calculated on behalf of the reporting entity through a standard process, minimizing the chance of misinterpretation of the measure specifications by an individual reporting entity.
- Reporting entities have access to patient level data reported to the repository and are required to randomly sample patients that didn't meet the numerator to ensure that they are not missing any data elements or sources in the data files.
- Measured entities using the alternate reporting method are required to upload patient-level data files and complete on-line denominator and numerator validation forms that describe how patients met both the denominator and numerator.
- Fields required for measure validation are provided in the measure testing attachment.
- Two entities attempting to report the measure using the alternate reporting method had issues warranting removal of performance results from the public website. The issues found were related to missing medication data, data systems being combined, and staff changes in areas that work directly with the WCHQ measures. Both entities have a goal to work on resolution of the issues and plan to report the measure when it is publicly reported again in November 2015.

Questions for the Committee:

- *Does the developer's validation process ensure sufficient validity so that conclusions about quality can be made?*
- *Do you agree that the score from this measure as specified is an indicator of quality?*

2b3-2b7. Threats to Validity

2b3. Exclusions:

- N/A

2b4. Risk adjustment:

- This measure is not risk-adjusted.

- ***Questions for the Committee:***
  - *Do you agree with the developer that risk adjustment is not necessary for this measure?*

2b5. Meaningful difference:

- The developer did not provide any information regarding the identification of statistically significant and meaningful differences in performance; however, the reliability testing results presented in Section 2a.2 of the testing attachment suggest that the measure's ability to reliably distinguish between measured entities is adequate.

Question for the Committee:

- *Does this measure identify meaningful differences about quality?*

2b6. Comparability of data sources/methods:

- N/A

2b7. Missing Data

- The developer reports that if any one of the four individual component measure is missing the result (i.e., patient does not have an active aspirin order), the patient will remain in the denominator but will fail the numerator. If there is no documentation of tobacco status, the patient is not compliant for this measure.

2d.Composite measure: construction

2d. Empirical analysis to support composite construction. Empirical analysis should demonstrate that the component measures add value to the composite and that the aggregation and weighting rules are consistent with the quality construct.

- The quality construct for this composite measure is 'optimal IVD care' – using multiple dimensions of performance, the measure assesses whether patients with Ischemic Vascular Disease (IVD) are receiving optimal care.
- Because this is an all-or-none measure, empirical analysis to demonstrate that the aggregation and weighting rules are consistent with the quality construct are not needed.

Questions for the Committee:

○ *Do the component measures fit the quality construct?*

○ *Are the objectives of parsimony and simplicity achieved while supporting the quality construct?*

Committee pre-evaluation comments

Criteria 2: Scientific Acceptability of Measure Properties (including all 2a, 2b, and 2d)

2a1. &2b1.: ***Committee's Comments on Reliability-Specifications:***

- No comments

2a2.: ***Committee's Comments on Reliability-Testing:***

- Testing data is derived from 17 group practice members of the Wisconsin Collaborative for Healthcare Quality (WCHQ).
  - 15 groups reported all electronically (Total Population) and 2 groups reported using the random sample methodology.
  - Testing included data from 121 clinic sites covering 50,758 patients.
  - Reliability testing was performed at the measure score level.
  - The developer conducted a signal-to-noise analysis of the measure score, which tests reliability by estimating the extent to which variation in scoring is caused by real differences in performance ('signal' – represented here as an estimate of provider-to-provider variance) as opposed to measurement error ('noise' – here represented as an estimate of provider-specific variance).
  - Scores of signal-to-noise reliability analyses generally range from 0.0 to 1.0, with a score of zero indicating that all variation is due to measurement error and a score of 1.0 indicating that all variation is attributable to real differences across measured entities.
  - Across the 121 measured clinics, average reliability was found to be 0.7817.
  - The developer states that a reliability score of greater than 0.70 is generally accepted to be sufficient for determining performance differences between groups.

2b1.: ***Committee's Comments on Validity-Specifications***:

- What is the rationale for excluding patients older than 75 years of age?
- There is a need for more clarity regarding CAD risk-equivalent condition.

2b2.: ***Committee's Comments on Validity-Testing:***

- It is reasonable.

2b3-7.: ***Committee's Comments on Threats to Validity:***

- Risk adjustment not applicable.

2d.: ***Committee's Comments on Composite Performance Measure:***

- Not Applicable

Criterion 3. Feasibility

3. Feasibility is the extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

- The measure can be reported through an all-electronic data collection method based on entire IVD Denominator, a hybrid method-based on Administrative Review Denominator and Manual Review Sample, or a random sample method-based on Sample Population. The hybrid or random sample method are used if there will be missing data elements
- Data for this measure may be derived from administrative claims (CPT, CPT-II, ICD-9, ICD-10, HCPCS) or extracted directly from electronic health records.
- The developer (Wisconsin Collaborative for Healthcare Quality) also serves as a qualified clinical data registry for group practice reporting under PQRS.
- The developer states that all data elements should be available in electronic form; however, if a practice is unable to obtain the data in an all-electronic format, sampling is allowed via either hybrid or random sampling, requiring manual

chart review on the part of reporting providers, who must then submit aggregate denominator and numerator data to WCHQ's web-based reporting tool for reporting results on WCHQ's public website.

- Members of the Wisconsin Collaborative for Healthcare Quality (WCHQ) submit global patient-level files of patient demographic, encounter, and clinical data into the WCHQ data repository through a secure, HIPAA compliant portal.
- Data are obtained via data extracts (.csv files) from each practice and then uploaded into the WCHQ Repository Based Submission (RBS) database.
- Alternatively, WCHQ members can use detailed measure specifications to program measures internally and submit aggregate denominator and numerator data to WCHQ's web-based reporting tool for reporting results on WCHQ's public website. De-identified patient level data is additionally submitted for validation purposes.
- The developer has provided a spreadsheet describing the process of data submission and creation of the data files.

Questions for the Committee:

- *Are the required data elements routinely generated and used during care delivery?*
- *Are the required data elements available in electronic form, e.g., EHR or other electronic sources?*
- *Is the data collection strategy ready to be put into operational use at a national level?If an eMeasure, does the eMeasure Feasibility Score Card demonstrate acceptable feasibility in multiple EHR systems and sites?*

Committee pre-evaluation comments

Criteria 3: Feasibility

3.: ***Committee's Comments on Feasibility:***

- Yes

Criterion 4: Usability and Use

4. Usability and Use evaluate the extent to which audiences (e.g., consumers, purchasers, providers, policymakers) use or could use performance results for both accountability and performance improvement activities.

- This measure is being used for quality improvement with benchmarking, as well as public reporting and other accountability applications:
  - WCHQ publicly reports performance information on group practices and clinics participating in the collaborative; this includes 17 organizations reporting at the group practice level and 121 at the clinic site level, for a total of 50,758 patients.
  - WCHQ's public website also provides a Measure Summary display where members can select a reporting organization and then look at their measure results. Measure results can be viewed by Top Performer, 95th, 90th, 75th and 50th percentiles, and by Average.
  - WCHQ is a Centers for Medicare and Medicaid (CMS) approved Qualified Clinical Data Registry (QCDR), allowing eligible providers to report to WCHQ under the Physician Quality Reporting System (PQRS) starting in 2015.
- 2014 is the first year this measure was published, so the developer does not have the ability to report progress on improvement at this time. WCHQ will report the measure again in November 2015 and collect data on improvement at that time.
- The developer does not report any unintended consequences.

Questions for the Committee*:*

- *Are performance results for this measure being used to further the goal of high-quality, efficient healthcare?*
- *Are you aware of any potential unintended consequences of this measure?*

Committee pre-evaluation comments

Criteria 4: Usability and Use

4.: ***Committee's Comments on Usability and Use:***

- This measure is being used for quality improvement with benchmarking, as well as public reporting and other accountability applications:
  - WCHQ publicly reports performance information on group practices and clinics participating in the collaborative; this includes 17 organizations reporting at the group practice level and 121 at the clinic site level, for a total of 50,758 patients.
  - WCHQ's public website also provides a Measure Summary display where members can select a reporting organization and then look at their measure results. Measure results can be viewed by Top Performer, 95th, 90th, 75th and 50th percentiles, and by Average.
  - WCHQ is a Centers for Medicare and Medicaid (CMS) approved Qualified Clinical Data Registry (QCDR), allowing eligible providers to report to WCHQ under the Physician Quality Reporting System (PQRS) starting in 2015.

Criterion 5: Related and Competing Measures

- List any related or competing measures based on harmonization protocol.
- Summarize any harmonization efforts, i.e., responses from the developers regarding harmonization.
- Briefly summarize next steps according to protocol

Pre-meeting public and member comments

Comment by: Ashish R. Trivedi, Pharm.D.
Organization: SPI
Comment#5116: "While Lilly is supportive of this measure, we suggest the use of dual anti-platelet therapy (treatment with aspirin and a P2Y12 inhibitor) as supported by the treatment guidelines for patients with acute coronary syndrome (ACS, including AMI) and/or those managed with revascularization [O'Gara et al 2013, Amsterdam et al, 2014, Levine et al, 2011].

NATIONAL QUALITY FORUM—Evidence (subcriterion 1a)

Component # 1 DAILY ASPIRIN OR OTHER ANTIPLATELET MEDICATIONS THERAPY UNLESS CONTRAINDICATED

Measure Number (*if previously endorsed*)**:** Click here to enter NQF number

Measure Title: Ischemic Vascular Disease Care: Daily Aspirin or Other Antiplatelet Medications Therapy Unless Contraindicated Component

IF the measure is a component in a composite performance measure, provide the title of the Composite Measure here: Ischemic Vascular Disease Care: All or None Outcome Measure-Optimal Control

Date of Submission: 6/29/2015

Instructions

- *For composite performance measures:*
  - *A separate evidence form is required for each component measure unless several components were studied together.*
  - *If a component measure is submitted as an individual performance measure, attach the evidence form to the individual measure submission.*
- Respond to all questions as instructed with answers immediately following the question. All information needed to demonstrate meeting the evidence subcriterion (1a) must be in this form. An appendix of *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 10 pages (*incudes questions/instructions*; minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the evidence for this measure meets NQF's evaluation criteria.

1a. Evidence to Support the Measure Focus

The measure focus is evidence-based, demonstrated as follows:

- Health outcome: [3] a rationale supports the relationship of the health outcome to processes or structures of care. Applies to patient-reported outcomes (PRO), including health-related quality of life/functional status, symptom/symptom burden, experience with care, health-related behavior.
- Intermediate clinical outcome: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured intermediate clinical outcome leads to a desired health outcome.
- Process: [5] a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured process leads to a desired health outcome.
- Structure: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured structure leads to a desired health outcome.
- Efficiency: [6] evidence not required for the resource use component.

Notes

3. Generally, rare event outcomes do not provide adequate information for improvement or discrimination; however, serious reportable events that are compared to zero are appropriate outcomes for public reporting and quality improvement.

4. The preferred systems for grading the evidence are the U.S. Preventive Services Task Force (USPSTF) grading definitions and methods, or Grading of Recommendations, Assessment, Development and Evaluation (GRADE) guidelines.

5. Clinical care processes typically include multiple steps: assess → identify problem/potential problem → choose/plan intervention (with patient input) → provide intervention → evaluate impact on health status. If the measure focus is one step in such a multistep process, the step with the strongest evidence for the link to the desired outcome should be selected as the focus of measurement. Note: A measure focused only on collecting PROM data is not a PRO-PM.

6. Measures of efficiency combine the concepts of resource use and quality (see NQF's Measurement Framework: Evaluating Efficiency Across Episodes of Care; AQA Principles of Efficiency Measures).

1a.1.This is a measure of: (*should be consistent with type of measure entered in De.1*)

Outcome

☐ Health outcome: Click here to name the health outcome

☐Patient-reported outcome (PRO): Click here to name the PRO

PROs include HRQoL/functional status, symptom/symptom burden, experience with care, health-related behaviors

☒ Intermediate clinical outcome (*e.g., lab value*): Daily Aspirin or Antiplatelet Use Unless Contraindicated for patients with ischemic vascular disease (IVD)

☐ Process: Click here to name the process

☐ Structure: Click here to name the structure

☐ Other: Click here to name what is being measured

HEALTH OUTCOME/PRO PERFORMANCE MEASURE *If not a health outcome or PRO, skip to 1a.3*

1a.2. Briefly state or diagram the path between the health outcome (or PRO) and the healthcare structures, processes, interventions, or services that influence it.

1a.2.1. State the rationale supporting the relationship between the health outcome (or PRO) to at least one healthcare structure, process, intervention, or service (*i.e., influence on outcome/PRO*).

Note: For health outcome/PRO performance measures, no further information is required; however, you may provide evidence for any of the structures, processes, interventions, or service identified above.

INTERMEDIATE OUTCOME, PROCESS, OR STRUCTURE PERFORMANCE MEASURE

1a.3. Briefly state or diagram the path between structure, process, intermediate outcome, and health outcomes. Include all the steps between the measure focus and the health outcome.

- Determine patients with diagnosis of IVD
- Assess patients with IVD that are on a daily aspirin or other antiplatelet unless contraindicated
- For those patients on daily aspirin or other antiplatelet risk of further cardiovascular complications is reduced.

1a.3.1. What is the source of the systematic review of the body of evidence that supports the performance measure?

☒ Clinical Practice Guideline recommendation – ***complete sections 1a.4, and 1a.7***

☐ US Preventive Services Task Force Recommendation – ***complete sections 1a.5 and 1a.7***

☐ Other systematic review and grading of the body of evidence (*e.g., Cochrane Collaboration, AHRQ Evidence Practice Center*) – ***complete sections 1a.6 and 1a.7***

☐ Other – ***complete section 1a.8***

Please complete the sections indicated above for the source of evidence. You may skip the sections that do not apply.

1a.4. CLINICAL PRACTICE GUIDELINE RECOMMENDATION

1a.4.1. Guideline citation (*including date*) and **URL for guideline** (*if available online*):

B/P Control, Tobacco Cessation and Daily Aspirin Guideline:

Sidney C. Smith, Jr, MD; Steven N. Blair, PED; Robert O. Bonow, MD; Lawrence M. Brass, MD; Manuel D. Cerqueira, MD; Kathleen Dracup, RN, DNSc; Valentin Fuster, MD, PhD; Antonio Gotto, MD, DPhil; Scott M. Grundy, MD, PhD; Nancy Houston Miller, RN, BSN; Alice Jacobs, MD; Daniel Jones, MD; Ronald M. Krauss, MD; Lori Mosca, MD, PhD; Ira Ockene, MD; Richard C. Pasternak, MD; Thomas Pearson, MD, PhD; Marc A. Pfeffer, MD, PhD; Rodman D. Starke, MD; Kathryn A. Taubert, PhD

AHA/ACC Guidelines for Preventing Heart Attack and Death in Patients with Atherosclerotic Cardiovascular Disease: 2001 Update (November 1, 2001)-

http://circ.ahajournals.org/content/124/22/2458.full.pdf+html

1a.4.2. Identify guideline recommendation number and/or page number and **quote verbatim, the specific guideline recommendation**.

Antiplatelet agents/anticoagulants	**Class I** 1. Aspirin 75–162 mg daily is recommended in all patients with coronary artery disease unless contraindicated.[64,81,82,116] ***(Level of Evidence: A)***

Daily Aspirin Guideline: Page 3: Goal - Aspirin 75–162 mg daily is recommended in all patients with coronary artery disease unless contraindicated

1a.4.3. Grade assigned to the quoted recommendation with definition of the grade:

Daily Aspirin Guideline: Class I, Level of Evidence A – Recommendation that treatment or procedure is effective. Sufficient evidence from multiple randomized trials or meta-analyses.

1a.4.4. Provide all other grades and associated definitions for recommendations in the grading system. (*Note: If separate grades for the strength of the evidence, report them in section 1a.7.*)

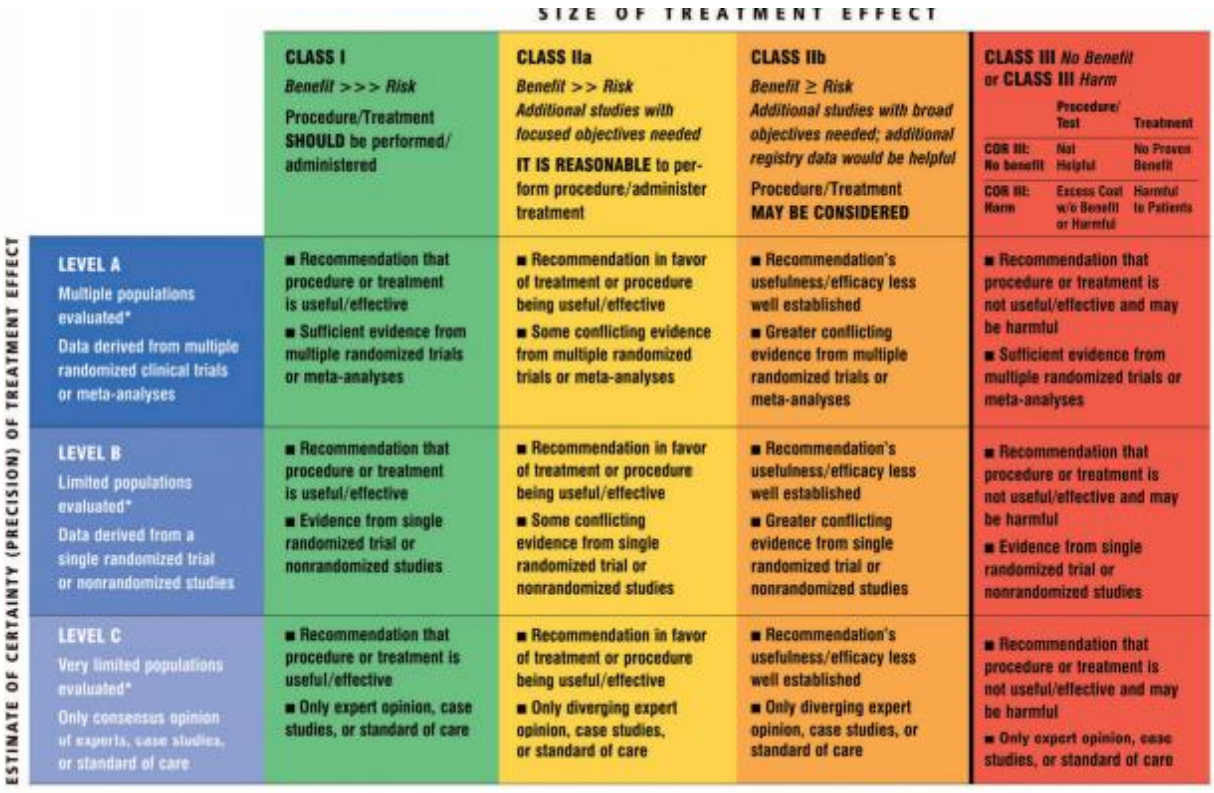
For more than 20 years, the American College of Cardiology (ACC) and the American Heart Association (AHA) have released clinical practice guidelines to provide recommendations on care of patients with cardiovascular disease. The ACC/AHA guidelines currently use a grading schema based on level of evidence and class of recommendation (available at *http://www.acc.org* and *http://www.aha.org*). The level of evidence classification combines an objective description of the existence and the types of studies supporting the recommendation and expert consensus, according to 1 of the following 3 categories:

- Level of evidence A: recommendation based on evidence from multiple randomized trials or meta-analyses
- Level of evidence B: recommendation based on evidence from a single randomized trial or nonrandomized studies
- Level of evidence C: recommendation based on expert opinion, case studies, or standards of care.

The class of recommendation designation indicates the strength of a recommendation and requires guideline writers not only to make a judgment about the relative strengths and weaknesses of the study data but also to make a value

judgment about the relative importance of the risks and benefits identified by the evidence and to synthesize conflicting findings among multiple studies. Definitions of the classes of recommendation are as follows:

- Class I: conditions for which there is evidence and/or general agreement that a given procedure or treatment is useful and effective
- Class II: conditions for which there is conflicting evidence and/or a divergence of opinion about the usefulness/efficacy of a procedure or treatment
- Class IIa: weight of evidence/opinion is in favor of usefulness/efficacy
- Class IIb: usefulness/efficacy is less well established by evidence/opinion
- Class III: conditions for which there is evidence and/or general agreement that the procedure/treatment is not useful/effective and in some cases may be harmful.



1a.4.5. Citation and URL for methodology for grading recommendations (*if different from 1a.4.1*)**:**

See 1a.4.1

1a.4.6. If guideline is evidence-based (rather than expert opinion), are the details of the quantity, quality, and consistency of the body of evidence available (e.g., evidence tables)?

☒ Yes → ***complete section 1a.7***

☐ No → ***report on another systematic review of the evidence in sections 1a.6 and 1a.7; if another review does not exist, provide what is known from the guideline review of evidence in 1a.7***

1a.5. UNITED STATES PREVENTIVE SERVICES TASK FORCE RECOMMENDATION

1a.5.1. Recommendation citation (*including date*) and **URL for recommendation** (*if available online*):

1a.5.2. Identify recommendation number and/or page number and **quote verbatim, the specific recommendation**.

1a.5.3. Grade assigned to the quoted recommendation with definition of the grade:

1a.5.4. Provide all other grades and associated definitions for recommendations in the grading system.
(*Note: the grading system for the evidence should be reported in section 1a.7.*)

1a.5.5. Citation and URL for methodology for grading recommendations (*if different from 1a.5.1*)**:**

Complete section 1a.7

1a.6. OTHER SYSTEMATIC REVIEW OF THE BODY OF EVIDENCE

1a.6.1. Citation (*including date*) and **URL** (*if available online*):

Complete section 1a.7

1a.7. FINDINGS FROM SYSTEMATIC REVIEW OF BODY OF THE EVIDENCE SUPPORTING THE MEASURE

If more than one systematic review of the evidence is identified above, you may choose to summarize the one (or more) for which the best information is available to provide a summary of the quantity, quality, and consistency of the body of evidence. Be sure to identify which review is the basis of the responses in this section and if more than one, provide a separate response for each review.

Antiplatelet agents/anticoagulants	**Class I** 1. Aspirin 75–162 mg daily is recommended in all patients with coronary artery disease unless contraindicated.[64,81,82,116] ***(Level of Evidence: A)***

Daily Aspirin Guideline: Page 3: Goal - Aspirin 75–162 mg daily is recommended in all patients with coronary artery disease unless contraindicated

1a.7.1. What was the specific structure, treatment, intervention, service, or intermediate outcome addressed in the evidence review?

Daily aspirin or antiplatelet unless contraindicated for patients with IVD.

1a.7.2. Grade assigned for the quality of the quoted evidence with definition of the grade:

Class 1 – Level of Evidence A.

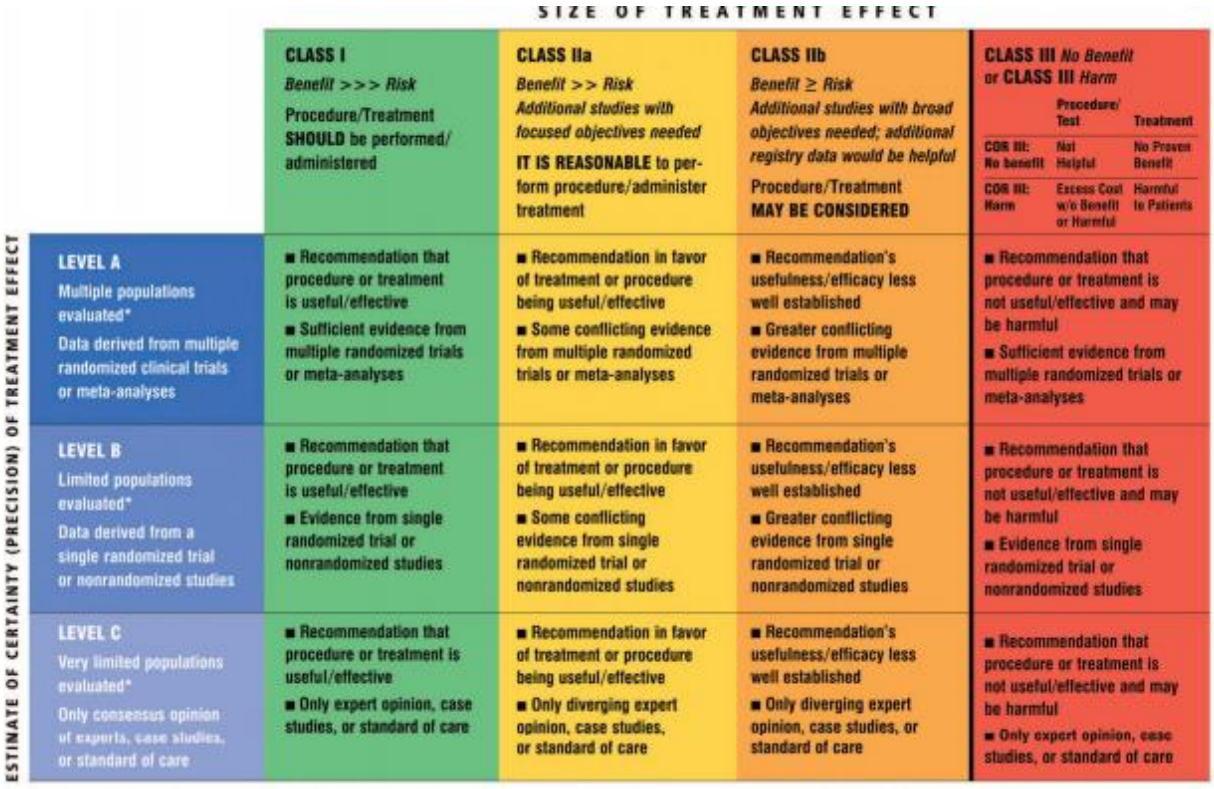
1a.7.3. Provide all other grades and associated definitions for strength of the evidence in the grading system.

For more than 20 years, the American College of Cardiology (ACC) and the American Heart Association (AHA) have released clinical practice guidelines to provide recommendations on care of patients with cardiovascular disease. The ACC/AHA guidelines currently use a grading schema based on level of evidence and class of recommendation (available at *http://www.acc.org* and *http://www.aha.org*). The level of evidence classification combines an objective description of the existence and the types of studies supporting the recommendation and expert consensus, according to 1 of the following 3 categories:

- Level of evidence A: recommendation based on evidence from multiple randomized trials or meta-analyses
- Level of evidence B: recommendation based on evidence from a single randomized trial or nonrandomized studies
- Level of evidence C: recommendation based on expert opinion, case studies, or standards of care.

The class of recommendation designation indicates the strength of a recommendation and requires guideline writers not only to make a judgment about the relative strengths and weaknesses of the study data but also to make a value judgment about the relative importance of the risks and benefits identified by the evidence and to synthesize conflicting findings among multiple studies. Definitions of the classes of recommendation are as follows:

- Class I: conditions for which there is evidence and/or general agreement that a given procedure or treatment is useful and effective
- Class II: conditions for which there is conflicting evidence and/or a divergence of opinion about the usefulness/efficacy of a procedure or treatment
- Class IIa: weight of evidence/opinion is in favor of usefulness/efficacy
- Class IIb: usefulness/efficacy is less well established by evidence/opinion
- Class III: conditions for which there is evidence and/or general agreement that the procedure/treatment is not useful/effective and in some cases may be harmful.



1a.7.4. What is the time period covered by the body of evidence? (*provide the date range, e.g., 1990-2010*).
Date range: 2006-2011

QUANTITY AND QUALITY OF BODY OF EVIDENCE

1a.7.5. How many and what type of study designs are included in the body of evidence? (*e.g., 3 randomized controlled trials and 1 observational study*)

Multiple populations evaluated in multiple clinical trials or meta-analysis

1a.7.6. What is the overall quality of evidence across studies in the body of evidence? (*discuss the certainty or confidence in the estimates of effect particularly in relation to study factors such as design flaws, imprecision due to small numbers, indirectness of studies to the measure focus or target population*)

The growing body of evidence confirms that in patients with atherosclerotic vascular disease, comprehensive risk factor management reduces risk as assessed by a variety of outcomes, including improved survival, reduced recurrent events, the need for revascularization procedures, and improved quality of life. It is important not only that the healthcare provider implement these recommendations in appropriate patients but also that healthcare systems support this implementation to maximize the benefit to the patient. Compelling evidence-based results from recent clinical trials and revised practice guidelines provide the impetus for this update of the 2006 recommendations with evidence-based results (see 1a.7). Classification of recommendations and level of evidence are expressed in ACCF/AHA format, as detailed in Table 2 (see table in 1a.73). Recommendations made herein are largely based on major practice guidelines from the National Institutes of Health and updated ACCF/AHA practice guidelines, as well as on results from recent clinical trials. Writing group members performed relevant supplemental literature searches on pertinent topics in this guideline. Additional searches cross-referenced these topics with the

subtopics of clinical trials, secondary prevention, atherosclerosis, and coronary/cerebral/peripheral artery disease. These searches were limited to studies, reviews, and other evidence conducted in human subjects and published in English. In addition, the writing group reviewed documents related to the subject matter previously published by the AHA, the ACCF, and the National Institutes of Health.

ESTIMATES OF BENEFIT AND CONSISTENCY ACROSS STUDIES IN BODY OF EVIDENCE

1a.7.7. What are the estimates of benefit—magnitude and direction of effect on outcome(s) <u>across studies</u> in the body of evidence? (*e.g., ranges of percentages or odds ratios for improvement/ decline across studies, results of meta-analysis, and statistical significance*)

Aspirin/antiplatelet therapy has been shown to be effective in secondary prevention of further cardiovascular risk.

1a.7.8. What harms were studied and how do they affect the net benefit (benefits over harms)?

UPDATE TO THE SYSTEMATIC REVIEW(S) OF THE BODY OF EVIDENCE

1a.7.9. If new studies have been conducted since the systematic review of the body of evidence, provide for <u>each</u> new study: 1) citation, 2) description, 3) results, 4) impact on conclusions of systematic review.

1a.8 OTHER SOURCE OF EVIDENCE

If source of evidence is NOT from a clinical practice guideline, USPSTF, or systematic review, please describe the evidence on which you are basing the performance measure.

1a.8.1 What process was used to identify the evidence?

1a.8.2. Provide the citation and summary for each piece of evidence.

Component # 2 BLOOD PRESSURE CONTROL

Measure Number (*if previously endorsed*)**:** Click here to enter NQF number

Measure Title: Ischemic Vascular Disease Care: Blood Pressure Control Component

IF the measure is a component in a composite performance measure, provide the title of the Composite Measure here: Ischemic Vascular Disease Care: All or None Outcome Measure-Optimal Control

Date of Submission: 6/29/2015

Instructions

- *For composite performance measures:*
  - *A separate evidence form is required for each component measure unless several components were studied together.*
  - *If a component measure is submitted as an individual performance measure, attach the evidence form to the individual measure submission.*
- Respond to all questions as instructed with answers immediately following the question. All information needed to demonstrate meeting the evidence subcriterion (1a) must be in this form. An appendix of *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 10 pages (*incudes questions/instructions*; minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the evidence for this measure meets NQF's evaluation criteria.

1a. Evidence to Support the Measure Focus

The measure focus is evidence-based, demonstrated as follows:

- Health outcome: [3] a rationale supports the relationship of the health outcome to processes or structures of care. Applies to patient-reported outcomes (PRO), including health-related quality of life/functional status, symptom/symptom burden, experience with care, health-related behavior.
- Intermediate clinical outcome: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured intermediate clinical outcome leads to a desired health outcome.
- Process: [5] a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured process leads to a desired health outcome.
- Structure: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured structure leads to a desired health outcome.
- Efficiency: [6] evidence not required for the resource use component.

Notes

3. Generally, rare event outcomes do not provide adequate information for improvement or discrimination; however, serious reportable events that are compared to zero are appropriate outcomes for public reporting and quality improvement.

4. The preferred systems for grading the evidence are the U.S. Preventive Services Task Force (USPSTF) grading definitions and methods, or Grading of Recommendations, Assessment, Development and Evaluation (GRADE) guidelines.

5. Clinical care processes typically include multiple steps: assess → identify problem/potential problem → choose/plan intervention (with patient input) → provide intervention → evaluate impact on health status. If the measure focus is one step in such a multistep process, the step with the

strongest evidence for the link to the desired outcome should be selected as the focus of measurement. Note: A measure focused only on collecting PROM data is not a PRO-PM.

6. Measures of efficiency combine the concepts of resource use and quality (see NQF's Measurement Framework: Evaluating Efficiency Across Episodes of Care; AQA Principles of Efficiency Measures).

1a.1.This is a measure of: (*should be consistent with type of measure entered in De.1*)

Outcome

☐ Health outcome: Click here to name the health outcome

☐Patient-reported outcome (PRO): Click here to name the PRO

PROs include HRQoL/functional status, symptom/symptom burden, experience with care, health-related behaviors

☒ Intermediate clinical outcome (*e.g., lab value*): Blood Pressure Control

☐ Process: Click here to name the process

☐ Structure: Click here to name the structure

☐ Other: Click here to name what is being measured

HEALTH OUTCOME/PRO PERFORMANCE MEASURE *If not a health outcome or PRO, skip to 1a.3*

1a.2. Briefly state or diagram the path between the health outcome (or PRO) and the healthcare structures, processes, interventions, or services that influence it.

1a.2.1. State the rationale supporting the relationship between the health outcome (or PRO) to at least one healthcare structure, process, intervention, or service (*i.e., influence on outcome/PRO*).

Note: For health outcome/PRO performance measures, no further information is required; however, you may provide evidence for any of the structures, processes, interventions, or service identified above.

INTERMEDIATE OUTCOME, PROCESS, OR STRUCTURE PERFORMANCE MEASURE

1a.3. Briefly state or diagram the path between structure, process, intermediate outcome, and health outcomes. Include all the steps between the measure focus and the health outcome.

