MEASURE WORKSHEET

This document summarizes the evaluation of the measure as it progresses through NQF's Consensus Development Process (CDP). The information submitted by measure developers/stewards is included after the Brief Measure Information, Preliminary Analysis, and Pre-meeting Public and Member Comments sections.

Brief Measure Information

NQF #: 0067
Measure Title: Chronic Stable Coronary Artery Disease: Antiplatelet Therapy
Measure Steward: American College of Cardiology
Brief Description of Measure: Percentage of patients aged 18 years and older with a diagnosis of coronary artery disease seen within a 12 month period who were prescribed aspirin or clopidogrel.
Developer Rationale: Improvement in the number of patients with CAD who are prescribed antiplatelet therapy.

Numerator Statement: Patients who were prescribed* aspirin or clopidogrel within a 12 month period.

*Prescribed may include prescription given to the patient for aspirin or clopidogrel at one or more visits in the measurement period OR patient already taking aspirin or clopidogrel as documented in current medication list.
Denominator Statement: All patients aged 18 years and older with a diagnosis of coronary artery disease seen within a 12 month period.
Denominator Exclusions: Documentation of medical reason(s) for not prescribing aspirin or clopidogrel (e.g., allergy, intolerance, receiving other thienopyridine therapy, receiving warfarin therapy, bleeding coagulation disorders, other medical reasons)

Documentation of patient reason(s) for not prescribing aspirin or clopidogrel (e.g., patient declined, other patient reasons)

Documentation of system reason(s) for not prescribing aspirin or clopidogrel (e.g., lack of drug availability, other reasons attributable to the health care system)

Measure Type: Process
Data Source: Electronic Clinical Data : Registry
Level of Analysis: Clinician : Individual
Is this an eMeasure? ☐ **Yes** ☒ **No** **If Yes, was it re-specified from a previously endorsed measure?** ☐ **Yes** ☐ **No**

Is this a MAINTENANCE measure submission? ☒ **Yes** ☐ **No, this is a NEW measure submission.**
For MAINTENANCE, state the Original Endorsement Date: 8/10/09 **Most Recent Endorsement Date:** 1/18/12

Previous Measure Evaluation - Public & Member Comments, Developer Responses & Steering Committee Recommendations from (Cardiology Project 2010):

0067 Chronic stable coronary artery disease: Antiplatelet therapy
Public and Member Comment
Comments included:
- Concern with broad exclusions.
- Data collection will be difficult for health plans.
- Overlaps with measure 0068 which is in wide use in the private sector.
- Composite measure 0076 is superior to this individual measure.

• Wording should be changed to anti-platelet therapy rather than aspirin or clopidogrel.

Developer Response: The level of analysis for this measure is individual clinician and groups, not health plans. The measure is limited to the only anti-platelet agents (i.e., aspirin and clopidogrel) recommended by the ACC/AHA clinical practice guidelines for patients with chronic stable angina which served as the primary evidence base to support measure development.

Steering Committee: The Committee reviewed the comments and developer responses and again considered the issue of competing measures (0068 & 0076). Ultimately the Committee identified the measures as "overlapping" rather than competing. The Committee identified the narrow population (CAD rather than IVD) as a weakness of this measure.

Preliminary Analysis

Criteria 1: Importance to Measure and Report

1a. Evidence

1a. Evidence. The evidence requirements for a *process* measure is that it is based on a systematic review (SR) and grading of the body of empirical evidence where the specific focus of the evidence matches what is being measured.

The developer provides the following evidence for this process measure:

- This is a clinician level measure that calculates the percentage of patients aged 18 years and older with a diagnosis of coronary artery disease seen within a 12-month period who were prescribed aspirin or clopidogrel in a clinician office/clinic, nursing facility or home health.
- The developer provides decision logic from secondary prevention to outcome for the use of antiplatelet therapy in decreasing morbidity, mortality, and hospitalization with patients in with chronic stable CAD.
- The developer provides 4 separate guidelines with 10 guideline statements for use of aspirin and clopidogrel in patients with CAD and provides the details of the Quantity/Quality/Consistency for the 2012 ACCF/AHA/ACP/AATS/PCNA/SCAI/STS guideline for the diagnosis and management of patients with stable IHD, which was Graded Class 1a & 1b and Levels of Evidence of A & B utilizing 2010 ACCF/AHA Task Force on Practice Guidelines. Methodology Manual and Policies From the ACCF/AHA.
- One meta-analysis for STEMI patients was published after the publication of the 2012 discussed guideline comparing intravenous P2Y12 inhibitors with clopidogrel on major ischemic and bleeding events, though the developer states does not conflict with the 10 guideline recommendation statements.

Questions for the Committee:

- *Should patients post-PCI with drug-eluding stents have BOTH aspirin and clopidogrel?*
- *For process measures:*
  - *Is the evidence directly applicable to the process of care being measured?*
  - *Is the process of care proximal and closely related to desired outcomes?*
- *For possible exception to the evidence criteria:*
  - *Are there, or could there be, performance measures of a related health outcome, OR evidence-based intermediate clinical outcomes, intervention/treatment?*
  - *Is there evidence of a systematic assessment of expert opinion beyond those involved in developing the measure?*
  - *Does the SC agree that it is acceptable (or beneficial) to hold providers accountable without empiric evidence?*

1b. Gap in Care/Opportunity for Improvement and 1b. Disparities

1b. Performance Gap. The performance gap requirements include demonstrating quality problems and opportunity for improvement.

- The developer provided 2013 and 2014 performance data from the Pinnacle registry:

	mean	Std dev	Min	Max	Interquartile score	#providers	#patients	Male	White	Black	Other
2013	86.2%	10.5%	0%	100%	10.3%	2407	1,023,530	62.6%	92.9%	5.1%	2.0%
2014	86.3%	9.49%	0%	100%	10.2%	2248	959,792	62.4%	92.0%	5.8%	2.2%

- Four additional studies cited demonstrating no significant improvement in the number of patients receiving antiplatelets; data demonstrates limited progress on the performance of this measure from 77% in 2006 to 84.9% using PINNACLE Registry data from 2008 to 2009 and 86.2% and 86.3% in 2013 and 2014.
- Disparities performance data from PINNACLE is detailed for total patients and providers based on sex, age. The developer states that race and insurance part of the PINNACLE data collection tool. The sample populations list diabetes, hypertension, Atrial Fibrillation/Flutter, Heart Failure, Peripheral Arterial Disease, Stroke/TIA and Myocardial Infarction co-morbidities.

Questions for the Committe:

- *Is there a gap in care that warrants a national performance measure?*
- *If no disparities information is provided, are you aware of evidence that disparities exist in this area of healthcare?*
- *Should this measure be indicated as disparities sensitive?*

Committee pre-evaluation comments

Criterion 1: Importance to Measure and Report (including 1a, 1b, 1c)

1. ***Committee's Overview Comments***:
   - This is a process measure that has uses 4 separate guidelines and 10 guideline statements to support the use of aspirin/clopidogrel in patients with CAD. For the guideline for stable IHD the recommendations are graded as 1a & 1b. The levels of of evidence are A (multiple RCTs) and B (single RCT).
   - Extensive/Adequete

1a. ***Committee's Comments on Evidence to Support Measure Focus:***

- Process - looks indirectly at ASA/Clopidogrel use via prescription/medicaton listing -- not actual patient use; however given that ASA is available without a prescription, it is as close a proxy as you can get. With Clopidogrel one could look at prescriptions filled but this is still a proxy for patient adherence.
- Yes

1b. ***Committee's Comments on Performance Gap:***

- Information was provided from the Pinnacle registry. This demonstrates a performance gap. There was 86.2% prescribing in 2013 and 86.3% in 2014. In 2009 the rate was 84.9%. This begs the question regarding whether this measure has topped out.
- I am concerned about that fact that the data is all from the Pinnacle Registry where the population was 92.0 - 92.9% White. If there are disparities related to race, they would not necessarily be picked up in the analysis provided. That being said, within the data reported from Pinnacle, there is about a 6% difference in performance rates between men and women patients. The difference between White and Blacks was smaller at around 3%
- Disparities are now well demonstrated
- There is little gap present as the administration of ASA is widely adopted

1c. ***Committee's Comments on Composite Performance Measure:***

- Not Applicable

- Yes

Criteria 2: Scientific Acceptability of Measure Properties

2a. Reliability

2a1. Reliability Specifications

2a1. Specifications requires the measure, as specified, to produce consistent (reliable) and credible (valid) results about the quality of care when implemented.

- The measure's data source is the PINNACLE Registry with the data dictionary and collection tool provided. ICD9, ICD10, and CPT codes are provided for numerator and denominator. The concepts of "prescribed" and "documented" are provided. Data used to calculate the measure is abstracted electronically from the EHR.
- Based on the title, the measure targets adult patients with "chronic" and "stable" CAD, though neither of these terms are described based on the duration of the diagnosis nor the time from and acute event until measurement. The ICD 9 codes for the denominator include codes for AMI (410) (including those less than 8 weeks old) and 411 other acute and subacute forms of ischemic heart disease (411) (includes acute coronary insufficiency and subendocardia ischemia).
- In 1.2, the developer states that practices with less than 10 patient encounters are excluded from the measure, though this is not included in the denominator exclusions.
- The developer describes both denominator exclusions (#3) and exceptions (#5) in the measure logic calculation in S.18, though only denominator exclusions are provided S.10. Generally, exceptions are noted in eMeasures, which this measure is not specified.
- The developer provides both narrative descriptions for patient, medical and system reason exclusions/exceptions in the submission, though the data collection tool has undefined patient, medical and system exclusions/exceptions.