- Assess Blood Pressure at each health care encounter
- Blood Pressure result should be less than 140 mmHg systolic and less than 90mmHg diastolic
- All patients with a BP of >=130/90 should be counseled regarding the need for lifestyle modification: weight control; increased physical activity; alcohol moderation; sodium reduction; and emphasis on increased consumption of fresh fruits, vegetables, and low-fat dairy products
- If result is 140/90 or greater patient should be treated, as tolerated, with blood pressure medication to achieve goal blood pressure
- Secondary prevention of further cardiovascular risk

1a.3.1. What is the source of the systematic review of the body of evidence that supports the performance measure?

☒ Clinical Practice Guideline recommendation – ***complete sections 1a.4, and 1a.7***

☐ US Preventive Services Task Force Recommendation – ***complete sections 1a.5 and 1a.7***

☐ Other systematic review and grading of the body of evidence (*e.g., Cochrane Collaboration, AHRQ Evidence Practice Center*) – ***complete sections 1a.6 and 1a.7***

☐ Other – ***complete section 1a.8***

Please complete the sections indicated above for the source of evidence. You may skip the sections that do not apply.

1a.4. CLINICAL PRACTICE GUIDELINE RECOMMENDATION

1a.4.1. Guideline citation (*including date*) and **URL for guideline** (*if available online*):

1a.2. Briefly state or diagram the path between the health outcome (or PRO) and the healthcare structures, processes, interventions, or services that influence it.

- Ask patient about tobacco status at each office visit
- If patient is a tobacco-user (cigarettes, pipe, smokeless, etc.) provide cessation advice/counseling
- Provide pharmacological therapy (i.e. medication, patch) if patient is willing
- Provide formal cessation counseling
- Desired outcome is that patient will be tobacco free

1a.2.1. State the rationale supporting the relationship between the health outcome (or PRO) to at least one healthcare structure, process, intervention, or service (*i.e., influence on outcome/PRO*).

http://www.ctri.wisc.edu/Researchers/Guideline_update/cpg_full2008.pdf

According to the 2008 Clinical Practice Guideline from the U.S. Department of Health and Human Services "Treating Tobacco Use and Dependence" Tobacco use has been cited as the chief avoidable cause of illness and death in our society and accounts for more than 435,000 deaths each year in the United States.37,38 Smoking is a known cause of multiple cancers, heart disease, stroke, complications of pregnancy, chronic obstructive pulmonary disease (COPD), and many other diseases. In addition, recent research has documented the substantial health dangers of involuntary exposure to tobacco smoke. Despite these health dangers and the public's awareness of those dangers, tobacco use remains surprisingly prevalent. Recent estimates are that about 21 percent of adult Americans smoke,3 representing approximately 45 million current adult smokers. Moreover, tobacco use remains a pediatric disease. Each day, about 4,000 youth ages 12 to 17 years smoke their first cigarette, and about 1,200 children and adolescents become daily cigarette smokers. As a result, new generations of Americans are at risk for the extraordinarily harmful consequences of tobacco use.

Tobacco use exacts a heavy cost to society as well as to individuals. Smoking-attributable health care expenditures are estimated at $96 billion per year in direct medical expenses and $97 billion in lost productivity. It has been estimated that the per pack additional cost of smoking to society is approximately $7.18 per pack, and the combined cost of each pack to society and the individual smoker and family is nearly $40.46 If all smokers covered by state Medicaid programs quit, the annual savings to Medicaid would be $9.7 billion after 5 years.

Despite the tragic consequences of tobacco use, clinicians and health care systems often fail to treat it consistently and effectively. For instance, in 1995, about the time of the release of the first clinical practice guideline, smoking status was identified in only about 65 percent of clinic visits, and smoking cessation counseling was provided in only 22 percent of smokers' clinic visits. Moreover, treatment typically was offered only to patients already suffering from tobacco-related diseases. This pattern gradually began to improve as of 2005, with up to 90 percent of smokers reporting they had been asked about smoking status and more than 70 percent reporting having received some counseling to quit. However, the failure to assess and intervene consistently with all tobacco users continues despite sub-stantial evidence that even brief interventions can be effective among many different populations of smokers. Also, the use of effective medications is low. Among current smokers who attempted to stop for at least 1 day in the past year, only 21.7 percent used cessation medication.

This Guideline concludes that tobacco use presents a rare confluence of circumstances: (1) a highly significant health threat; (2) a lack of consistent intervention by clinicians; and (3) the presence of effective interventions. This last point is buttressed by evidence that tobacco use interventions, if delivered in a timely and effective manner, can rapidly reduce the risk of suffering from smoking-related disease. Indeed, it is difficult to identify any other condition that presents such a mix of lethality, prevalence, and neglect, despite effective and readily available interventions.

Note: For health outcome/PRO performance measures, no further information is required; however, you may provide evidence for any of the structures, processes, interventions, or service identified above.

INTERMEDIATE OUTCOME, PROCESS, OR STRUCTURE PERFORMANCE MEASURE

1a.3. Briefly state or diagram the path between structure, process, intermediate outcome, and health outcomes. Include all the steps between the measure focus and the health outcome.

1a.3.1. What is the source of the systematic review of the body of evidence that supports the performance measure?

☐ Clinical Practice Guideline recommendation – ***complete sections 1a.4, and 1a.7***

☐ US Preventive Services Task Force Recommendation – ***complete sections 1a.5 and 1a.7***

☐ Other systematic review and grading of the body of evidence (*e.g., Cochrane Collaboration, AHRQ Evidence Practice Center*) – ***complete sections 1a.6 and 1a.7***

☐ Other – ***complete section 1a.8***

Please complete the sections indicated above for the source of evidence. You may skip the sections that do not apply.

1a.7. FINDINGS FROM SYSTEMATIC REVIEW OF BODY OF THE EVIDENCE SUPPORTING THE MEASURE

If more than one systematic review of the evidence is identified above, you may choose to summarize the one (or more) for which the best information is available to provide a summary of the quantity, quality, and consistency of the body of evidence. Be sure to identify which review is the basis of the responses in this section and if more than one, provide a separate response for each review.

1a.7.1. What was the specific structure, treatment, intervention, service, or intermediate outcome addressed in the evidence review?

1a.7.2. Grade assigned for the quality of the quoted evidence with definition of the grade:

1a.7.3. Provide all other grades and associated definitions for strength of the evidence in the grading system.

1a.7.4. What is the time period covered by the body of evidence? (*provide the date range, e.g., 1990-2010*).
Date range: Click here to enter date range

QUANTITY AND QUALITY OF BODY OF EVIDENCE

1a.7.5. How many and what type of study designs are included in the body of evidence? (*e.g., 3 randomized controlled trials and 1 observational study*)

1a.7.6. What is the overall quality of evidence across studies in the body of evidence? (*discuss the certainty or confidence in the estimates of effect particularly in relation to study factors such as design flaws, imprecision due to small numbers, indirectness of studies to the measure focus or target population*)

ESTIMATES OF BENEFIT AND CONSISTENCY ACROSS STUDIES IN BODY OF EVIDENCE

1a.7.7. What are the estimates of benefit—magnitude and direction of effect on outcome(s) <u>across studies</u> in the body of evidence? (*e.g., ranges of percentages or odds ratios for improvement/ decline across studies, results of meta-analysis, and statistical significance*)

1a.7.8. What harms were studied and how do they affect the net benefit (benefits over harms)?

UPDATE TO THE SYSTEMATIC REVIEW(S) OF THE BODY OF EVIDENCE

1a.7.9. If new studies have been conducted since the systematic review of the body of evidence, provide for <u>each</u> new study: 1) citation, 2) description, 3) results, 4) impact on conclusions of systematic review.

1a.8 OTHER SOURCE OF EVIDENCE

If source of evidence is NOT from a clinical practice guideline, USPSTF, or systematic review, please describe the evidence on which you are basing the performance measure.

1a.8.1 What process was used to identify the evidence?

1a.8.2. Provide the citation and summary for each piece of evidence.

Component # 4 STATIN USE

Measure Number (*if previously endorsed*)**:** Click here to enter NQF number

Measure Title: Ischemic Vascular Disease Care: Statin Use Component

IF the measure is a component in a composite performance measure, provide the title of the Composite Measure here: Ischemic Vascular Disease Care: All or None Outcome Measure-Optimal Control

Date of Submission: 6/29/2015

Instructions

- *For composite performance measures:*
  - *A separate evidence form is required for each component measure unless several components were studied together.*
  - *If a component measure is submitted as an individual performance measure, attach the evidence form to the individual measure submission.*
- Respond to all questions as instructed with answers immediately following the question. All information needed to demonstrate meeting the evidence subcriterion (1a) must be in this form. An appendix of *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 10 pages (*incudes questions/instructions*; minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the evidence for this measure meets NQF's evaluation criteria.

1a. Evidence to Support the Measure Focus

The measure focus is evidence-based, demonstrated as follows:

- Health outcome: [3] a rationale supports the relationship of the health outcome to processes or structures of care. Applies to patient-reported outcomes (PRO), including health-related quality of life/functional status, symptom/symptom burden, experience with care, health-related behavior.
- Intermediate clinical outcome: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured intermediate clinical outcome leads to a desired health outcome.
- Process: [5] a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured process leads to a desired health outcome.
- Structure: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured structure leads to a desired health outcome.
- Efficiency: [6] evidence not required for the resource use component.

Notes

3. Generally, rare event outcomes do not provide adequate information for improvement or discrimination; however, serious reportable events that are compared to zero are appropriate outcomes for public reporting and quality improvement.

4. The preferred systems for grading the evidence are the U.S. Preventive Services Task Force (USPSTF) grading definitions and methods, or Grading of Recommendations, Assessment, Development and Evaluation (GRADE) guidelines.

5. Clinical care processes typically include multiple steps: assess → identify problem/potential problem → choose/plan intervention (with patient input) → provide intervention → evaluate impact on health status. If the measure focus is one step in such a multistep process, the step with the

strongest evidence for the link to the desired outcome should be selected as the focus of measurement. Note: A measure focused only on collecting PROM data is not a PRO-PM.

6. Measures of efficiency combine the concepts of resource use and quality (see NQF's Measurement Framework: Evaluating Efficiency Across Episodes of Care; AQA Principles of Efficiency Measures).

1a.1.This is a measure of: (*should be consistent with type of measure entered in De.1*)

Outcome

☐ Health outcome: Click here to name the health outcome

☐Patient-reported outcome (PRO): Click here to name the PRO

PROs include HRQoL/functional status, symptom/symptom burden, experience with care, health-related behaviors

☒ Intermediate clinical outcome (*e.g., lab value*): Click here to name the intermediate outcome

☐ Process: Click here to name the process

☐ Structure: Click here to name the structure

☐ Other: Click here to name what is being measured

HEALTH OUTCOME/PRO PERFORMANCE MEASURE *If not a health outcome or PRO, skip to 1a.3*

1a.2. Briefly state or diagram the path between the health outcome (or PRO) and the healthcare structures, processes, interventions, or services that influence it.

1a.2.1. State the rationale supporting the relationship between the health outcome (or PRO) to at least one healthcare structure, process, intervention, or service (*i.e., influence on outcome/PRO*).

Note: For health outcome/PRO performance measures, no further information is required; however, you may provide evidence for any of the structures, processes, interventions, or service identified above.

INTERMEDIATE OUTCOME, PROCESS, OR STRUCTURE PERFORMANCE MEASURE

1a.3. Briefly state or diagram the path between structure, process, intermediate outcome, and health outcomes. Include all the steps between the measure focus and the health outcome.

- Determine patients with diagnosis of IVD
- Assess patients with IVD that are on a statin medication
- If patient has IVD and is not on a statin medication, prescribe an appropriate medication, if it can be tolerated
- For those patients on appropriate statin medication risk of further cardiovascular complications is reduced.

1a.3.1. What is the source of the systematic review of the body of evidence that supports the performance measure?

☒ Clinical Practice Guideline recommendation – ***complete sections 1a.4, and 1a.7***

☐ US Preventive Services Task Force Recommendation – ***complete sections 1a.5 and 1a.7***

☐ Other systematic review and grading of the body of evidence (*e.g., Cochrane Collaboration, AHRQ Evidence Practice Center*) – ***complete sections 1a.6 and 1a.7***

☐ Other – ***complete section 1a.8***

Please complete the sections indicated above for the source of evidence. You may skip the sections that do not apply.

1a.4. CLINICAL PRACTICE GUIDELINE RECOMMENDATION

1a.4.1. Guideline citation (*including date*) and **URL for guideline** (*if available online*):

Blood Cholesterol Guideline:

Stone NJ, Robinson J, Lichtenstein AH, Bairey Merz CN, Blum CB, Eckel RH, Goldberg AC, Gordon D, Levy D, Lloyd-Jones DM, McBride P, Schwartz JS, Shero ST, Smith SC Jr, Watson K, Wilson PWF. 2013 ACC/AHA guideline on the treatment of blood cholesterol to reduce atherosclerotic cardiovascular risk in adults: a report of the American College of Cardiology/American Heart Association Task Force on Practice Guidelines. Circulation. 2013;00:000–000.

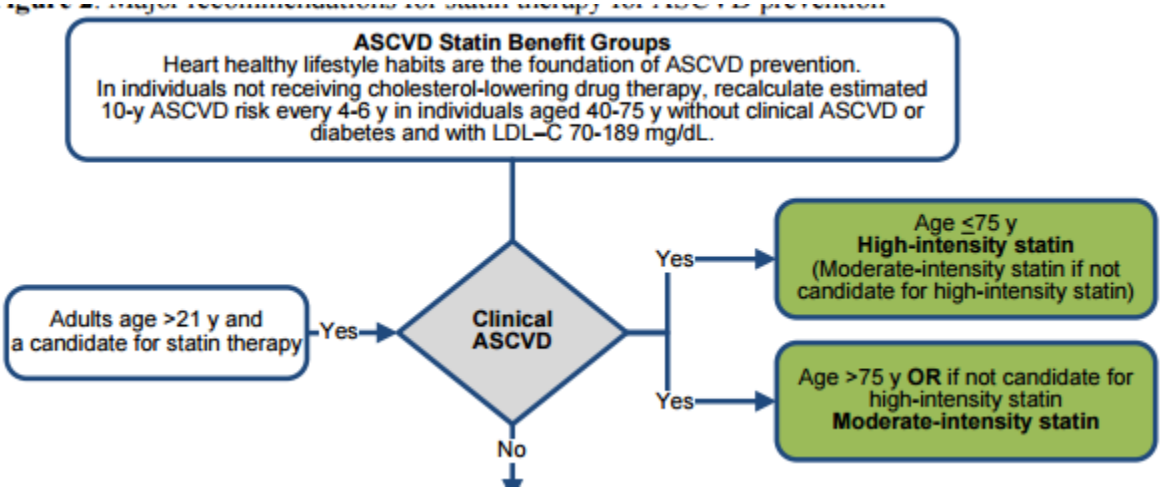
1a.4.2. Identify guideline recommendation number and/or page number and **quote verbatim, the specific guideline recommendation**.



The statin RCTs provide the most extensive evidence for the greatest magnitude of ASCVD event reduction, with the best margin of safety. Identification of 4 Statin Benefit Groups - in which the potential for an ASCVD risk reduction benefit clearly exceeds the potential for adverse effects in individuals with clinical ASCVD (only one benefit group shown here, pertinent to this measure of IVD)

AHA/ACC Blood Cholesterol Guideline: Secondary Prevention #1, page 16: Goal - High-intensity statin therapy should be initiated or continued as first-line therapy in women and men ≤75 years of age who have clinical ASCVD*, unless contraindicated.

1a.4.3. Grade assigned to the quoted recommendation with definition of the grade:

NHLBI Grade A (Strong) - There is high certainty based on evidence that the net benefit† is substantial.

Recommendations	NHLBI Grade	NHLBI Evidence Statements	ACC/AHA COR	ACC/AHA LOE
Secondary Prevention				
1. High-intensity statin therapy should be initiated or continued as first-line therapy in women and men ≤75 years of age who have *clinical ASCVD**, unless contraindicated.	A (Strong)	1, 6-8, 10-23, 26-28	I	A

1a.4.4. Provide all other grades and associated definitions for recommendations in the grading system.
(*Note: If separate grades for the strength of the evidence, report them in section 1a.7.*)

See tables below:

Table 1a. NHLBI Grading the Strength of Recommendations

Grade	Strength of Recommendation*
A	**Strong recommendation** There is high certainty based on evidence that the net benefit† is substantial.
B	**Moderate recommendation** There is moderate certainty based on evidence that the net benefit is moderate to substantial, or there is high certainty that the net benefit is moderate.
C	**Weak recommendation** There is at least moderate certainty based on evidence that there is a small net benefit.
D	**Recommendation against** There is at least moderate certainty based on evidence that it has no net benefit or that risks/harms outweigh benefits.
E	**Expert opinion ("There is insufficient evidence or evidence is unclear or conflicting, but this is what the Work Group recommends.")** Net benefit is unclear. Balance of benefits and harms cannot be determined because of no evidence, insufficient evidence, unclear evidence, or conflicting evidence, but the Work Group thought it was important to provide clinical guidance and make a recommendation. Further research is recommended in this area.
N	**No recommendation for or against ("There is insufficient evidence or evidence is unclear or conflicting.")** Net benefit is unclear. Balance of benefits and harms cannot be determined because of no evidence, insufficient evidence, unclear evidence, or conflicting evidence, and the Work Group thought no recommendation should be made. Further research is recommended in this area.

*In most cases, the strength of the recommendation should be closely aligned with the quality of the evidence;

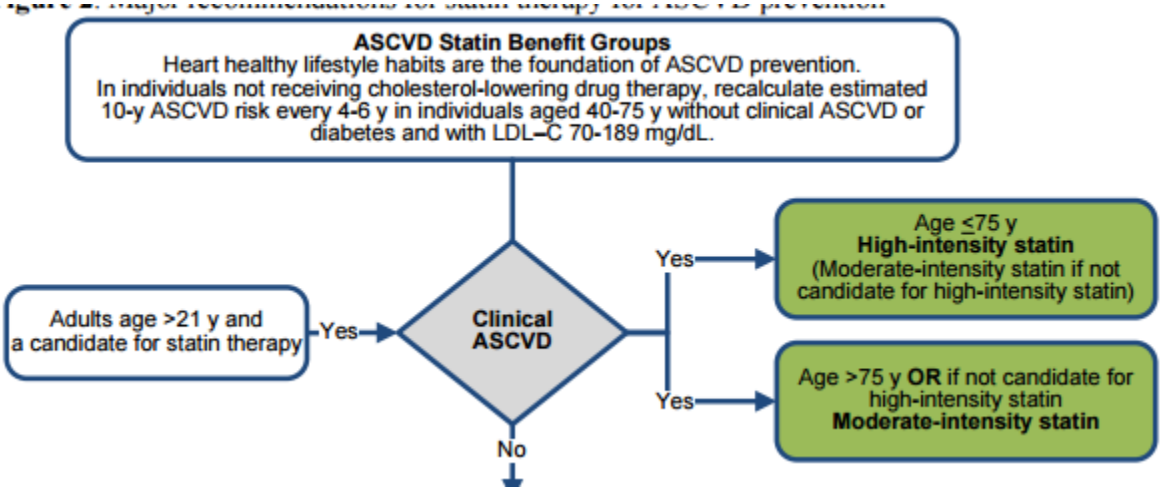
1a.7. FINDINGS FROM SYSTEMATIC REVIEW OF BODY OF THE EVIDENCE SUPPORTING THE MEASURE

If more than one systematic review of the evidence is identified above, you may choose to summarize the one (or more) for which the best information is available to provide a summary of the quantity, quality, and consistency of the body of evidence. Be sure to identify which review is the basis of the responses in this section and if more than one, provide a separate response for each review.



The statin RCTs provide the most extensive evidence for the greatest magnitude of ASCVD event reduction, with the best margin of safety. Identification of 4 Statin Benefit Groups - in which the potential for an ASCVD risk reduction benefit clearly exceeds the potential for adverse effects in individuals with clinical ASCVD. (only one benefit group shown here, pertinent to this measure of IVD)

AHA/ACC Blood Cholesterol Guideline: Secondary Prevention #1, page 16: Goal - High-intensity statin therapy should be initiated or continued as first-line therapy in women and men ≤75 years of age who have clinical ASCVD*, unless contraindicated.

1a.7.1. What was the specific structure, treatment, intervention, service, or intermediate outcome addressed in the evidence review?

High-intensity statin therapy should be initiated or continued as first-line therapy in women and men ≤75 years of age who have clinical ASCVD*, unless contraindicated.

1a.7.2. Grade assigned for the quality of the quoted evidence with definition of the grade:

NHLBI Grade A (Strong) - There is high certainty based on evidence that the net benefit† is substantial.

Recommendations	NHLBI Grade	NHLBI Evidence Statements	ACC/AHA COR	ACC/AHA LOE
Secondary Prevention				
1. High-intensity statin therapy should be initiated or continued as first-line therapy in women and men ≤75 years of age who have *clinical ASCVD**, unless contraindicated.	A (Strong)	1, 6-8, 10-23, 26-28	I	A

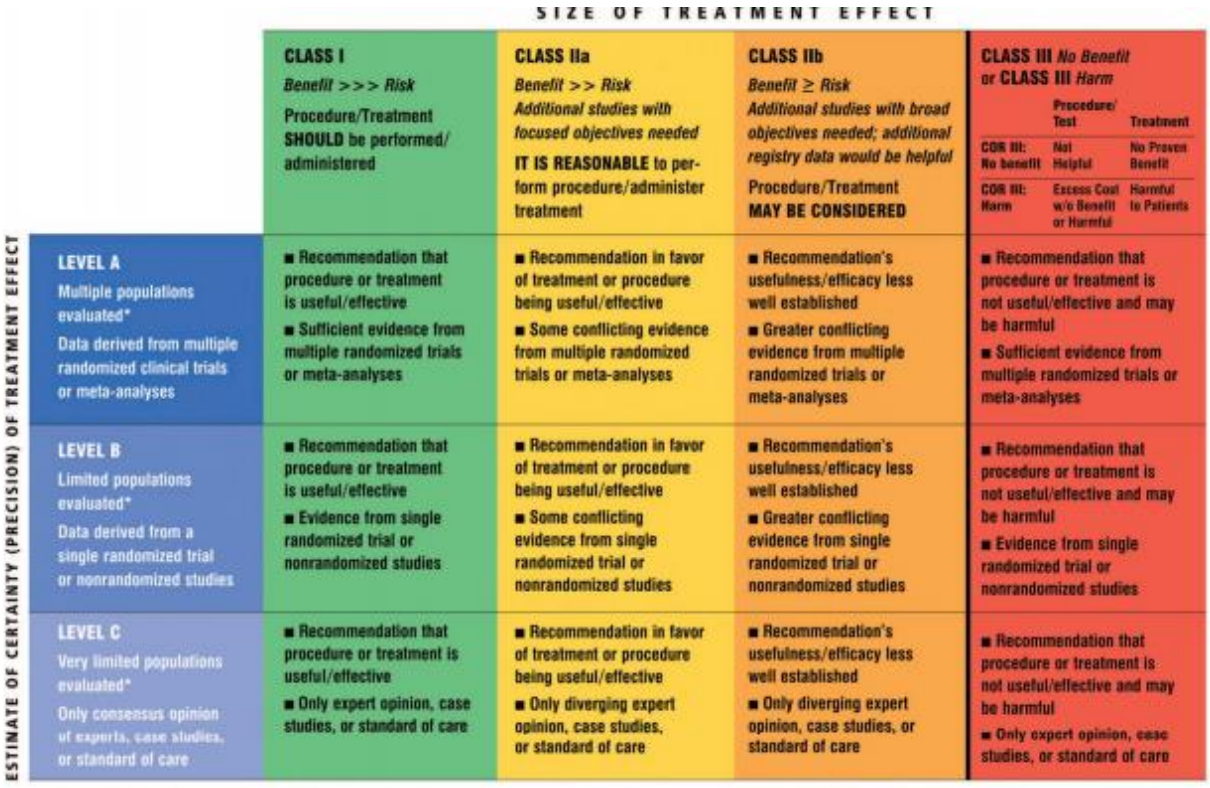
1a.7.3. Provide all other grades and associated definitions for strength of the evidence in the grading system.

Table 1a. NHLBI Grading the Strength of Recommendations

Grade	Strength of Recommendation*
A	**Strong recommendation** There is high certainty based on evidence that the net benefit† is substantial.
B	**Moderate recommendation** There is moderate certainty based on evidence that the net benefit is moderate to substantial, or there is high certainty that the net benefit is moderate.
C	**Weak recommendation** There is at least moderate certainty based on evidence that there is a small net benefit.
D	**Recommendation against** There is at least moderate certainty based on evidence that it has no net benefit or that risks/harms outweigh benefits.
E	**Expert opinion ("There is insufficient evidence or evidence is unclear or conflicting, but this**

	is what the Work Group recommends.") Net benefit is unclear. Balance of benefits and harms cannot be determined because of no evidence, insufficient evidence, unclear evidence, or conflicting evidence, but the Work Group thought it was important to provide clinical guidance and make a recommendation. Further research is recommended in this area.
N	**No recommendation for or against ("There is insufficient evidence or evidence is unclear or conflicting.")** Net benefit is unclear. Balance of benefits and harms cannot be determined because of no evidence, insufficient evidence, unclear evidence, or conflicting evidence, and the Work Group thought no recommendation should be made. Further research is recommended in this area.

*In most cases, the strength of the recommendation should be closely aligned with the quality of the evidence;



1a.7.4. What is the time period covered by the body of evidence? (*provide the date range, e.g., 1990-2010*).
Date range: 2011-2013

QUANTITY AND QUALITY OF BODY OF EVIDENCE

1a.7.5. How many and what type of study designs are included in the body of evidence? (*e.g., 3 randomized controlled trials and 1 observational study*)

Guideline data is from randomized controlled trials (RCTs), five of them, systematic reviews and meta-analyses of RCTs.

1a.7.6. What is the overall quality of evidence <u>across studies</u> in the body of evidence? (*discuss the certainty or confidence in the estimates of effect particularly in relation to study factors such as design flaws, imprecision due to small numbers, indirectness of studies to the measure focus or target population*)

Methodology and Evidence Review: Although the Expert Panel was convened prior to the Institute of Medicine reports on practice guidelines, our evidence-based process followed most of the standards from the Institute of Medicine report, "Clinical Practice Guidelines We Can Trust" (1). The systematic review was limited to RCTs with ASCVD outcomes and systematic reviews and meta-analyses of RCTs with ASCVD outcomes. Observational studies and those with:

- The Expert Panel constructed CQs relevant to clinical practice.
- The Expert Panel identified (a priori) inclusion/exclusion (I/E) criteria for each CQ.
- An independent contractor developed a literature search strategy, based on I/E criteria, for each CQ.
- An independent contractor executed a systematic electronic search of the published literature from relevant bibliographic databases for each CQ. The date for the overall literature search was from January 1, 1995 through December 1, 2009. However, RCTs with hard ASCVD outcomes of MI, stroke, and cardiovascular death published after that date were eligible for consideration until the Expert Panel began deliberations on relevant recommendations.
- RCTs that met the inclusion criteria and were independently graded as fair or good quality were included in the evidence tables for the consideration of the Expert Panel. RCTs that were graded as poor quality were excluded.
- With the assistance of independent methodologists, this evidence base was used to develop a series of evidence statements graded on the level of the evidence (high, medium, or low).
- The Expert Panel then synthesized the evidence statements into treatment recommendations/summaries graded as A (strong), B (moderate), C (weak), D (recommend against), E (expert), and N (no recommendation).
- The final evidence statements and treatment recommendations were approved by at least a majority of voting members of the Expert Panel.
- Performed guideline implementability appraisals, planned and coordinated by the NHLBI Implementation Work Group, to identify and address barriers to guideline implementation.

Overview of the Guidelines: The RCTs identified in the systematic evidence review indicated a consistent reduction in ASCVD events from 3-hydroxy-3-methylglutaryl-coenzyme A reductase inhibitors (statins) therapy in secondary and primary prevention populations, with the exception of no ASCVD event reduction in those with New York Heart Association (NYHA) class II-IV heart failure or receiving maintenance hemodialysis. The RCTs either compared fixed doses of statins with placebo or untreated controls, or compared fixed doses of higher-intensity statins with moderate-intensity statins. These trials were not designed to evaluate the effect of titrated (dose-adjusted) statin treatment to achieve pre-specified LDL–C or non-HDL–C goals.
Therefore, the Expert Panel was unable to find RCT evidence to support titrating cholesterol lowering drug therapy to achieve target LDL–C or non-HDL-C levels, as recommended by ATP III . However, the Expert Panel did find RCT evidence that use of therapy (e.g., niacin) to additionally lower non-HDL–C, once an LDL–C target was achieved, did not further reduce ASCVD outcomes. However, the Expert Panel did find extensive RCT evidence that the appropriate intensity of statin therapy should be used to reduce ASCVD risk in those most likely to benefit. The work of the Expert Panel was informed by the report of the Lifestyle and Risk Assessment Work Groups.

Evidence Statement (ES)	Level of Evidence	Rec(s)/ Section	References

In adults with CHD or acute coronary syndromes, more intensive-dose statin therapy reduced LDL–C to a greater degree (by 20 mg/dL or an additional 20%) than less intensive-dose statin therapy or placebo and produced a greater reduction in CVD events. Each 1 mmol/L (38.7 mg/dL) reduction in LDL–C reduced the RR for CVD events by approximately 28%. See Table 4 for definition of high-, moderate-, and low-intensity statin therapy. More intensive statin therapy = atorvastatin 80 mg, simvastatin 80 mg.	H	Secondary Prevention	CTT 2010(20)—data from 5 trials TNT(46) IDEAL(47) PROVE-IT(48) A–Z(119) SEARCH (128) (not included in CQ1)
Less intensive statin therapy = atorvastatin 10 mg, pravastatin 40 mg or simvastatin 20–40 mg.			
In trials of more intensive statin therapy (atorvastatin 80 mg, simvastatin 80 mg) compared with less intensive statin therapy (atorvastatin 10 mg, pravastatin 40 mg, or simvastatin 20–40 mg), women with CHD or acute coronary syndromes experienced a similar (approximately 25%) magnitude of relative CVD reduction as men (approximately 29%). Women also experienced a similar magnitude of absolute risk reduction as men	H	Secondary Prevention (women included)	CTT 2010(20)— 5 trials TNT(46) IDEAL(47) PROVE-IT(48) A–Z(119) SEARCH (128) (not included in CQ1)

ESTIMATES OF BENEFIT AND CONSISTENCY ACROSS STUDIES IN BODY OF EVIDENCE

1a.7.7. What are the estimates of benefit—magnitude and direction of effect on outcome(s) <u>across studies</u> in the body of evidence? (*e.g., ranges of percentages or odds ratios for improvement/ decline across studies, results of meta-analysis, and statistical significance*)

The findings support the use of statins to prevent both nonfatal and fatal ASCVD events. Such an approach can reduce the large burden of disability from nonfatal stroke (for which women are at higher risk than men) and nonfatal CHD events. Primary and secondary prevention of ASCVD with statins can positively impact rising healthcare costs. In addition, a high level of evidence was found that statins reduce total mortality in individuals with a history of prior ASCVD events (e.g., secondary prevention settings). In individuals with no prior history of ASCVD events (e.g., primary prevention setting), there is moderate evidence that statins reduce total mortality in individuals at increased ASCVD risk. It should be noted, 2 meta-analyses published after the completion of the Expert Panel's systematic review provide strong evidence that statins reduce total mortality in primary prevention.

The Expert Panel defines the intensity of statin therapy on the basis of the average expected LDL–C response to a specific statin and dose. "High-intensity," "moderate-intensity," and "lower-intensity" statin therapy definitions were derived from the systematic reviews for CQ1 and CQ2. The basis for differentiation among specific statins and doses arose from the RCTs included in CQ1, where there was a high level of evidence that high-intensity statin therapy with atorvastatin 40 mg to 80 mg reduced ASCVD risk more than moderate-intensity statin therapy with atorvastatin 10 mg, pravastatin 40 mg, or simvastatin 20 mg to 40 mg bid. Classifying specific statins and doses by the percent reduction in LDL–C level is based on evidence that the relative reduction in ASCVD risk from statin therapy is related to the degree by which LDL–C is lowered. However, no variation in the relative reduction in ASCVD risk was observed after the data were adjusted for LDL–C reduction. Furthermore, there is no differentiation between the specific statins and doses used in primary and secondary prevention RCTs, based on a high level of evidence that statins reduce ASCVD risk similarly in both populations.

Percent reductions in LDL–C for a specific statin and dose were calculated for the RCTs included in individual meta-analyses conducted by the Cholesterol Treatment Trialists (CTT) in 2010 (20) in which statin therapy reduced ASCVD events. High-intensity statin therapy on average lowers LDL–C by approximately ≥50%, moderate-intensity statin therapy lowers LDL–C by approximately 30% to <30%

Table 5. High- Moderate- and Low-Intensity Statin Therapy (Used in the RCTs reviewed by the Expert Panel)*

High-Intensity Statin Therapy	Moderate-Intensity Statin Therapy	Low-Intensity Statin Therapy
Daily dose lowers LDL–C on average, by approximately ≥50%	Daily dose lowers LDL–C on average, by approximately 30% to <50%	Daily dose lowers LDL–C on average, by <30%
Atorvastatin (40†)–80 mg **Rosuvastatin 20** *(40)* **mg**	**Atorvastatin 10** *(20)* **mg** **Rosuvastatin** (*5*) **10 mg** **Simvastatin 20–40 mg‡** **Pravastatin 40** *(80)* **mg** **Lovastatin 40 mg** *Fluvastatin XL 80 mg* **Fluvastatin 40 mg bid** *Pitavastatin 2–4 mg*	*Simvastatin 10 mg* **Pravastatin 10–20 mg** **Lovastatin 20 mg** *Fluvastatin 20–40 mg* *Pitavastatin 1 mg*

Specific statins and doses are noted in bold that were evaluated in RCTs (17,18,46-48,64-67,69-78) included in CQ1, CQ2 and the CTT 2010 meta-analysis included in CQ3 (20). All of these RCTs demonstrated a reduction in major cardiovascular events. Statins and doses that are approved by the U.S. FDA but were not tested in the RCTs reviewed are listed in *italics*.