Questions for the Committee:

- *Are all the data elements clearly defined? Are all appropriate codes included?*
- *Is the logic or calculation algorithm clear?*
- *Is it likely this measure can be consistently implemented?*

eMeasure Technical Advisor(s) review (if not an eMeasure, delete this section): This is not an eMeasure

Prior to 2014, this measure was previously specified as an EHR-reportable measure for PQRS, though it does not meet NQF's current definition of an eMeasure. The developers did not submit an eMeasure with this submission.

2a2. Reliability Testing Testing attachment

2a2. Reliability testing demonstrates if the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise enough to distinguish differences in performance across providers.

- Reliability testing was conducted on the performance score, using PINNACLE data source at the individual clinician level during calendar year 2013 for 2407 providers and 1,023,530 patients; & 2014 for 2248 providers and 959,792 patients.
- A signal-to-noise analysis using the beta-binomial model was conducted. This type of analysis, which is appropriate for the measure, quantifies the amount of variation in performance that is due to differences between providers (as opposed to differences that are due to random measurement error). A reliability of zero implies that all the variability in a measure is attributable to measurement error. A reliability of one implies that all the variability is attributable to real differences in physician performance. The method results in a reliability statistic for each clinician.

- At the minimum number of patient visits required (>10) the average reliability was 0.994 for 2013 & 0.986 for 2014. For providers with the median number of patient encounters, the reliability was even higher, with 0.998 for both years. A reliability of 0.70 is generally considered a minimum threshold for acceptability, and 0.80 is considered very good reliability. Very high quartiles reliability statistics are also provided for both 2013 and 2014.

Questions for the Committee:

- *Specific questions on the method and results of reliability testing.*
- *Is the test sample adequate to generalize for widespread implementation?*
- *Do the results demonstrate sufficient reliability so that differences in performance can be identified?*

2b. Validity

2b1. Validity: Specifications

2b1. Validity Specifications. This section should determine if the measure specifications are consistent with the evidence.

- The clinical practice guidelines supporting this measure recommend the use of aspirin or clopidogrel in patients with CAD.

Question for the Committee:

- *Are the specifications consistent with the evidence?*

2b2. Validity testing

2b2. Validity Testing should demonstrate the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality.

- Content validity was assessed by an expert work group, public comment, concurrent formal peer review process, approval by the ACC Board of Trustee & Science Advisory & Coordination Committees, and PCPI membership.
- The developers state that construct validity (the degree to which the measure is assessing what it claims to be measuring) was difficult to assess as independent auditing has not occurred, though as the data is abstracted from the EHR by direct transfer, errors would occur by mapping or incorrect auditor abstracting.
- Face validity was systematically assessed via survey by 2 committees (one ACC & one AHA) of 42 members with 83.3% agreeing the measure scores as specified provide an accurate reflection of quality and can be used to distinguish good and poor quality. Using a Likert Scale from 1-5, the mean importance rate was 4.26.

Questions for the Committee:

- *Is the test sample adequate to generalize for widespread implementation?*
- *Do the results demonstrate sufficient validity so that conclusions about quality can be made?*
- *Do you agree that the score from this measure as specified is an indicator of quality?*
- *Are further definitions and timing required with the concepts of "chronic" and "stable" for CAD?*

2b3-2b7. Threats to Validity

2b3. Exclusions:

- The developer is encouraged to provide clarification if patient, medical and system exclusions/exceptions are directly calculated from a "yes/no" question, or by calculating performance from numerous data elements. Example: Patients excluded from the measure include patients with documented medical (e.g., allergy, intolerance, receiving other thienopyridine therapy, receiving warfarin therapy, bleeding coagulation disorders, other medical reasons), patient (e.g., patient declined, other patient reasons), or system reason (e.g., lack of drug availability, other reasons attributable to the health care system) for not on aspirin or clopidogrel or patients were on warfarin.

- In the PINNACLE data collection tool, the definition and use of patient, medical and system exclusion/exception reasons appear to be left to the provider and/or the EHR vendor mapping the data elements to the clinical registry.
- In PINNACLE missing values are interpreted as "no" for most variables, therefore missing documentation of antiplatelet medication indicates a failure to meet the measure. Providers with less than 10 eligible patient encounters during the study period are also excluded due to small sample sizes. The developers state they did not conduct an empirical analysis of frequency or distribution of missing data.
- There is a wide variation between providers in their rate of exclusions/exceptions.
    - In the 2013 testing sample 3.1% of providers had no exceptions, among those who did, the exclusion rate ranges from 0.2% to 35.3% (mean = 6.0%). Of those patients removed from the measure, 0.72% were removed due to a medical reason, 9.47% were removed for a patient reason, 1.48% were removed for a system reason, 0.30% were removed due to multiple reasons, and 88.03% were removed due to patients who were on warfarin or another thienopyridine that is not included in this measure (e.g. prasugrel or ticagrelor) and the physician felt that the addition of aspirin or a clopidogrel provided an increased risk of bleeding with minimal benefits in the prevention of recurrent cardiovascular events.
    - In the 2014 testing sample 2.5% of the providers had no exceptions, among those who did, the exclusion rate ranges from 0.3% to 27.4% (mean = 5.8%). Of those patients removed from the measure, 0.80% were removed due to a medical reason, 9.52% were removed for a patient reason, 1.88% were removed for a system reason, 0.31% were removed due to multiple reasons, and 87.50% were removed due to concomitant medications that either provide anti-platelet or systemic anti-coagulation.

Questions for the Committee:

- *For the 2013 & 2014 performance and testing data, were all the patients abstracted from EHRs only? If the measure calculates performance electronically abstracted data only, is the population limited only to patients whose providers have an EHR?*
- *Are the exclusions consistent with the evidence?*
- *Are any patients or patient groups inappropriately excluded from the measure?*
- *Are the exclusions/exceptions of sufficient frequency and variation across providers to be needed (and outweigh the data collection burden)?*

2b4. Risk adjustment:

- This process measure is not risk adjusted.

2b5. Meaningful difference:

- The overall mean performance on this measure is 86.2% (SD = 10.5%) for 2013 and 86.3% (SD = 9.49%) for 2014.
- The developer notes a small amount of variability across providers for statistically 'identical' patients and suggests that a patient presenting to 1 provider, as opposed to another, would on average, be 11% (2013) and 9% (2014) more likely to be treated with an anti-platelet agent.

Question for the Committee:

- *Does this measure identify meaningful differences about quality?*

2b6. Comparability of data sources/methods:

- N/A

2b7. Missing Data

- The developer notes that in the PINNACLE registry, most missing values are interpreted as "NO".
- Also see missing values.

Committee pre-evaluation comments

Criterion 2: Scientific Acceptability of Measure Properties (including all 2a, 2b, and 2d)

2a1. & 2b1.: ***Committee's Comments on Reliability-Specifications:***

- If this is supposed to be about stable IHD, the codes for AMI (410) and acute and subacute IHD should not be included. There are measures that look at ASA and thienopyridine use in these populations. Exceptions - I do not understand why there would be systems exclusions for this measure.
- The patients that are receiving dual anti platelet therapy for another reason (DAPT) might be included in the numerator - these are technically not chronic stable CAD patients
    - other anti-platelets are not included - prasugrel, ticagrelor
    - I'm not sure that the definition of chronic CAD does specifically exclude patients who had an acute event within the period observed with this measure
    - Patients receiving ASA for other indication might me incorrectly counted as receiving ASA for CAD

2a2.: ***Committee's Comments on Reliability-Testing:***

- Signal-to-noise analysis was performed. The value was very good when the patient visits were >10 (0.994 and 0.986).
- The test sample is adequate. Also the developers provided information about antiplatelet therapy monitoring by other groups and showed similar results
- Yes

2b1.: ***Committee's Comments on Validity-Specifications***:

- The specifications are somewhat broad in that they do not specify a dose or frequency of the antiplatelet therapy. The drugs recommended are consistent with the guidelines.
- Content and face validity were tested as they pertain to the use of antiplatelet therapy in stable IHD.
- It would be reasonable to drop AMI and other acute/subacute IHD from the diagnosis codes in the denominator or put a time stipulation on them to be more reflective of stable outpatients.
- No

2b2.: ***Committee's Comments on Validity-Testing:***

- The developers primarily refer to the Pinnacle Registry testing information; however in a separate testing results document, they provide comparisons concerning antiplatelet medication prescription in other monitoring programs. The results are similar.
- I do believe that the score would be a meaure of quality of stable IHD care. It might be good to put time stipulations on the use of AMI in the denominator although if the patient is being seen in the outpatient setting, it must be at least a few days post-event in most cases.
- Yes

2b3-7.: ***Committee's Comments on Threats to Validity:***

- 2b3 Exclusions - The biggest exclusion was for warfarin use and this is totally appropriate. As mentioned previously, I cannot think of a system reason for not prescribing either ASA or clopidogrel to these patients.
- It does appear that for the performance and testing data, only patients with EHRs were used. Pinnacle can be used without an EHR but requires personnel for data entry.
- 2b4 Risk adjustment - not done; ASA is cheap and easily attainable but it bothers me that the Pinnacle Registry patients were 92% White.
- There was not a lot of variability of performance across the various types of insurance. In fact, those without insurance had higher rates of having prescriptions."
- The patients that are receiving dual anti platelet therapy for another reason (DAPT) might be included in the numerator - these are technically not chronic stable CAD patients
    - other anti-platelets are not included - prasugrel, ticagrelor
    - I'm not sure that the definition of chronic CAD does specifically exclude patients who had an acute event within the period observed with this measure
    - Patients receiving ASA for other indication might me incorrectly counted as receiving ASA for CAD

2d.: ***Committee's Comments on Composite Performance Measure:***

- Not Applicable

Criterion 3. Feasibility

3. Feasibility is the extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

- The data source is electronic abstraction from the clinical record, MDS, OASIS to the PINNACLE Registry from readily available data occurring during patient care.
- As one of the earliest NQF endorsed measures utilized, the developers state the data collection strategy is implemented, though no information for abstraction time and costs are provided.