*Individual responses to statin therapy varied in the RCTs and should be expected to vary in clinical practice. There might be a biologic basis for a less-than-average response.

†Evidence from 1 RCT only: down-titration if unable to tolerate atorvastatin 80 mg in IDEAL (47).

‡Although simvastatin 80 mg was evaluated in RCTs, initiation of simvastatin 80 mg or titration to 80 mg is not recommended by the FDA due to the increased risk of myopathy, including rhabdomyolysis.

bid indicates twice daily; FDA, Food and Drug Administration; IDEAL, Incremental Decrease through Aggressive Lipid Lowering study; LDL–C, low-density lipoprotein cholesterol; and RCTs, randomized controlled trials.

1a.7.8. What harms were studied and how do they affect the net benefit (benefits over harms)?

No real harms but potential for patients with a low tolerance or intolerance to statins:

Adherence to lifestyle and to statin therapy should be re-emphasized before the addition of a nonstatin drug is considered (Figure 5). RCTs evaluating the ASCVD event reductions from nonstatins used as monotherapy were reviewed as well as RCTs evaluating the additional reduction in ASCVD events from nonstatin therapy added to statin therapy. The panel could find no data supporting the routine use of nonstatin drugs combined with statin therapy to reduce further ASCVD events. In addition, identification of any RCTs that assessed ASCVD outcomes in statin-intolerant patients was not found.

Clinicians treating high-risk patients who have a less-than-anticipated response to statins, who are unable to tolerate a less-than-recommended intensity of a statin, or who are completely statin intolerant may consider the addition of a nonstatin cholesterol-lowering therapy. High-risk individuals include those with ASCVD, those with LDL–C ≥190 mg/dL and individuals with diabetes. In this situation, this guideline recommends clinicians preferentially prescribe drugs that have been shown in RCTs to provide ASCVD risk-reduction benefits that outweigh the potential for adverse effects drug-drug interaction, and patient preferences.

UPDATE TO THE SYSTEMATIC REVIEW(S) OF THE BODY OF EVIDENCE

1a.7.9. If new studies have been conducted since the systematic review of the body of evidence, provide for <u>each</u> new study: 1) citation, 2) description, 3) results, 4) impact on conclusions of systematic review.

1a.8 OTHER SOURCE OF EVIDENCE

If source of evidence is NOT from a clinical practice guideline, USPSTF, or systematic review, please describe the evidence on which you are basing the performance measure.

1a.8.1 What process was used to identify the evidence?

1a.8.2. Provide the citation and summary for each piece of evidence.

1. Evidence, Performance Gap, Priority – Importance to Measure and Report

Extent to which the specific measure focus is evidence-based, important to making significant gains in healthcare quality, and improving health outcomes for a specific high-priority (high-impact) aspect of healthcare where there is variation in or overall less-than-optimal performance. ***Measures must be judged to meet all subcriteria to pass this criterion and be evaluated against the remaining criteria.***

1a. Evidence to Support the Measure Focus – See attached Evidence Submission Form
Template_MeasSubm_Evidence_062915_WCHQ.pdf

1b. Performance Gap

Demonstration of quality problems and opportunity for improvement, i.e., data demonstrating:

- considerable variation, or overall less-than-optimal performance, in the quality of care across providers; and/or
- disparities in care across population groups.

1b.1. **Briefly explain the rationale for this measure** *(e.g., the benefits or improvements in quality envisioned by use of this measure)*
Is a composite measure - all or none.

1b.2. **Provide performance scores on the measure as specified (current and over time) at the specified level of analysis.** *(This is required for endorsement maintenance. Include mean, std dev, min, max, interquartile range, scores by decile. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities included). This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*
Level of Analysis: Clinic
Number of Clinics: 121
Minimum Number of Patients/Clinic: 100
Minimum Number of Providers/Clinic: 3
Number of Patients: 42,290
Number of Medical Groups Represented: 14
Measurement Period: January 1, 2014 – December 31, 2014

1b.3. **If no or limited performance data on the measure as specified is reported in 1b2, then provide a summary of data from the literature that indicates opportunity for improvement or overall less than optimal performance on the specific focus of measurement.**
N/A -see above 1b.2

1b.4. **Provide disparities data from the measure as specified (current and over time) by population group, e.g., by race/ethnicity, gender, age, insurance status, socioeconomic status, and/or disability.** *(This is required for endorsement maintenance. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities include.) This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*
At this time WCHQ is not reporting this measure using disparities data. We do collect some race/ethnicity data, payer data, gender and age within our data repository so this could provided in the future.

1b.5. **If no or limited data on disparities from the measure as specified is reported in 1b4, then provide a summary of data from the literature that addresses disparities in care on the specific focus of measurement. Include citations.**
N/A - see 1b.4 above.

1c. High Priority (previously referred to as High Impact)

The measure addresses:

- a specific national health goal/priority identified by DHHS or the National Priorities Partnership convened by NQF; OR
- a demonstrated high-priority (high-impact) aspect of healthcare (e.g., affects large numbers of patients and/or has a substantial impact for a smaller population; leading cause of morbidity/mortality; high resource use (current and/or future); severity of illness; and severity of patient/societal consequences of poor quality).

1c.1. **Demonstrated high priority aspect of healthcare**
Affects large numbers, A leading cause of morbidity/mortality, High resource use, Severity of illness
1c.2. **If Other:**

1c.3. **Provide epidemiologic or resource use data that demonstrates the measure addresses a high priority aspect of healthcare. List citations in 1c.4.**
The Wisconsin Department of Health Services publication "The Epidemic of Chronic Disease in Wisconsin" indicates that heart disease is one of the leading causes of mortality in the state of Wisconsin ranking with Cancer at 24%. It is also the 4th highest annual Medicaid cost out of six chronic disease.

Prevention of Chronic Diseases is Powerful and Cost-effective
Given the huge economic impact of chronic diseases it is not surprising that their prevention yields a remarkable return on investment (ROI), as documented by the Trust for America's Health (2008). In Wisconsin, adequately funded community-based programs that address insufficient physical activity, unhealthy diet, and tobacco use would yield a return of $6.20 for every $1 spent over the course of five years, with a potential annual savings of $338 million. Remarkably, even such a substantial return can be considered an underestimate since it does not include gains in worker productivity, reduced absenteeism at work and school, and

enhanced quality of life. Despite these convincing numbers, the vast majority of health care spending in the United States, as much as 95 percent, is directed toward medical care and biomedical research and not on prevention (Institute of Medicine, 2003). The recent passage of national health care reform (The Patient Protection and Affordable Care Act) however, focuses on the importance of prevention as a means to reduce future health care costs.
Promoting healthy environments in communities is smart policy, because they enable community residents to live healthier lives. Studies increasingly suggest that businesses are also likely to benefit. For example, relatively low-cost environmental changes in the workplace that resulted in a 5% weight loss for overweight or obese employees would reduce annual medical/absenteeism costs by about $90 per person (Trogdon, et al., 2009).

Additionally a second publication titled "Wisconsin Heart Disease and Stroke Surveillance Summary Update" January 2007 by the Wisconsin Cardiovascular Health Program, the Wisconsin Department of Health and Family Services, the Division of Public Health and the Bureau of Community Health Promotion indicates that cardiovascular disease (CVD) is the leading cause of death and disability in the United States and in the state of Wisconsin. In 2004 there were 96,000 hospitalizations due to cardiovascular related illness in Wisconsin resulting in over 2.5 billion in associated charges. Death and disability from CVD can be reduced by modifiable risk factors such as quitting smoking and lowering Blood Pressure, both component measures in this all or none measure.

1c.4. **Citations for data demonstrating high priority provided in 1a.3**
The Wisconsin Department of Health Services publication "The Epidemic of Chronic Disease in Wisconsin" P-00238 (12/10)

Wisconsin Heart Disease and Stroke Surveillance Summary Update" January 2007 by the Wisconsin Cardiovascular Health Program, the Wisconsin Department of Health and Family Services, the Division of Public Health and the Bureau of Community Health Promotion

1c.5. **If a PRO-PM (e.g. HRQoL/functional status, symptom/burden, experience with care, health-related behaviors), provide evidence that the target population values the measured PRO and finds it meaningful.** *(Describe how and from whom their input was obtained.)*

1d. Composite Quality Construct and Rationale

1d.1. **A composite performance measure is a combination of two or more component measures, each of which individually reflects quality of care, into a single performance measure with a single score.**

For purposes of NQF measure submission, evaluation, and endorsement, the following will be considered composites:

- Measures with two or more individual performance measure scores combined into one score for an accountable entity.
- Measures with two or more individual component measures assessed separately for each patient and then aggregated into one score for an accountable entity:
  - all-or-none measures (e.g., all essential care processes received, or outcomes experienced, by each patient); or
  - any-or-none measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient).

1d.1. Please identify the composite measure construction: two or more individual performance measure scores combined into one score

1d.2. **Describe the quality construct, including:**

- the overall area of quality
- included component measures and
- the relationship of the component measures to the overall composite and to each other.

In November 2013, the ACC and AHA Task Force on Practice Guidelines released updated guidance for the treatment of blood cholesterol. The new recommendations remove treatment targets for LDL-C for the primary or secondary prevention of atherosclerotic cardiovascular disease (ASCVD) and recommend high or moderate intensity statin therapy based on patient risk factors. Four major statin benefit groups were identified for whom ASCVD risk clearly outweighs the risk of adverse events. Individuals with ASCVD are one of the identified groups. Based on these guidelines changes the WCHQ Measurement Advisory Committee made the decision to no longer publicly report LDL Testing and Control measures for this population and to replace these measures with a measure of Statin Use with. Simultaneously the decision was made to publicly report a measure if IVD All or None Optimal Control. These decisions were made with guidance from the WCHQ Measure Selection Policy and associated criteria. The

All-Or-None method is a more complete way of reporting the IVD measure and has multiple goals. All goals must be reached by each patient in order to meet this intermediate clinical outcome measure. This method was chosen because of the benefits it provides to both the patient and the practitioner. First, this methodology more closely reflects the interests and likely desires of the patient. With the data collected in a single score, patients can easily look and see how their provider group is performing on these criteria rather than trying to make sense of multiple scores on individual measures. Second, this method represents a systems perspective emphasizing the importance of optimal care through a patient´s entire healthcare experience. Third, this method gives a more sensitive scale for improvement. Whether reported at the organization, clinic site or provider level, for those scoring high marks on individual measures, the All-or-None measure will give room for benchmarks and additional improvements to be made.

This measure contains four goals. All four goals within a measure must be reached in order to meet that measure. The numerator for the all-or-none measure should be collected from the organization´s total IVD denominator. Using the IVD denominator optimal results include: 1) Most recent blood pressure measurement is less than 140/90 mm Hg -- And 2) Most recent tobacco status is Tobacco Free -- And 3) Daily Aspirin or Other Antiplatelet Unless Contraindicated -- And 4) Statin Use.

The four individual measures and resulting composite are based on current primary prevention guidelines from the American Heart Association (AHA) and the American College of Cardiology (ACC). Evidence from clinical trials supports and broadens the merits of risk-reduction therapies for patients with established coronary and other atherosclerotic vascular disease, including peripheral arterial disease, atherosclerotic aortic disease, and carotid artery disease.

1d.3. **Describe the rationale for constructing a composite measure, including how the composite provides a distinctive or additive value over the component measures individually.**

Also indicated in 1d.2 above, this method was chosen because of the benefits it provides to both the patient and the practitioner. First, this methodology more closely reflects the interests and likely desires of the patient. With the data collected in a composite score, patients can easily look and see how their provider group is performing on these criteria rather than trying to make sense of multiple scores on individual measures. Second, this method represents a systems perspective emphasizing the importance of optimal care through a patient's entire healthcare experience. Third, this method gives a more sensitive scale for improvement. Whether reported at the organization, clinic site or provider level, for those scoring high marks on individual measures, the All-or-None measure will give room for benchmarks and additional improvements to be made.

Support for All-or-None measurement referenced by Nolan T, Berwick DM. All-or-None Measurement Raises the Bar on Performance. JAMA. 2006 Mar 8;295(10):1168-70.

1d.4. **Describe how the aggregation and weighting of the component measures are consistent with the stated quality construct and rationale.**

The composite measure result is based off of the four individual measure numerators that construct the all or none measure. The numerator for the all-or-none measure is collected from the organization, clinic site or provider´s total IVD denominator and the patient must meet all four individual measures to be numerator compliant for the all or none measure. All individual component scores are given equal weighting when combined into the composite. The measure can be reported through an all electronic data collection method-based on entire IVD Denominator, a hybrid method-based on Administrative Review Denominator and Manual Review Sample, or a random sample method-based on Sample Population. The hybrid or random sample method are used if there will be missing data elements. The sample size for for chart review is determined by the WCHQ Sample Size Calculator, available at the following link: http://www.wchq.org/calculator/index.php.

NATIONAL QUALITY FORUM—Composite Measure Testing (subcriteria 2a2, 2b2-2b7, 2d)

Measure Number (*if previously endorsed*)**:** Click here to enter NQF number
Composite Measure Title: Ischemic Vascular Disease Care: All or None Outcome Measure-Optimal Control
Date of Submission: 6/29/2015
Composite Construction:

☐Two or more individual performance measure scores combined into one score
☒ All-or-none measures (e.g., all essential care processes received or outcomes experienced by each patient)
☐ Any-or-none measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient)

Instructions: Please contact NQF staff before you begin.

- If a component measure is submitted as an individual performance measure, the non-composite measure testing form must also be completed and attached to the individual measure submission.
- Measures must be tested for all the data sources and levels of analyses that are specified. ***If there is more than one set of data specifications or more than one level of analysis, contact NQF staff*** about how to present all the testing information in one form.
- **For all composite measures, sections 1, 2a2, 2b2, 2b3, 2b5, and 2d must be completed.**
- **For composites with outcome and resource use measures**, section **2b4** also must be completed.
- If specified for **multiple data sources/sets of specificaitions** (e.g., claims and EHRs), section **2b6** also must be completed.
- Respond to all questions as instructed with answers immediately following the question. All information on testing to demonstrate meeting the subcriteria for reliability (2a2), validity (2b2-2b6), and composites (2d) must be in this form. An appendix for *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 25 pages (*incuding questions/instructions;* minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the testing results for this measure meet NQF's evaluation criteria for testing.

2a2. Reliability testing [10] demonstrates the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise. For **PRO-PMs and composite performance measures**, reliability should be demonstrated for the computed performance score.

2b2. Validity testing [11] demonstrates that the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality. For **PRO-PMs and composite performance measures**, validity should be demonstrated for the computed performance score.

2b3. Exclusions are supported by the clinical evidence; otherwise, they are supported by evidence of sufficient frequency of occurrence so that results are distorted without the exclusion; [12]

AND

If patient preference (e.g., informed decisionmaking) is a basis for exclusion, there must be evidence that the exclusion impacts performance on the measure; in such cases, the measure must be specified so that the information about patient preference and the effect on the measure is transparent (e.g., numerator category computed separately, denominator exclusion category computed separately). [13]

2b4. For outcome measures and other measures when indicated (e.g., resource use):

- **an evidence-based risk-adjustment strategy** (e.g., risk models, risk stratification) is specified; is based on patient factors that influence the measured outcome (but not factors related to disparities in care or the quality of care) and are present at start of care; [14,15] and has demonstrated adequate discrimination and calibration

OR

- rationale/data support no risk adjustment/ stratification.

2b5. Data analysis of computed measure scores demonstrates that methods for scoring and analysis of the specified measure allow for **identification of statistically significant and practically/clinically meaningful** [16] **differences in performance**;

OR

there is evidence of overall less-than-optimal performance.

2b6. If multiple data sources/methods are specified, there is demonstration they produce comparable results.

2b7. For **eMeasures, composites, and PRO-PMs** (or other measures susceptible to missing data), analyses identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias.

2d. For composite performance measures, empirical analyses support the composite construction approach and demonstrate that:

2d1. the component measures fit the quality construct and add value to the overall composite while achieving the related objective of parsimony to the extent possible; and

2d2.the aggregation and weighting rules are consistent with the quality construct and rationale while achieving the related objective of simplicity to the extent possible.

(*if not conducted or results not adequate, justification must be submitted and accepted)*

Notes

10. Reliability testing applies to both the data elements and computed measure score. Examples of reliability testing for data elements include, but are not limited to: inter-rater/abstractor or intra-rater/abstractor studies; internal consistency for multi-item scales; test-retest for survey items. Reliability testing of the measure score addresses precision of measurement (e.g., signal-to-noise).

11. Validity testing applies to both the data elements and computed measure score. Validity testing of data elements typically analyzes agreement with another authoritative source of the same information. Examples of validity testing of the measure score include, but are not limited to: testing hypotheses that the measures scores indicate quality of care, e.g., measure scores are different for groups known to have differences in quality assessed by another valid quality measure or method; correlation of measure scores with another valid indicator of quality for the specific topic; or relationship to conceptually related measures (e.g., scores on process measures to scores on outcome measures). Face validity of the measure score as a quality indicator may be adequate if accomplished through a systematic and transparent process, by identified experts, and explicitly addresses whether performance scores resulting from the measure as specified can be used to distinguish good from poor quality.

12. Examples of evidence that an exclusion distorts measure results include, but are not limited to: frequency of occurrence, variability of exclusions across providers, and sensitivity analyses with and without the exclusion.

13. Patient preference is not a clinical exception to eligibility and can be influenced by provider interventions.

14. Risk factors that influence outcomes should not be specified as exclusions.

15. With large enough sample sizes, small differences that are statistically significant may or may not be practically or clinically meaningful. The substantive question may be, for example, whether a statistically significant difference of one percentage point in the percentage of patients who received smoking cessation counseling (e.g., 74 percent v. 75 percent) is clinically meaningful; or whether a statistically significant difference of $25 in cost for an episode of care (e.g., $5,000 v. $5,025) is practically meaningful. Measures with overall less-than-optimal performance may not demonstrate much variability across providers.

1. DATA/SAMPLE USED FOR ALL TESTING OF THIS MEASURE

Often the same data are used for all aspects of measure testing. In an effort to eliminate duplication, the first five questions apply to all measure testing. If there are differences by aspect of testing,(e.g., reliability vs. validity) be sure to indicate the specific differences in question 1.7.

1.1. What type of data was used for testing? (*Check all the sources of data identified in the measure specifications and data used for testing the measure. Testing must be provided for all the sources of data specified and intended for measure implementation. If different data sources are used for different components in the composite, indicate the component after the checkbox.*)

Measure Specified to Use Data From: (***must be consistent with data sources entered in S.23***)	**Measure Tested with Data From:**
☒ abstracted from paper record	☒ abstracted from paper record

☒ administrative claims	☒ administrative claims
☒ clinical database/registry	☒ clinical database/registry
☒ abstracted from electronic health record	☒ abstracted from electronic health record
☐ eMeasure (HQMF) implemented in EHRs	☐ eMeasure (HQMF) implemented in EHRs
☐ other: Click here to describe	☐ other: Click here to describe

1.2. If an existing dataset was used, identify the specific dataset (*the dataset used for testing must be consistent with the measure specifications for target population and healthcare entities being measured; e.g., Medicare Part A claims, Medicaid claims, other commercial insurance, nursing home MDS, home health OASIS, clinical registry*).

Background of WCHQ's Reporting Activities: WCHQ is a voluntary, non-profit (501c3) consortium of organizations committed to using the public reporting of comparative measures of performance to catalyze improvements in the quality and affordability of healthcare, as well as the health status of individuals and communities, in Wisconsin. In addition, WCHQ designs and facilitates collaborative learning sessions to promote the active sharing of "best practices" in an effort to elevate and accelerate improvement across the state. WCHQ has received national recognition for its work and has made numerous contributions to the emerging evidence base on the science of measurement and reporting. Equally important, WCHQ and the healthcare provider organizations within its membership have directly contributed to a significant improvement in the quality of care, as reflected in the measures reported via the WCHQ website (www.wchq.org). Peer-reviewed research has shown that WCHQ's public reporting has played a significant role in catalyzing quality improvement among the physician groups in Wisconsin. WCHQ has a total of 38 members organizations, representing approximately 65% of the physicians licensed to practice in Wisconsin.

Dataset Background: An existing data set was used. WCHQ members submit data in one of two ways as follows:

Repository Based Submission (RBS):

- WCHQ members submit global patient level files of patient demographic, encounter, and clinical (labs, other tests, tobacco related elements, blood pressure dates and results, medications) data into the data repository through a secure, HIPAA compliant portal. See the attached RBS File Formats document for complete documentation on data elements and file formats in Appendix A.
- Certain data elements that are unique to a given organization are mapped within the data tool to be recognized as a standard data element. Data can be normalized prior to upload to ensure that data is clean in certain cases, i.e. a lab test should be the final result.
- The RBS tool's centrally programmed measure specifications calculate performance results for internal use by the member organization, for purposes of PQRS reporting to CMS, and for reporting on WCHQ's public website- http://www.wchq.org/reporting/results.php?category_id=0&topic_id=27&source_id=0&providerType=0&region=0&measure_id=205

Alternative Data Submission Method:

- WCHQ members use detailed measure specifications to program measures internally and submit aggregate denominator and numerator data to WCHQ's web-based reporting tool for reporting results on WCHQ's public website. De-identified patient level data is additionally submitted for validation purposes.

Testing for the IVD Care All or None Optimal Control measure involved the following:

- 50,758 patients in the population denominator at the group level
- 17 WCHQ member organizations (group level) publicly reported this measure
- 121 member clinic sites reported on 42,290 patients. This number is smaller than the group level patient number because at the clinic site level there must be a minimum of 100 patients in the denominator at each clinic in order to report to avoid variance in results that could occur with a smaller minimum.

15 groups reported all electronically (Total Population) and 2 groups reported using the random sample methodology.

1.3. What are the dates of the data used in testing? 01/01/2013-12/31/2014

1.4. What levels of analysis were tested? (*testing must be provided for <u>all</u> the levels specified and intended for measure implementation, e.g., individual clinician, hospital, health plan*)

Measure Specified to Measure Performance of: (***must be consistent with levels entered in item S.26***)	**Measure Tested at Level of:**
☐ individual clinician	☐ individual clinician
☒ group/practice	☒ group/practice
☐ hospital/facility/agency	☐ hospital/facility/agency
☐ health plan	☐ health plan
☐ other: Click here to describe	☐ other: Click here to describe

1.5. How many and which <u>measured entities</u> were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of measured entities included in the analysis (e.g., size, location, type); if a sample was used, describe how entities were selected for inclusion in the sample*)

1.6. How many and which <u>patients</u> were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of patients included in the analysis (e.g., age, sex, race, diagnosis); if a sample was used, describe how patients were selected for inclusion in the sample*)

- 50,758 patients in the population denominator at the group level, including:
  - Male and Female
  - Ages 18-75
  - All races
  - All payers
  - Diagnosis of IVD
  - Alive as of the last day of the Measurement Period
- 17 WCHQ member organizations (group level) publicly reported this measure
- 121 member clinic sites reported on 42,290 patients. This number is smaller than the group level patient number because at the clinic site level there must be a minimum of 100 patients in the denominator at each clinic in order to report in order for the result to be considered statistically significant.

Includes all primary care providers employed by the member organization. This measure can include cardiologists as a "Measure Specific Specialist", if the organization chooses to include them and typically if they are included one of the visits that counts towards the denominator would be with a PCP.

All patients 50,578 are included in the numerator testing. Because the data base is global, all patients that reside in the data repository are initially included and many gradually fall out by not meeting the specific denominator criteria (see below):

[Question 1] – **Is this a patient with the disease, or condition?**

CORONARY ARTERY DISEASE (OR CAD RISK EQUIVALENT) DIAGNOSIS RELATED OUTPATIENT VISITS

Those patients with a total of two or more visits during the last 24 months [Measurement Period + Prior Year] from Table IVD-4 (Office Visit Encounter Codes-Outpatient) with any provider (MD, DO, PA, NP) within the Physician Group on different dates of service coded *(including primary and secondary diagnoses)* with diagnosis codes from Table IVD-1 (Coronary Artery Disease) or Table IVD-2 (CAD Risk-Equivalent Conditions). The following criteria apply:

Any combination of two or more diagnosis codes from either Table IVD-1 or Table IVD-2, on different dates of service.

OR

ACUTE CORONARY EVENT- RELATED HOSPITAL VISITS Those patients who had a minimum of *one* hospital related visit (excluding Emergency and Lab Only visits) for an Acute Coronary Event from Table IVD-3 during the last 24 Months [Measurement Period + Prior Year].

[Question 2] – **Is this a patient whose care is managed within the physician group?**

Those patients who have at least two Primary Care Office Visit (Table IVD-4) in an ambulatory setting, regardless of diagnosis code, on different dates of service, to a PCP or Cardiologist in the past 24 months [Measurement Period + Prior Year]. If Cardiologist is not considered a PCP, at least one of the two office visits must be to a PCP.

[Question 3] – **Is this a patient current in our system?**

Those patients who had at least *one* Primary Care Office Visit (Table IVD-4) in an ambulatory setting, regardless of diagnosis code, with a PCP or a Cardiologist during the last 12 Months [Measurement Period].

1.7. If there are differences in the data or sample used for different aspects of testing (e.g., reliability, validity, exclusions, risk adjustment), identify how the data or sample are different for each aspect of testing reported below.

There are no differences in the data for different aspects of testing.

2a2. RELIABILITY TESTING

2a2.1. What level of reliability testing was conducted?

Note*: Current guidance for composite measure evaluation states that reliability must be demonstrated for the composite performance measure score.*

☒ **Performance measure score** (e.g., *signal-to-noise analysis*)

2a2.2. Describe the method of reliability testing and what it tests (*describe the steps—do not just name a method; what type of error does it test; what statistical analysis was used*)

The WCHQ staff used the methodology outlined by John L. Adams, Ph.D in his tutorial, "Reliability in Provider Profiling". Dr. Adams' methodology was applied to the clinic-level performance of the IVD: All – or-None

measure for clinics with greater than 100 patients in the denominator, and greater than 2 providers attributed to the clinic site, which are the public reporting parameters established by WCHQ.

The methodology outlined by Adams' and used to calculate the average reliability of a WCHQ clinic performance score involves several steps, including:

1. The calculation of clinic-to-clinic variance, using the following process:
    a. Variance equation: $\sigma^2_{\text{clinic-to-clinic}} = (\alpha\ \beta) / (\alpha + \beta + 1)(\alpha + \beta)^2$
    b. The α and β were calculated using the publicly available beta binomial SAS macro, BETABIN, developed by Qi Statistics
    c. $\alpha = 35.6267$, $\beta = 25.0007$, $\sigma^2_{\text{clinic-to-clinic}} = 0.00393$

2. The reliability of each individual clinic, using the equation, Reliability = $\sigma^2 / (\sigma^2 + (p(1 - p)/n))$
    a. p = clinic performance rate, n = number of patients in the measure denominator

3. The reliability for each clinic was then calculated. The summary statistics are below:
    a. n = 121 clinics
    b. Average reliability = .7817
    c. Median reliability = .7739
    d. Max = .9911, Min = .6159

2a2.3. What were the statistical results from reliability testing? (e.g., *percent agreement and kappa for the critical data elements; distribution of reliability statistics from a signal-to-noise analysis*)

Average Reliability = 0.7817

Below is the output of the BETABIN macro.

IVD All or None: Raw Data Summary

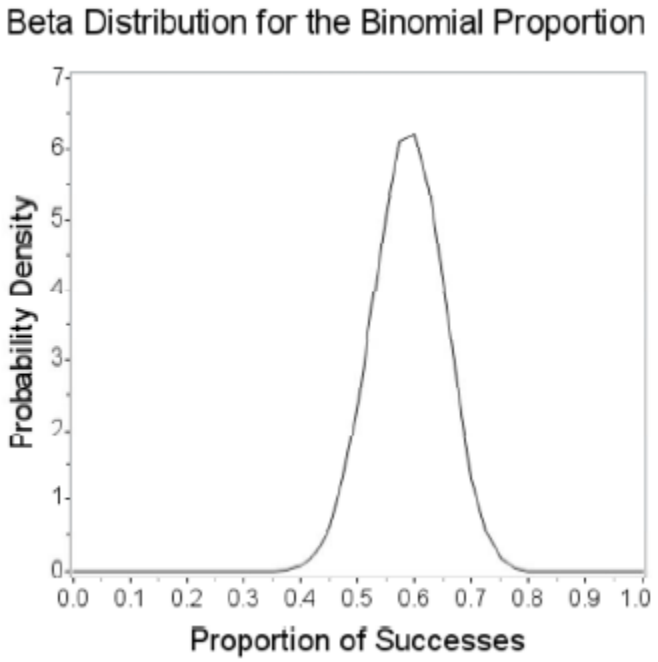
Item	Value
Data Set	WORK.WCHQII
Response Variable (Events)	NumRound
Response Variable (Trials)	Population_Denominator
Number of Observations Read	121
Number of Observations Used	121
Number of Events	24991
Number of Trials	42290

IVD All or None: Simple Binomial Model

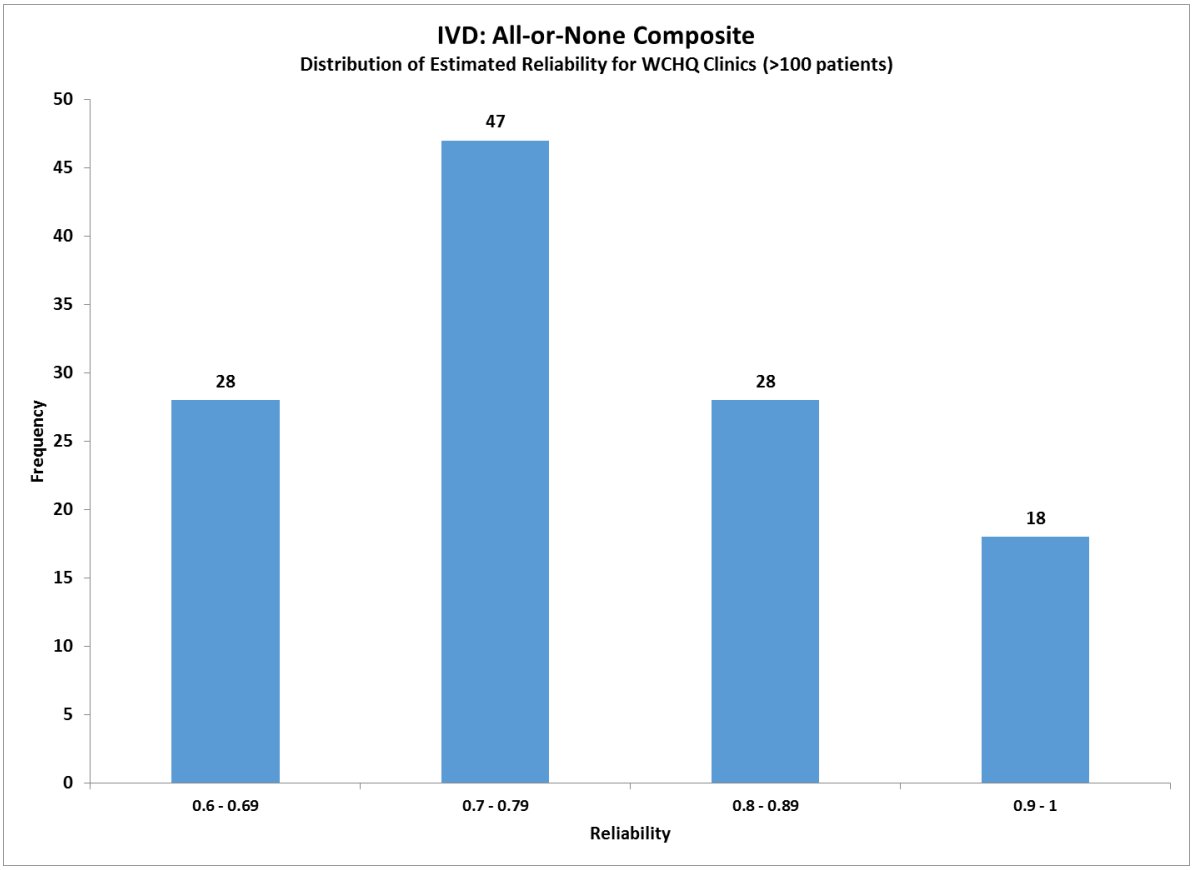
parameter	Estimate	Standard Error	t Value	Prob > |t|	Alpha	Lower	Upper
mu	0.5909	0.0024	247.17	<.0001	0.05	0.5863	0.5956
|mu-0.5|	0.0909	0.0024	38.04	<.0001	0.05	0.0863	0.0956

IVD All or None: Beta-Binomial Model Parameters

parameter	Estimate	Standard Error	t Value	Pr > |t|	Alpha	Lower	Upper
mu	0.5876	0.006453	91.07	<.0001	0.05	0.5750	0.6003
alpha	35.6267	5.7659	6.18	<.0001	0.05	24.3254	46.9281
beta	25.0007	4.0170	6.22	<.0001	0.05	17.1273	32.8741
gamma	0.01623	0.002567	6.32	<.0001	0.05	0.01119	0.02126
theta	0.01649	0.002653	6.22	<.0001	0.05	0.01129	0.02169
|mu-0.5|	0.08763	0.006453	13.58	<.0001	0.05	0.07499	0.1003



Below is a chart outlining the reliability distribution for all of the clinics included in this analysis.



2a2.4 What is your interpretation of the results in terms of demonstrating reliability? (i.*e., what do the results mean and what are the norms for the test conducted?*)

It is generally accepted that a reliability score of greater than 0.70 is sufficient for determining performance differences between groups. The average level of reliability for the WCHQ member clinics is 0.7817, above the minimal reliability threshold. In fact, of those clinics used in this sample, 77% of them have a reliability score greater than .70, and zero clinics below .60. This analysis demonstrates that this IVD: All-or-None measure has a sufficient level of average reliability to determine performance differences between clinics.

2b2. VALIDITY TESTING

Note*: Current guidance for composite measure evaluation states that validity should be demonstrated for the composite performance measure score. If not feasible for initial endorsement, acceptable alternatives include assessment of content or face validity of the composite OR demonstration of validity for each component. Empirical validity testing of the composite measure score is expected by the time of endorsement maintenance.*

2b2.1. What level of validity testing was conducted?

☐ **Composite performance measure score**

☐ **Empirical validity testing**

☒ **Systematic assessment of face validity of performance measure score as an indicator** of quality or resource use (*i.e., is an accurate reflection of performance on quality or resource use and can distinguish good from poor performance*)

☒ **Systematic assessment of content validity**

☐ **Validity testing for component measures** *(check all that apply)*

Note*: applies to ALL component measures, unless already endorsed or are being submitted for individual endorsement.*

☐ **Endorsed (or submitted) as individual performance measures**

☒ **Critical data elements** (*data element validity must address ALL critical data elements*)

☐ **Empirical validity testing of the component measure score(s)**

☒ **Systematic assessment of face validity of component measure score(s) as an indicator** of quality or resource use (*i.e., is an accurate reflection of performance on quality or resource use and can distinguish good from poor performance*)

2b2.2. For each level of testing checked above, describe the method of validity testing and what it tests (*describe the steps—do not just name a method; what was tested, e.g., accuracy of data elements compared to authoritative source, relationship to another measure as expected; what statistical analysis was used)*

WCHQ's validation model ensures the accuracy of the publicly reported performance measures. Denominator validation is done for each reporting entity (RE) on all measures annually. The validation process also includes a 3-year numerator validation schedule, based upon the following selection criteria:

1. **Random Selection without Replacement:** Following baseline validation, each RE is randomly selected over a 3-year period to be validated for each measure numerator. Once validation has been completed for a given RE for a given numerator, it is not selected again for the same numerator during the 3-year period of time, unless an identified issue arises.
2. **Outlier Results:** Results that appear significantly higher or lower than the mean or results that vary greatly for a RE between two reporting periods will be validated.
3. **New Organizations:** In the first year that a new RE reports measures, they are validated for all measure elements (denominator and numerator) during each reporting period.
4. **New Measures**: Upon the release of a new measure, all REs are validated for each measure element (denominator and numerator).
5. **Significant Changes to Database Structure**: For any significant change to a RE's database structure, all elements (denominators and numerators) are validated for a given reporting period.

The majority of WCHQ members report through the repository based submission (RBS) outlined in section 1.2 above and as such submit global patient and encounter files and access to patient level data is available through this data source. Files needed for this measure are the Patient File, Encounter File, Clinical Data File, Blood Pressure File, Medication File and Tobacco File. All necessary data elements are documented in the RBS File Formats document (attached in Appendix A). In addition, certain data elements are cross-mapped in order to meet a standard code (i.e. if the data element is an A1C in their system they need to cross-map it within RBS to indicate that it is the equivalent of CPT code 83036. Primary Care Provider documentation is also mapped to ensure that the correct providers are included in the respective measures. Additionally, when the data files are uploaded there are various checks to ensure that all data elements that need to be cross-mapped are considered and that files are in the correct format so that there will not be missing data. All of the WCHQ quality measures and selected PQRS measures are programmed into the RBS according to the detailed measures specifications and the measures are then calculated on behalf of the reporting entity through this standard process, so there is no chance of misinterpretation of the measure specification by an individual reporting entity. The results are then available for each measure at the group level, clinic site level and the provider-patient level. Patient level results are used to verify that all data elements are cross-mapped correctly, that the right patients meet the denominator criteria (i.e. appropriate office visit codes and dates, and diagnosis if that is part of the measure)and to ensure that there is no missing data. Reporting entities have access to this patient level data and are required to randomly sample patients that didn't meet the numerator to ensure that they are not missing any data elements or sources in the data files. WCHQ also performs occasional on-site visits to assist members with data collection processes.

Four of the 19 entities that attempted to report the IVD All or None Measure used the alternate reporting method (described in section 1.2 above). These entities used the detailed measure specification to program the measure internally and report aggregate results through the WCHQ data tool portal using a group and clinic site

level reporting template. In addition these entities are required to upload patient level data files and complete on-line denominator and numerator validation forms that describe how patients met both the denominator and numerator. See "Fields Required for Measure Validation" below, which is taken from the detailed measure specification. Members are required to provide documentation outlining their PCP and Measure Specific Specialist definition and any internal data elements that map to a standard code.

FIELDS REQUIRED FOR MEASURE VALIDATION

Validation of this measure will require patient level data files for Administrative Data and/or for Manual Review. The following indicates fields needed for validation, which may be helpful to consider when querying the measure:

Denominator Data File fields:

1. Generic Patient Identifier (can be medical record number or other ID)
2. Primary Care Office Visit Dates
3. Inpatient Visit Date (if applicable)
4. Provider Specialty
5. Patient Date of Birth
6. CAD or CAD Risk-Equivalent Diagnosis Codes

Numerator Data File fields:

1. Daily Aspirin or Daily Other Antiplatelet Therapy documented as active in the medical record at any time during the measurement period with data entry including:
   - Generic Patient Identifier (can be medical record number or other ID)
   - Aspirin or other Antiplatelet medication drug name
   - Drug frequency
   - Medication status indicated as active during the measurement period
   - Contraindications (if any apply)

2. Blood Pressure Control within the last 12 months
   - Patient Identifier
   - Blood Pressure Date(s) of Service
   - Blood Pressure Result(s)

3. Most Recent Tobacco Status
   - Patient Identifier (Can be medical record number or other ID)
   - Tobacco Status
   - Encounter Date of Service Associated with Tobacco Status

4. Statin Use
   - Patient Identifier (Can be medical record number or other ID)
   - IVD Diagnosis, if applicable
   - Statin Medication name
   - Medication status indicated as active during the measurement period

Site Level Reporting fields:

- Clinic Name
- Period
- Metric ID
- Clinical Topic
- Measure
- Clinic ID
- Clinic Name
- Metric Level (for A1C and LDL Testing and Control measures)
- Payer (optional)
- Numerator
- Denominator
- Percentage

- Provider Count
- Provider Minimum Count Flag
- Patient Minimum Count Flag

Two of the 19 entities that attempted to report this measure had issues that were discovered during the validation process and the decision was made for them to be listed as "Did Not Report" for this measurement period on the public website. The issues found were related to missing medication data, data systems being combined and staff changes in areas that work directly with the WCHQ measures. Both entities have a goal to work on resolution of the issues and plan to report the measure when it is publicly reported again in November 2015. The four individual component measure results were reviewed for accuracy as well as the combined score for the all or none measure and one issue was found in a group that sampled with selection of the wrong sampling method and this was corrected and they were still able to publicly report. Seventeen entities passed validation for reporting publicly reporting the measure.

Published results at the group level ranged from 44.80% to 70.02%. At the clinic site level results ranged from 37.92% to 75.00%.

2b2.3. What were the statistical results from validity testing? (*e.g., correlation; t-test*)

2b2.4. What is your interpretation of the results in terms of demonstrating validity? (i.*e., what do the results mean and what are the norms for the test conducted?*)

2b3. EXCLUSIONS ANALYSIS

Note: *Applies to the composite performance measure, as well all component measures unless they are already endorsed or are being submitted for individual endorsement.*

NA ☒ no exclusions — *skip to section 2b4*

2b3.1. Describe the method of testing exclusions and what it tests (*describe the steps—do not just name a method; what was tested, e.g., whether exclusions affect overall performance scores; what statistical analysis was used*)

2b3.2. What were the statistical results from testing exclusions? (*include overall number and percentage of individuals excluded, frequency distribution of exclusions across measured entities, and impact on performance measure scores*)

2b3.3. What is your interpretation of the results in terms of demonstrating that exclusions are needed to prevent unfair distortion of performance results? (*i.e., the value outweighs the burden of increased data collection and analysis. Note: **If patient preference is an exclusion**, the measure must be specified so that the effect on the performance score is transparent, e.g., scores with and without exclusion*)

2b4. RISK ADJUSTMENT/STRATIFICATION FOR OUTCOME OR RESOURCE USE MEASURES

Note: *Applies to all outcome or resource use component measures, unless already endorsed or are being submitted for individual endorsement.*

If not an intermediate or health outcome, or PRO-PM, or resource use measure, skip to section 2b5.

2b4.1. What method of controlling for differences in case mix is used? *(check all that apply)*

☐ **Endorsed (or submitted) as individual performance measures**

☒ **No risk adjustment or stratification**
☐ **Statistical risk model**
☐ **Stratification by risk categories**
☐ **Other,** Click here to enter description

2b4.2. If an outcome or resource use component measure is not risk adjusted or stratified, provide rationale and analyses to demonstrate that controlling for differences in patient characteristics (case mix) is not needed to achieve fair comparisons across measured entities.
WCHQ does not currently risk adjust our data.. Risk adjustment of ambulatory clinical outcome and process measures is not currently done that we are aware of at the regional or national level by virtue of the type of measures that these are in comparison to hospital-based measures. In addition, WCHQ reports on all patients and all payers.

2b4.3. Describe the conceptual/clinical and statistical methods and criteria used to select patient factors used in the statistical risk model or for stratification by risk (*e.g., potential factors identified in the literature and/or expert panel; regression analysis; statistical significance of p<0.10; correlation of x or higher; patient factors should be present at the start of care and not related to disparities*)

2b4.4. What were the statistical results of the analyses used to select risk factors?

2b4.5. Describe the method of testing/analysis used to develop and validate the adequacy of the statistical model or stratification approach (*describe the steps—do not just name a method; what statistical analysis was used*)

Provide the statistical results from testing the approach to controlling for differences in patient characteristics (case mix) below.
if stratified, skip to 2b4.9

2b4.6. Statistical Risk Model Discrimination Statistics (*e.g., c-statistic, R-squared*)**:**

2b4.7. Statistical Risk Model Calibration Statistics (*e.g., Hosmer-Lemeshow statistic*):

2b4.8. Statistical Risk Model Calibration – Risk decile plots or calibration curves:

2b4.9. Results of Risk Stratification Analysis:

2b4.10. What is your interpretation of the results in terms of demonstrating adequacy of controlling for differences in patient characteristics (case mix)? (i.*e., what do the results mean and what are the norms for the test conducted?*)

***2b4.11. Optional Additional Testing for Risk Adjustment** (*not required, but would provide additional support of adequacy of risk model, e.g., testing of risk model in another data set; sensitivity analysis for missing data; other methods that were assessed*)

2b5. IDENTIFICATION OF STATISTICALLY SIGNIFICANT & MEANINGFUL DIFFERENCES IN PERFORMANCE
Note: *Applies to the composite performance measure.*

2b5.1. Describe the method for determining if statistically significant and clinically/practically meaningful differences in performance measure scores among the measured entities can be identified (*describe the steps—do not just name a method; what statistical analysis was used? Do not just repeat the information provided related to performance gap in 1b)*

2b5.2. What were the statistical results from testing the ability to identify statistically significant and/or clinically/practically meaningful differences in performance measure scores across measured entities? (e.g., *number and percentage of entities with scores that were statistically significantly different from mean or some benchmark, different from expected; how was meaningful difference defined*)

2b5.3. What is your interpretation of the results in terms of demonstrating the ability to identify statistically significant and/or clinically/practically meaningful differences in performance across measured entities? (i.*e., what do the results mean in terms of statistical and meaningful differences?*)

2b6. COMPARABILITY OF PERFORMANCE SCORES WHEN MORE THAN ONE SET OF SPECIFICATIONS
Note: *Applies to all component measures, unless already endorsed or are being submitted for individual endorsement.*
If only one set of specifications for each component, this section can be skipped.

Note*: This criterion is directed to measures with more than one set of specifications/instructions (e.g., one set of specifications for how to identify and compute the measure from medical record abstraction and a different set of specifications for claims or eMeasures). It does not apply to measures that use more than one source of data in one set of specifications/instructions (e.g., claims data to identify the denominator and medical record abstraction for the numerator).* ***If comparability is not demonstrated, the different specifications should be submitted as separate measures.***

2b6.1. Describe the method of testing conducted to demonstrate comparability of performance scores for the same entities across the different data sources/specifications (*describe the steps—do not just name a method; what statistical analysis was used*)

2b6.2. What were the statistical results from testing comparability of performance scores for the same entities when using different data sources/specifications? (*e.g., correlation, rank order*)

2b6.3. What is your interpretation of the results in terms of demonstrating comparability of performance measure scores for the same entities across the different data sources/specifications? (i.*e., what do the results mean and what are the norms for the test conducted?*)

2b7. MISSING DATA ANALYSIS AND MINIMIZING BIAS
Note: *Applies to the overall composite measure.*

2b7.1. Describe the method of testing conducted to identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias (*describe the steps—do not just name a method; what statistical analysis was used*)

If any one of the four individual component measure is missing the result, i.e. patient does not have an active aspirin order the patient will remain in the denominator but will fail the numerator. If there is no documentation of tobacco status, the patient is not compliant for this measure.

2b7.2. What is the overall frequency of missing data, the distribution of missing data across providers, and the results from testing related to missing data? (*e.g., results of sensitivity analysis of the effect of various rules for missing data/nonresponse; if no empirical sensitivity analysis, identify the approaches for handling missing data that were considered and pros and cons of each*)

WCHQ receives global data files into RBS and patient level data files for validation using the alternate reporting method so any instances of missing data are found during the validation process and the determination is made at that time through verification of the reason for the missing data or result and whether or not the measure can be reported publicly. Reasons could be an unknown data source, a documentation process issue or an incorrectly mapped data element.

2b7.3. What is your interpretation of the results in terms of demonstrating that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias**?** (i*.e., what do the results mean in terms of supporting the selected approach for missing data and what are the norms for the test conducted; if no empirical analysis, provide rationale for the selected approach for missing data*)

Patients with missing data are not excluded from the all or none measure. Data elements missing from any component are counted as a numerator fail and the patient remains in the denominator. See 2b7.1 above.

2d. EMPIRICAL ANALYSIS TO SUPPORT COMPOSITE CONSTRUCTION APPROACH

Note: *If empirical analyses do not provide adequate results—or are not conducted—justification must be provided and accepted in order to meet the must-pass criterion of Scientific Acceptability of Measure Properties. Each of the following questions has instructions if there is no empirical analysis.*

2d1. Empirical analysis demonstrating that the component measures fit the quality construct, add value to the overall composite, and achieve the object of parsimony to the extent possible.

2d1.1 Describe the method used (*describe the steps—do not just name a method; what statistical analysis was used; if no empirical analysis, provide justification)*

This all or none method was chosen because of the benefits it provides to both the patient and the practitioner. First, this methodology more closely reflects the interests and likely desires of the patient. With the data collected in a composite score, patients can easily look and see how their provider group is performing on these criteria rather than trying to make sense of multiple scores on individual measures. Second, this method represents a systems perspective emphasizing the importance of optimal care through a patient's entire healthcare experience. Third, this method gives a more sensitive scale for improvement. For those organizations scoring high marks on individual measures, the All-or-None measure will give room for benchmarks and additional improvements to be made.

Nolan T, Berwick DM. All-or-none measurement raises the bar on performance. *JAMA*. 2006 Mar 8;295(10):1168-70.

2d1.2. What were the statistical results obtained from the analysis of the components? (e.g., *correlations, contribution of each component to the composite score, etc*.; *if no empirical analysis, identify the components that were considered and the pros and cons of each*)

The components of this measure were selected as secondary prevention, Level A AHA/ACC recommendations that can significantly reduce the IVD patient's risk of developing additional cardiovascular conditions.

2d1.3. What is your interpretation of the results in terms of demonstrating that the components included in the composite are consistent with the described quality construct and add value to the overall composite? (i.*e., what do the results mean in terms of supporting inclusion of the components; if no empirical analysis, provide rationale for the components that were selected)*

This all or none method was chosen because of the benefits it provides to both the patient and the practitioner. First, this methodology more closely reflects the interests and likely desires of the patient. With the data collected in a composite score, patients can easily look and see how their provider group is performing on these criteria rather than trying to make sense of multiple scores on individual measures. Second, this method represents a systems perspective emphasizing the importance of optimal care through a patient's entire healthcare experience. Third, this method gives a more sensitive scale for improvement. For those organizations scoring high marks on individual measures, the All-or-None measure will give room for benchmarks and additional improvements to be made.

Nolan T, Berwick DM. All-or-none measurement raises the bar on performance. *JAMA*. 2006 Mar 8;295(10):1168-70.

2d2. Empirical analysis demonstrating that the aggregations and weighting rules are consistent with the quality construct and achieve the objective of simplicity to the extent possible

2d2.1 Describe the method used (*describe the steps—do not just name a method; what statistical analysis was used; if no empirical analysis, provide justification)*

There is no weighting of the component measures.

2d2.2. What were the statistical results obtained from the analysis of the aggregation and weighting rules? (e.g., *results of sensitivity analysis of effect of different aggregations and/or weighting rules; if no empirical analysis, identify the aggregation and weighting rules that were considered and the pros and cons of each*)

N/A

2d2.3. What is your interpretation of the results in terms of demonstrating the aggregation and weighting rules are consistent with the described quality construct? (i.*e., what do the results mean in terms of supporting the selected rules for aggregation and weighting; if no empirical analysis, provide rationale for the selected rules for aggregation and weighting*)

N/A

2. Reliability and Validity—Scientific Acceptability of Measure Properties

Extent to which the measure, as specified, produces consistent (reliable) and credible (valid) results about the quality of care when implemented. ***Measures must be judged to meet the subcriteria for both reliability and validity to pass this criterion and be evaluated against the remaining criteria.***

2a.1. Specifications The measure is well defined and precisely specified so it can be implemented consistently within and across organizations and allows for comparability. eMeasures should be specified in the Health Quality Measures Format (HQMF) and the Quality Data Model (QDM).

De.5. **Subject/Topic Area** *(check all the areas that apply):*
Cardiovascular : Ischemic Heart Disease, Coronary Artery Disease

De.6. **Cross Cutting Areas** *(check all the areas that apply):*

S.1. **Measure-specific Web Page** *(Provide a URL link to a web page specific for this measure that contains current detailed specifications including code lists, risk model details, and supplemental materials. Do not enter a URL linking to a home page or to general information.)*
http://onlinecommunity.wchq.org/default.asp?page=qcdr

S.2a. **If this is an eMeasure**, HQMF specifications must be attached. Attach the zipped output from the eMeasure authoring tool (MAT) - if the MAT was not used, contact staff. (Use the specification fields in this online form for the plain-language description of the specifications)
This is not an eMeasure **Attachment:**

S.2b. **Data Dictionary, Code Table, or Value Sets** *(and risk model codes and coefficients when applicable) must be attached. (Excel or csv file in the suggested format preferred - if not, contact staff)*
Attachment **Attachment:** WCHQ_IVD_Care_Measure_Code_List.xlsx

S.3. **For endorsement maintenance**, please briefly describe any changes to the measure specifications since last endorsement date and explain the reasons.
Measure has not been previously endorsed.

S.4. **Numerator Statement** *(Brief, narrative description of the measure focus or what is being measured about the target population, i.e., cases from the target population with the target process, condition, event, or outcome)*
IF an OUTCOME MEASURE, state the outcome being measured. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
All-or-None Outcome Measure (Optimal Control) - Using the IVD denominator optimal results include:

- Most recent blood pressure measurement is less than 140/90 mm Hg

And

- Most recent tobacco status is Tobacco Free

NOTE: If there is No Documentation of Tobacco Status the patient is not compliant for this measure.
And

- Daily Aspirin or Other Antiplatelet Unless Contraindicated

And

- Statin Use

S.5. **Time Period for Data** *(What is the time period in which data will be aggregated for the measure, e.g., 12 mo, 3 years, look back to August for flu vaccination? Note if there are different time periods for the numerator and denominator.)*
Denominator: A minimum of two CAD or CAD Risk-Equivalent Condition coded office visits OR one Acute Coronary Event (AMI, PCI, CABG) from a hospital visit and must be seen by a PCP / Cardiologist for two office visits in 24 months and one office visit in 12 months.

Numerators: Twelve Month Measurement Period

S.6. **Numerator Details** *(All information required to identify and calculate the cases from the target population with the target process, condition, event, or outcome such as definitions, specific data collection items/responses, code/value sets – Note: lists of*

individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)
IF an OUTCOME MEASURE, describe how the observed outcome is identified/counted. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.

NOTE: All code tables and associated codes referenced in this document are included in the Excel File attached at step S2b.

• DAILY ASPIRIN OR OTHER ANTIPLATELET MEDICATIONS THERAPY UNLESS CONTRAINDICATED (Figure IVD-2) This measure assesses the percentage of patients with documentation within the medical record of daily Aspirin or daily other antiplatelet agent at any time during the measurement period demonstrated through any of the following:

1. Documentation of an active prescription for daily Aspirin (see suggested list in Table IVD-6) or daily or other antiplatelet medications (see acceptable medications in Table IVD-7)
2. Documentation on the patient's medication list of active daily usage of Aspirin (see suggested list in Table IVD-6) or daily other antiplatelet medications (see acceptable medications in Table IVD-7)
3. Contraindication to Aspirin

a. Contraindications will count as numerator compliant. Any valid contraindication date prior to the end of the measure end date will count as compliant. There is no limit on the look back date, but the date of documentation or onset date must occur prior to the end of the measurement period.

b. Accepted contraindications:

i. History of gastrointestinal (GI) bleed (see codes in Table IVD-8)

ii. History of intracranial bleed (ICB) (see codes in Table IVD-8)

iii. History of GI Bleed or ICB from an ICD-9 diagnosis-based problem list or past medical history. There is no limit on the look back date, but the date of documentation or onset date must occur prior to the end of the measurement period.

iv. Anticoagulant Use (see acceptable list of Medications in Table IVD-9). There must be documentation of an active anticoagulant at any time during the Measurement Period.

• BLOOD PRESSURE CONTROL (Figure IVD-2)

The number of patients in the denominator whose blood pressure (BP) is adequately controlled during the Measurement Period. Adequate control is a representative systolic Blood Pressure less than 140 mm Hg and a representative diastolic Blood Pressure less than 90 mm Hg.

IDENTIFYING A REPRESENTATIVE BLOOD PRESSURE

Blood Pressure Selection Criteria:

a) Blood Pressure reading must have been obtained during the Measurement Period.

b) Systolic and Diastolic numbers must be from the same BP reading.

c) A controlled BP requires that both the systolic and diastolic readings must be less than140/90.

d) Exclusions: Inpatient Stays, Emergency Room Visits, Urgent Care Visits, and Patient Self-Reported BP's (Home and Health Fair Blood Pressures)

e) Inclusions: Any office visit encounter, including Nurse Only BP Checks, not listed under Exclusions above. NOTE: A BP performed at a patient's home by a nurse who then inputs the result into an EMR counts as a Nurse Only BP.

• Select the Blood Pressure from the most recent visit.

• In the event that multiple Blood Pressures are recorded in the same day of service, select any reading that is controlled. If none are in control, select an uncontrolled reading.

• If no Blood Pressure is recorded during the Measurement Period, the patient is assumed to be "not controlled".

3. TOBACCO FREE (Figure IVD-2)

The number of patients in the denominator whose most recent tobacco documentation status with any provider within the 12 month measurement period is Tobacco Free.

Tobacco Use Definition:

• Cigarette
• Cigar
• Pipe Smoking
• Smokeless Tobacco (Chewing Tobacco, Snuff, etc.)

Tobacco Use Status can be identified by any of the following criteria:

1. Documentation stating that the patient has been asked if they are one of the following during the Measurement Period with the numerator compliant goal of Tobacco-Free:

1. Tobacco-Free (see examples below):

a. Former tobacco user

b. Never used
c. Non-tobacco user
d. Passive smoker
2. Non Tobacco-Free
a. Current tobacco user
3. No Documentation: The subset of denominator patients who did not have documentation of tobacco status during the last 12 Months [Measurement Period]
2. ICD-9, CPT, HCPCS and CPT-II Codes indicating tobacco use status during the Measurement Period) from billing or encounter data only. Do not use the problem list for these codes. (Table IVD-10)

4. STATIN USE (Figure IVD-2)
This measure assesses the percentage of patients with documentation within the medical record of statin use at any time during the measurement period demonstrated through any of the following:
1. Documentation of an active prescription for a statin (see acceptable medications in Table IVD-11)
2. Documentation on the patient's medication list of active usage of a statin (see acceptable medications in Table IVD-11)

5. ALL OR NONE OUTCOME MEASURE

IVD All-or-None Measure
The IVD All-or-None Measure is one outcome measure (optimal control). The measure contains four goals. All goals must be reached in order to meet that measure. The numerator for the all-or-none measure should be collected from the organization's total IVD denominator.

All-or-None Outcome Measure (Optimal Control) - Using the IVD denominator optimal results include:
- Most recent blood pressure measurement is less than 140/90 mm Hg

And

- Most recent tobacco status is Tobacco Free

NOTE: If there is No Documentation of Tobacco Status the patient is not compliant for this measure.
And
- Daily Aspirin or Other Antiplatelet Unless Contraindicated

And
- Statin Use

S.7. Denominator Statement *(Brief, narrative description of the target population being measured)*
Patients with CAD or a CAD Risk-Equivalent Condition 18-75 years of age and alive as of the last day of the MP.

S.8. Target Population Category *(Check all the populations for which the measure is specified and tested if any):*
Populations at Risk : Individuals with multiple chronic conditions

S.9. Denominator Details *(All information required to identify and calculate the target population/denominator such as definitions, specific data collection items/responses , code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
NOTE: All code tables and associated codes referenced in this document are included in the Excel File attached at step S2b.

Patients eligible for inclusion in the denominator include (See Figure IVD-1):
[Question 1] – Is this a patient with the disease, or condition?

CORONARY ARTERY DISEASE (OR CAD RISK EQUIVALENT) DIAGNOSIS RELATED OUTPATIENT VISITS
Those patients with a total of two or more visits during the last 24 months [Measurement Period + Prior Year] from Table IVD-4 (Office Visit Encounter Codes-Outpatient) with
any provider (MD, DO, PA, NP) within the Physician Group on different dates of service coded (including primary and secondary diagnoses) with diagnosis codes from Table
IVD-1 (Coronary Artery Disease) or Table IVD-2 (CAD Risk-Equivalent Conditions). The following criteria apply:

Any combination of two or more diagnosis codes from either Table IVD-1 or Table IVD-2, on different dates of service.

OR

ACUTE CORONARY EVENT- RELATED HOSPITAL VISITS
Those patients who had a minimum of one hospital related visit (excluding Emergency and Lab Only visits) for an Acute Coronary Event from Table IVD-3 during the last 24 Months [Measurement Period + Prior Year].

[Question 2] – Is this a patient whose care is managed within the physician group?
Those patients who have at least two Primary Care Office Visit (Table IVD-4) in an ambulatory setting, regardless of diagnosis code, on different dates of service, to a PCP or Cardiologist in the past 24 months [Measurement Period + Prior Year]. If Cardiologist is not considered a PCP, at least one of the two office visits must be to a PCP.
[Question 3] – Is this a patient current in our system?
Those patients who had at least one Primary Care Office Visit (Table IVD-4) in an ambulatory setting, regardless of diagnosis code, with a PCP or a Cardiologist during the last 12 Months [Measurement Period].

S.10. **Denominator Exclusions** *(Brief narrative description of exclusions from the target population)*
There are no denominator exclusions

S.11. **Denominator Exclusion Details** *(All information required to identify and calculate exclusions from the denominator such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
N/A

S.12. **Stratification Details/Variables** *(All information required to stratify the measure results including the stratification variables, definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format with at S.2b)*
This measure could be stratified by payer and this is documented in Appendix A of the measure specification, however, WCHQ does not currently publicly report the measure in a stratified manner.

S.13. **Risk Adjustment Type** (Select type. Provide specifications for risk stratification in S.12 and for statistical model in S.14-15)
No risk adjustment or risk stratification
If other:

S.14. **Identify the statistical risk model method and variables** *(Name the statistical method - e.g., logistic regression and list all the risk factor variables. Note - risk model development and testing should be addressed with measure testing under Scientific Acceptability)*
N/A

S.15. **Detailed risk model specifications** *(must be in attached data dictionary/code list Excel or csv file. Also indicate if available at measure-specific URL identified in S.1.)*
Note: Risk model details (including coefficients, equations, codes with descriptors, definitions), should be provided on a separate worksheet in the suggested format in the Excel or csv file with data dictionary/code lists at S.2b.

S.15a. **Detailed risk model specifications** (*if not provided in excel or csv file at S.2b*)
N/A

S.16. **Type of score:**
Other (specify):
If other: Percentage

S.17. **Interpretation of Score** *(Classifies interpretation of score according to whether better quality is associated with a higher score, a lower score, a score falling within a defined interval, or a passing score)*
Better quality = Higher score

S.18. **Calculation Algorithm/Measure Logic** *(Describe the calculation of the measure score as an ordered sequence of steps including identifying the target population; exclusions; cases meeting the target process, condition, event, or outcome; aggregating data; risk*

adjustment; etc.)
NOTE: Flow diagrams outlining the measure logic are included in step S.19.below at A.1 and is also included in the measure specification on pages 4 and 8 available at the URL identified in S.1.

The denominator algorithm is applied by identifying the target population based on codes and appropriate office visits during the designated timeframe. Once the denominator population has been identified the numerator logic is applied to all patients in the denominator to determine which patients meet each individual numerator and for the All or None measure which patients meet all four numerators for the timeframe.

S.19. **Calculation Algorithm/Measure Logic Diagram URL or Attachment** *(You also may provide a diagram of the Calculation Algorithm/Measure Logic described above at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
Available in attached appendix at A.1

S.20. **Sampling** *(If measure is based on a sample, provide instructions for obtaining the sample and guidance on minimum sample size.)*
IF a PRO-PM, identify whether (and how) proxy responses are allowed.
If a practice is unable to obtain the data in an all electronic format, sampling is allowed via either hybrid or random sampling.

RANDOM SAMPLE METHODOLOGY:
- Population Denominator (N) (CAD or CAD Risk-Equivalent patients 18-75 years of age)
? Population Sample (n) (r) (Patients in Denominator Population whose records will be reviewed)
o (n)=Population Sample and (r)=Patients Reviewed equal the same number
o The Population Sample size must be determined using the WCHQ Sample Calculator http://www.wchq.org/calculator/index.php
- Numerators

1. Daily Aspirin or daily other Antiplatelet Medication Therapy unless contraindicated documented in the medical record as active at any time during the measurement period
2. Most recent Blood pressure controlled to a level of less than 140/90 mm Hg
3. Most recent Tobacco Status
4. Statin Use
5. All or None Optimal Control

Upon entry of these numbers, the rate is automatically calculated

HYBRID METHODOLOGY:
- Population Denominator (N) (CAD or CAD Risk-Equivalent patients 18-75 years of age)
? Administrative Review Denominator (Patients in Total Denominator Population whose numerator information is obtained through administrative data)

? Administrative Review Numerators

1. Daily Aspirin or daily other Antiplatelet Medication Therapy unless contraindicated documented in the medical record as active at any time during the measurement period
2. Most recent Blood pressure controlled to a level of less than 140/90 mm Hg
3. Most recent Tobacco Status
4. Statin Use
5. All or None Optimal Control

? Manual Review Denominator (Patients in Total Denominator Population whose numerator information cannot be obtained through administrative data)
? Manual Review Sample Size (Patients in Manual Review Denominator Population whose records will be reviewed)
o The Manual Review Sample size must be determined using the WCHQ Sample Calculator plus a 10% over sample http://www.wchq.org/calculator/index.php
- Manual Review Numerators

1. Daily Aspirin or daily other Antiplatelet Medication Therapy unless contraindicated documented in the medical record as active at any time during the measurement period
2. Most recent Blood pressure controlled to a level of less than 140/90 mm Hg
3. Most recent Tobacco Status
4. Statin Use
5. All or None Optimal Control

Upon entry of these numbers for each numerator, the Rates, Weight Factors and Total Reviewed are automatically calculated. Total Reviewed equals Administrative Review Denominator + Manual Review Sample Size.

These instructions are also included in the specification identified in S.1.

S.21. **Survey/Patient-reported data** *(If measure is based on a survey, provide instructions for conducting the survey and guidance on minimum response rate.)*
IF a PRO-PM, specify calculation of response rates to be reported with performance measure results.
N/A

S.22. **Missing data** (specify how missing data are handled, e.g., imputation, delete case.)
Required for Composites and PRO-PMs.
When possible data is collected in an all electronic format and will be all-inclusive. A patient level validation and verification process that involves comparing results at the patient level to the practice EMR data source is performed to assist with finding any missing data. If practices are aware that they will have gaps in the electronic data that is available, the numerator can be obtained through sampling, as described in S.20 above.

S.23. **Data Source** *(Check ONLY the sources for which the measure is SPECIFIED AND TESTED).*
If other, please describe in S.24.
Administrative claims, Electronic Clinical Data, Electronic Clinical Data : Electronic Health Record, Electronic Clinical Data : Registry

S.24. **Data Source or Collection Instrument** *(Identify the specific data source/data collection instrument e.g. name of database, clinical registry, collection instrument, etc.)*
IF a PRO-PM, identify the specific PROM(s); and standard methods, modes, and languages of administration.
Data is obtained via data extracts (.csv files) from the practice and then uploaded into the WCHQ Repository Based Submission (RBS) database. Primary files consist of a Patient File, Encounter File, Problem List File, Clinical Data File, Tobacco File, Blood Pressure File and a Medication File. Certain data elements are cross-mapped to identify internal codes. The data is then calculated for the measure and is available with results at the group, clinic site and provider level. There is documentation provided describing the process of data submission and creation of the data files. This documentation is attached at A.1.