Questions for the Committee:

- *Are the required data elements routinely generated and used during care delivery?*
- *Are the required data elements available in electronic form, e.g., EHR or other electronic sources?*
- *Is the data collection strategy ready to be put into operational use?*

Committee pre-evaluation comments
Criterion 3: Feasibility

3.: ***Committee's Comments on Feasibility:***

- The required data is readily available in patient records. Finding the reason for an exception might be more challenging.
- The prescription and diagnosis data elements are readily available. Rationale for not prescribing could be in text fields or written notes making them less accessible. Linking of EHR to Pinnacle extraction would potentially address these issues.
- For the measure to be used outside the Pinnacle registry there could be some data extraction issues.
- The measure is feasible.

Criterion 4: Usability and Use

4. Usability and Use evaluate the extent to which audiences (e.g., consumers, purchasers, providers, policymakers) use or could use performance results for both accountability and performance improvement activities.

- The measure is currently reported in Physician Quality Reporting System (PQRS). Beginning in 2015, a payment adjustment to providers who do not satisfactorily report data on quality measures will be implemented. The measure will also be reported to CMS by the PINNACLE Registry as part of PQRS in 2015 as a Qualified Clinical Data Registry.
- The measure is currently used in the ACC PINNACLE Registry for quality improvement.
- The developers state they continue to seek additional opportunities for measure use in other public reporting and quality improvement programs, and do not have policies that would restrict use.
- In 2014 the Measure Applications Partnership (MAP) Clinician Workgroup did not support the measure for the Physician Compare and Value-Based Payment Modifier Programs because the measure does not adequately address any current needs of the program. Included in a MAP family of measures. Preferring other outcome measures that address coronary artery disease. In 2015, the Clinician Workgroup did not support the measure for the Medicare Shared Savings Program as Optimal Vascular Care measure (E0076) contains this measure as a component of the composite. Both measures would be redundant.

***Questions for the Committee**:*

- *Is the measure publicly reported?*
- *For maintenance measures – is the measure used in at least one accountability application?*
- *How can the performance results be used to further the goal of high-quality, efficient healthcare?*
- *Do the benefits of the measure outweigh any potential unintended consequences?*

Committee pre-evaluation comments

Criterion 4: Usability and Use

4.: ***Committee's Comments on Usability and Use:***

- Not currently publically reported.
- Measure is reported in the PQRS system and within Pinnacle itself
- Multiple other quality monitoring programs use antiplatelet therapy prescription in their plans.
- Unintended consequences are problematic
- It appears that the plateau has been reached and no further improvements are possible
- Public reporting might penalize providers although additional increase in the population receiving ASA is unlikely to happen

Criterion 5: Related and Competing Measures

- 0465 : Perioperative Anti-platelet Therapy for Patients undergoing Carotid Endarterectomy
- 0964 : Therapy with aspirin, P2Y12 inhibitor, and statin at discharge following PCI in eligible patients
- The developer states that the measure specifications are not completely harmonized because 0465 and 0964 address a different patient demographic and focus on inpatient prescribed ASA or clopidogrel.

0067 Chronic Stable Coronary Artery Disease: Antiplatelet Therapy.
(Clinician level measure, used for patients with CAD in OP, NH & HH settings)

Competing Measures

NQF# - Title & Description– how it differs – If not in CV, state the other project

Pre-meeting public and member comments

Comment by: Dr. Kathy Gans-Brangs, PhD
Organization: SPI

Comment#5119: "We urge adding Brilinta (ticagrelor) to the specification for NQF# 0067. BRILINTA is an FDA approved P2Y12 platelet inhibitor indicated to reduce the rate of thrombotic cardiovascular (CV) events in patients with acute coronary syndrome (ACS) when given with maintenance doses of aspirin less than 100 mg. In patients treated with percutaneous coronary intervention (PCI), it also reduces the rate of stent thrombosis. The EHR specifications, version 2.0 measure Value Set ID 000200 through 000208 (final 2 pages) include the following drug code descriptions: Thienopyridine therapy-excluding clopidogrel and specifically lists prasugrel, Effient, Ticlopidine and

Ticlid. The measure list does not include Brilinta (ticagrelor).

Supporting Information: The safety and efficacy of BRILINTA was evaluated in PLATO, a multicenter, randomized, double-blind study comparing ticagrelor to clopidogrel in 18,624 patients with ACS.1,2 At 12 months, the rate of CV death/MI/stroke was 9.8% for ticagrelor versus 11.7% for clopidogrel resulting in a relative risk reduction of 16% (p<0.001). The difference between treatments was driven by CV death and MI with no difference in stroke. The relative risk reduction of CV death was 21% and MI was 16% for ticagrelor versus clopidogrel (p=0.0013 and p=0.0045, respectively).1,2 In PLATO, 11,289 (60.6%) patients either had a previous stent implanted (n=1404) or underwent stent implantation during the study (n=9885).7 There was a lower risk of stent thrombosis with ticagrelor (1.3% for adjudicated "definite") than with clopidogrel (1.9%) (hazard ratio [HR], 0.67; 95% CI, 0.50-0.91; p=0.009).1,2,3 The results were similar for drug-eluting stents and bare metal stents.3 The reduction in definite stent thrombosis with ticagrelor was numerically greater for late [> 30 days: HR 0.48, (CI 0.24 – 0.96)], and subacute [24 h – 30 days: HR 0.60, (CI 0.39 – 0.93)] vs. acute stent thrombosis [< 24 h: HR 0.94 (CI 0.43 – 2.05)].

Please refer to the BRILINTA Prescribing Information for Boxed Warnings related to increased risk of bleeding and reduced effectiveness with maintenance doses of ASA greater than 100 mg per day (https//www.brilinta.com)."

Comment by: Ashish R. Trivedi, Pharm.D.
Organization: SPI-Lilly
Comment#5114: "While Lilly is supportive of this measure, we suggest the addition of lipid lowering therapy to this measure as supported by treatment guidelines for patients with coronary artery disease (CAD) [Stone et al, 2013]. Also, we would like to point out that comprehensive and routine lipoprotein lipid assessment is still an integral part of managing risk in patients with ASCVD (including CAD) [Jacobson et al, 2015]. In addition, clinical trial data indicates significant residual cardiovascular risk in ASCVD patients treated with statins, even in the setting of optimal LDL-C reduction (eg, <70 mg/dL and <100 mg/dL), thus highlighting the need to consider alternative CV risk reduction algorithms beyond the focus on LDL-C levels and/or the use of statins [Cannon et al 2004, LaRosa et al 2005, Pedersen et al 2005].

Comment by: Dr. Kathy Gans-Brangs, PhD
Organization: SPI
Comment#5118: "REQUEST FOR HARMONIZATION OF SIMILAR MEASURES: We believe that reviews undertaken by NQF in 2013-2014 and 2015 present an opportunity to ensure measure specification drug lists are current – that they exclude obsolete drug products based on inactive NDC codes and include all relevant FDA approved products. We urge the committee to review a side-by-side table of the specification for NQF measure # 0067 with measures 0964, 2452 and 2379 and any other relevant measures to ensure that the P2Y12 platelet inhibitor agents included are consistent (see Measure Comment Report for Cardiovascular Project 2013, Comment Period from May 27, 2014 to June 25, 2014)."

NATIONAL QUALITY FORUM—Evidence (subcriterion 1a)

Measure Number (*if previously endorsed*)**:** 0067
Measure Title: Chronic Stable Coronary Artery Disease: Antiplatelet Therapy
IF the measure is a component in a composite performance measure, provide the title of the Composite Measure here: Click here to enter composite measure #/ title

Date of Submission: 6/23/2015

Instructions

- *For composite performance measures:*
  - *A separate evidence form is required for each component measure unless several components were studied together.*
  - *If a component measure is submitted as an individual performance measure, attach the evidence form to the individual measure submission.*
- Respond to all questions as instructed with answers immediately following the question. All information needed to demonstrate meeting the evidence subcriterion (1a) must be in this form. An appendix of *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 10 pages (*incudes questions/instructions*; minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the evidence for this measure meets NQF's evaluation criteria.