S.25. **Data Source or Collection Instrument** *(available at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
Available in attached appendix at A.1

S.26. **Level of Analysis** *(Check ONLY the levels of analysis for which the measure is SPECIFIED AND TESTED)*
Clinician : Group/Practice

S.27. **Care Setting** *(Check ONLY the settings for which the measure is SPECIFIED AND TESTED)*
Ambulatory Care : Clinician Office/Clinic
If other:

S.28. **COMPOSITE Performance Measure** - Additional Specifications *(Use this section as needed for aggregation and weighting rules, or calculation of individual performance measures if not individually endorsed.)*

2a. Reliability – See attached Measure Testing Submission Form
2b. Validity – See attached Measure Testing Submission Form
Template_MeasSubm_CompositeMeasTesting_2013-08-20-WCHQ_IVD_All_or_None-635711968805327166.docx

3. Feasibility

Extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

3a. Byproduct of Care Processes

For clinical measures, the required data elements are routinely generated and used during care delivery (e.g., blood pressure, lab test, diagnosis, medication order).

3a.1. **Data Elements Generated as Byproduct of Care Processes.**
Generated or collected by and used by healthcare personnel during the provision of care (e.g., blood pressure, lab value, diagnosis, depression score), Coded by someone other than person obtaining original information (e.g., DRG, ICD-9 codes on claims), Abstracted from a record by someone other than person obtaining original information (e.g., chart abstraction for quality measure or registry)
If other:

3b. Electronic Sources

The required data elements are available in electronic health records or other electronic sources. If the required data are not in electronic health records or existing electronic sources, a credible, near-term path to electronic collection is specified.

3b.1. **To what extent are the specified data elements available electronically in defined fields?** *(i.e., data elements that are needed to compute the performance measure score are in defined, computer-readable fields)*
ALL data elements are in defined fields in a combination of electronic sources

3b.2. **If ALL the data elements needed to compute the performance measure score are not from electronic sources, specify a credible, near-term path to electronic capture, OR provide a rationale for using other than electronic sources.**

3b.3. **If this is an eMeasure, provide a summary of the feasibility assessment in an attached file or make available at a measure-specific URL.**
Attachment:

3c. Data Collection Strategy

Demonstration that the data collection strategy (e.g., source, timing, frequency, sampling, patient confidentiality, costs associated with fees/licensing of proprietary measures) can be implemented (e.g., already in operational use, or testing demonstrates that it is ready to put into operational use). For eMeasures, a feasibility assessment addresses the data elements and measure logic and demonstrates the eMeasure can be implemented or feasibility concerns can be adequately addressed.

3c.1. **Describe what you have learned/modified as a result of testing and/or operational use of the measure regarding data collection, availability of data, missing data, timing and frequency of data collection, sampling, patient confidentiality, time and cost of data collection, other feasibility/implementation issues.**
IF a PRO-PM, consider implications for both individuals providing PROM data (patients, service recipients, respondents) and those whose performance is being measured.
WCHQ has been collecting data for reporting clinical quality measures since 2004. Over this time we have refined our data submission and measure calculation process through use of our Repository Based Submission (RBS) system which allows us to have a large data repository of claims and clinical data. Use of RBS has streamlined the measurement and reporting process for our reporting entities by allowing them to upload and map their data and not have to build complex measure queries for multiple measures. The programming of each measure is done by WCHQ´s Technology Vendor, Ancilla Partners and this in turn ensures the measure is always calculated in a standard format when reporting via RBS. In addition, the data set can be used for multiple measure initiatives. The validation process is also streamlined because the data is at the patient level and readily accessible. Reporting entities can also use the RBS data tool to run their measures at a more frequent time-frame and produce group, clinic site,and provider level reports for internal quality improvement work. The data is uploaded initially into a secure file transfer protocol site and from there is is uploaded into the RBS database. The data base is HIPAA compliant and has been audited. In addition, WCHQ members sign a Business Associated Agreement that allows them to provide this data to WCHQ for measurement reporting.

3c.2. **Describe any fees, licensing, or other requirements to use any aspect of the measure as specified** *(e.g., value/code set, risk model, programming code, algorithm)*.
There are no fees associated with reporting this measure. Results for WCHQ members are available on the public website, www.wchq.org. There is resource time involved in preparing the data files, cross-mapping data elements and verifying results.

4. Usability and Use

Extent to which potential audiences (e.g., consumers, purchasers, providers, policy makers) are using or could use performance results for both accountability and performance improvement to achieve the goal of high-quality, efficient healthcare for individuals or populations.

4a. Accountability and Transparency

Performance results are used in at least one accountability application within three years after initial endorsement and are publicly reported within six years after initial endorsement (or the data on performance results are available). If not in use at the time of initial endorsement, then a credible plan for implementation within the specified timeframes is provided.

4.1. Current and Planned Use

NQF-endorsed measures are expected to be used in at least one accountability application within 3 years and publicly reported within 6 years of initial endorsement in addition to performance improvement.

Planned	Current Use (for current use provide URL)
	Public Reporting Wisconsin Collaborative for Health Care Qualifty http://www.wchq.org/reporting/results.php?site_level_flag=0&measure_id=205 Payment Program Qualified Clinical Data Registry (QCDR) approved by CMS http://onlinecommunity.wchq.org/?page=qcdr Quality Improvement with Benchmarking (external benchmarking to multiple organizations) WCHQ Measures Summary http://www.wchq.org/reporting/wchq_measures_summary.php

4a.1. For each CURRENT use, checked above, provide:

- Name of program and sponsor
- Purpose
- Geographic area and number and percentage of accountable entities and patients included

a. Public Reporting: The Wisconsin Collaborative for Healthcare Quality (WCHQ) publicly reports and brings meaning to performance measurement information that improves the quality and affordability of healthcare in Wisconsin, in turn improving the health of individuals and communities.WCHQ is a multi-stakeholder, voluntary consortium of Wisconsin organizations. WCHQ draws its membership from health systems, medical groups, hospitals and health plans. This diverse and dynamic group includes the state´s largest health systems, Aurora Health Care and the University of Wisconsin Hospital and Clinics / University of Wisconsin Medical Foundation. The geographic area included in public reporting is statewide and also includes some patients from neighboring states, Minnesota, Iowa, Michigan and Illinois. There are 38 member organizations but not all currently publicly report this measure yet. For 2014, the first time this measure was reported, there were 17 member organization reporting at the group level and 121 at the clinic site level. There are 50,758 patients reported for this measure.

c. Payment Program: WCHQ is a Centers for Medicare and Medicaid approved Qualified Clinical Data Registry (QCDR). This is a vetted, non-PQRS measure that has been approved by CMS to report on behalf of an eligible provider for purposes of meeting PQRS reporting requirements. Because the measure was not available as a PQRS measure for reporting through the QCDR for the 2014 measurement period but will be for the 2015 PQRS reporting period. The geographic area could potentially be across the United States and and the number of entities and patients is not known at this time. The measure could also be publicly reported on Physician Compare in 2016.

f. Quality Improvement with Benchmarking: On the wchq public website there is a Measure Summary display where members can select a reporting organization and then look at their measure results. Measure results can be viewed by Top Performer, 95th, 90th, 75th and 50th percentiles, and by Average. The geographic area included in public reporting is statewide and also includes some patients from neighboring states, Minnesota, Iowa, Michigan and Illinois. There are 38 member organizations but not all currently publicly report this measure yet. For 2014, the first time this measure was reported, there were 17 member organization reporting at the group level and 121 at the clinic site level. There are 50,758 patients reported for this measure.

4a.2. If not currently publicly reported OR used in at least one other accountability application (e.g., payment program, certification, licensing) what are the reasons? (*e.g., Do policies or actions of the developer/steward or accountable entities restrict access to performance results or impede implementation?*)

4a.3. **If not currently publicly reported OR used in at least one other accountability application, provide a credible plan for implementation within the expected timeframes -- any accountability application within 3 years and publicly reported within 6 years of initial endorsement.** (*Credible plan includes the specific program, purpose, intended audience, and timeline for implementing the measure within the specified timeframes. A plan for accountability applications addresses mechanisms for data aggregation and reporting.*)

4b. Improvement

Progress toward achieving the goal of high-quality, efficient healthcare for individuals or populations is demonstrated. If not in use for performance improvement at the time of initial endorsement, then a credible rationale describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.

4b.1. **Progress on Improvement. (Not required for initial endorsement unless available.)**
Performance results on this measure (current and over time) should be provided in 1b.2 and 1b.4. Discuss:

- **Progress (trends in performance results, number and percentage of people receiving high-quality healthcare)**
- **Geographic area and number and percentage of accountable entities and patients included**

2014 is the first year this measure was published so there is no progress on improvement at this time. We will report the measure again in November 2015 and this can be measured at that time.

4b.2. **If no improvement was demonstrated, what are the reasons? If not in use for performance improvement at the time of initial endorsement, provide a credible rationale that describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.**
As stated in 4b.1 above, 2014 is the first year this measure was published so there is no progress on improvement at this time. We will report the measure again in November 2015 and improvement will be measured at that time.

4c. Unintended Consequences

The benefits of the performance measure in facilitating progress toward achieving high-quality, efficient healthcare for individuals or populations outweigh evidence of unintended negative consequences to individuals or populations (if such evidence exists).

4c.1. **Were any unintended negative consequences to individuals or populations identified during testing; OR has evidence of unintended negative consequences to individuals or populations been reported since implementation? If so, identify the negative unintended consequences and describe how benefits outweigh them or actions taken to mitigate them.**
None.

5. Comparison to Related or Competing Measures

If a measure meets the above criteria and there are endorsed or new related measures (either the same measure focus or the same target population) or competing measures (both the same measure focus and the same target population), the measures are compared to address harmonization and/or selection of the best measure.

5. Relation to Other NQF-endorsed Measures
Are there related measures (conceptually, either same measure focus or target population) or competing measures (conceptually both the same measure focus and same target population)? If yes, list the NQF # and title of all related and/or competing measures.
Yes

5.1a. **List of related or competing measures (selected from NQF-endorsed measures)**
0076 : Optimal Vascular Care

5.1b. **If related or competing measures are not NQF endorsed please indicate measure title and steward.**

5a. Harmonization

The measure specifications are harmonized with related measures;
OR
The differences in specifications are justified

5a.1. **If this measure conceptually addresses EITHER the same measure focus OR the same target population as NQF-endorsed**

measure(s):
Are the measure specifications completely harmonized?
No

5a.2. **If the measure specifications are not completely harmonized, identify the differences, rationale, and impact on interpretability and data collection burden.**
The measure specifications are very similar for three of the measure components, Daily Aspirin, Blood Pressure Control and Tobacco Free. However, the WCHQ measure also adds the Statin Use component which is a secondary prevention according to the AHA/ACC revised guidelines in November 2013. There are also some slight denominator differences in number and time frame of visits required.

5b. Competing Measures

The measure is superior to competing measures (e.g., is a more valid or efficient way to measure);
OR
Multiple measures are justified.

5b.1. **If this measure conceptually addresses both the same measure focus and the same target population as NQF-endorsed measure(s):**
Describe why this measure is superior to competing measures (e.g., a more valid or efficient way to measure quality); OR provide a rationale for the additive value of endorsing an additional measure. (Provide analyses when possible.)
Because this measure includes the secondary prevention element of Statin Use from the updated AHA/ACC guidelines from November 2013. It also uses a denominator algorithm that allows patient level lists to be generated for internal practice quality improvement purposes.

Appendix

A.1 Supplemental materials may be provided in an appendix. All supplemental materials (such as data collection instrument or methodology reports) should be organized in one file with a table of contents or bookmarks. If material pertains to a specific submission form number, that should be indicated. Requested information should be provided in the submission form and required attachments. There is no guarantee that supplemental materials will be reviewed.

Contact Information

Co.1 **Measure Steward (Intellectual Property Owner):** Wisconsin Collaborative for Healthcare Quality
Co.2 **Point of Contact:** Mary, Gordon, mgordon@wchq.org, 608-775-4519-
Co.3 **Measure Developer if different from Measure Steward:** Wisconsin Collaborative for Healthcare Quality
Co.4 **Point of Contact:** Mary, Gordon, mgordon@wchq.org, 608-775-4519-

Additional Information

Ad.1 **Workgroup/Expert Panel involved in measure development**
Provide a list of sponsoring organizations and workgroup/panel members' names and organizations. Describe the members' role in measure development.
The WCHQ Measurement Advisory Committee (MAC). The MAC serves as a subcommittee of the Board of Directors for purposes of directing policy, actual changes to measures, and procedural or clinical decisions for WCHQ workgroups involved with new measures development or other measurement-related initiatives.

Member Names: Geoffrey Lamb, MD-Medical College of Wisconsin, Dan Collins -ThedaCare, Dirk Steinert, MD-Columbia St. Mary's, Greg Blommel, MD-Froedtert West Bend, Kristine Bruno, MD-Aurora Advanced, Robert Mead, MD-Bellin, Steve Kulick, MD-ProHealth Care, Kim Volberg – Dean, Rhonda Struckm MD-Wheaton Franciscan, John Zlabek, MD-Gundersen Health System.

Ambulatory Care Specifications (ACS) work group. The Ambulatory Care Specifications Workgroup develops, monitors, and revises the WCHQ ambulatory process and clinical outcome measure specifications. This work group is open to all WCHQ member, meets generally weekly and is generally attended by 18-20 member organizations and 30-40 people.

Measure Developer/Steward Updates and Ongoing Maintenance
Ad.2 **Year the measure was first released:** 2015

Ad.3 **Month and Year of most recent revision:** 10, 2014
Ad.4 **What is your frequency for review/update of this measure?** Annually
Ad.5 **When is the next scheduled review/update for this measure?** 10, 2015

Ad.6 **Copyright statement:** None
Ad.7 **Disclaimers:** Disclaimer: Measures reported by WCHQ healthcare organizations represent a specific aspect of care in relation to an evidence-based standard, but are not clinical guidelines and do not establish standards of care. All providers should have an individual care plan established with their patient.

Ad.8 **Additional Information/Comments:**

NATIONAL QUALITY FORUM

MEASURE WORKSHEET

This document summarizes the evaluation of the measure as it progresses through NQF's Consensus Development Process (CDP). The information submitted by measure developers/stewards is included after the Brief Measure Information, Preliminary Analysis, and Pre-meeting Public and Member Comments sections.

To navigate the links in the worksheet: Ctrl + click link to go to the link; ALT + LEFT ARROW to return

Brief Measure Information

NQF #: 2764
Measure Title: Fixed-dose Combination of Hydralazine and Isosorbide Dinitrate Therapy for Self-identified Black or African American Patients with Heart Failure and LVEF <40% on ACEI or ARB and Beta-blocker Therapy
Measure Steward: National Minority Quality Froum
Brief Description of Measure: Percentage of patients aged 18 years and older with a diagnosis of heart failure (HF) and a current or prior ejection fraction (EF) <40% who are self-identified Black or African Americans and receiving ACEI or ARB and Beta-blocker therapy who were prescribed a fixed-dose combination of hydralazine and isosorbide dinitrate seen for an office visit in the measurement period in the outpatient setting or at each hospital discharge
Developer Rationale: The African-American Heart Failure Trial (A-HeFT) first published in 2004 demonstrated that there is significant benefit for African American patients who receive the fixed-dose combination therapy of hydralazine and isosorbide dinitrate. A-HeFT built on the findings from the two Vasodilator-Heart Failure Trials (V-HeFT). A-HeFT, which was ended early due to the mortality rates in the placebo population, demonstrated a 43% reduction in mortality, a 33% decrease in initial hospitalizations, and a 50% improvement in patient-reported quality of life (Taylor, 2004; Sharma, 2014). These results clearly demonstrate that the fixed-dose combination therapy significantly improves patient morbidity, mortality and quality of life in this clinical cohort. There is no substitute for the fixed-dose combination therapy.

Even with this strong evidence of unprecedented efficacy and cost-effectiveness, research shows that more than 85% of African American patients are not receiving the quality of care that this therapy affords, constituting a significant gap in care quality (Dickson, 2015). The underuse of the fixed-dose combination of hydralazine plus isosorbide dinitrate in African Americans with severe heart failure is a health care and health quality disparity that exposes these patients to an elevated risk for mortality and hospitalization, and compromises efforts to contain the escalating system costs by preventing or reducing unnecessary hospitalizations and readmissions.

Based upon research on the mortality benefit of the fixed-dose combination (Fonarow, 2011), the National Minority Quality Forum estimates that 51,542 (27%) of the 189,891 African American Medicare beneficiaries who were being treated for heart failure and received their prescription drugs under Part D should have been treated with the fixed-dose combination; but only 2,377 (5%) had at least one prescription (30-day supply) of the therapy. Further, the National Minority Quality Forum estimates that between 2008 and 2010, only 3% of the eligible patient cohort in Medicare received the therapy. Given the documented number to treat to receive the mortality benefit (21), it can be estimated that from 2007 through 2010, 20,000 African American Medicare beneficiaries died as a result of the failure to receive quality care as defined by evidence-based guidelines.

Research continues to explore if the fixed-dose combination of hydralazine and isosorbide dinitrate is linked to a particular genetic polymorphism (NIH funded Genomic Response Analysis of Heart Failure Therapy in African Americans). While we anticipate that the evidence supporting this treatment will be refined over time, the proven benefits to this patient population is significant and there is a clear opportunity for improvement. Failure to do so constitutes a failure to provide quality and cost-effective care.

Preliminary Analysis

The preliminary analysis was developed in response to recommendations from NQF's Consensus Task Force and measurement stakeholders as a way to enhance and streamline the measures evaluation and voting processes. The preliminary analysis will help to guide the Standing Committee evaluation of each measure by summarizing the measure developer submission, guide measure evaluation discussion, and identify topic areas for additional input. **NQF staff would like to stress that the preliminary analysis is intended to be used as a guide to facilitate the Committee's discussion and evaluation.**

Criteria 1: Importance to Measure and Report

1a. Evidence

1a. Evidence. The evidence requirements for a *process* measure is that it is based on a systematic review (SR) and grading of the body of empirical evidence where the specific focus of the evidence matches what is being measured.

The developer provides the following evidence for this *process eMeasure*:

- This clinician-level process eMeasure calculates the percentage of patients aged 18 years and older with a diagnosis of heart failure (HF) and a current or prior ejection fraction (EF) <40% who are self-identified Black or African Americans and receiving ACEI or ARB and Beta-blocker therapy who were prescribed a fixed-dose combination of hydralazine and isosorbide dinitrate seen for an office visit in the measurement period in the outpatient setting or at each hospital discharge.
- The developer provides the 2013 ACCF/AHA guideline for the management of heart failure (**Class I; Level of Evidence: A**) with one recommendation for the combination of hydralazine and isosorbide dinitrate for patients self-described as African Americans (**Class I**) and the HFSA 2010 Comprehensive Heart Failure Practice Guideline (**Strength of Recommendation: Is Recommended**) with two recommendations: hydralazine and isosorbide dinitrate is recommended in addition to beta blockers and ACE inhibitors for African Americans with HF and reduced LVEF (**Strength of Evidence = A and B**) and hydralazine/isosorbide dinitrate is recommended for African American women with moderate to severe HF symptoms who are on background neurohormonal inhibition (**Strength of Evidence = B**).
- The evidence review supporting the hydralazine/isosorbide dinitrate recommendations was conducted through October 2011 and includes other references through April 2013 for the 2013 ACCF/AHA guideline. No information on the time period for the HFSA 2010 guideline was provided.

- QQC - 4 randomized controlled trials (RCTs) and 2 post hoc retrospective analyses supporting the 2013 ACCF/AHA guideline. No specific information on the number of studies included in the body of evidence for the HFSA 2010 Comprehensive Heart Failure Practice Guideline.
- Two additional analyses were published after the publication of the 2013 ACCF/AHA guideline and the developers conclude that, "While additional research on whether use of hydralazine and isosorbide dinitrate is linked to a genetic polymorphism may refine the clinical recommendations, findings in these publications further support the current recommendations and level of evidence ratings for the use of combination therapy in African American patients."
- The developer provides a diagram that demonstrates how the use of a fixed-dose combination of hydralazine and isosorbide dinitrate in self-identified black or African American patients with HF and LVSD receiving ACEI/ARB and beta-blocker therapy is linked to patient outcomes.

Questions for the Committee:

- *For process measures:*
  - *Is the evidence directly applicable to the process of care being measured?*
  - *Is the process of care proximal and closely related to desired outcomes?*
- *For possible exception to the evidence criteria:*
  - *Are there, or could there be, performance measures of a related health outcome, OR evidence-based intermediate clinical outcomes, intervention/treatment?*
  - *Is there evidence of a systematic assessment of expert opinion beyond those involved in developing the measure?*
  - *Does the SC agree that it is acceptable (or beneficial) to hold providers accountable without empiric evidence?*

1b. Gap in Care/Opportunity for Improvement and 1b. Disparities

1b. Performance Gap. The performance gap requirements include demonstrating quality problems and opportunity for improvement.

- Because this is a newly developed measure the developers do not yet have overall performance data or data on disparities from the measure as specified.
- The developer provides a summary of data from the literature that demonstrates the existence of a significant opportunity for improvement of whether eligible patients are receiving the hydralazine/isosorbide dinitrate combination therapy in the ambulatory setting and at hospital discharge.
- The developer provides a summary of data from the literature that demonstrates that HF is more prevalent in African Americans than in whites, occurs earlier, imposes higher rates of death and morbidity, and has a more malignant course. The developers also report that, "Much of the disparity can be assigned to modifiable risk factors such as uncontrolled hypertension and on suboptimal health care. Therefore, when African Americans are treated according to guidelines, discrepant outcomes can be minimized (Sharma, 2014)."

Questions for the Committee:

- *Is there a gap in care that warrants a national performance measure?*
- *If no disparities information is provided, are you aware of evidence that disparities exist in this area of healthcare?*
- *Should this measure be indicated as disparities sensitive?*

Committee pre-evaluation comments

Criteria 1: Importance to Measure and Report (including 1a, 1b,)

1. ***Committee's Overview Comments***:
   - The evidence presented is from the 2013 ACCF/AHA clinical practice guidelines for managing heart failure as well as the Heart Failure Society of America's 2010 heart failure practice guidelines. ACCF/AHA recommendation is

Class I, Level A, and the HFSA recommendation is Strength of evidence level A for NYHA class 3 or 4, and level B for NYHA class 2. Evidence is based on 4 RCTs, one of which was conducted in AA, and found significant mortality benefit in this population with a 43% reduction in mortality and 33% relative reduction in hospitalizations. The evidence directly applies to the measure. The time period reviewed for the guidelines was through April 2013. Estimate of benefit (Fonarow) over 6000 lives saved per year, and a 50% improvement in QOL. QQC was provided from the 4 RCT's and 2 post-hoc analyses. An additional study was published that suggested a possible genetic link for use of this medication, and the authors felt that this further supports the recommendation. Suggests moderate evidence rating

1a. ***Committee's Comments on Evidence to Support Measure Focus:***

- The evidence directly relates to this process measure

1b. ***Committee's Comments on Performance Gap:***

- Performance gap was demonstrated to be quite large. A review of GWTG found only 7.3% of the AA HF population on this treatment compared to an estimated 27% that should have been. An analysis from the measure developer's estimate. The NNT is 21 for mortality benefit. Because this is a new measure submitted for trial request, the developers do not have specific data on performance gap identified by their e-measure.
- Disparities – this measure addresses a common condition that disproportionately affects a minority population and the treatment addressed by the measure has a significantly beneficial impact on the minority population. It addresses the National Quality Strategy of effective clinical care. Heart failure affects approximately 3% of the Black population and affects men and women approximately the same.

1c. ***Committee's Comments on Composite Performance Measure:***

- Not Applicable

Criteria 2: Scientific Acceptability of Measure Properties
2a. Reliability
2a1. Reliability Specifications
2a1. Specifications requires the measure, as specified, to produce consistent (reliable) and credible (valid) results about the quality of care when implemented.

- This individual and group clinician eMeasure assesses whether self identified Black or African American Heart Failure(HF) patients (identified by diagnosis, and LVEF < 40% or moderate or severe LVSD) who are currently taking ACEI/ARBs and beta-blockades are prescribed a fixed-dose combination of hydralazine and isosorbide dinitrate at an outpatient encounter or at hospital discharge.
- The measure's data source is an EHR. ICD 9, ICD 10, CPT, SNOMED, LOINC and prescription codes provided for the numerator and denominator for inpatient and outpatient setting. ICD-10 conversion methodology is not discussed. Higher scores equal better quality.
- The developers report that the measure is intended for use in a clinician office/clinic and hospital/acute care facility; however, the value sets include nursing facility, long-term residential facility and home care services which are not traditionally considered outpatient settings. If hospital discharges are included in the measure population, instructions for identifying the accountable clinician at the time of the hospital discharge is not provided.
- The HQMF specifications state that 2 or more outpatient (OP) encounters are required during the measurement year to establish a patient/provider relationship, rather than ≥ 2 encounters at any time.
- "Provider interactions" are listed as encounters in the value set spreadsheet and in the eMeasure specifications that include both face-to-face visits and non-face-to-face communications. The developer is encouraged to provide reasoning for inclusion, and clarify if all provider interactions are included in the denominator definition for a patient encounter.
- The HQMF denominator logic states that both ACEI/ARBs and beta-blockades should start before and overlap the HF encounter to be considered for a fixed-dose combination of hydralazine and isosorbide dinitrate therapy. The

developer is encouraged to clarify if both medications must be started before the 2nd encounter.

- Denominator exceptions include hypotension (severe or symptomatic), severe lupus erythematosus, unstable angina, peripheral neuritis, and patient actively taking Phosphodiesterase Type 5 (PDE5) Inhibitors. Hypotension is *not* also defined with diastolic and systolic parameters in the specifications.
- Missing numerator data present a quality failure.
- The calculation algorithm is included. The measure is not risk adjusted.
- The eMeasure specifications and values sets meet all current NQF eMeasure technical requirements and are provided on Sharepoint for SC review.

Questions for the Committee:

- *Are all the data elements clearly defined? Are all appropriate codes included?*
- *Is the logic or calculation algorithm clear?*
- *Is it likely this measure can be consistently implemented?*
- *For an eMeasure:*
  - *Does the submission meet NQF's eMeasure criteria?*
  - *Are there questions or identified gaps with the value sets, data elements or HQMF logic?*
  - *Are there inconsistencies between the evidence, the Measure Information Form (MIF) and the eMeasure components or logic?*

2a2. Reliability Testing Testing attachment

2a2. Reliability testing demonstrates if the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise enough to distinguish differences in performance across providers.

- In section3c.1, the developer indicates, "Because this measure is submitted for eMeasure trial approval and testing is not yet completed, we are not yet able to share information on data availability and collection beyond what is provided in the feasibility assessment in 3b.3. This information will be collected during our testing and modifications made to the measure based on the results."
- In addition to the above statement, the developer additionally submitted a reliability testing plan.
- The developer submitted pre-testing from the Measure Authoring Tool within the Bonnie Output that tests eMeasure logic. The measure logic successfully validated through the Bonnie Output.

Questions for the Committee:

- *Other specific questions regarding validity testing.*

2b. Validity

2b1. Validity: Specifications

2b1. Validity Specifications. This section should determine if the measure specifications are consistent with the evidence.

- The developer provides evidence that states Black or African American adults with HF who are currently taking ACEI/ARB and beta-blockade therapies should be also be taking a fixed-dose combination of hydralazine and isosorbide dinitrate.

Question for the Committee:

- *Are the specifications consistent with the evidence?*

2b2. Validity testing

2b2. Validity Testing should demonstrate the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality.

- In section3c.1, the developer indicates, "Because this measure is submitted for eMeasure trial approval and testing is not yet completed, we are not yet able to share information on data availability and collection beyond what is provided in the feasibility assessment in 3b.3. This information will be collected during our testing and modifications made to the measure based on the results."
- In addition to the above statement, the developer additionally submitted a validity testing plan.
- The developer submitted pre-testing from the Measure Authoring Tool within the Bonnie Output that also tests eMeasure performance calculation. This testing does use "live" EHR patients, though NQF currently accepts Bonnie Output pre-testing when EHR testing was not provided. Results in the 15 "pre-test" patients demonstrated 100% agreement for identifying both expected and actual initial patient population, denominator, denominator exclusions, numerator, and denominator exceptions. Testing characteristics are provided for the 15 "pre-test" patients, with 76% of all possible data elements included in the pre-test sample.

Questions for the Committee:

- *Other specific question of the validity testing?*

2b3-2b7. Threats to Validity

2b3. Exclusions:

- Denominator exceptions include hypotension (severe or symptomatic), severe lupus erythematosus, unstable angina, peripheral neuritis, and patient actively taking Phosphodiesterase Type 5 (PDE5) Inhibitors.
- Impact of exclusions on the measure to be provided when testing is completed.

Questions for the Committee:

- *Are the exclusions consistent with the evidence?*
- *Are any patients or patient groups inappropriately excluded from the measure?*
- *Are the exclusions/exceptions of sufficient frequency and variation across providers to be needed (and outweigh the data collection burden)?*

2b4. Risk adjustment:

- This process measure is not risk adjusted.
- The developer did not consider either clinical or SDS adjustment for this measure.

2b5. Meaningful difference:

- A testing plan was provided.

2b6. Comparability of data sources/methods:

- This section is not applicable as the developer submitted a single specification (eMeasure) with one data source (EHR).

2b7. Missing Data

- Missing numerator data present a quality failure.
- A testing plan was provided.

Committee pre-evaluation comments

Criteria 2: Scientific Acceptability of Measure Properties (including all 2a, 2b, and 2d)

2a1. &2b1.: ***Committee's Comments on Reliability-Specifications:***

- All data elements are defined with VSAC registered value sets, and is specified in the HQMF format using the QDM. Again, because it is submitted for trial use testing is not complete. They did submit a testing plan that appears to comply with all required testing. The measure is intended for the outpatient population and the hospital acute care population. Bonnie output from pre-testing successfully validated the measure logic, with a 100% pass rate, for 85% of the data elements that were covered in the testing.
- The exclusions are identical to that listed in the FDA prescribing information as contraindications and/or warnings. Severe or symptomatic heart failure was defined using codes – not by a defined BP level, which seems appropriate. The only concern identified was the potential for missing information on ejection fraction in the EHR. One question for the developer is whether there is any concern in interpreting adherence to the measure based on what has been noted in the literature of poor tolerance/adherence to the medication. The measure logic requires the patient to have at least 2 encounters during the measurement year to establish a relationship. Those encounters can be in any setting including electronic/phone encounters. Specifications are

consistent with the measure description. Reliability testing is not required for this measure as it was submitted for trial approval. Reliability testing plan included and will address all data elements and the effect of missing data, and compare to chart abstracted records, using Cohen's Kappa.

2a2.: ***Committee's Comments on Reliability-Testing:***

- Reliability testing plan included and will address all data elements and the effect of missing data, and compare to chart abstracted records, using Cohen's Kappa. Not required for a trial measures

2b1.: ***Committee's Comments on Validity-Specifications***:

- It was tested in a test EHR population size 15 and had 76% of data elements covered with a 100% pass rate. The testing plan specifies the number needed to test to assure 80% power to test for differences in Kappa statistics and performance rates. Measure testing will compare chart abstraction vs. electronic abstraction, sensitivity and specificity. They will also test for the frequency of exclusions to address threats to validity in more than one EHR. The measure is not risk-adjusted. Testing not required for a trial measure.

2b2.: ***Committee's Comments on Validity-Testing:***

- It was tested in a test EHR population size 15 and had 76% of data elements covered with a 100% pass rate. The testing plan specifies the number needed to test to assure 80% power to test for differences in Kappa statistics and performance rates. Measure testing will compare chart abstraction vs. electronic abstraction, sensitivity and specificity. They will also test for the frequency of exclusions to address threats to validity in more than one EHR. The measure is not risk-adjusted. Testing not required for a trial measure.

2b3-7.: ***Committee's Comments on Threats to Validity:***

- Potential threats to validity would be missing data and possibly the fact that patient refusal or allergies and other patients reasons are not exclusions. It was noted that many people are unable to comply with the dosing regimen.
- The measure is not risk adjusted - it is intended for a minority population.

2d.: ***Committee's Comments on Composite Performance Measure:***

- Not Applicable

Criterion 3. Feasibility

3. Feasibility is the extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

- The eMeasure is specified for use with an EHR as the data source.
- The developers provide an eMeasure Feasibility Scorecard of 2 EHRS (hospital and outpatient) testing all data elements required to calculation the measure. All data elements for both EHRs scored 3s (except Ejection Fraction < 40%) meaning the data elements are routinely collected as part of routine care and require no additional data entry from the clinician for the quality measure and no EHR user interface changes. Ejection Fraction <40% scored 2 in data standards meaning data element is not routinely collected as part of routine care and additional time and effort over and above routine care is required, but perceived to have some benefit.
- Per the Writing Committee recommendation, the developer changed "Diagnosis of Worsening Ischemic Heart Disease* to "Unstable Angina" better identify applicable patients for fixed combination therapy. As unstable angina is seen as a subset of ischemic heart disease, the feasibility rating would not be impacted.
- The developer provides the measure specifications free of charge to provider end users.

Questions for the Committee:

- *Are the required data elements routinely generated and used during care delivery?*
- *Are the required data elements available in electronic form, e.g., EHR or other electronic sources?*
- *Is the data collection strategy ready to be put into operational use?*
- *If an eMeasure, does the eMeasure Feasibility Score Card demonstrate acceptable feasibility in multiple EHR systems*

and sites?

Committee pre-evaluation comments
Criteria 3: Feasibility

3.: ***Committee's Comments on Feasibility:***

- Developers provide a feasibility scorecard from 1 inpatient and 1 outpatient EHR from the same vendor. Scorecard measured data availability, data accuracy, data standards, workflow and a total data element feasibility score for all data elements. Each data element scored at the highest level with the exception of ejection fraction < 40%, which scored 11 out of 12. Testing will continue. This meets the requirements for a trial measure.

Criterion 4: Usability and Use

4. Usability and Use evaluate the extent to which audiences (e.g., consumers, purchasers, providers, policymakers) use or could use performance results for both accountability and performance improvement activities.

- The developer provides plans for future accountability and quality improvement use for this new eMeasure.
- As the measure is newly developed, the developer states unintended consequences have yet to be identified.

Questions for the Committee *:*

- *Is the measure publicly reported?*
- *How can the performance results be used to further the goal of high-quality, efficient healthcare?*
- *Do the benefits of the measure outweigh any potential unintended consequences?*

Committee pre-evaluation comments
Criteria 4: Usability and Use

4.: ***Committee's Comments on Usability and Use:***

- As a new measure, it is intended for use at the clinician level. If successful in the trial, they plan to submit for CMS use under PQRS, possibly as early as 2017. A similar measure is currently used in the AHA's GWTG program for QI and benchmarking. A publication from that data suggested that 22% of eligible patients discharged from the hospital were discharged on the medication. This meets the requirements for a trial measure.

Criterion 5: Related and Competing Measures

Currently endorsed measures:

- 0081 : Heart Failure (HF): Angiotensin-Converting Enzyme (ACE) Inhibitor or Angiotensin Receptor Blocker (ARB) Therapy for Left Ventricular Systolic Dysfunction (LVSD)
- 0083 : Heart Failure (HF): Beta-Blocker Therapy for Left Ventricular Systolic Dysfunction (LVSD)

Previously endorsed measures:

- 0162: ACEI or ARB for left ventricular systolic dysfunction - Heart Failure (HF) Patients (CMS)
- 0610: Heart Failure - Use of ACE Inhibitor (ACEI) or Angiotensin Receptor Blocker (ARB) Therapy (ActiveHealth Management)
- 0615: Heart Failure - Use of Beta Blocker Therapy (ActiveHealth Management)

- The developer reports that measure specifications for the target population and medication therapies for ACEI, ARB, and beta-blocker are completely harmonized with 0081 and 0083.

Pre-meeting public and member comments

Comment by: David Smith
Organization: Public – Yale University
Comment#5147: I am writing in support of a proposed quality measure that has the potential to save thousands of lives annually by highlighting a preventable treatment deficiency, namely, the National Minority Quality Forum's submission (# 2764) regarding a fixed-dose Combination of Hydralazine and Isosorbide Dinitrate Therapy for Self-identified Black or African American Patients with Heart Failure (HF) and LVEF <40% on ACEI or ARB and Beta-blocker Therapy.
Today, less than 10% of eligible heart failure patients are being prescribed an FDA-approved treatment that's been proven to significantly reduce hospitalization and mortality rates. That's why I'm writing in support of the measure submitted by the National Minority Quality Forum (NMQF) that strongly encourages healthcare providers to ensure that eligible African American patients with heart disease receive the proper course of treatment. More despairingly is the fact that our current trainees are learning little about this treatment opportunity in their current curricula. As a professor, it is most alarming that other teachers and attending professionals do not know how to adequately prescribe or dose the medicines appropriately and that there IS NO GENERIC EQIVALENT. So, the perpetuation of this type of neglect has vast repercussions and dreadful prediction for the future that immediate address of this problem promises immense future returns.
The science behind the impact of this FDA-approved drug has been well documented. Its benefits have been published in the New England Journal of Medicine and other peer-reviewed sources, and the American College of Cardiology and American Heart Association have released detailed practice guidelines calling for this specific treatment protocol. Nonetheless, while published studies estimate that there are over 150,000 African Americans living in America who could benefit from this treatment, only 7% (or 11,000) of them are receiving it. As a consequence, experts have estimated that 6,655 blacks die prematurely every year.
An endorsement from the National Quality Forum (NQF) is considered the highest standard for healthcare quality, and sends a strong message to providers that measures are evidence-based, valid, and can help patients achieve better outcomes. I strongly believe that the proposed heart failure measure meets NQF's criteria, and encourage you to provide your formal endorsement in order to help facilitate widespread adoption of this treatment.
I appreciate the opportunity to weigh in on this important issue, and urge NQF to approve this quality measure submission. If I may lend any further words of support, please do not hesitate to call me.

Comment by: Jan Neil Basile, MD
Organization: Public - Medical University of South Carolina
Comment#5130: I am a clinical trialist and hypertension specialist who cares for patients with heart failure including a large panel of AA patients.
Health care disparities continue to exist in minority populations for many reasons including clinical access, formulary availability, mistrust, socioeconomic position, and cultural and language issues just to mention a few. When there is solid clinical trial evidence of outcome benefit in a minority population given a IA recommendation of benefit from the American Heart Association (2014), quality measures should ensure that clincians are held to this standard of care when having the opportunity to treat such patients.
Based on the African American Heart Failure Trial (AHEFT) in 2004 published in the NEJM, self described blacks who had heart failure (HF) with a reduced ejection fraction gained a significant 43% reduction in death, a reduction in first or recurrent hospitalization for HF, and an improvement in quality of life when fixed-dose isosorbide dinitrate/hydralazine was added to an ACE inhibitor or ARB + a Beta Blocker. This is believed to occur because of a unique pathophysiologic derangement in nitric oxide upregulation in Blacks.
By making isosorbide dinitrate/hydralaziine a quality improvement measure in blacks who meet the definition of the AHEFT clinical trial we will ensure that this minority population who face tremendous obstacles from the social determinants of health to at least be assured of getting the best evidence base for clinical care.

Comment by: Dr. David A. Mann, MD, PhD
Organization: Public
Comment#5129: Representing my own opinions, and not that of any organizations that I work for or are affiliated with, I support the aim of proposed measure 2764 but not necessarily its exact language.
I fully support the goal of providing Black heart failure patients with optimal therapy for their heart failure. And I think that combination therapy with hydralazine and isosorbide dinitrate in the setting described in the measure has good evidence behind it.
I am not sure, however, that medical science is certain that only the specific dose combination used in the A-HeFT trial, provided in one particular proprietary combination formulation, is effective for this indication. Therefore I am hesitant to endorse a measure that appears to require the use of one particular proprietary formulation.
Immediate prescription of this fixed dose proprietary product bypasses dose titration, does not allow for individualized therapy, precludes use of more affordable generics, and may potentially generate more adverse effects than would occur with individualized dose titration to this therapeutic goal. I don't think that represents optimal care for patients.
How does the current language match up with underlying intent? If the intent is to encourage combination therapy with these two agents without requiring a particular product or a particular dosage, the language seems too restrictive. If the intent is to encourage the exact doses used in the A-HeFT trial, then the language is too lenient: any fixed dose

combination at any doses of the agents would meet the stated measure.
As a quality measure, the current language could be problematic. If a patient is titrated to 100% of the A-HeFT dose of agent 1 but only tolerates 75% of the dose of agent 2, is that patient a fail on this metric? I would hope not, but by its exact language, the answer would seem to be yes.

Comment by: Elizabeth O. Ofili, MD
Organization: Public
Comment#5123: I am a cardiologist in clinical practice with a large number of African American patients. I see the daily struggles of patients whose quality of life is deeply impacted. The African American Heart Failure Trial (AHEFT) was prematurely stopped by the DSMB and published in NEJM in 2004. This landmark study showed that self-described African Americans or Blacks, had over 40% survival, as well as hospitalization and quality of life benefits when treated with fixed dose combination of isosorbide dinitrate and hydralazine (FDC I/H) on top of standard therapy.The evidence was so strong that it received a level 1A by the guideline writing committee and has been affirmed by each committee since then. It is a health equity issue that the most recent analysis of America's superior hospitals, show that very few African American patients are receiving this therapy. I join with others concerned with health disparities and the attainment of health equity, in asking NQF to add FDC I/H as a standard of care for self-described African Americans, as contained in every heart failure guideline since 2004.Thank you for helping us to deliver quality heart failure care for our patients. Elizabeth Ofili, MD, MPH, FACC Professor of Medicine and Attending Cardiologist

Comment by: Dr. Traci Ferguson, WellCare; Ms. Kiersten Adams
Organization: HPL- WellCare Health Plans
Comment#5121: WellCare Health Plans, Inc. fully supports the endorsement of NQF quality measure #2764, "Fixed-dose Combination of Hydralazine and Isosorbide Dinitrate Therapy for Self-identified Black or African American Patients with Heart Failure and LVEF <40% on ACEI or ARB and Beta-blocker Therapy." The benefits of combining Hydralazine and Isosorbide Dinitrate have been published in various peer-reviewed sources, including the New England Journal of Medicine. Additionally, this approach is supported by both the American College of Cardiology and the American Heart Association.
As one of the country's largest health care companies dedicated solely to serving public program beneficiaries, we see the effects that disparities can have on health outcomes. Adoption of this measure will ensure that eligible African American patients with symptomatic heart failure receive the proposed course of treatment. WellCare believes that endorsement of this quality measure submitted by the National Minority Quality Forum will increase the utilization of this evidence-based standard of care, thus saving thousands of lives each year.

Comment by: Tamarah Duperval-Brownlee, MD, MPH, MBA
Organization: Public
Comment#5120: An endorsement from the National Quality Forum (NQF) is considered the highest standard for healthcare quality, and sends a strong message to providers that measures are evidence-based, valid, and can help patients achieve better outcomes. I strongly believe that the proposed heart failure measure meets NQF's criteria, and encourage you to provide your formal endorsement in order to help facilitate widespread adoption of this treatment.
I appreciate the opportunity to weigh in on this important issue, and urge NQF to approve this quality measure submission.

Comment by: Cassandra McCullough; Mr. Andrew M. Rosenberg
Organization: Association of Black Cardiologists
Comment#5117: On behalf of over 1,500 healthcare professionals dedicated to treating patients with cardiovascular disease and to achieving health equity for all through the elimination of disparities, we are writing to express our strong support of quality measure #2764 to promote the most effective course of treatment for eligible African Americans with heart failure (HF).
Founded in 1974, the ABC is a nonprofit organization with an international membership comprised of health professionals, lay members of the community (Community Health Advocates), corporate members, and institutional members. At the Association of Black Cardiologists (ABC), there is no issue more central to our cause than ensuring that all Americans are given the foremost care to combat, treat, and overcome cardiovascular disease. This includes the

recognition that cardiovascular disease occurs disproportionately in African Americans. The National Minority Quality Forum's (NMQF's) recently proposed quality measure represents a critical step towards furthering these goals, and we hope that you will join us in encouraging its widespread adoption by providers across the country.
The ABC is not new to this issue, indeed, our organization played a key role in the execution of the landmark African-American Heart Failure Trial (A-HeFT) that provided the clinical evidence upon which the NMQF's proposed quality measure is based. That data was published in 2004 in the New England Journal of Medicine as "breaking news," and was highlighted later that year at the annual American Heart Association Scientific Meeting.
We recall that the A-HeFT trial was terminated prematurely due to the significant outcomes present in the treated group. In fact, the results were so positive, the FDA's Data Safety Monitoring board deemed it unethical to allow the untreated group to proceed without the opportunity to receive this profound benefit.
The merit of this proposed measure—and our support of it—is defined by hard data and indisputable evidence: the A-HeFT study demonstrated that its fixed-dose standard of care reduced mortality rates in African Americans with heart failure by over 40% while also significantly reducing first-time hospitalizations. Yet despite the consensus that emerged from the medical community on the regimen's benefits, today it reaches only 7% of over 150,000 clinically-eligible African American patients across the country.
This concern should not be unique to ABC, NMQF, and other organizations focused on eliminating healthcare disparities. Instead, this issue speaks to anyone who believes that standards of care should be evidence-based, valid, and help patients achieve better outcomes. The role of our organization is to advocate for the cardiovascular treatments that will help all patients live fuller and longer lives, but nowhere is this more important than in our efforts to address disparities among people of color.

Comment by: Mr. Ilen Bell
Organization: Public
Comment#5112: As a co-founder of Black Fitness Today, a leader in promoting health in the African American community, I am writing in support of a proposed quality measure that has the potential to save thousands of lives annually by highlighting a preventable treatment deficiency, namely, the National Minority Quality Forum's submission (# 2764) regarding a fixed-dose Combination of Hydralazine and Isosorbide Dinitrate Therapy for Self-identified Black or African American Patients with Heart Failure (HF) and LVEF <40% on ACEI or ARB and Beta-blocker Therapy.. When considering the number of lives that can potentially be saved annually -- over the past decade, approximately 66,550 African Americans have perished without being provided the opportunity to choose Hydralazine and Isosorbide Dinitrate Therapy.
It is alarming that only "10% of eligible heart failure patients are being prescribed this FDA-approved treatment," which "has been proven to reduce mortality in blacks by 43% and first-time hospitalizations for HF by 38%." That's why I'm writing in support of the measure submitted by the National Minority Quality Forum (NMQF) that strongly encourages healthcare providers to ensure that eligible African American patients with heart disease receive the proper course of treatment.

Comment by: Oladipupo Olafiranye
Organization: Public
Comment#5111: "I am writing in strong support of the National Minority Quality Forum's (NMQF's) submission regarding a fixed-dose Combination of Hydralazine and Isosorbide Dinitrate Therapy for Self-identified Black or African American Patients with Heart Failure and left ventricular ejection fraction of less 40% on ACEI or ARB and Beta-blocker Therapy. As a member of the Association of Black Cardiologists (ABC), I strongly believe that this quality measure has the potential to save thousands of lives annually by highlighting a preventable treatment deficiency.Although, heart failure affects millions of Americans, African American are disproportionately affected by heart failure with age-adjusted death rates remaining higher in African Americans than other populations. And despite the fact that there is an FDA-approved treatment that has been proven to be particularly effective in African Americans, only a small percentage of those who are clinically eligible are receiving the treatment."

Comment by: David Maron, MD
Organization: Public
Comment#5107: "Although clinical trial evidence supports the use of fixed-dose hydralazine and isosorbide dinitrate to

improve survival in African Americans with advanced heart failure, less than 10% of eligible patients receive this therapy. This proposed quality measure will raise awareness and increase the appropriate treatment of eligible African American patients with heart failure."

Comment by: James Januzzi, Jr., MD
Organization: Public - Harvard Medical School
Comment#5094: "As a clinician and clinical trialist, I am amazed at the gap between trial results and real-world prescription of a life-saving therapy for patients with HF such as we see with the under-use of hydralazine/nitrates in Blacks/African Americans. I agree this is a hugely important topic in need of further scrutiny and comment.
James Januzzi, MD; Professor of Medicine, Harvard Medical School."

Comment by: LaVarne Burton; Mr. Michael Spigler
Organization: American Kidney Fund
Comment#5049: "The American Kidney Fund (AKF) offers its full support of NQF# 2764. AKF is dedicated to ensuring that every kidney patient has access to health care, and that every person at risk for kidney disease is empowered to prevent it. As the nation's largest not-for-profit organization serving people with, and at risk for, kidney disease, we have helped more than 1 million low-income dialysis patients to access lifesaving medical care since our founding in 1971.
There are currently 31 million Americans living with some level of chronic kidney disease (CKD). Of these 31 million, minority populations face a greater risk of progressing from early CKD to kidney failure. African Americans with CKD, in particular, are disproportionately affected. More than 1 in 3 kidney failure patients living in the United States is African American.
Several studies have also shown that heart disease is a primary risk factor for developing kidney failure. That means that for the estimated 150,000 African Americans living with heart failure (HF), their risk for ultimately developing kidney failure is even greater.
AKF is committed to eliminating health disparities in CKD. The benefits of fixed-dose hyralazine and isosorbide dinitrate have been published in the New England Journal of Medicine and other peer-reviewed sources, yet only 7% of clinically eligible African Americans receive the treatment. We believe that adoption of this quality measure will improve African Americans' access to this life-saving treatment and will not only directly improve the outcomes for HF, but also indirectly improve the outcomes for African Americans at-risk for CKD."

Comment by: Nilam Sheth, PharmD
Organization: Public
Comment#5039: "I am writing in support of a proposed quality measure that has the potential to save thousands of lives annually by highlighting a preventable treatment deficiency, namely, the National Minority Quality Forum's submission (# 2764) regarding a fixed-dose Combination of Hydralazine and Isosorbide Dinitrate Therapy for Self-identified Black or African American Patients with Heart Failure (HF) and LVEF <40% on ACEI or ARB and Beta-blocker Therapy.
Today, less than 10% of eligible heart failure patients are being prescribed an FDA-approved treatment that's been proven to significantly reduce hospitalization and mortality rates. That's why I'm writing in support of the measure submitted by the National Minority Quality Forum (NMQF) that strongly encourages healthcare providers to ensure that eligible African American patients with heart disease receive the proper course of treatment.
The science behind the impact of this FDA-approved drug has been well documented. Its benefits have been published in the New England Journal of Medicine and other peer-reviewed sources, and the American College of Cardiology and American Heart Association have released detailed practice guidelines calling for this specific treatment protocol.
Nonetheless, while published studies estimate that there are over 150,000 African Americans living in America who could benefit from this treatment, only 7% (or 11,000) of them are receiving it. As a consequence, experts have estimated that 6,655 blacks die prematurely every year.
An endorsement from the National Quality Forum (NQF) is considered the highest standard for healthcare quality, and sends a strong message to providers that measures are evidence-based, valid, and can help patients achieve better outcomes. I strongly believe that the proposed heart failure measure meets NQF's criteria, and encourage you to provide your formal endorsement in order to help facilitate widespread adoption of this treatment.
I appreciate the opportunity to weigh in on this important issue, and urge NQF to approve this quality measure submission."

Comment by: Chris Adamec, MPA
Organization: Public -The Healthcare Leadership Council (HLC)
Comment#5038: "Comments on Fixed-dose Combination of Hydralazine and Isosorbide Dinitrate Therapy for Self-identified Black or African American Patients with Heart Failure and LVEF <40% on ACEI or ARB and Beta-blocker Therapy
The Healthcare Leadership Council (HLC) respectfully submits these comments in connection with NQF 2015 Cardiovascular Project. In this response, we support efforts by the National Minority Quality Forum (NMQF), the Association of Black Cardiologists (ABC), and other stakeholders to support the proposed measure that would support fixed-dose hyralazine and isosorbide dinitrate for self - identified Black or African American patients with heart failure. As you may be aware, today, only a very small number (about 7%) of African Americans who are clinically eligible for the FDA-approved therapy are getting it. As a consequence, over 6,500 blacks die prematurely every year because they are not receiving or adhering to standard of care. The quality measure would act to strongly encourage healthcare providers to ensure that eligible African American patients with heart disease receive the proper course of care treatment.
HLC, a coalition of chief executives from all disciplines within American healthcare, is the exclusive forum for the nation's healthcare leaders to jointly develop policies, plans, and programs to achieve their vision of a 21st century system that makes affordable, high-quality care accessible to all Americans. Members of HLC – hospitals, academic health centers, health plans, pharmaceutical companies, medical device manufacturers, biotech firms, health product distributors, pharmacies, and information technology companies – envision a quality-driven system that fosters innovation. HLC members advocate measures to increase the quality and efficiency of American healthcare by emphasizing wellness and prevention, care coordination, and the use of evidence-based medicine, while utilizing consumer choice and competition to elevate value.
We encourage NQF to endorse quality measure #2764, "Fixed-dose Combination of Hydralazine and Isosorbide Dinitrate Therapy for Self-identified Black or African American Patients with Heart Failure and LVEF <40% on ACEI or ARB and Beta-blocker Therapy." The benefits of this approach have been published in the New England Journal of Medicine and other peer-reviewed sources. They also align with guidelines from the American College of Cardiology and the American Heart Association.
HLC appreciates this opportunity to comment on the proposed Cardiovascular measures. We believe there is tremendous potential for the health care industry as a whole to bring about robust collaboration and quality improvement in achieving our shared goal of improving the value of healthcare delivery for all.**"**

Comment by: Mr. Juan M. Cofield
Organization: NAACP Board of Directors
Comment#5037: "The NAACP Board of Directors adopted Health equality for all Americans includig a healthy life and high-quality health care as one of 5 Game changers. In support of the this Game Changer, the New England Area Conference (NEAC) of the NAACP strongly supports and advocates that African Americans who are clinical eligible for the FDA-approved therapy for Heart Failure. Further, NEAC encourages healthcare providersensure that eligible African American patients with heart disease receive the proper course of care treatment - namely, the fixed dose of Hydralazine and isosobide dinitrate."

Comment by: Mark S. Johnson
Organization: Howard University
Comment#5154: I would like to comment about the above referenced recommendation. While I agree that it would be useful to have more African American HF patients take Hydralazine and Isosorbide Nitrate as part of the HF arsenal, I strongly reject the recommendation that this only be given in the fixed dose combination that is currently on the market. In my clinical experience few patients, especially elderly patients have been able to tolerate the fixed combination dose. The mean age of the patients who were in the NEJM article was the 57. Even in these patients the side effects rates were high (48% had headache and 27% had dizziness). Only 68% were able to reach target dose.
It is possible that the current fixed dose was chosen to avoid generic duplication. Patients should be given lower doses and titrated slowly.
Mark Johnson, MD MPH
Professor, Community and Family Medicine

Measure Number (*if previously endorsed*)**:** Click here to enter NQF number

Measure Title: Heart Failure: Fixed-dose Combination of Hydralazine and Isosorbide Dinitrate Therapy for Self-identified Black and African American Patients with Heart Failure and LVEF <40% on ACEI or ARB and Beta-blocker Therapy

IF the measure is a component in a composite performance measure, provide the title of the Composite Measure here: Click here to enter composite measure #/ title

Date of Submission: Click here to enter a date

Instructions

- *For composite performance measures:*
  - *A separate evidence form is required for each component measure unless several components were studied together.*
  - *If a component measure is submitted as an individual performance measure, attach the evidence form to the individual measure submission.*
- Respond to all questions as instructed with answers immediately following the question. All information needed to demonstrate meeting the evidence subcriterion (1a) must be in this form. An appendix of *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 10 pages (*incudes questions/instructions*; minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the evidence for this measure meets NQF's evaluation criteria.

Evidence to Support the Measure Focus

The measure focus is evidence-based, demonstrated as follows:

- Health outcome: [3] a rationale supports the relationship of the health outcome to processes or structures of care. Applies to patient-reported outcomes (PRO), including health-related quality of life/functional status, symptom/symptom burden, experience with care, health-related behavior.
- Intermediate clinical outcome: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured intermediate clinical outcome leads to a desired health outcome.
- Process: [5] a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured process leads to a desired health outcome.
- Structure: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured structure leads to a desired health outcome.
- Efficiency: [6] evidence not required for the resource use component.

Notes

3. Generally, rare event outcomes do not provide adequate information for improvement or discrimination; however, serious reportable events that

are compared to zero are appropriate outcomes for public reporting and quality improvement.

4. The preferred systems for grading the evidence are the U.S. Preventive Services Task Force (USPSTF) grading definitions and methods, or Grading of Recommendations, Assessment, Development and Evaluation (GRADE) guidelines.

5. Clinical care processes typically include multiple steps: assess → identify problem/potential problem → choose/plan intervention (with patient input) → provide intervention → evaluate impact on health status. If the measure focus is one step in such a multistep process, the step with the strongest evidence for the link to the desired outcome should be selected as the focus of measurement. Note: A measure focused only on collecting PROM data is not a PRO-PM.

6. Measures of efficiency combine the concepts of resource use and quality (see NQF's Measurement Framework: Evaluating Efficiency Across Episodes of Care; AQA Principles of Efficiency Measures).

HEALTH OUTCOME/PRO PERFORMANCE MEASURE *If not a health outcome or PRO, skip to 1a.3*

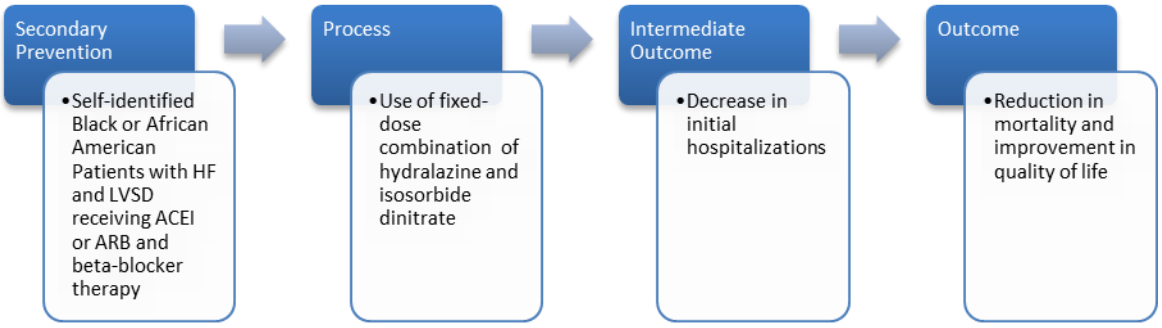
1a.2. Briefly state or diagram the path between the health outcome (or PRO) and the healthcare structures, processes, interventions, or services that influence it.

1a.2.1. State the rationale supporting the relationship between the health outcome (or PRO) to at least one healthcare structure, process, intervention, or service (*i.e., influence on outcome/PRO*).

Note: For health outcome/PRO performance measures, no further information is required; however, you may provide evidence for any of the structures, processes, interventions, or service identified above.

INTERMEDIATE OUTCOME, PROCESS, OR STRUCTURE PERFORMANCE MEASURE

1a.3. Briefly state or diagram the path between structure, process, intermediate outcome, and health outcomes. Include all the steps between the measure focus and the health outcome.



The African-American Heart Failure Trial (A-HeFT) first published in 2004 demonstrated that there is significant benefit for African American patients who receive a fixed-dose combination therapy of hydralazine and isosorbide dinitrate. This trial built on the findings from the two Vasodilator-Heart Failure Trials (V-HeFT). A-HeFT, which was ended early due to the mortality rates in the placebo population, demonstrated a 43% reduction in mortality, 33% decrease in initial hospitalizations, and a 50% improvement in patient-reported quality of life (Taylor, 2004, Sharma, 2014). These results clearly demonstrate that the fixed-dose combination therapy significantly improves patient morbidity, mortality and quality of life in this clinical cohort. There is no substitute for the fixed-dose combination therapy.

1a.4.2. Identify guideline recommendation number and/or page number and **quote verbatim, the specific guideline recommendation**.

2013 ACCF/AHA Guideline for the Management of Heart Failure (e179)

The combination of hydralazine and isosorbide dinitrate is recommended to reduce morbidity and mortality for patients self-described as African Americans with NYHA class III–IV HFrEF receiving optimal therapy with ACE inhibitors and beta blockers, unless contraindicated. (**Class I; Level of Evidence: A**)

HFSA 2010 Comprehensive Heart Failure Practice Guideline

p. e80-81:

A combination of hydralazine and isosorbide dinitrate is recommended as part of standard therapy in addition to beta blockers and ACE inhibitors for African Americans with HF and reduced LVEF.

- NYHA III or IV HF (**Strength of Evidence = A**)
- NYHA II HF (**Strength of Evidence = B**)

p. e171:

The combination of hydralazine/isosorbide dinitrate is recommended as standard therapy for African American women with moderate to severe HF symptoms who are on background neurohormonal inhibition. (**Strength of Evidence = B**)

1a.4.3. Grade assigned to the quoted recommendation with definition of the grade:

2013 ACCF/AHA Guideline for the Management of Heart Failure

Class of Recommendation: Class I

Definitions:

Class of Recommendation (COR) is an estimate of the size of the treatment effect considering risks versus benefits in addition to evidence and/or agreement that a given treatment or procedure is or is not useful/effective or in some situations may cause harm.

Class I: Procedure/Treatment should be performed/administered

HFSA 2010 Comprehensive Heart Failure Practice Guideline

Strength of Recommendation: Is recommended

Definition: The phrase ‘‘is recommended’’ should be taken to mean that the recommended therapy or management process should be followed as often as possible in individual patients. Exceptions are carefully delineated.

1a.4.4. Provide all other grades and associated definitions for recommendations in the grading system. (*Note: If separate grades for the strength of the evidence, report them in section 1a.7.*)

2013 ACCF/AHA Guideline for the Management of Heart Failure

Class of Recommendation (COR) is an estimate of the size of the treatment effect considering risks versus benefits in addition to evidence and/or agreement that a given treatment or procedure is or is not useful/effective or in some situations may cause harm.

Class I: Procedure/Treatment should be performed/administered

Class IIa: It is reasonable to perform procedure/administer treatment

Class IIb: Procedure/Treatment may be considered

Class III: No benefit (Not helpful or No proven benefit)

Class III: Harm (Excess cost w/o benefit or Harmful to patients)

HFSA 2010 Comprehensive Heart Failure Practice Guideline

Strength of Recommendation:

The HFSA guideline employs the categorization for strength of recommendation outlined in Table 1.3. There are several degrees of favorable recommendations and a single category for therapies felt to be not effective. The phrase ‘‘is recommended’’ should be taken to mean that the recommended therapy or management process should be followed as often as possible in individual patients. Exceptions are carefully delineated. ‘‘Should be considered’’ means that a majority of patients should receive the intervention, with some discretion involving individual patients. ‘‘May be considered’’ means that individualization of therapy is indicated (Table 1.3). When the available evidence is considered to be insufficient or too premature, or consensus fails, issues are labeled un-resolved and included as appropriate at the end of the relevant section.

Is recommended: Part of routine care; exceptions to therapy should be minimized

Should be considered: Majority of patients should receive the intervention; some discretion in application to individual patients should be allowed

May be considered: Individualization of therapy is indicated

Is not recommended: Therapeutic intervention should not be used

1a.7. FINDINGS FROM SYSTEMATIC REVIEW OF BODY OF THE EVIDENCE SUPPORTING THE MEASURE

If more than one systematic review of the evidence is identified above, you may choose to summarize the one (or more) for which the best information is available to provide a summary of the quantity, quality, and consistency of the body of evidence. Be sure to identify which review is the basis of the responses in this section and if more than one, provide a separate response for each review.

1a.7.1. What was the specific structure, treatment, intervention, service, or intermediate outcome addressed in the evidence review?

2013 ACCF/AHA Guideline for the Management of Heart Failure

This guideline covers multiple management issues for the adult patient with Heart Failure (HF) including the guideline-directed medical therapy (GDMT) such as the combination of hydralazine and isosorbide dinitrate for African American patients receiving ACE/ARB therapy.

HFSA 2010 Comprehensive Heart Failure Practice Guideline

The guideline developed by HFSA in 2010 addresses prevention, evaluation, disease management and therapies (pharmacologic and device) and end of life management.

1a.7.2. Grade assigned for the quality of the quoted evidence with definition of the grade:

2013 ACCF/AHA Guideline for the Management of Heart Failure

An overall grade for the quality of evidence was not assigned. Rather, the quality of a study (or set of studies) supporting a recommendation was graded on an estimate of the certainty or precision of the treatment effect.

The recommendation to support this measure is Level of Evidence of A: Data derived from multiple randomized clinical trials or meta- analyses. References used to determine level of evidence must be provided and cited with the recommendation.

HFSA 2010 Comprehensive Heart Failure Practice Guideline

The recommendations from this guideline in support of the measure are Strength of Evidence:

- A: Randomized, Controlled, Clinical Trials; May be assigned based on results of a single methodologically rigorous trial and
- B: Cohort and Case-Control Studies Post hoc, subgroup analysis, and meta-analysis; Prospective observational studies or registries

1a.7.3. Provide all other grades and associated definitions for strength of the evidence in the grading system.

2013 ACCF/AHA Guideline for the Management of Heart Failure

Level of Evidence (LOE) is an estimate of the certainty or precision of the treatment effect.

Level of Evidence of A: Data derived from multiple randomized clinical trials or meta- analyses.

Level of Evidence B: Data derived from a single randomized trial, or nonrandomized studies. References used to determine level of evidence must be provided and cited with the recommendation.

Level of Evidence C: Consensus opinion of experts, case studies, or standard of care.

HFSA 2010 Comprehensive Heart Failure Practice Guideline

Strength of evidence is determined both by the type of evidence available and the assessment of validity, applicability, and certainty of a specific type of evidence. Following the lead of previous guidelines, strength of evidence in this guideline is heavily dependent on the source or type of evidence used. The HFSA guideline process has used three grades (A, B, or C) to characterize the type of evidence available to support specific recommendations.

Strength of Evidence A: Randomized, Controlled, Clinical Trials; May be assigned based on results of a single methodologically rigorous trial and

Strength of evidence B: Cohort and Case-Control Studies Post hoc, subgroup analysis, and meta-analysis; Prospective observational studies or registries

Strength of Evidence C: Expert Opinion; Observational studies-epidemiologic findings; Safety reporting from large-scale use in practice

1a.7.4. What is the time period covered by the body of evidence? (*provide the date range, e.g., 1990-2010*).
Date range: An extensive evidence review was conducted through October 2011 and includes selected other

references through April 2013 for the 2013 ACCF/AHA Guideline for the Management of Heart Failure. No information on the time period was provided for the HFSA 2010 Comprehensive Heart Failure Practice Guideline.

QUANTITY AND QUALITY OF BODY OF EVIDENCE

1a.7.5. How many and what type of study designs are included in the body of evidence? (*e.g., 3 randomized controlled trials and 1 observational study*)

2013 ACCF/AHA Guideline for the Management of Heart Failure

The body of evidence supporting the recommendations on guideline-directed medical therapy includes:

4 randomized controlled trials (RCTs)

2 post hoc retrospective analyses

HFSA 2010 Comprehensive Heart Failure Practice Guideline

Specific information on the number of studies included in the body of evidence not provided.

1a.7.6. What is the overall quality of evidence <u>across studies</u> in the body of evidence? (*discuss the certainty or confidence in the estimates of effect particularly in relation to study factors such as design flaws, imprecision due to small numbers, indirectness of studies to the measure focus or target population*)

2013 ACCF/AHA Guideline for the Management of Heart Failure

The recommendation for this medication therapy is rated as Level of Evidence A, meaning that the data was derived from multiple RCTs or meta-analyses. Additional information on the overall quality of evidence across the RCTs is not provided.

HFSA 2010 Comprehensive Heart Failure Practice Guideline

The recommendations for hydralazine and isosorbide dinitrate therapy are rated as Strength of Evidence A and B, meaning that the data was derived from RCTs, cohort and Case-Control Studies Post hoc, subgroup analysis, meta-analysis or prospective observational studies or registries. Additional information on the overall quality of evidence is not provided.

ESTIMATES OF BENEFIT AND CONSISTENCY ACROSS STUDIES IN BODY OF EVIDENCE

1a.7.7. What are the estimates of benefit—magnitude and direction of effect on outcome(s) <u>across studies</u> in the body of evidence? (*e.g., ranges of percentages or odds ratios for improvement/ decline across studies, results of meta-analysis, and statistical significance*)

Fonarow GC, Yancy CW, Hernandez AF, Peterson ED, Spertus JA, Heidenreich PA. Potential impact of optimal implementation of evidence-based heart failure therapies on mortality. Am Heart J. 2011;161:1024–1030.e3.