1a. Evidence to Support the Measure Focus
The measure focus is evidence-based, demonstrated as follows:

- Health outcome: [3] a rationale supports the relationship of the health outcome to processes or structures of care. Applies to patient-reported outcomes (PRO), including health-related quality of life/functional status, symptom/symptom burden, experience with care, health-related behavior.
- Intermediate clinical outcome: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured intermediate clinical outcome leads to a desired health outcome.
- Process: [5] a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured process leads to a desired health outcome.
- Structure: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the

measured structure leads to a desired health outcome.
- Efficiency: [6] evidence not required for the resource use component.

Notes

3. Generally, rare event outcomes do not provide adequate information for improvement or discrimination; however, serious reportable events that are compared to zero are appropriate outcomes for public reporting and quality improvement.

4. The preferred systems for grading the evidence are the U.S. Preventive Services Task Force (USPSTF) grading definitions and methods, or Grading of Recommendations, Assessment, Development and Evaluation (GRADE) guidelines.

5. Clinical care processes typically include multiple steps: assess → identify problem/potential problem → choose/plan intervention (with patient input) → provide intervention → evaluate impact on health status. If the measure focus is one step in such a multistep process, the step with the strongest evidence for the link to the desired outcome should be selected as the focus of measurement. Note: A measure focused only on collecting PROM data is not a PRO-PM.

6. Measures of efficiency combine the concepts of resource use and quality (see NQF's Measurement Framework: Evaluating Efficiency Across Episodes of Care; AQA Principles of Efficiency Measures).

1a.1.This is a measure of: (*should be consistent with type of measure entered in De.1*)

Outcome

☐ Health outcome: Click here to name the health outcome

☐ Patient-reported outcome (PRO): Click here to name the PRO

PROs include HRQoL/functional status, symptom/symptom burden, experience with care, health-related behaviors

☐ Intermediate clinical outcome (*e.g., lab value*): Click here to name the intermediate outcome

☒ Process: Antiplatelet therapy for patients with chronic stable coronary artery disease

☐ Structure: Click here to name the structure

☐ Other: Click here to name what is being measured

HEALTH OUTCOME/PRO PERFORMANCE MEASURE *If not a health outcome or PRO, skip to 1a.3*

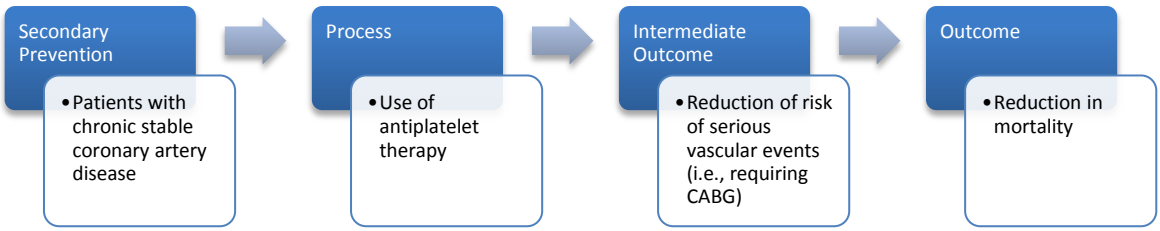
1a.2. Briefly state or diagram the path between the health outcome (or PRO) and the healthcare structures, processes, interventions, or services that influence it.

1a.2.1. State the rationale supporting the relationship between the health outcome (or PRO) to at least one healthcare structure, process, intervention, or service (*i.e., influence on outcome/PRO*).

Note: For health outcome/PRO performance measures, no further information is required; however, you may provide evidence for any of the structures, processes, interventions, or service identified above.

INTERMEDIATE OUTCOME, PROCESS, OR STRUCTURE PERFORMANCE MEASURE

1a.3. Briefly state or diagram the path between structure, process, intermediate outcome, and health outcomes. Include all the steps between the measure focus and the health outcome.



Use of antiplatelet therapy can decrease morbidity, mortality, and hospitalizations for patients with chronic stable coronary artery disease.

1a.3.1. What is the source of the systematic review of the body of evidence that supports the performance measure?
☒ Clinical Practice Guideline recommendation – ***complete sections 1a.4, and 1a.7***
☐ US Preventive Services Task Force Recommendation – ***complete sections 1a.5 and 1a.7***
☐ Other systematic review and grading of the body of evidence (*e.g., Cochrane Collaboration, AHRQ Evidence Practice Center*) – ***complete sections 1a.6 and 1a.7***
☐ Other – ***complete section 1a.8***

Please complete the sections indicated above for the source of evidence. You may skip the sections that do not apply.

1a.4. CLINICAL PRACTICE GUIDELINE RECOMMENDATION
1a.4.1. Guideline citation (*including date*) and **URL for guideline** (*if available online*):

1a.4.2. Identify guideline recommendation number and/or page number and **quote verbatim, the specific guideline recommendation**.

AHA/ACCF secondary prevention and risk reduction therapy for patients with coronary and other atherosclerotic vascular disease: 2011 update (p. e2434)

1. Aspirin 75–162 mg daily is recommended in all patients with coronary artery disease unless contraindicated. **Class I: Level of Evidence: A**
2. Clopidogrel 75 mg daily is recommended as an alternative for patients who are intolerant of or allergic to aspirin. **Class I: Level of Evidence: B**

2014 AHA/ACC guideline for the management of patients with non–ST-elevation acute coronary syndromes (p. e161, 171, 175, 187)

p. e161:

3. Non–enteric-coated, chewable aspirin (162 mg to 325 mg) should be given to all patients with NSTE-ACS without contraindications as soon as possible after presentation, and a maintenance dose of aspirin (81 mg/d to 325 mg/d) should be continued indefinitely. **Class I: Level of Evidence: A**

4. In patients with NSTE-ACS who are unable to take aspirin because of hypersensitivity or major gastrointestinal intolerance, a loading dose of clopidogrel followed by a daily maintenance dose should be administered. **Class I: Level of Evidence: A**

p. e171:

5. After PCI, aspirin should be continued indefinitely at a dose of 81 mg to 325 mg daily. **Class I: Level of Evidence: B**

p. e175:

6. Aspirin should be continued indefinitely. The maintenance dose should be 81 mg daily in patients treated with ticagrelor and 81 mg to 325 mg daily in all other patients. **Class I: Level of Evidence: A**

p. e187:

7. Patients with prior CABG and NSTE-ACS should receive antiplatelet and anticoagulant therapy according to GDMT and should be strongly considered for early invasive strategy because of their increased risk. **Class I: Level of Evidence: B**

2013 ACCF/AHA guideline for the management of ST-elevation myocardial infarction (p. e91)

8. After PCI, aspirin should be continued indefinitely. **Class I: Level of Evidence: A**

2012 ACCF/AHA/ACP/AATS/PCNA/SCAI/STS guideline for the diagnosis and management of patients with stable ischemic heart disease (p. e95)

9. Treatment with aspirin 75 to 162 mg daily should be continued indefinitely in the absence of contraindications in patients with SIHD. **Class I: Level of Evidence: A**

10. Treatment with clopidogrel is reasonable when aspirin is contraindicated in patients with SIHD. **Class I: Level of Evidence: B**

1a.4.3. Grade assigned to the quoted recommendation with definition of the grade:

Guideline Statement # (see 1a.4.2 above)	Class of Recommendation/Level of Evidence (for definitions see 1a.4.4 below)
1	Class Ia
2	Class Ib
3	Class Ia
4	Class Ia
5	Class Ib
6	Class Ia
7	Class Ib
8	Class Ia
9	Class Ia
10	Class Ib

1a.4.4. Provide all other grades and associated definitions for recommendations in the grading system. (*Note: If separate grades for the strength of the evidence, report them in section 1a.7.*)

Class of Recommendation (COR) is an estimate of the size of the treatment effect considering risks versus benefits in addition to evidence and/or agreement that a given treatment or procedure is or is not useful/effective or in some situations may cause harm.