In 2011, Fonarow and colleagues complete a post hoc retrospective analysis to identify current gaps in care for patients with HF and reduced LVEF and to quantify the potential benefits of specific evidence based therapies. Review of RCT data for combination of hydralazine and isosorbide dinitrate showed that a patient's relative risk for death was reduced by 43% and the number needed to treat for mortality (standardized to 12 months) was 21. If this combination was prescribed to all of the patients for which it was appropriate, then 9.8% or 6,655 lives could be saved each year.

2013 ACCF/AHA Guideline for the Management of Heart Failure

p. e179:

In a large-scale trial that compared the vasodilator combination with placebo, the use of hydralazine and isosorbide dinitrate reduced mortality but not hospitalizations in patients with HF treated with digoxin and diuretics but not an ACE inhibitor or beta blocker. However, in 2 other trials that compared the vasodilator combination with an ACE inhibitor, the ACE inhibitor produced more favorable effects on survival. A post hoc retrospective analysis of these vasodilator trials demonstrated particular efficacy of isosorbide dinitrate and hydralazine in the African American cohort. In a subsequent trial, which was limited to patients self-described as African American, the addition of a fixed-dose combination of hydralazine and isosorbide dinitrate to standard therapy with an ACE inhibitor or ARB, a beta blocker, and an aldosterone antagonist offered significant benefit.

The combination of hydralazine and isosorbide dinitrate is recommended for African Americans with HFrEF who remain symptomatic despite concomitant use of ACE inhibitors, beta blockers, and aldosterone antagonists. Whether this benefit is evident in non–African Americans with HFrEF remains to be investigated. The combination of hydralazine and isosorbide dinitrate should not be used for the treatment of HFrEF in patients who have no prior use of standard neurohumoral antagonist therapy and should not be substituted for ACE inhibitor or ARB therapy in patients who are tolerating therapy without difficulty. Despite the lack of data with the vasodilator combination in patients who are intolerant of ACE inhibitors or ARBs, the combined use of hydralazine and isosorbide dinitrate may be considered as a therapeutic option in such patients.

HFSA 2010 Comprehensive Heart Failure Practice Guideline

p. e81:

The Vasodilator Heart Failure Trial (V-HeFT) was the first major randomized HF trial and was conducted in Veterans Administration hospitals throughout the US. Patients who remained symptomatic with mild to severe symptoms of HF despite treatment with diuretics and digoxin were randomized to a combination of hydralazine and isosorbide dinitrate or prazosin or placebo. The combination of hydralazine and isosorbide dinitrate was associated with a reduction in all-cause mortality compared to both placebo and prazosin that was of borderline statistical significance (P = .053). In V-HeFT II, the combination of hydralazine and isosorbide dinitrate was compared with enalapril in a population similar to V-HeFT I. All- cause mortality was 28% lower with enalapril than with the hydralazine isosorbide dinitrate combination. However, quality of life and peak exercise capacity as measured by peak oxygen consumption were better with hydralazine-isosorbide dinitrate.

The African-American Heart Failure Trial (A-HeFT) enrolled 1050 self-identified African-American patients

who had NYHA class III or IV HF with dilated ventricles and reduced LVEF. In this placebo-controlled, blinded, and randomized trial, subjects were randomly assigned to receive a fixed combination of isosorbide dinitrate plus hydralazine or placebo in addition to standard therapy for HF. The primary end point was a composite score made up of weighted values for death from any cause, a first hospitalization for HF, and change in the quality of life. The study was terminated early because of a significantly higher mortality rate in the placebo group than in the group given the fixed combination of isosorbide dinitrate plus hydralazine (10.2% vs 6.2%, P = .02). The mean primary composite score was significantly better in the group given isosorbide dinitrate plus hydralazine than in the placebo group, as were its individual components: 43% reduction in the rate of death from any cause, 33% relative reduction in the rate of first hospitalization for HF, and an improvement in the quality of life. These results taken together constitute a strong recommendation for the addition of the fixed combination of isosorbide dinitrate/hydralazine to the standard medical regimen for HF in African Americans. Data cannot exclude a benefit of the isosorbide dinitrate/hydralazine combination in non-African Americans when added to the standard medical regimen for HF.

p. e171:

The A-HeFT (African-American Heart Failure Trial) confirmed the benefit of hydralazine/isosorbide dinitrate in black HF patients. Importantly, 40% of the A-HeFT cohort were women. An analysis of outcomes by gender in A-HeFT showed that fixed-dose combined hydralazine/ isosorbide dinitrate improved HF outcomes in both men and women. There were no gender differences between men and women in the benefit of hydralazine/isosorbide dinitrate on the primary composite score, time to first HF hospitalization, and event-free survival.

1a.7.8. What harms were studied and how do they affect the net benefit (benefits over harms)?

2013 ACCF/AHA Guideline for the Management of Heart Failure

p. e179:

Adherence to this combination has generally been poor because of the large number of tablets required, frequency of administration, and the high incidence of adverse reactions. Frequent adverse effects include headache, dizziness, and gastrointestinal complaints. Nevertheless, the benefit of these drugs can be substantial and warrant a slower titration of the drugs to enhance tolerance of the therapy.

HFSA 2010 Comprehensive Heart Failure Practice Guideline

Potential harms were not addressed in this review of the evidence.

UPDATE TO THE SYSTEMATIC REVIEW(S) OF THE BODY OF EVIDENCE

1a.7.9. If new studies have been conducted since the systematic review of the body of evidence, provide for <u>each</u> new study: 1) citation, 2) description, 3) results, 4) impact on conclusions of systematic review.

Two additional analyses from A-HeFT were published after the publication of the 2013 ACCF/AHA Guideline for the Management of Heart Failure.

Note: Text below for description and results is verbatim from the article abstract.

Anand IS, Win S, Rector TS, Cohn JN, Taylor AL. Effect of fixed-dose combination of isosorbide dinitrate and hydralazine on all hospitalizations and on 30-day readmission rates in patients with heart failure: results from the African-American Heart Failure Trial. Circ Heart Fail. 2014;7:759-65. doi: 10.1161/CIRCHEARTFAILURE.114.001360. Epub 2014 Jun 26.

Background: Fixed-dose combination of isosorbide dinitrate and hydralazine (FDC-I/H) reduced mortality by 43% and death or first hospitalization for heart failure (HF) by 37% in the African-American Heart Failure Trial (A-HeFT). Reduction in mortality makes it difficult to determine the effect on hospitalizations unless the analysis adjusts for death as a competing risk.

Methods and Results: In A-HeFT, 1050 self-identified black patients with moderate to severe HF were randomized to FDC-I/H or placebo. The effects of FDC-I/H on first and all hospitalizations and 30-day readmission rates were analyzed. Deaths as competing risks were adjusted using Fine-Gray regression and joint models of hospitalizations and mortality. There were 558 all-cause and 251 HF hospitalizations in placebo compared with 435 and 173 hospitalizations in the FDC-I/H group. Adjusting for deaths as a competing risk, the effect of FDC-I/H on the first hospitalization for HF, expressed in hazard ratio (95% confidence interval), was 0.61 (0.47-0.80; P<0.001) and 0.88 (0.72-1.06; P=0.18) on the first all-cause hospitalization. The effect of FDC-I/H on all recurrent hospitalizations for HF was 0.66 (0.52-0.83; P=0.0005), similar to the effect on the first hospitalizations for HF, whereas the effect on all hospitalizations for any cause was 0.75 (0.63-0.91; P=0.003). The 30-day all-cause readmission rate after the first hospitalization for HF was 23.6% (29 of 123) in placebo versus 14.8% (12 of 81) in the FDC-I/H group, but the effect (0.59; 0.30-1.16; P=0.12) in this small subgroup was not significant.

Conclusions: Treatment with FDC-I/H was associated with a substantial reduction in the first and recurrent HF hospitalizations, and in total all-cause hospitalizations, reducing the total burden of costly and distressing hospitalizations.

McNamara DM, Taylor AL, Tam SW, Worcel M, Yancy CW, Hanley-Yanez K, Cohn JN, Feldman AM. G-protein beta-3 subunit genotype predicts enhanced benefit of fixed-dose isosorbide dinitrate and hydralazine: results of A-HeFT. JACC Heart Fail. 2014;2:551-7. doi: 10.1016/j.jchf.2014.04.016. Epub 2014 Oct 8.

Objectives: The purpose of this study was to evaluate the influence of the guanine nucleotide-binding proteins (G-proteins), beta-3 subunit (GNB3) genotype on the effectiveness of a fixed-dose combination of isosorbide dinitrate and hydralazine (FDC I/H) in A-HeFT (African American Heart Failure Trial).

Background: GNB3 plays a role in alpha2-adrenergic signaling. A polymorphism (C825T) exists, and the T allele is linked to enhanced alpha-adrenergic tone and is more prevalent in African Americans.

Methods: A total of 350 subjects enrolled in the genetic substudy (GRAHF [Genetic Risk Assessment of Heart Failure in African Americans]) were genotyped for the C825T polymorphism. The impact of FDC I/H on a composite score (CS) that incorporated death, hospital stay for heart failure, and change in quality of life (QoL) and on event-free survival were assessed in GNB3 genotype subsets.

Results: The GRAHF cohort was 60% male, 25% ischemic, 97% New York Heart Association functional class III, age 57 ± 13 years, with a mean qualifying left ventricular ejection fraction of 0.24 ± 0.06. For GNB3 genotype, 184 subjects were TT (53%), 137 (39%) CT, and 29 (8%) were CC. In GNB3 TT subjects, FDC I/H improved the CS (FDC I/H = 0.50 ± 1.6; placebo = -0.11 ± 1.8, p = 0.02), QoL (FDC I/H = 0.69 ± 1.4; placebo = 0.24 ± 1.5, p = 0.04), and event-free survival (hazard ratio: 0.51, p = 0.047), but not in subjects with the C allele (for CS, FDC I/H = -0.05 ± 1.7; placebo = -0.09 ± 1.7, p = 0.87; for QoL, FDC I/H = 0.28 ± 1.5; placebo = 0.14 ± 1.5, p = 0.56; and for event-free survival, p = 0.35).

Conclusions: The GNB3 TT genotype was associated with greater therapeutic effect of FDC I/H in A-HeFT. The role of the GNB3 genotype for targeting therapy with FDC I/H deserves further study.

Impact on conclusions of systematic review: While additional research on whether use of hydralazine and isosorbide dinitrate is linked to a genetic polymorphism may refine the clinical recommendations, findings in these publications further support the current recommendations and level of evidence ratings for the use of combination therapy in African American patients.

1a.8 OTHER SOURCE OF EVIDENCE

If source of evidence is NOT from a clinical practice guideline, USPSTF, or systematic review, please describe the evidence on which you are basing the performance measure.

1a.8.1 What process was used to identify the evidence?

1a.8.2. Provide the citation and summary for each piece of evidence.

1. Evidence, Performance Gap, Priority – Importance to Measure and Report

Extent to which the specific measure focus is evidence-based, important to making significant gains in healthcare quality, and improving health outcomes for a specific high-priority (high-impact) aspect of healthcare where there is variation in or overall less-than-optimal performance. ***Measures must be judged to meet all subcriteria to pass this criterion and be evaluated against the remaining criteria.***

1a. Evidence to Support the Measure Focus – See attached Evidence Submission Form
NMQF_HF_Fixed_Dose_Therapy_evidence_form_final.pdf

1b. Performance Gap

Demonstration of quality problems and opportunity for improvement, i.e., data demonstrating:

- considerable variation, or overall less-than-optimal performance, in the quality of care across providers; and/or
- disparities in care across population groups.

1b.1. **Briefly explain the rationale for this measure** *(e.g., the benefits or improvements in quality envisioned by use of this measure)*
The African-American Heart Failure Trial (A-HeFT) first published in 2004 demonstrated that there is significant benefit for African American patients who receive the fixed-dose combination therapy of hydralazine and isosorbide dinitrate. A-HeFT built on the findings from the two Vasodilator-Heart Failure Trials (V-HeFT). A-HeFT, which was ended early due to the mortality rates in the placebo population, demonstrated a 43% reduction in mortality, a 33% decrease in initial hospitalizations, and a 50% improvement in patient-reported quality of life (Taylor, 2004; Sharma, 2014). These results clearly demonstrate that the fixed-dose combination therapy significantly improves patient morbidity, mortality and quality of life in this clinical cohort. There is no substitute for the fixed-dose combination therapy.

Even with this strong evidence of unprecedented efficacy and cost-effectiveness, research shows that more than 85% of African American patients are not receiving the quality of care that this therapy affords, constituting a significant gap in care quality (Dickson, 2015). The underuse of the fixed-dose combination of hydralazine plus isosorbide dinitrate in African Americans with severe heart failure is a health care and health quality disparity that exposes these patients to an elevated risk for mortality and hospitalization, and compromises efforts to contain the escalating system costs by preventing or reducing unnecessary hospitalizations and readmissions.

Based upon research on the mortality benefit of the fixed-dose combination (Fonarow, 2011), the National Minority Quality Forum estimates that 51,542 (27%) of the 189,891 African American Medicare beneficiaries who were being treated for heart failure and received their prescription drugs under Part D should have been treated with the fixed-dose combination; but only 2,377 (5%) had at least one prescription (30-day supply) of the therapy. Further, the National Minority Quality Forum estimates that between 2008 and 2010, only 3% of the eligible patient cohort in Medicare received the therapy. Given the documented number to treat to receive the

mortality benefit (21), it can be estimated that from 2007 through 2010, 20,000 African American Medicare beneficiaries died as a result of the failure to receive quality care as defined by evidence-based guidelines.

Research continues to explore if the fixed-dose combination of hydralazine and isosorbide dinitrate is linked to a particular genetic polymorphism (NIH funded Genomic Response Analysis of Heart Failure Therapy in African Americans). While we anticipate that the evidence supporting this treatment will be refined over time, the proven benefits to this patient population is significant and there is a clear opportunity for improvement. Failure to do so constitutes a failure to provide quality and cost-effective care.

1b.2. Provide performance scores on the measure as specified (current and over time) at the specified level of analysis. *(This is required for endorsement maintenance. Include mean, std dev, min, max, interquartile range, scores by decile. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities included). This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*
As this is a newly developed measure, we do not yet have data on the overall performance of the measure but will be able to submit this information at the time of maintenance.

1b.3. If no or limited performance data on the measure as specified is reported in 1b2, then provide a summary of data from the literature that indicates opportunity for improvement or overall less than optimal performance on the specific focus of measurement.
Several analyses on whether eligible patients are receiving the hydralazine and isosorbide dinitrate combination therapy as supported by current evidence have been published. All demonstrate the existence of a significant opportunity for improvement both in the ambulatory setting and at the time of discharge from a hospital.

- A secondary analysis of data identified that more than 85% of African American patients were not receiving the combination therapy (Dickson, 2015).
- An observational analysis of data from the Get With the Guidelines-Heart Failure Registry showed that just over 22% of African American patients were discharged from the hospital with a prescription for the combination therapy. Rates did increase from 16% to 24% over four years (Golwala, 2013).
- A post hoc retrospective analysis conducted by Fonarow and colleagues using data from IMPROVE HF and Get with the Guidelines registry identified that only 7.3% of African American patients received the recommended combination therapy of hydralazine and isosorbide dinitrate (Fonarow, 2011).
- Rates are similarly low in the outpatient setting with the IMPROVE-HF, a prospective cohort study, showing that only 7.3% of patients received hydralazine and isosorbide dinitrate (Yancy, 2010).
- Only 4.5% of African American patients with HF and LVSD included in the OPTIMIZE-HF registry received the combination therapy (Yancy, 2008).

1b.4. Provide disparities data from the measure as specified (current and over time) by population group, e.g., by race/ethnicity, gender, age, insurance status, socioeconomic status, and/or disability. *(This is required for endorsement maintenance. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities include.) This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*
As this is a newly developed measure, we do not yet have data on the overall performance of the measure but will be able to submit this information at the time of maintenance.

1b.5. If no or limited data on disparities from the measure as specified is reported in 1b4, then provide a summary of data from the literature that addresses disparities in care on the specific focus of measurement. Include citations.
Heart failure is a major public health burden in the United States that disproportionately affects African Americans, who have not experienced the same benefit from treatment as white patients have. More than 5 million people = 20 years of age in the United States have heart failure, with 550,000 new cases of heart failure diagnosed each year. In the US, heart failure affects about 3% of the African American populations; whereas this rate is about 2% in the general population (Ferdinand, 2014). According to the American Heart Association heart disease and stroke statistics 2014 update, annual rates per 1,000 population of new heart failure events are 16.9 and 25.5 for Black men aged 65-74 and 75-84, respectively; and 14.2 and 25.5 for Black women aged 65-74 and 75-84, respectively (Go, 2014).

Heart failure is more prevalent in African Americans than in whites, occurs earlier, imposes higher rates of death and morbidity, and has a more malignant course. Much of the disparity can be assigned to modifiable risk factors such as uncontrolled hypertension and on suboptimal health care. Therefore, when African Americans are treated according to guidelines, discrepant outcomes can be minimized (Sharma, 2014). According to American Heart Association statistics, the annual incidence of heart failure in whites is approximately 6 per 1,000 person-years, while in African Americans it is 9.1 per 1,000 person years. In the Atherosclerosis Risk in Communities Study, the incidence of new heart failure as 1.0 per 1,000 person-years in Chinese Americans, 2.4 in whites, 3.5 in Hispanics, and 4.6 in African Americans. Moreover, when hospitalized for heart failure, African Americans have a 45% greater risk of death or decline in functional status than whites. In the Women's Health Initiative — a 15-year study initiated by the National Institutes of Health in 1991 — African American women had higher rates of heart failure than white women, possibly linked to higher rates of diabetes (Sharma, 2014).

This measure specifically targets Black or African American patients with heart failure and left ventricular systolic dysfunction where a specific therapy is supported by evidence-based guidelines. For this reason, the data provided here are identical to 1b.3.

Several published analyses on whether eligible patients are receiving the hydralazine and isosorbide dinitrate combination therapy as supported by current evidence are highlighted below. All demonstrate the existence of a significant opportunity for improvement both in the ambulatory setting and at the time of discharge from a hospital.

- A secondary analysis of data identified that more than 85% of African American patients were not receiving the combination therapy (Dickson, 2015).
- An observational analysis of data from the Get With the Guidelines-Heart Failure Registry showed that just over 22% of African American patients were discharged from the hospital with a prescription for the combination therapy. Rates did increase from 16% to 24% over four years (Golwala, 2013).
- A post hoc retrospective analysis conducted by Fonarow and colleagues using data from IMPROVE HF and Get with the Guidelines registry identified that only 7.3% of African American patients received the recommended combination therapy of hydralazine and isosorbide dinitrate (Fonarow, 2011).
- Rates are similarly low in the outpatient setting with the IMPROVE-HF, a prospective cohort study, showing that only 7.3% of patients received hydralazine and isosorbide dinitrate (Yancy, 2010).
- Only 4.5% of African American patients with HF and LVSD included in the OPTIMIZE-HF registry received the combination therapy (Yancy, 2008).

1c. High Priority (previously referred to as High Impact)

The measure addresses:

- a specific national health goal/priority identified by DHHS or the National Priorities Partnership convened by NQF; OR
- a demonstrated high-priority (high-impact) aspect of healthcare (e.g., affects large numbers of patients and/or has a substantial impact for a smaller population; leading cause of morbidity/mortality; high resource use (current and/or future); severity of illness; and severity of patient/societal consequences of poor quality).

1c.1. Demonstrated high priority aspect of healthcare

A leading cause of morbidity/mortality, Patient/societal consequences of poor quality, Severity of illness

1c.2. If Other:

1c.3. Provide epidemiologic or resource use data that demonstrates the measure addresses a high priority aspect of healthcare. List citations in 1c.4.

This measure specifically relates to the National Quality Strategy (NQS) priority area of Effective Clinical Care: Promoting the most effective prevention and treatment practices for the leading causes of mortality, starting with cardiovascular disease.

Heart failure is a major public health burden in the United States that disproportionately affects African Americans, who have not experienced the same benefit from treatment as white patients have.

- More than 5 million people = 20 years of age in the United States have heart failure, with 550,000 new cases of heart failure diagnosed each year (Ferdinand, 2014).
- In the US, heart failure affects about 3% of the African American populations; whereas, this rate is about 2% in the general population (Ferdinand, 2014).
- According to the American Heart Association (AHA) heart disease and stroke statistics 2014 update, annual rates per 1,000 population of new heart failure events are 16.9 and 25.5 for Black men aged 65-74 and 75-84, respectively; and 14.2 and 25.5 for Black women aged 65-74 and 75-84, respectively (Go, 2014).

Heart failure is more prevalent in African Americans than in whites, occurs earlier, imposes higher rates of death and morbidity, and has a more malignant course. Much of the disparity can be assigned to modifiable risk factors such as uncontrolled hypertension and on suboptimal health care. Therefore, when African Americans are treated according to guidelines, discrepant outcomes can be minimized (Sharma, 2014).

- According to AHA statistics, the annual incidence of heart failure in whites is approximately 6 per 1,000 person-years, while in African Americans it is 9.1 per 1,000 person years.
- In the Atherosclerosis Risk in Communities Study, the incidence of new heart failure as 1.0 per 1,000 person-years in Chinese Americans, 2.4 in whites, 3.5 in Hispanics, and 4.6 in African Americans. Moreover, when hospitalized for heart failure, African Americans have a 45% greater risk of death or decline in functional status than whites.
- In the Women's Health Initiative — a 15-year study initiated by the National Institutes of Health in 1991 — African American women had higher rates of heart failure than white women, possibly linked to higher rates of diabetes (Sharma, 2014).

The African-American Heart Failure Trial (A-HeFT) first published in 2004 demonstrated that there is significant benefit for African American patients who receive the fixed-dose combination therapy of hydralazine and isosorbide dinitrate. A-HeFT built on the findings from the two Vasodilator-Heart Failure Trials (V-HeFT). A-HeFT, which was ended early due to the mortality rates in the placebo population, demonstrated a 43% reduction in mortality, a 33% decrease in initial hospitalizations, and a 50% improvement in patient-reported quality of life (Taylor, 2004; Sharma, 2014). These results clearly demonstrate that the fixed-dose combination therapy significantly improves patient morbidity, mortality and quality of life in this clinical cohort. There is no substitute for the fixed-dose combination therapy.

Based upon research on the mortality benefit of the fixed-dose combination (Fonarow, 2011), the National Minority Quality Forum estimates that 51,542 (27%) of the 189,891 African American Medicare beneficiaries who were being treated for heart failure and received their prescription drugs under Part D should have been treated with the fixed-dose combination; but only 2,377 (5%) had at least one prescription (30-day supply) of the therapy. Further, the National Minority Quality Forum estimates that between 2008 and 2010, only 3% of the eligible patient cohort in Medicare received the therapy. Given the documented number to treat to receive the mortality benefit (21), it can be estimated that from 2007 through 2010, 20,000 African American Medicare beneficiaries died as a result of the failure to receive quality care as defined by evidence-based guidelines.

S.5. **Time Period for Data** *(What is the time period in which data will be aggregated for the measure, e.g., 12 mo, 3 years, look back to August for flu vaccination? Note if there are different time periods for the numerator and denominator.)*
Measurement period (12 months)

S.6. **Numerator Details** *(All information required to identify and calculate the cases from the target population with the target process, condition, event, or outcome such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
IF an OUTCOME MEASURE, describe how the observed outcome is identified/counted. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
The following data element is used to calculate the numerator:
1. Fixed-dose combination of hydralazine and isosorbide dinitrate prescription

Logic for calculating the numerator is included in the eMeasure specification.

Value sets used:
Fixed dose combination of hydralazine and isosorbide dinitrate (2.16.840.1.113762.1.4.1124.15)

S.7. **Denominator Statement** *(Brief, narrative description of the target population being measured)*
All patients aged 18 years and older with a diagnosis of heart failure with a current or prior EF <40% who are self-identified Black or African Americans and receiving ACEI or ARB and Beta-blocker therapy

S.8. **Target Population Category** *(Check all the populations for which the measure is specified and tested if any):*
Populations at Risk, Senior Care

S.9. **Denominator Details** *(All information required to identify and calculate the target population/denominator such as definitions, specific data collection items/responses , code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
The following data elements are used to calculate the denominator:
1. Diagnosis of heart failure
2. Ejection Fraction <40% or diagnosis of left ventricular systolic dysfunction
3. Self-identified as Black or African American
4. ACEI or ARB therapy

5. Beta-blocker therapy
6. Office visit
7. Hospital Discharge

Logic for calculating the denominator is included in the eMeasure specification.

Value sets used:
Heart Failure (2.16.840.1.113883.3.526.2.23, 2.16.840.1.113883.3.526.2.24, 2.16.840.1.113883.3.526.2.25, 2.16.840.1.113883.3.526.3.376)
Left Ventricular Systolic Dysfunction (2.16.840.1.113883.3.526.2.859, 2.16.840.1.113883.3.526.3.1091)
Moderate or Severe LVSD (2.16.840.1.113883.3.526.2.861, 2.16.840.1.113883.3.526.3.1090)
Ejection Fraction (2.16.840.1.113883.3.526.2.1238, 2.16.840.1.113883.3.526.3.1134)
Moderate or Severe (2.16.840.1.113883.3.526.3.1092)
Care Services in Long-Term Residential Facility (2.16.840.1.113883.3.464.1003.101.11.1070, 2.16.840.1.113883.3.464.1003.101.12.1014)
Self identified as Black or African American (2.16.840.1.113762.1.4.1124.1)
Discharge Services - Hospital Inpatient (2.16.840.1.113883.3.464.1003.101.11.1035, 2.16.840.1.113883.3.464.1003.101.12.1007)
Face-to-Face Interaction (2.16.840.1.113883.3.464.1003.101.11.1216, 2.16.840.1.113883.3.464.1003.101.12.1048)
Home Healthcare Services (2.16.840.1.113883.3.464.1003.101.11.1080, 2.16.840.1.113883.3.464.1003.101.12.1016)
Nursing Facility Visit (2.16.840.1.113883.3.464.1003.101.11.1060, 2.16.840.1.113883.3.464.1003.101.12.1012)
Office Visit (2.16.840.1.113883.3.464.1003.101.11.1005, 2.16.840.1.113883.3.464.1003.101.12.1001)
Outpatient Consultation (2.16.840.1.113883.3.464.1003.101.11.1040, 2.16.840.1.113883.3.464.1003.101.12.1008)
Patient provider interaction (2.16.840.1.113883.3.526.2.1049, 2.16.840.1.113883.3.526.3.1012)
ACE Inhibitor or ARB (2.16.840.1.113883.3.526.2.39, 2.16.840.1.113883.3.526.3.1139)
Beta Blocker Therapy for LVSD (2.16.840.1.113883.3.526.2.133, 2.16.840.1.113883.3.526.3.1174)

S.10. Denominator Exclusions *(Brief narrative description of exclusions from the target population)*
Denominator exclusions include:
- Hypotension (severe or symptomatic)
- Severe lupus erythematosus
- Unstable angina
- Peripheral neuritis
- Patient actively taking Phosphodiesterase Type 5 (PDE5) Inhibitors

S.11. Denominator Exclusion Details *(All information required to identify and calculate exclusions from the denominator such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
The following data elements are used to calculate the denominator exclusions:
1. Hypotension (severe or symptomatic)
2. Severe lupus erythematosus
3. Unstable angina
4. Peripheral neuritis
5. Patient actively taking Phosphodiesterase Type 5 (PDE5) Inhibitors

Logic for calculating the denominator exclusions are included in the eMeasure specification.

Value sets used:
Hypotension (2.16.840.1.113883.3.526.2.175, 2.16.840.1.113883.3.526.2.180, 2.16.840.1.113883.3.526.2.185, 2.16.840.1.113883.3.526.3.370)
Lupus erythematosus (2.16.840.1.113762.1.4.1124.9, 2.16.840.1.113762.1.4.1124.10, 2.16.840.1.113762.1.4.1124.11, 2.16.840.1.113762.1.4.1124.12)
Unstable angina (2.16.840.1.113762.1.4.1124.16, 2.16.840.1.113762.1.4.1124.17, 2.16.840.1.113762.1.4.1124.18)
Peripheral neuritis (2.16.840.1.113762.1.4.1124.4, 2.16.840.1.113762.1.4.1124.5, 2.16.840.1.113762.1.4.1124.6, 2.16.840.1.113762.1.4.1124.7)
Patient actively taking Phosphodiesterase Type 5 (PDE5) Inhibitors (2.16.840.1.113762.1.4.1124.14)
Severe (2.16.840.1.113762.1.4.1124.19)
Symptomatic (2.16.840.1.113762.1.4.1124.20)

S.12. **Stratification Details/Variables** *(All information required to stratify the measure results including the stratification variables, definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format with at S.2b)*
Not applicable

S.13. **Risk Adjustment Type** (Select type. Provide specifications for risk stratification in S.12 and for statistical model in S.14-15)
No risk adjustment or risk stratification
If other:

S.14. **Identify the statistical risk model method and variables** *(Name the statistical method - e.g., logistic regression and list all the risk factor variables. Note - risk model development and testing should be addressed with measure testing under Scientific Acceptability)*
Not applicable

S.15. **Detailed risk model specifications** *(must be in attached data dictionary/code list Excel or csv file. Also indicate if available at measure-specific URL identified in S.1.)*
Note: Risk model details (including coefficients, equations, codes with descriptors, definitions), should be provided on a separate worksheet in the suggested format in the Excel or csv file with data dictionary/code lists at S.2b.

S.15a. **Detailed risk model specifications** (*if not provided in excel or csv file at S.2b*)
Not applicable

S.16. **Type of score:**
Rate/proportion
If other:

S.17. **Interpretation of Score** *(Classifies interpretation of score according to whether better quality is associated with a higher score, a lower score, a score falling within a defined interval, or a passing score)*
Better quality = Higher score

S.18. **Calculation Algorithm/Measure Logic** *(Describe the calculation of the measure score as an ordered sequence of steps including identifying the target population; exclusions; cases meeting the target process, condition, event, or outcome; aggregating data; risk adjustment; etc.)*
The measure logic is provided in the eMeasure specification.

Performance is calculated as:

1. Identify the initial patient population for the measure.
2. From those patients in the initial patient population, identify those that meet the denominator criteria.
3. From the patients who qualify for the denominator, identify those who meet the numerator criteria.
4. Identify those patients who did not meet the numerator criteria and determine whether an appropriate exclusion is documented.
5. Remove those patients with an exclusion from the denominator.
6. Calculation: Numerator/Denominator-Denominator Exclusions

S.19. **Calculation Algorithm/Measure Logic Diagram URL or Attachment** *(You also may provide a diagram of the Calculation Algorithm/Measure Logic described above at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
No diagram provided

S.20. **Sampling** *(If measure is based on a sample, provide instructions for obtaining the sample and guidance on minimum sample size.)*
IF a PRO-PM, identify whether (and how) proxy responses are allowed.
Not applicable

S.21. **Survey/Patient-reported data** *(If measure is based on a survey, provide instructions for conducting the survey and guidance on minimum response rate.)*
IF a PRO-PM, specify calculation of response rates to be reported with performance measure results.

Not applicable

S.22. **Missing data** (specify how missing data are handled, e.g., imputation, delete case.)
Required for Composites and PRO-PMs.
This measure is specified with specific criteria, data elements and value sets. If a patient record does not include one or more of these components for the initial patient population or denominator, then patients are not considered eligible for the measure and not included.

If data to determine whether a patient should be considered for the numerator or exclusions is missing, then the numerator or exclusions not considered to be met and the provider will not get credit for meeting performance for that patient.

S.23. **Data Source** *(Check ONLY the sources for which the measure is SPECIFIED AND TESTED).*
If other, please describe in S.24.
Electronic Clinical Data : Electronic Health Record

S.24. **Data Source or Collection Instrument** *(Identify the specific data source/data collection instrument e.g. name of database, clinical registry, collection instrument, etc.)*
IF a PRO-PM, identify the specific PROM(s); and standard methods, modes, and languages of administration.
Not applicable

S.25. **Data Source or Collection Instrument** *(available at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
No data collection instrument provided

S.26. **Level of Analysis** *(Check ONLY the levels of analysis for which the measure is SPECIFIED AND TESTED)*
Clinician : Group/Practice, Clinician : Individual

S.27. **Care Setting** *(Check ONLY the settings for which the measure is SPECIFIED AND TESTED)*
Ambulatory Care : Clinician Office/Clinic, Hospital/Acute Care Facility
If other:

S.28. **COMPOSITE Performance Measure** - Additional Specifications *(Use this section as needed for aggregation and weighting rules, or calculation of individual performance measures if not individually endorsed.)*
Not applicable

2a. Reliability – See attached Measure Testing Submission Form
2b. Validity – See attached Measure Testing Submission Form

National Quality Forum—Measure Testing (subcriteria 2a2, 2b2-2b7)

Measure Number (*if previously endorsed*)**:** 2764

Measure Title: Heart Failure: Fixed-dose Combination of Hydralazine and Isosorbide Dinitrate Therapy for Self-identified Black and African American Patients with Heart Failure and LVEF <40% on ACEI or ARB and Beta-blocker Therapy

Date of Submission: 8/12/2015

Type of Measure:

☐ Composite – ***STOP – use composite testing form***	☐ Outcome (*including PRO-PM*)
☐ Cost/resource	☒ Process

☐ Efficiency	☐ Structure

Instructions

- Measures must be tested for all the data sources and levels of analyses that are specified. ***If there is more than one set of data specifications or more than one level of analysis, contact NQF staff*** about how to present all the testing information in one form.
- **For all measures, sections 1, 2a2, 2b2, 2b3, and 2b5 must be completed.**
- **For outcome and resource use measures**, section **2b4** also must be completed.
- If specified for **multiple data sources/sets of specificaitons** (e.g., claims and EHRs), section **2b6** also must be completed.
- Respond to all questions as instructed with answers immediately following the question. All information on testing to demonstrate meeting the subcriteria for reliability (2a2) and validity (2b2-2b6) must be in this form. An appendix for *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 20 pages (*incuding questions/instructions;* minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.
- For information on the most updated guidance on how to address sociodemographic variables and testing in this form refer to the release notes for version 6.6 of the Measure Testing Attachment.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the testing results for this measure meet NQF's evaluation criteria for testing.