Class I: Procedure/Treatment should be performed/administered

Class 1a
- Recommendation that procedure or treatment is useful/effective
- Sufficient evidence from multiple randomized trials or meta-analyses

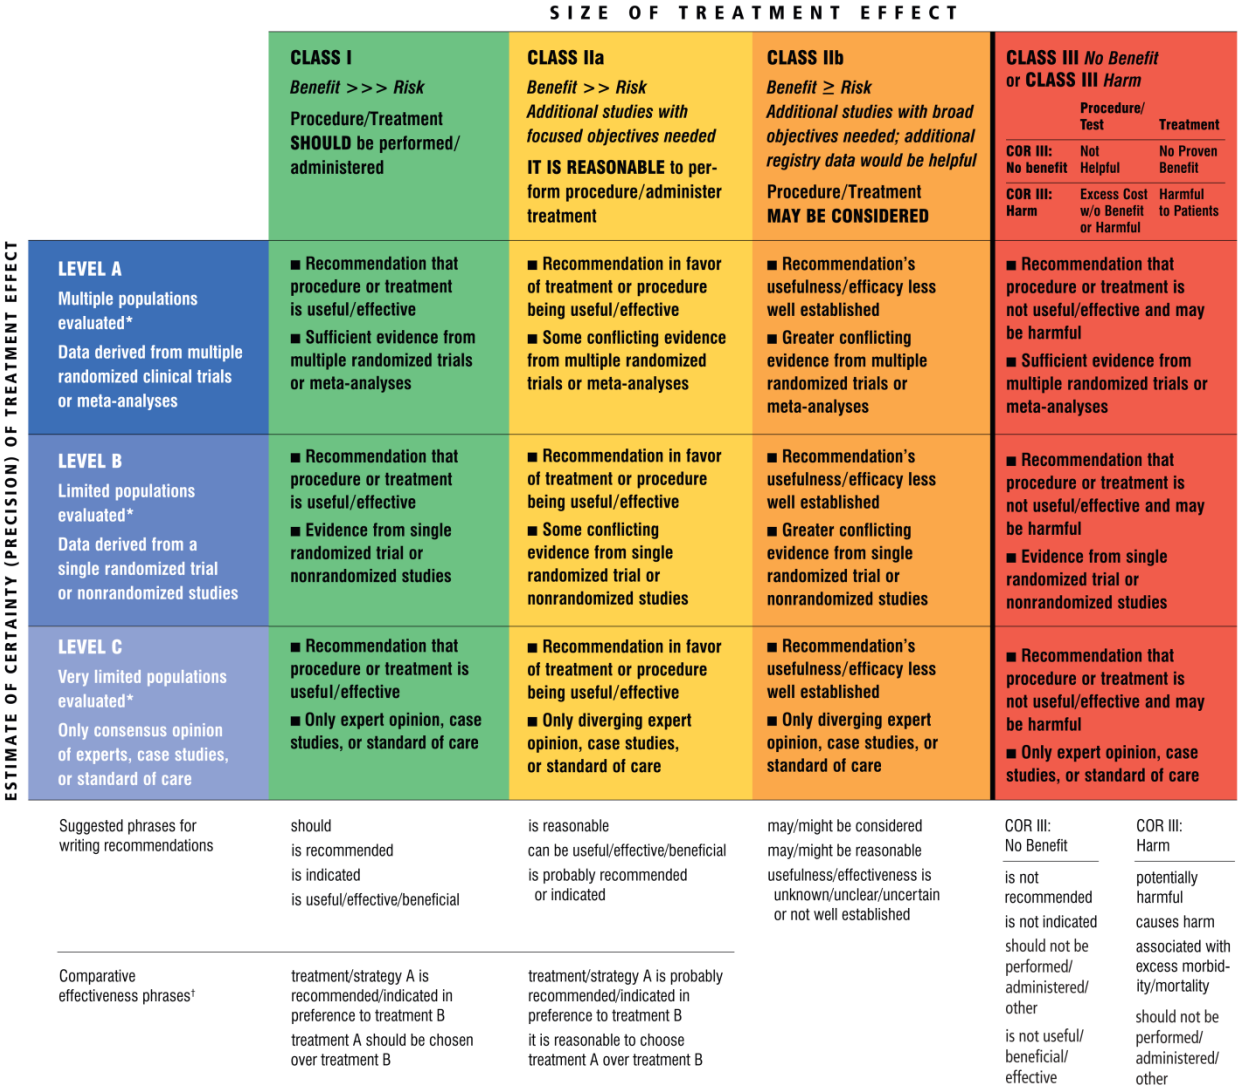
Class 1b
- Recommendation that procedure or treatment is useful/effective
- Evidence from single randomized trial or nonrandomized studies

Class 1c
- Recommendation that procedure or treatment is useful/effective
- Only expert opinion, case studies, or standard of care

Class IIa: It is reasonable to perform procedure/administer treatment
Class IIb: Procedure/Treatment may be considered
Class III: No benefit (Not helpful or No proven benefit)
Class III: Harm (Excess cost w/o benefit or Harmful to patients)

Specific COR definitions are included in Table 1 below.

Table 1. Applying Classification of Recommendation and Level of Evidence



Note: A recommendation with Level of Evidence B or C does not imply that the recommendation is weak. Many important clinical questions addressed in the guidelines do not lend themselves to clinical trials. Although randomized trials are unavailable, there may be a very clear clinical consensus that a particular test or therapy is useful or effective. *Data available from clinical trials or registries about the usefulness/efficacy in different subpopulations, such as sex, age, history of diabetes, history of prior myocardial infarction, history of heart failure, and prior aspirin use. †For comparative effectiveness recommendations (Class I and IIa; Level of Evidence A and B only), studies that support the use of comparator verbs should involve direct comparisons of the treatments or strategies being evaluated.

1a.4.5. Citation and URL for methodology for grading recommendations (*if different from 1a.4.1*)**:**

Complete section 1a.7

1a.7. FINDINGS FROM SYSTEMATIC REVIEW OF BODY OF THE EVIDENCE SUPPORTING THE MEASURE

If more than one systematic review of the evidence is identified above, you may choose to summarize the one (or more) for which the best information is available to provide a summary of the quantity, quality, and consistency of the body of evidence. Be sure to identify which review is the basis of the responses in this section and if more than one, provide a separate response for each review.

1a.7.1. What was the specific structure, treatment, intervention, service, or intermediate outcome addressed in the evidence review?

2012 ACCF/AHA/ACP/AATS/PCNA/SCAI/STS guideline for the diagnosis and management of patients with stable ischemic heart disease

This guideline covers multiple management issues for the adult patient with stable known or suspected ischemic heart disease (SIHD) including the guideline-directed medical therapy (GDMT) such as antiplatelet therapy.

1a.7.2. Grade assigned for the quality of the quoted evidence with definition of the grade:

An overall grade for the quality of evidence was not assigned. Rather, the quality of a study (or set of studies) supporting a recommendation was graded on an estimate of the certainty or precision of the treatment effect (see 1a.4.3).

Recommendations used to support this measure have a:

- Level of Evidence of A: Data derived from multiple randomized clinical trials or meta- analyses. References used to determine level of evidence must be provided and cited with the recommendation

OR

- Level of Evidence B: Data derived from a single randomized trial, or nonrandomized studies. References used to determine level of evidence must be provided and cited with the recommendation.

1a.7.3. Provide all other grades and associated definitions for strength of the evidence in the grading system.
Level of Evidence (LOE) is an estimate of the certainty or precision of the treatment effect.

Level of Evidence A: Data derived from multiple randomized clinical trials or meta- analyses. References used to determine level of evidence must be provided and cited with the recommendation.

Level of Evidence B: Data derived from a single randomized trial, or nonrandomized studies. References used to determine level of evidence must be provided and cited with the recommendation.

Level of Evidence C: Consensus opinion of experts, case studies, or standard of care.

Specific LOE definitions are included in Table 1 in 1a.4.4.

1a.7.4. What is the time period covered by the body of evidence? (*provide the date range, e.g., 1990-2010*). Date range: An extensive evidence review was conducted through December 2008 and includes selected other references through December 2011.

QUANTITY AND QUALITY OF BODY OF EVIDENCE

1a.7.5. How many and what type of study designs are included in the body of evidence? (*e.g., 3 randomized controlled trials and 1 observational study*)

2012 ACCF/AHA/ACP/AATS/PCNA/SCAI/STS guideline for the diagnosis and management of patients with stable ischemic heart disease

The body of evidence supporting the recommendations on antiplatelet therapy with patients with a prior MI includes randomized controlled trials and meta-analyses. The number of which is not provided in the guideline.

1a.7.6. What is the overall quality of evidence <u>across studies</u> in the body of evidence? (*discuss the certainty or confidence in the estimates of effect particularly in relation to study factors such as design flaws, imprecision due to small numbers, indirectness of studies to the measure focus or target population*)

2012 ACCF/AHA/ACP/AATS/PCNA/SCAI/STS guideline for the diagnosis and management of patients with stable ischemic heart disease

All of the recommendations for this process are rated as Level of Evidence A or B, meaning that the data was derived from one or more RCTs or meta-analyses. Additional information on the overall quality of evidence across the RCTs is not provided.

ESTIMATES OF BENEFIT AND CONSISTENCY ACROSS STUDIES IN BODY OF EVIDENCE

1a.7.7. What are the estimates of benefit—magnitude and direction of effect on outcome(s) across studies in the body of evidence? (*e.g., ranges of percentages or odds ratios for improvement/ decline across studies, results of meta-analysis, and statistical significance*)

2012 ACCF/AHA/ACP/AATS/PCNA/SCAI/STS guideline for the diagnosis and management of patients with stable ischemic heart disease

p. e95

Among 2,920 patients with SIHD, a comprehensive meta-analysis of source data revealed an association of aspirin use with a 37% reduction in the risk of serious vascular events, including a 46% decrease in the risk for UA and a 53% decrease in the risk of requiring coronary angioplasty. (Collaborative meta-analysis of randomised trials of antiplatelet therapy for prevention of death, myocardial infarction, and stroke in high risk patients. BMJ. 2002;324:71– 86.)