2a2. Reliability testing [10] demonstrates the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise. For **PRO-PMs and composite performance measures**, reliability should be demonstrated for the computed performance score.

2b2. Validity testing [11] demonstrates that the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality. For **PRO-PMs and composite performance measures**, validity should be demonstrated for the computed performance score.

2b3. Exclusions are supported by the clinical evidence; otherwise, they are supported by evidence of sufficient frequency of occurrence so that results are distorted without the exclusion; [12]

AND

If patient preference (e.g., informed decisionmaking) is a basis for exclusion, there must be evidence that the exclusion impacts performance on the measure; in such cases, the measure must be specified so that the information about patient preference and the effect on the measure is transparent (e.g., numerator category computed separately, denominator exclusion category computed separately). [13]

2b4. For outcome measures and other measures when indicated (e.g., resource use):

- **an evidence-based risk-adjustment strategy** (e.g., risk models, risk stratification) is specified; is based on patient factors (including clinical and sociodemographic factors) that influence the measured outcome and are present at start of care; [14,15] and has demonstrated adequate discrimination and calibration

OR

- rationale/data support no risk adjustment/ stratification.

2b5. Data analysis of computed measure scores demonstrates that methods for scoring and analysis of the specified measure allow for **identification of statistically significant and practically/clinically meaningful** [16] **differences in performance**;

OR

there is evidence of overall less-than-optimal performance.

2b6. If multiple data sources/methods are specified, there is demonstration they produce comparable results.

2b7. For **eMeasures, composites, and PRO-PMs** (or other measures susceptible to missing data), analyses identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias.

Notes

10. Reliability testing applies to both the data elements and computed measure score. Examples of reliability testing for data elements include, but are not limited to: inter-rater/abstractor or intra-rater/abstractor studies; internal consistency for multi-item scales; test-retest for survey items. Reliability testing of the measure score addresses precision of measurement (e.g., signal-to-noise).

11. Validity testing applies to both the data elements and computed measure score. Validity testing of data elements typically analyzes agreement with another authoritative source of the same information. Examples of validity testing of the measure score include, but are not limited to: testing hypotheses that the measures scores indicate quality of care, e.g., measure scores are different for groups known to have differences in quality assessed by another valid quality measure or method; correlation of measure scores with another valid indicator of quality for the specific topic; or relationship to conceptually related measures (e.g., scores on process measures to scores on outcome measures). Face validity of the measure score as a quality indicator may be adequate if accomplished through a systematic and transparent process, by identified experts, and explicitly addresses whether performance scores resulting from the measure as specified can be used to distinguish good from poor quality.

12. Examples of evidence that an exclusion distorts measure results include, but are not limited to: frequency of occurrence, variability of exclusions across providers, and sensitivity analyses with and without the exclusion.

13. Patient preference is not a clinical exception to eligibility and can be influenced by provider interventions.

14. Risk factors that influence outcomes should not be specified as exclusions

15. With large enough sample sizes, small differences that are statistically significant may or may not be practically or clinically meaningful. The substantive question may be, for example, whether a statistically significant difference of one percentage point in the percentage of patients who received smoking cessation counseling (e.g., 74 percent v. 75 percent) is

clinically meaningful; or whether a statistically significant difference of $25 in cost for an episode of care (e.g., $5,000 v. $5,025) is practically meaningful. Measures with overall less-than-optimal performance may not demonstrate much variability across providers.

1. DATA/SAMPLE USED FOR ALL TESTING OF THIS MEASURE

Often the same data are used for all aspects of measure testing. In an effort to eliminate duplication, the first five questions apply to all measure testing. If there are differences by aspect of testing,(e.g., reliability vs. validity) be sure to indicate the specific differences in question 1.7.

1.1. What type of data was used for testing? (*Check all the sources of data identified in the measure specifications and data used for testing the measure. Testing must be provided for all the sources of data specified and intended for measure implementation.* ***If different data sources are used for the numerator and denominator, indicate N [numerator] or D [denominator] after the checkbox.***)

Measure Specified to Use Data From: (***must be consistent with data sources entered in S.23***)	**Measure Tested with Data From:**
☐ abstracted from paper record	☐ abstracted from paper record
☐ administrative claims	☐ administrative claims
☐ clinical database/registry	☐ clinical database/registry
☒ abstracted from electronic health record	☒ abstracted from electronic health record
☒ eMeasure (HQMF) implemented in EHRs	☒ eMeasure (HQMF) implemented in EHRs
☐ other: Click here to describe	☐ other: Click here to describe

1.2. If an existing dataset was used, identify the specific dataset (*the dataset used for testing must be consistent with the measure specifications for target population and healthcare entities being measured; e.g., Medicare Part A claims, Medicaid claims, other commercial insurance, nursing home MDS, home health OASIS, clinical registry*).

Not applicable

1.3. What are the dates of the data used in testing? Exact dates TBD but will include 12 months of performance data at a minimum to be consistent with the measure specifications.

1.4. What levels of analysis were tested? (*testing must be provided for all the levels specified and intended for measure implementation, e.g., individual clinician, hospital, health plan*)

Measure Specified to Measure Performance of:	**Measure Tested at Level of:**

(*must be consistent with levels entered in item S.26*)	
☒ individual clinician	☒ individual clinician
☒ group/practice	☒ group/practice
☐ hospital/facility/agency	☐ hospital/facility/agency
☐ health plan	☐ health plan
☐ other: Click here to describe	☐ other: Click here to describe

1.5. How many and which measured entities were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of measured entities included in the analysis (e.g., size, location, type); if a sample was used, describe how entities were selected for inclusion in the sample*)

NMQF testing will examine whether all the data elements required to calculate the performance score are correctly identified; specifically, the accuracy of the electronic data in the automated report produced from implementation of the eMeasure specifications against the manual review and abstraction of the medical record (the gold standard). NMQF will analyze and test all data elements required to capture the denominator, numerator and exclusions. We will not only look to determine the ability of the measure to identify positive results (agreement with the discrete fields used to obtain the electronic data within the automated report). We will also examine whether the measure can identify negative results – the data elements were missing in the automated report, yet identified in text fields (e.g., progress notes) and whether the absence of the data elements potentially negatively impacts performance scores (i.e., not captured in discrete fields).

NMQF testing will address aspects across the NQF measure evaluation criteria including:

- Reliability analyses – parallel forms (agreement between automated reports and the manual review of the medical record) and Cohen's Kappa statistic with 95 percent confidence intervals
- Validity analyses – extraction accuracy (criterion validity); sensitivity (ability of a measure to identify positive results), specificity (ability of a measure to identify negative results) and percent agreement between the extracted and gold standard data
- Usability – measures element average and a weighted average of measure elements
- Feasibility – analysis of the feasibility of EHRs to collect the needed data elements (current and future) through site interviews with both clinical and informatics staff at each testing site

To power the analysis for statistical significance, the sample sizes required are estimated to be between 165 and 200 patients (given 80 percent power, and a 0.05 significance level for testing differences in Kappa statistics and performance rates). To yield an adequate sample size, an abstractor will review an estimated average of 55 medical records for each of the anticipated three to four sites in the cohort. Larger sites could provide larger samples of cases and smaller sites provide fewer; yet, all will provide a representative sample of eligible cases seen at their sites.

NMQF intends to include more than one electronic health record system (EHRs) in the testing of this measure as specified by the NQF Measure Evaluation Criteria for eMeasures. Because the measure examines the care provided at the time of discharge from a hospital, and routine care in an ambulatory practice, both settings will

be included in the testing and analyses. NMQF will also seek to include testing sites of various sizes and geographic locations to the greatest extent possible to ensure representative results.

1.6. How many and which patients were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of patients included in the analysis (e.g., age, sex, race, diagnosis); if a sample was used, describe how patients were selected for inclusion in the sample*)

A random sample of patients meeting the measure specifications will be used in the testing and analysis. To power the analysis for statistical significance, the sample sizes required are estimated to be between 165 and 200 patients (given 80 percent power, and a 0.05 significance level for testing differences in Kappa statistics and performance rates). To yield an adequate sample size, an abstractor will review an estimated average of 55 medical records for each of the anticipated three to four practice sites in the cohort. Larger sites could provide larger samples of cases and smaller sites provide fewer; yet, all will provide a representative sample of eligible cases seen at their practice sites.

1.7. If there are differences in the data or sample used for different aspects of testing (e.g., reliability, validity, exclusions, risk adjustment), identify how the data or sample are different for each aspect of testing reported below.

One data set will be produced from the hospitals and ambulatory practices identified in 1.5; therefore, no differences in the data or samples across the various aspects of testing are anticipated.

1.8 What were the patient-level sociodemographic (SDS) variables that were available and analyzed in the data or sample used? For example, patient-reported data (e.g., income, education, language), proxy variables when SDS data are not collected from each patient (e.g. census tract), or patient community characteristics (e.g. percent vacant housing, crime rate).

Not applicable

2a2. RELIABILITY TESTING

Note*: If accuracy/correctness (validity) of data elements was empirically tested*, *separate reliability testing of data elements is not required – in 2a2.1 check critical data elements; in 2a2.2 enter "see section 2b2 for validity testing of data elements"; and skip 2a2.3 and 2a2.4.*

2a2.1. What level of reliability testing was conducted? (*may be one or both levels*)

☒ **Critical data elements used in the measure** (*e.g., inter-abstractor reliability; data element reliability must address ALL critical data elements*)

☐ **Performance measure score** (e.g., *signal-to-noise analysis*)

2a2.2. For each level checked above, describe the method of reliability testing and what it tests (*describe the steps—do not just name a method; what type of error does it test; what statistical analysis was used*)

NMQF testing will examine whether all the data elements required to calculate the performance score are correctly identified; specifically, the accuracy of the electronic data in the automated report produced from implementation of the eMeasure specifications against the manual review and abstraction of the medical record (the gold standard). NMQF will analyze and test all data elements required to capture the denominator, numerator and exclusions. We will not only look to determine the ability of the measure to identify positive results (agreement with the discrete fields used to obtain the electronic data within the automated report). We will also examine whether the measure can identify negative results – the data elements were missing in the automated report, yet identified in text fields (e.g., progress notes) and whether the absence of the data elements potentially negatively impacts performance scores (i.e., not captured in discrete fields).

The data analysis will provide results (overall and by denominator, numerator and exclusions) on the:

- Reliability analyses – parallel forms (agreement between automated reports and the manual review of the medical record) and Cohen's Kappa statistic with 95 percent confidence intervals
- Validity analyses – extraction accuracy (criterion validity); sensitivity (ability of a measure to identify positive results), specificity (ability of a measure to identify negative results) and percent agreement between the extracted and gold standard data
- Usability – measure element average and a weighted average of measure elements
- Feasibility – analysis of the feasibility of EHRs to collect the needed data elements through site interviews with both clinical and informatics staff at each testing site

2a2.3. For each level of testing checked above, what were the statistical results from reliability testing? (e.*g., percent agreement and kappa for the critical data elements; distribution of reliability statistics from a signal-to-noise analysis*)

To be provided when testing is completed

2a2.4 What is your interpretation of the results in terms of demonstrating reliability? (i.*e., what do the results mean and what are the norms for the test conducted?*)

To be provided when testing is completed

2b2. VALIDITY TESTING

2b2.1. What level of validity testing was conducted? (*may be one or both levels*)

☒ **Critical data elements** (*data element validity must address ALL critical data elements*)

☐ **Performance measure score**

☐ **Empirical validity testing**

☐ **Systematic assessment of face validity of <u>performance measure score</u> as an indicator** of quality or resource use (*i.e., is an accurate reflection of performance on quality or resource use and can distinguish good from poor performance*)

2b2.2. For each level of testing checked above, describe the method of validity testing and what it tests (*describe the steps—do not just name a method; what was tested, e.g., accuracy of data elements compared to authoritative source, relationship to another measure as expected; what statistical analysis was used)*

NMQF testing will examine whether all the data elements required to calculate the performance score are correctly identified; specifically, the accuracy of the electronic data in the automated report produced from implementation of the eMeasure specifications against the manual review and abstraction of the medical record (the gold standard). NMQF will analyze and test all data elements required to capture the denominator, numerator and exclusions. We will not only look to determine the ability of the measure to identify positive results (agreement with the discrete fields used to obtain the electronic data within the automated report). We will also examine whether the measure can identify negative results – the data elements were missing in the automated report, yet identified in text fields (e.g., progress notes) and whether the absence of the data elements potentially negatively impacts performance scores (i.e., not captured in discrete fields).

The data analysis will provide results (overall and by denominator, numerator and exclusions) on the:

- Reliability analyses – parallel forms (agreement between automated reports and the manual review of the medical record) and Cohen's Kappa statistic with 95 percent confidence intervals
- Validity analyses – extraction accuracy (criterion validity); sensitivity (ability of a measure to identify positive results), specificity (ability of a measure to identify negative results) and percent agreement between the extracted and gold standard data
- Usability – measure element average and a weighted average of measure elements
- Feasibility – analysis of the feasibility of EHRs to collect the needed data elements through site interviews with both clinical and informatics staff at each testing site

2b2.3. What were the statistical results from validity testing? (*e.g., correlation; t-test*)

To be provided when testing is completed

2b2.4. What is your interpretation of the results in terms of demonstrating validity? (i.*e., what do the results mean and what are the norms for the test conducted?*)

To be provided when testing is completed

2b3. EXCLUSIONS ANALYSIS

NA □ no exclusions — *skip to section 2b4*

2b3.1. Describe the method of testing exclusions and what it tests (*describe the steps—do not just name a method; what was tested, e.g., whether exclusions affect overall performance scores; what statistical analysis was used*)

NMQF will examine the overall frequency of the exclusions as well as variability across the testing sites to demonstrate the need for exclusions. As discussed in 2b2.2, NMQF testing will examine whether all the data elements required to calculate the performance score are correctly identified; specifically, the accuracy of the electronic data in the automated report produced from implementation of the eMeasure specifications against the manual review and abstraction of the medical record (the gold standard). NMQF will analyze and test all data elements required to capture the denominator, numerator and exclusions. We will not only look to determine the ability of the measure to identify positive results (agreement with the discrete fields used to

obtain the electronic data within the automated report). We will also examine whether the measure can identify negative results – the data elements were missing in the automated report, yet identified in text fields (e.g., progress notes) and whether the absence of the data elements potentially negatively impacts performance scores (i.e., not captured in discrete fields).

The data analysis will provide results (overall and by denominator, numerator and exclusions) on the:

- Reliability analyses – parallel forms (agreement between automated reports and the manual review of the medical record) and Cohen's Kappa statistic with 95 percent confidence intervals
- Validity analyses – extraction accuracy (criterion validity); sensitivity (ability of a measure to identify positive results), specificity (ability of a measure to identify negative results) and percent agreement between the extracted and gold standard data
- Usability – measure element average and a weighted average of measure elements
- Feasibility – analysis of the feasibility of EHRs to collect the needed data elements through site interviews with both clinical and informatics staff at each testing site

2b3.2. What were the statistical results from testing exclusions? (*include overall number and percentage of individuals excluded, frequency distribution of exclusions across measured entities, and impact on performance measure scores*)

To be provided when testing is completed

2b3.3. What is your interpretation of the results in terms of demonstrating that exclusions are needed to prevent unfair distortion of performance results? (*i.e., the value outweighs the burden of increased data collection and analysis. Note: **If patient preference is an exclusion**, the measure must be specified so that the effect on the performance score is transparent, e.g., scores with and without exclusion*)

To be provided when testing is completed

2b4. RISK ADJUSTMENT/STRATIFICATION FOR OUTCOME OR RESOURCE USE MEASURES
If not an intermediate or health outcome, or PRO-PM, or resource use measure, skip to section 2b5.

2b4.1. What method of controlling for differences in case mix is used?

☒ **No risk adjustment or stratification**

☐ **Statistical risk model with** Click here to enter number of factors **risk factors**

☐ **Stratification by** Click here to enter number of categories **risk categories**

☐ **Other,** Click here to enter description

2b4.2. If an outcome or resource use measure is not risk adjusted or stratified, provide rationale and analyses to demonstrate that controlling for differences in patient characteristics (case mix) is not needed to achieve fair comparisons across measured entities.

Not applicable

2b4.3. Describe the conceptual/clinical and statistical methods and criteria used to select patient factors (clinical factors or sociodemographic factors) used in the statistical risk model or for stratification by risk (*e.g., potential factors identified in the literature and/or expert panel; regression analysis; statistical significance of p<0.10; correlation of x or higher; patient factors should be present at the start of care*)

Not applicable

2b4.4a. What were the statistical results of the analyses used to select risk factors?

Not applicable

2b4.4b. Describe the analyses and interpretation resulting in the decision to select SDS factors (e.g. prevalence of the factor across measured entities, empirical association with the outcome, contribution of unique variation in the outcome, assessment of between-unit effects and within-unit effects)

Not applicable

2b4.5. Describe the method of testing/analysis used to develop and validate the adequacy of the statistical model or stratification approach (*describe the steps—do not just name a method; what statistical analysis was used*)

Provide the statistical results from testing the approach to controlling for differences in patient characteristics (case mix) below.
If stratified, skip to 2b4.9

Not applicable

2b4.6. Statistical Risk Model Discrimination Statistics (*e.g., c-statistic, R-squared*)**:**

Not applicable

2b4.7. Statistical Risk Model Calibration Statistics (*e.g., Hosmer-Lemeshow statistic*):

Not applicable

2b4.8. Statistical Risk Model Calibration – Risk decile plots or calibration curves:

Not applicable

2b4.9. Results of Risk Stratification Analysis:

Not applicable

2b4.10. What is your interpretation of the results in terms of demonstrating adequacy of controlling for differences in patient characteristics (case mix)? (i.*e., what do the results mean and what are the norms for the test conducted*)

Not applicable

2b4.11. Optional Additional Testing for Risk Adjustment (*not required, but would provide additional support of adequacy of risk model, e.g., testing of risk model in another data set; sensitivity analysis for missing data; other methods that were assessed*)

Not applicable

2b5. IDENTIFICATION OF STATISTICALLY SIGNIFICANT & MEANINGFUL DIFFERENCES IN PERFORMANCE

2b5.1. Describe the method for determining if statistically significant and clinically/practically meaningful differences in performance measure scores among the measured entities can be identified (*describe the steps—do not just name a method; what statistical analysis was used? Do not just repeat the information provided related to performance gap in 1b)*

NMQF will examine the variation in performance scores across the testing sites. Specifically, we will look at the mean, standard deviations, and range (minimum and maximum) levels of performance to determine if there is room for improvement and meaningful differences in performance.

NMQF will initially classify a provider or site as high or low performing using a known or proven measurement of quality. Then a discriminant analysis will be performed to determine the total probability of misclassification using the new measure. If the underlying assumption of a multivariate distribution is not met, a logistic regression may be performed instead of a discriminant analysis. This logistic regression will also require an initial classification as low or high performing using a known/proven measurement of quality. The result of the logistic regression will determine the probability that a provider belongs to a particular category.

Furthermore, a chi square test will examine whether the proportion of the high performing group with a specific score is different from the proportion of the low performing group with a specific score (i.e. is there a difference between high and low performing scoring 80% or greater on the new measure).

2b5.2. What were the statistical results from testing the ability to identify statistically significant and/or clinically/practically meaningful differences in performance measure scores across measured entities? (e.g., *number and percentage of entities with scores that were statistically significantly different from mean or some benchmark, different from expected; how was meaningful difference defined*)

To be provided when testing is completed

2b5.3. What is your interpretation of the results in terms of demonstrating the ability to identify statistically significant and/or clinically/practically meaningful differences in performance across measured entities? (i*.e., what do the results mean in terms of statistical and meaningful differences?*)

To be provided when testing is completed

2b6. COMPARABILITY OF PERFORMANCE SCORES WHEN MORE THAN ONE SET OF SPECIFICATIONS

If only one set of specifications, this section can be skipped.

Note: *This criterion is directed to measures with more than one set of specifications/instructions (e.g., one set of specifications for how to identify and compute the measure from medical record abstraction and a different set of specifications for claims or eMeasures). It does not apply to measures that use more than one source of data in one set of specifications/instructions (e.g., claims data to identify the denominator and medical record abstraction for the numerator).* ***If comparability is not demonstrated, the different specifications should be submitted as separate measures.***

2b6.1. Describe the method of testing conducted to demonstrate comparability of performance scores for the same entities across the different data sources/specifications (*describe the steps—do not just name a method; what statistical analysis was used*)

Not applicable

2b6.2. What were the statistical results from testing comparability of performance scores for the same entities when using different data sources/specifications? (*e.g., correlation, rank order*)

Not applicable

2b6.3. What is your interpretation of the results in terms of demonstrating comparability of performance measure scores for the same entities across the different data sources/specifications? (i*.e., what do the results mean and what are the norms for the test conducted*)

Not applicable

2b7. MISSING DATA ANALYSIS AND MINIMIZING BIAS

2b7.1. Describe the method of testing conducted to identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias (*describe the steps—do not just name a method; what statistical analysis was used*)

As discussed in 2b2.2, NMQF testing will examine whether all the data elements required to calculate the performance score are correctly identified; specifically, the accuracy of the electronic data in the automated report produced from implementation of the eMeasure specifications against the manual review and abstraction of the medical record (the gold standard). NMQF will analyze and test all data elements required to capture the denominator, numerator and exclusions. We will not only look to determine the ability of the measure to identify positive results (agreement with the discrete fields used to obtain the electronic data within the automated report). We will also examine whether the measure can identify negative results – the data elements were missing in the automated report, yet identified in text fields (e.g., progress notes) and whether the absence of the data elements potentially negatively impacts performance scores (i.e., not captured in discrete fields).

The data analysis will provide results (overall and by denominator, numerator and exclusions) on the:

- Reliability analyses – parallel forms (agreement between automated reports and the manual review of the medical record) and Cohen's Kappa statistic with 95 percent confidence intervals
- Validity analyses – extraction accuracy (criterion validity); sensitivity (ability of a measure to identify positive results), specificity (ability of a measure to identify negative results) and percent agreement between the extracted and gold standard data
- Usability – measure element average and a weighted average of measure elements
- Feasibility – analysis of the feasibility of EHRs to collect the needed data elements through site interviews with both clinical and informatics staff at each testing site

2b7.2. What is the overall frequency of missing data, the distribution of missing data across providers, and the results from testing related to missing data? (*e.g., results of sensitivity analysis of the effect of various rules for missing data/nonresponse; if no empirical sensitivity analysis, identify the approaches for handling missing data that were considered and pros and cons of each*)

To be provided when testing is completed

2b7.3. What is your interpretation of the results in terms of demonstrating that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias**?** (i.*e., what do the results mean in terms of supporting the selected approach for missing data and what are the norms for the test conducted; if no empirical analysis, provide rationale for the selected approach for missing data*)

To be provided when testing is completed

3. Feasibility

Extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

3a. Byproduct of Care Processes

For clinical measures, the required data elements are routinely generated and used during care delivery (e.g., blood pressure, lab test, diagnosis, medication order).

3a.1. **Data Elements Generated as Byproduct of Care Processes.**

Generated or collected by and used by healthcare personnel during the provision of care (e.g., blood pressure, lab value, diagnosis, depression score)

If other:

3b. Electronic Sources

The required data elements are available in electronic health records or other electronic sources. If the required data are not in electronic health records or existing electronic sources, a credible, near-term path to electronic collection is specified.

3b.1. **To what extent are the specified data elements available electronically in defined fields?** *(i.e., data elements that are needed to compute the performance measure score are in defined, computer-readable fields)*
ALL data elements are in defined fields in electronic health records (EHRs)

3b.2. **If ALL the data elements needed to compute the performance measure score are not from electronic sources, specify a credible, near-term path to electronic capture, OR provide a rationale for using other than electronic sources.**

3b.3. **If this is an eMeasure, provide a summary of the feasibility assessment in an attached file or make available at a measure-specific URL.**
Attachment **Attachment:** National_Minority_Quality_Forum_Feasibility_Assessment_of_Fixed_Dose_Therapy_Measure.pdf

3c. Data Collection Strategy

Demonstration that the data collection strategy (e.g., source, timing, frequency, sampling, patient confidentiality, costs associated with fees/licensing of proprietary measures) can be implemented (e.g., already in operational use, or testing demonstrates that it is ready to put into operational use). For eMeasures, a feasibility assessment addresses the data elements and measure logic and demonstrates the eMeasure can be implemented or feasibility concerns can be adequately addressed.

3c.1. **Describe what you have learned/modified as a result of testing and/or operational use of the measure regarding data collection, availability of data, missing data, timing and frequency of data collection, sampling, patient confidentiality, time and cost of data collection, other feasibility/implementation issues.**
IF a PRO-PM, consider implications for both individuals providing PROM data (patients, service recipients, respondents) and those whose performance is being measured.
Because this measure is submitted for eMeasure trial approval and testing is not yet completed, we are not yet able to share information on data availability and collection beyond what is provided in the feasibility assessment in 3b.3. This information will be collected during our testing and modifications made to the measure based on the results.

3c.2. **Describe any fees, licensing, or other requirements to use any aspect of the measure as specified** *(e.g., value/code set, risk model, programming code, algorithm)*.
Not applicable

4. Usability and Use

Extent to which potential audiences (e.g., consumers, purchasers, providers, policy makers) are using or could use performance results for both accountability and performance improvement to achieve the goal of high-quality, efficient healthcare for individuals or populations.

4a. Accountability and Transparency

Performance results are used in at least one accountability application within three years after initial endorsement and are publicly reported within six years after initial endorsement (or the data on performance results are available). If not in use at the time of initial endorsement, then a credible plan for implementation within the specified timeframes is provided.

4.1. **Current and Planned Use**
NQF-endorsed measures are expected to be used in at least one accountability application within 3 years and publicly reported within 6 years of initial endorsement in addition to performance improvement.

Planned	Current Use (for current use provide URL)
Payment Program	Quality Improvement with Benchmarking (external benchmarking to multiple organizations)

	Get with the Guideline-Heart Failure Registry http://www.heart.org/HEARTORG/HealthcareResearch/GetWithTheGuidelines/GetWithTheGuidelines-HF/Get-With-The-Guidelines-Heart-Failure_UCM_306087_SubHomePage.jsp

4a.1. **For each CURRENT use, checked above, provide:**

- Name of program and sponsor
- Purpose
- Geographic area and number and percentage of accountable entities and patients included

A similar measure focused on hospital performance is currently used for quality improvement and benchmarking purposes in the American Heart Association´s Get with the Guidelines-Heart Failure registry. Information on the geographic area, number and percentage of hospitals, providers and patients is not available on the registry web site.

4a.2. **If not currently publicly reported OR used in at least one other accountability application (e.g., payment program, certification, licensing) what are the reasons?** (*e.g., Do policies or actions of the developer/steward or accountable entities restrict access to performance results or impede implementation?*)

This is a newly developed measure intended to be used and reported at the clinician level. Information on additional uses including accountability applications will be provided at the time of maintenance. NMQF is dedicated to ensuring that this measure is implemented widely and submitted the measure for consideration by the Centers for Medicare & Medicaid Services (CMS) under its recent Physician Quality Reporting System (PQRS) call for measures. This measure could be considered for inclusion in CMS programs as early as 2017.

4a.3. **If not currently publicly reported OR used in at least one other accountability application, provide a credible plan for implementation within the expected timeframes -- any accountability application within 3 years and publicly reported within 6 years of initial endorsement.** (*Credible plan includes the specific program, purpose, intended audience, and timeline for implementing the measure within the specified timeframes. A plan for accountability applications addresses mechanisms for data aggregation and reporting.*)

This is a newly developed measure intended to be used and reported at the clinician level. Information on additional uses including accountability applications will be provided at the time of maintenance. NMQF is dedicated to ensuring that this measure is implemented widely and submitted the measure for consideration by the Centers for Medicare & Medicaid Services (CMS) under its recent Physician Quality Reporting System (PQRS) call for measures. This measure could be considered for inclusion in CMS programs as early as 2017.

4b. Improvement

Progress toward achieving the goal of high-quality, efficient healthcare for individuals or populations is demonstrated. If not in use for performance improvement at the time of initial endorsement, then a credible rationale describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.

4b.1. **Progress on Improvement. (Not required for initial endorsement unless available.)**

Performance results on this measure (current and over time) should be provided in 1b.2 and 1b.4. Discuss:

- **Progress (trends in performance results, number and percentage of people receiving high-quality healthcare)**
- **Geographic area and number and percentage of accountable entities and patients included**

As this is a newly developed measure, we do not yet have data on the overall performance and progress on improvement of the measure but will be able to submit this information at the time of maintenance.

4b.2. **If no improvement was demonstrated, what are the reasons? If not in use for performance improvement at the time of initial endorsement, provide a credible rationale that describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.**

Because this is a newly developed measure, we do not have data on improvement other than what has been published. Specifically, Golwala and colleagues completed an observational analysis of data from the Get With the Guidelines-Heart Failure Registry. They showed that just over 22% of African American patients were discharged from the hospital with a prescription for the combination therapy. While performance would be considered low overall, rates increased from 16% to 24% over four years (Golwala, 2013). NMQF is also aware of individual providers and hospitals who are tracking this data through the Get with the Guidelines-Heart Failure registry and actively working toward improving performance on this measure. This measure is based on Class IA clinical guideline recommendations with clear reductions in mortality and initial hospitalizations and improved quality of life in patients.

4c. Unintended Consequences

The benefits of the performance measure in facilitating progress toward achieving high-quality, efficient healthcare for individuals or populations outweigh evidence of unintended negative consequences to individuals or populations (if such evidence exists).

4c.1. **Were any unintended negative consequences to individuals or populations identified during testing; OR has evidence of unintended negative consequences to individuals or populations been reported since implementation? If so, identify the negative unintended consequences and describe how benefits outweigh them or actions taken to mitigate them.**

Because this measure is submitted for eMeasure trial approval and testing is not yet completed, we are not yet able to share information on whether unintended negative consequences were identified. This information will be collected during our testing and modifications and other actions to mitigate them will be made to the measure based on the results.

5. Comparison to Related or Competing Measures

If a measure meets the above criteria and there are endorsed or new related measures (either the same measure focus or the same target population) or competing measures (both the same measure focus and the same target population), the measures are compared to address harmonization and/or selection of the best measure.

5. Relation to Other NQF-endorsed Measures

Are there related measures (conceptually, either same measure focus or target population) or competing measures (conceptually both the same measure focus and same target population)? If yes, list the NQF # and title of all related and/or competing measures.

Yes

5.1a. **List of related or competing measures (selected from NQF-endorsed measures)**

0081 : Heart Failure (HF): Angiotensin-Converting Enzyme (ACE) Inhibitor or Angiotensin Receptor Blocker (ARB) Therapy for Left Ventricular Systolic Dysfunction (LVSD)

0083 : Heart Failure (HF): Beta-Blocker Therapy for Left Ventricular Systolic Dysfunction (LVSD)

5.1b. **If related or competing measures are not NQF endorsed please indicate measure title and steward.**

Previously endorsed measure:

0162: ACEI or ARB for left ventricular systolic dysfunction - Heart Failure (HF) Patients (CMS)

0610: Heart Failure - Use of ACE Inhibitor (ACEI) or Angiotensin Receptor Blocker (ARB) Therapy (ActiveHealth Management)

0615: Heart Failure - Use of Beta Blocker Therapy (ActiveHealth Management)

5a. Harmonization

The measure specifications are harmonized with related measures;

OR

The differences in specifications are justified

5a.1. **If this measure conceptually addresses EITHER the same measure focus OR the same target population as NQF-endorsed measure(s):**

Are the measure specifications completely harmonized?

Yes

5a.2. **If the measure specifications are not completely harmonized, identify the differences, rationale, and impact on interpretability and data collection burden.**

Measure specifications for the target population and medication therapies for ACEI, ARB, and beta-blocker are completely harmonized with 0081 and 0083.

5b. Competing Measures

The measure is superior to competing measures (e.g., is a more valid or efficient way to measure);

OR

Multiple measures are justified.

5b.1. **If this measure conceptually addresses both the same measure focus and the same target population as NQF-endorsed measure(s):**
Describe why this measure is superior to competing measures (e.g., a more valid or efficient way to measure quality); OR provide a rationale for the additive value of endorsing an additional measure. (Provide analyses when possible.)
Not applicable

Appendix

A.1 Supplemental materials may be provided in an appendix. All supplemental materials (such as data collection instrument or methodology reports) should be organized in one file with a table of contents or bookmarks. If material pertains to a specific submission form number, that should be indicated. Requested information should be provided in the submission form and required attachments. There is no guarantee that supplemental materials will be reviewed.

This committee advised on the underlying evidence, measure statements construction, and detailed specifications during the development of the Fixed-dose combination therapy measure. They will continue to provide input and clinical expertise as the measure is tested and finalized and during every measure update.

Measure Developer/Steward Updates and Ongoing Maintenance

Ad.2 **Year the measure was first released:** 2015

Ad.3 **Month and Year of most recent revision:** 06, 2015

Ad.4 **What is your frequency for review/update of this measure?** Specifications are updated annually; supporting guidelines reviewed 3 years or as evidence changes

Ad.5 **When is the next scheduled review/update for this measure?** 12, 2016

Ad.7 **Disclaimers:** These Measures are intended to assist physicians in enhancing quality of care. Measures are designed for use by any physician who manages the care of a patient for a specific condition, or for prevention. These performance Measures are not clinical guidelines and do not establish a standard of medical care, and have not been tested for all potential applications. NMQF encourages the testing and evaluation of its Measures.

THE MEASURES AND SPECIFICATIONS ARE PROVIDED "AS IS" WITHOUT WARRANTY OF ANY KIND.