Clopidogrel 75 mg has been compared with aspirin 325 mg in patients with previous MI, stroke, or symptomatic PAD in the prospective, randomized CAPRIE (Clopidogrel versus Aspirin in Patients at Risk of Ischaemic Events) study. (A randomised, blinded, trial of clopidogrel versus aspirin in patients at risk of ischaemic events (CAPRIE). CAPRIE Steering Committee. Lancet. 1996;348:1329 –39.) Although clopidogrel demonstrated superiority over aspirin in the secondary prevention of MI and death in this group of patients, the magnitude of difference was small. Because no additional trials comparing aspirin and clopidogrel in patients with SIHD have been conducted, clopidogrel remains an acceptable alternative agent to aspirin.

1a.7.8. What harms were studied and how do they affect the net benefit (benefits over harms)?

2012 ACCF/AHA/ACP/AATS/PCNA/SCAI/STS guideline for the diagnosis and management of patients with stable ischemic heart disease

The guideline does not discuss potential harms of aspirin or clopidogrel therapy alone but the potential risks for major bleeding when both therapies are prescribed is discussed.

p. e95

In a meta-analysis of 5 RCTs comparing clopidogrel plus aspirin to aspirin alone in patients with IHD, the incidence of all-cause mortality, MI, and stroke was found to be reduced in the clopidogrel-plus- aspirin group, whereas the risk of major bleeding increased significantly. The incidence of all-cause mortality was 6.3% in the aspirin plus clopidogrel group versus 6.7% in the aspirin group (odds ratio [OR] 0.94; 95% CI 0.89, 0.99; $p = 0.026$). The incidence of myocardial infarction was 2.7% and 3.3% (OR 0.82; 95% CI 0.75, 0.89; $p < 0.0001$), and stroke was 1.2% and 1.4% (OR 0.82; 95% CI 0.73, 0.93; $p = 0.002$). Similarly, the incidence of major bleeding was 1.6% and 1.3% (OR 1.26; 95% CI 1.11, 1.41; $p < 0.0001$), and fatal bleeding was 0.28% and 0.27% (OR 1.04; 95% CI 0.76, 1.43; $p = 0.79$). (Helton TJ, Bavry AA, Kumbhani DJ, et al. Incremental effect of clopidogrel on important outcomes in patients with cardiovascular disease: a meta-analysis of randomized trials. Am J Cardiovasc Drugs. 2007;7:289 –97.)

UPDATE TO THE SYSTEMATIC REVIEW(S) OF THE BODY OF EVIDENCE

1a.7.9. If new studies have been conducted since the systematic review of the body of evidence, provide for <u>each</u> new study: 1) citation, 2) description, 3) results, 4) impact on conclusions of systematic review.

One meta-analysis was published after the publication of the 2012 ACCF/AHA/ACP/AATS/PCNA/SCAI/STS guideline for the diagnosis and management of patients with stable ischemic heart disease.

Note: Text below for description and results is verbatim from the article abstract.

Tang XF, Fan JU, Meng J, Jin C, Yan JQ, Yang YJ. Impact of new oral or intravenous P2Y12 inhibitors and clopidogrel on major ischemic and bleeding events in patients with coronary artery disease: a meta-analysis of randomized trials. Atherosclerosis. 2014;233:568-78.

Description and Results: Twelve randomized, placebo-controlled studies and two subgroup analyses of included studies on ST-segment elevation myocardial infarction (STEMI) were included. The database consisted of 82,784 patients, with 43,875 (53%) on new oral P2Y12 inhibitors and 38909 (47%) on intravenous P2Y12 inhibitors compared with clopidogrel. The primary efficacy endpoint was major adverse cardiac events (MACEs). The primary safety endpoint was thrombolysis in myocardial infarction (TIMI) major bleeding. New oral P2Y12 inhibitors significantly decreased MACEs (odds ratio: 0.85, $p<0.0001$ for the whole cohort; OR: 0.77, $p=0.04$ for STEMI) and all-cause death (OR: 0.88, $p=0.04$ for the whole cohort; OR: 0.77, $p=0.01$ for STEMI). Among new intravenous P2Y12 inhibitors, only cangrelor significantly decreased the risk of MACEs. An increase in TIMI major bleeding was observed only by prasugrel among the new P2Y12 inhibitors.

Conclusion: New oral P2Y12 inhibitors reduce ischemic events, but there is no obvious increase in major bleeding in patients with CAD, and the risk/benefit ratio is particularly favorable for STEMI patients. Moreover, only cangrelor is beneficial for ischemic events in patients on new intravenous P2Y12 inhibitors.

Impact on conclusions of systematic review: This additional meta-analysis does not impact the current guideline recommendations on which this measure is based.

1a.8 OTHER SOURCE OF EVIDENCE

If source of evidence is NOT from a clinical practice guideline, USPSTF, or systematic review, please describe the evidence on which you are basing the performance measure.

1a.8.1 What process was used to identify the evidence?

1a.8.2. Provide the citation and summary for each piece of evidence.

1. Evidence, Performance Gap, Priority – Importance to Measure and Report
Extent to which the specific measure focus is evidence-based, important to making significant gains in healthcare quality, and improving health outcomes for a specific high-priority (high-impact) aspect of healthcare where there is variation in or overall less-than-optimal performance. ***Measures must be judged to meet all subcriteria to pass this criterion and be evaluated against the remaining criteria.***
1a. Evidence to Support the Measure Focus – See attached Evidence Submission Form CAD_Antiplatelet_0067_Evidence_Form_06_22_15.pdf
1b. Performance Gap Demonstration of quality problems and opportunity for improvement, i.e., data demonstrating:

- considerable variation, or overall less-than-optimal performance, in the quality of care across providers; and/or
- disparities in care across population groups.

1b.1. Briefly explain the rationale for this measure *(e.g., the benefits or improvements in quality envisioned by use of this measure)*
Improvement in the number of patients with CAD who are prescribed antiplatelet therapy.

1b.2. Provide performance scores on the measure as specified (current and over time) at the specified level of analysis. *(This is required for endorsement maintenance. Include mean, std dev, min, max, interquartile range, scores by decile. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities included). This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*
2013 performance data from the Pinnacle registry.

Overall mean performance on this measure is 86.2%, with a standard deviation of 10.5%. The minimum score equals 0.00%, while the maximum score equals 100.00%. The interquartile score is equal to 10.3%.

2,407 providers were measured, and the patient study sample equals 1,023,530. 62.4% of the sample is male. 92.0% of the sample is white, 5.8% is black, and 2.2 % identified as "other." The sample reached across all US regions, with 12.7% of providers in the Northeast, 29.0% of providers in the Midwest, 39.7 % of providers in the South, and 18.6% of providers in the West.
Mean

Decile 1 62.6%
Decile 2 77.7%
Decile 3 82.6%
Decile 4 85.5%
Decile 5 87.6%
Decile 6 89.5%
Decile 7 91.2%
Decile 8 93.0%
Decile 9 94.9%
Decile 10 97.6%

2014 performance data from the Pinnacle registry.

Overall mean performance on this measure is 86.3%, with a standard deviation of 9.49%. The minimum score equals 0.00%, while the maximum score equals 100.00%. The interquartile score is equal to 10.2%.

2,248 providers were measured, and the patient study sample equals 959,792. 62.6% of the sample is male. 92.9% of the sample is white, 5.1% is black, and 2.0% identified as "other." The sample reached across all US regions, with 11.4% of providers in the Northeast, 28.5% of providers in the Midwest, 40.3 % of providers in the South, and 19.8% of providers in the West.

Mean
Decile 1 65.4%
Decile 2 77.8%
Decile 3 82.4%
Decile 4 85.1%
Decile 5 87.3%
Decile 6 89.2%
Decile 7 91.0%
Decile 8 92.8%
Decile 9 94.7%
Decile 10 97.4%

1b.3. If no or limited performance data on the measure as specified is reported in 1b2, then provide a summary of data from the literature that indicates opportunity for improvement or overall less than optimal performance on the specific focus of measurement.

Additional data in support to the importance of CAD antiplatelet use. One study found 77% of patients were prescribed antiplatelet therapy, 51.8% were prescribed BBs, 49.5% were prescribed ACEIs, and 76.9% were prescribed statins [1]. Follow-up assessments 4 years later found no significant change in rates [2]. Most recently, Chan et al. [3], using 2008 to 2009 data from the PINNACLE registry, found higher rates of secondary prevention medication prescription among CAD patients. In their analysis, 84.9% of patients were receiving anti-platelets, 86.4% received BB, 72.4% received ACEI/ARB, and 84.3% received lipid lowering agents [3].

[3] Chan PS, Oetgen WJ, Buchanan D, et al. Cardiac performance measure compliance in outpatients: the American College of Cardiology and National Cardiovascular Data registry's PINNACLE (Practice Innovation and Clinical Excellence) program. J Am Coll Cardiol 2010;56: 8–14.

1b.4. Provide disparities data from the measure as specified (current and over time) by population group, e.g., by race/ethnicity, gender, age, insurance status, socioeconomic status, and/or disability. *(This is required for endorsement maintenance. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities include.) This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*

We examined variation in provider performance on this measure based on sex, age, race and a number of other patient factors to identify variations. The findings are represented for 2013 and 2014 respectively.

To see the data tables in formatted fashion, see testing form page 15.

2013

2013 stratified descriptive statistics of performance rate from Pinnacle Registry.

1b.5. **If no or limited data on disparities from the measure as specified is reported in 1b4, then provide a summary of data from the literature that addresses disparities in care on the specific focus of measurement. Include citations.**
We are not aware of any publications/evidence outlining disparities in this area, but would refer the reader to information provided in 1b.4.

1c. High Priority (previously referred to as High Impact)

The measure addresses:

- a specific national health goal/priority identified by DHHS or the National Priorities Partnership convened by NQF; OR
- a demonstrated high-priority (high-impact) aspect of healthcare (e.g., affects large numbers of patients and/or has a substantial impact for a smaller population; leading cause of morbidity/mortality; high resource use (current and/or future); severity of illness; and severity of patient/societal consequences of poor quality).

1c.1. **Demonstrated high priority aspect of healthcare**

Affects large numbers, A leading cause of morbidity/mortality, Severity of illness

1c.2. **If Other:**

1c.3. **Provide epidemiologic or resource use data that demonstrates the measure addresses a high priority aspect of healthcare. List citations in 1c.4.**

•Coronary heart disease (CHD) alone caused about 1 of every 6 deaths in the United States in 2010. In 2010, 379, 559 Americans died of CHD. [1]

•Each year, an estimated 620,000 Americans have a new coronary attack (defined as first hospitalized myocardial infarction or coronary heart disease death) and about 295, 000 have a recurrent attack. [2]

•It is estimated that an additional 150,000 silent first myocardial infarctions occur each year. Approximately every 34 seconds, 1 American has a coronary event, and approximately every 1 minute 23 seconds, an American will die of one.[2]

•Between 2013 and 2030, medical costs of CHD (real 2010$) are projected to increase by approximately 100% Indirect costs for all CVD (real 2010$) are projected to increase 52% (from $202.5 billion to $308.2 billion) between 2013 and 2030. Of these indirect costs, CHD is projected to account for about 43% and has the largest indirect costs (AHA computation, based on methodology described by Heidenreich et al.[3]

•On the basis of the NHLBI-sponsored FHS CHD makes up more than half of all cardiovascular events in men and women <75 years of age. The incidence of CHD in women lags behind men by 10 years for total CHD and by 20 years for more serious. [4]

•In 2006, $11.7 billion was paid to Medicare beneficiaries for in-hospital costs when CHD was the principal diagnosis ($14 009 per discharge for AMI, $12 977 per discharge for coronary atherosclerosis, and $10 630 per discharge for other ischemic HD). [5]

•On the basis of data from NHANES 2007 to 2010 (NHLBI tabulation), an estimated 15.4 million Americans =20 years of age have CHD.
  -Total CHD prevalence is 6.4% in US adults >=20 years of age. CHD prevalence is 7.9% for men and 5.1% for women.
  -Among non-Hispanic whites, CHD prevalence is 8.2% for men and 4.6% for women.
  -Among non-Hispanic blacks, CHD prevalence is 6.8% for men and 7.1% for women
  -Among Mexican Americans, CHD prevalence is 6.7% for men and 5.3% for women.

•On the basis of data from the 2012 NHIS
  -Among Hispanic or Latino individuals >=18 years of age, CHD prevalence is 5.9%.1
  -Among American Indian/Alaska Natives >=18 years of age, it is estimated that 8.1% have CHD, and among Asians >=18 years of age, the estimate is 4.5%[6]

1c.5. **If a PRO-PM (e.g. HRQoL/functional status, symptom/burden, experience with care, health-related behaviors), provide evidence that the target population values the measured PRO and finds it meaningful.** *(Describe how and from whom their input was obtained.)*
Not Applicable.

2. Reliability and Validity—Scientific Acceptability of Measure Properties

Extent to which the measure, as specified, produces consistent (reliable) and credible (valid) results about the quality of care when implemented. ***Measures must be judged to meet the subcriteria for both reliability and validity to pass this criterion and be evaluated against the remaining criteria.***

2a.1. Specifications The measure is well defined and precisely specified so it can be implemented consistently within and across organizations and allows for comparability. eMeasures should be specified in the Health Quality Measures Format (HQMF) and the Quality Data Model (QDM).

De.5. **Subject/Topic Area** *(check all the areas that apply):*
Cardiovascular, Cardiovascular : Ischemic Heart Disease, Coronary Artery Disease

De.6. **Cross Cutting Areas** *(check all the areas that apply):*

S.1. **Measure-specific Web Page** *(Provide a URL link to a web page specific for this measure that contains current detailed specifications including code lists, risk model details, and supplemental materials. Do not enter a URL linking to a home page or to general information.)*
http://www.ama-assn.org/ama1/pub/upload/mm/pcpi/cadminisetjune06.pdf

S.2a. **If this is an eMeasure**, HQMF specifications must be attached. Attach the zipped output from the eMeasure authoring tool (MAT) - if the MAT was not used, contact staff. (Use the specification fields in this online form for the plain-language description of the specifications)
This is not an eMeasure **Attachment:**

S.2b. **Data Dictionary, Code Table, or Value Sets** *(and risk model codes and coefficients when applicable) must be attached. (Excel or csv file in the suggested format preferred - if not, contact staff)*
No data dictionary **Attachment:**

S.3. **For endorsement maintenance**, please briefly describe any changes to the measure specifications since last endorsement date and explain the reasons.
For endorsement maintenance, we are not including e-measure specifications as we did in the previous submission cycle. We have

updated the measure specifications to included are the applicable CPT and ICD-10 codes.

S.4. **Numerator Statement** *(Brief, narrative description of the measure focus or what is being measured about the target population, i.e., cases from the target population with the target process, condition, event, or outcome)*
IF an OUTCOME MEASURE, state the outcome being measured. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
Patients who were prescribed* aspirin or clopidogrel within a 12 month period.

*Prescribed may include prescription given to the patient for aspirin or clopidogrel at one or more visits in the measurement period OR patient already taking aspirin or clopidogrel as documented in current medication list.

S.5. **Time Period for Data** *(What is the time period in which data will be aggregated for the measure, e.g., 12 mo, 3 years, look back to August for flu vaccination? Note if there are different time periods for the numerator and denominator.)*
Once during the measurement period.

S.6. **Numerator Details** *(All information required to identify and calculate the cases from the target population with the target process, condition, event, or outcome such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
IF an OUTCOME MEASURE, describe how the observed outcome is identified/counted. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
For Claims/Administrative: Report CPT II Code 4086F: Aspirin or clopidogrel prescribed.

S.7. **Denominator Statement** *(Brief, narrative description of the target population being measured)*
All patients aged 18 years and older with a diagnosis of coronary artery disease seen within a 12 month period.

S.8. **Target Population Category** *(Check all the populations for which the measure is specified and tested if any):*
Senior Care

S.9. **Denominator Details** *(All information required to identify and calculate the target population/denominator such as definitions, specific data collection items/responses , code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
See 'Registry Supplemental Resources' attached in appendix field A.1 for data dictionary and form.

Codes that are applicable for the denominator are:

Diagnosis for coronary artery disease (ICD-9-CM) 410.00, 410.01, 410.02, 410.10, 410.11, 410.12, 410.20, 410.21, 410.22, 410.30, 410.31, 410.32, 410.40, 410.41, 410.42, 410.50, 410.51, 410.52, 410.60, 410.61, 410.62, 410.70, 410.71, 410.72, 410.80, 410.81, 410.82, 410.90, 410.91, 410.92, 411.0, 411.1, 411.81, 411.89, 412, 413.0, 413.1, 413.9, 414.00, 414.01, 414.02, 414.03, 414.04, 414.05, 414.06, 414.07, 414.2, 414.3, 414.8, 414.9, V45.81, V45.82

Diagnosis for coronary artery disease (ICD-10-CM): I20.0, I20.1, I20.8, I20.9, I21.01, I21.02, I21.09, I21.11, I21.19, I21.21, I21.29, I21.3, I21.4, I22.0, I22.1, I22.2, I22.8, I22.9, I24.0, I24.1, I24.8, I24.9, I25.10, I25.110, I25.111, I25.118, I25.119, I25.2, I25.5, I25.6, I25.700, I25.701, I25.708, I25.709, I25.710, I25.711, I25.718, I25.719, I25.720, I25.721, I25.728, I25.729, I25.730, I25.731, I25.738, I25.739, I25.750, I25.751, I25.758, I25.759, I25.760, I25.761, I25.768, I25.769, I25.790, I25.791, I25.798, I25.799, I25.810, I25.811, I25.812, I25.82, I25.83, I25.89, I25.9, Z95.1, Z95.5, Z98.61

Patient encounter during the reporting period (CPT): 99201, 99202, 99203, 99204, 99205, 99212, 99213, 99214, 99215, 99304, 99305, 99306, 99307, 99308, 99309, 99310, 99324, 99325, 99326, 99327, 99328, 99334, 99335, 99336, 99337, 99341, 99342, 99343, 99344, 99345, 99347, 99348, 99349, 99350

S.10. **Denominator Exclusions** *(Brief narrative description of exclusions from the target population)*
Documentation of medical reason(s) for not prescribing aspirin or clopidogrel (e.g., allergy, intolerance, receiving other

thienopyridine therapy, receiving warfarin therapy, bleeding coagulation disorders, other medical reasons)

Documentation of patient reason(s) for not prescribing aspirin or clopidogrel (e.g., patient declined, other patient reasons)

Documentation of system reason(s) for not prescribing aspirin or clopidogrel (e.g., lack of drug availability, other reasons attributable to the health care system)

S.11. **Denominator Exclusion Details** *(All information required to identify and calculate exclusions from the denominator such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
For Claims/Administrative:

Documentation of medical reason(s) for not prescribing aspirin or clopidogrel
• Append modifier to CPT II code 4086F-1P

Documentation of patient reason(s) for not prescribing aspirin or clopidogrel
• Append modifier to CPT II code 4086F-2P

Documentation of system reason(s) for not prescribing aspirin or clopidogrel
• Append modifier to CPT II code 4086F-3P

S.12. **Stratification Details/Variables** *(All information required to stratify the measure results including the stratification variables, definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format with at S.2b)*
Not Applicable.

S.13. **Risk Adjustment Type** (Select type. Provide specifications for risk stratification in S.12 and for statistical model in S.14-15)
No risk adjustment or risk stratification
If other:

S.14. **Identify the statistical risk model method and variables** *(Name the statistical method - e.g., logistic regression and list all the risk factor variables. Note - risk model development and testing should be addressed with measure testing under Scientific Acceptability)*
Not Applicable.

S.15. **Detailed risk model specifications** *(must be in attached data dictionary/code list Excel or csv file. Also indicate if available at measure-specific URL identified in S.1.)*
Note: Risk model details (including coefficients, equations, codes with descriptors, definitions), should be provided on a separate worksheet in the suggested format in the Excel or csv file with data dictionary/code lists at S.2b.

S.15a. **Detailed risk model specifications** (*if not provided in excel or csv file at S.2b*)
Not Applicable.

S.16. **Type of score:**
Rate/proportion
If other:

S.17. **Interpretation of Score** *(Classifies interpretation of score according to whether better quality is associated with a higher score, a lower score, a score falling within a defined interval, or a passing score)*
Better quality = Higher score

S.18. **Calculation Algorithm/Measure Logic** *(Describe the calculation of the measure score as an ordered sequence of steps including*

identifying the target population; exclusions; cases meeting the target process, condition, event, or outcome; aggregating data; risk adjustment; etc.)
To calculate performance rates:

1) Find the patients who meet the initial patient population (i.e., the general group of patients that a set of performance measures is designed to address).

2) From the patients within the initial patient population criteria, find the patients who qualify for the denominator. (i.e., the specific group of patients for inclusion in a specific performance measure based on defined criteria). Note: in some cases the initial patient population and denominator are identical.

3) Find the patients who quality for exclusions and subtract from the denominator.

4) From the patients within the denominator (after exclusions have been subtracted from the denominator), find the patients who qualify for the Numerator (i.e., the group of patients in the denominator for whom a process or outcome of care occurs). Validate that the number of patients in the numerator is less than or equal to the number of patients in the denominator

5) From the patients who did not meet the numerator criteria, determine if the physician has documented that the patient meets any criteria for exception when exceptions have been specified [for this measure: medical reason(s)(e.g., eg, allergy, intolerance, receiving other thienopyridine therapy, receiving warfarin therapy, bleeding coagulation disorders, other medical reasons) or patient reason(s)(e.g., economic, social, and/or religious impediments, noncompliance, patient refusal, other patient reason)]. If the patient meets any exception criteria, they should be removed from the denominator for performance calculation. --Although the exception cases are removed from the denominator population for the performance calculation, the exception rate (i.e., percentage of patients with valid exceptions) should be calculated and reported along with performance rates to track variations in care and highlight possible areas of focus for QI. If the patient does not meet the numerator and a valid exception is not present, this case represents a quality failure.

S.19. **Calculation Algorithm/Measure Logic Diagram URL or Attachment** *(You also may provide a diagram of the Calculation Algorithm/Measure Logic described above at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
No diagram provided

S.20. **Sampling** *(If measure is based on a sample, provide instructions for obtaining the sample and guidance on minimum sample size.)*
IF a PRO-PM, identify whether (and how) proxy responses are allowed.
Not Applicable. This measure is not based on sampling.

S.21. **Survey/Patient-reported data** *(If measure is based on a survey, provide instructions for conducting the survey and guidance on minimum response rate.)*
IF a PRO-PM, specify calculation of response rates to be reported with performance measure results.
Not Applicable. This measure is not based on a survey.

S.22. **Missing data** (specify how missing data are handled, e.g., imputation, delete case.)
Required for Composites and PRO-PMs.
If data required to determine if an individual patient should be included in a specific performance measure based on defined criteria is missing, those cases would ineligible for inclusion in the denominator and therefore the case would be deleted. If data required to determine if a denominator eligible patient qualifies for the numerator (or has a valid exclusion/exception) is missing, this case would represent a quality failure.

S.23. **Data Source** *(Check ONLY the sources for which the measure is SPECIFIED AND TESTED).*
If other, please describe in S.24.
Electronic Clinical Data : Registry

S.24. **Data Source or Collection Instrument** *(Identify the specific data source/data collection instrument e.g. name of database, clinical registry, collection instrument, etc.)*
IF a PRO-PM, identify the specific PROM(s); and standard methods, modes, and languages of administration.
This measure is currently being used in the ACCF PINNACLE registry for the outpatient office setting.

S.25. **Data Source or Collection Instrument** *(available at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
Available in attached appendix at A.1

S.26. **Level of Analysis** *(Check ONLY the levels of analysis for which the measure is SPECIFIED AND TESTED)*
Clinician : Individual

S.27. **Care Setting** *(Check ONLY the settings for which the measure is SPECIFIED AND TESTED)*
Ambulatory Care : Clinician Office/Clinic
If other:

S.28. **COMPOSITE Performance Measure** - Additional Specifications *(Use this section as needed for aggregation and weighting rules, or calculation of individual performance measures if not individually endorsed.)*
Not Applicable

2b. Validity – See attached Measure Testing Submission Form
CAD_Antiplatelet_0067_Testing_Form_Version_6.5_6.23.15.pdf

NATIONAL QUALITY FORUM—Measure Testing (subcriteria 2a2, 2b2-2b7)

Measure Number (*if previously endorsed*)**:** 0067
Measure Title: Chronic Stable Coronary Artery Disease: Antiplatelet Therapy
Date of Submission: 6/23/2015
Type of Measure:

☐ Composite – ***STOP – use composite testing form***	☐ Outcome (*including PRO-PM*)
☐ Cost/resource	☒ Process
☐ Efficiency	☐ Structure

Instructions

- Measures must be tested for all the data sources and levels of analyses that are specified. ***If there is more than one set of data specifications or more than one level of analysis, contact NQF staff*** about how to present all the testing information in one form.
- **For all measures, sections 1, 2a2, 2b2, 2b3, and 2b5 must be completed.**
- **For outcome and resource use measures**, section **2b4** also must be completed.
- If specified for **multiple data sources/sets of specificaitons** (e.g., claims and EHRs), section **2b6** also must be completed.
- Respond to all questions as instructed with answers immediately following the question. All information on testing to demonstrate meeting the subcriteria for reliability (2a2) and validity (2b2-2b6) must be in this form. An appendix for *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 20 pages (*incuding questions/instructions;* minimum font size 11 pt; do not change margins). ***Contact***

NQF staff if more pages are needed.

- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.
- For information on the most updated guidance on how to address sociodemographic variables and testing in this form refer to the release notes for version 6.6 of the Measure Testing Attachment.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the testing results for this measure meet NQF's evaluation criteria for testing.

2a2. Reliability testing [10] demonstrates the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise. For **PRO-PMs and composite performance measures**, reliability should be demonstrated for the computed performance score.

2b2. Validity testing [11] demonstrates that the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality. For **PRO-PMs and composite performance measures**, validity should be demonstrated for the computed performance score.

2b3. Exclusions are supported by the clinical evidence; otherwise, they are supported by evidence of sufficient frequency of occurrence so that results are distorted without the exclusion; [12]

AND

If patient preference (e.g., informed decisionmaking) is a basis for exclusion, there must be evidence that the exclusion impacts performance on the measure; in such cases, the measure must be specified so that the information about patient preference and the effect on the measure is transparent (e.g., numerator category computed separately, denominator exclusion category computed separately). [13]

2b4. For outcome measures and other measures when indicated (e.g., resource use):

- **an evidence-based risk-adjustment strategy** (e.g., risk models, risk stratification) is specified; is based on patient factors (including clinical and sociodemographic factors) that influence the measured outcome and are present at start of care; [14,15] and has demonstrated adequate discrimination and calibration

OR

- rationale/data support no risk adjustment/ stratification.

2b5. Data analysis of computed measure scores demonstrates that methods for scoring and analysis of the specified measure allow for **identification of statistically significant and practically/clinically meaningful** [16] **differences in performance**;

OR

there is evidence of overall less-than-optimal performance.

2b6. If multiple data sources/methods are specified, there is demonstration they produce comparable results.

2b7. For **eMeasures, composites, and PRO-PMs** (or other measures susceptible to missing data), analyses identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias.

Notes

10. Reliability testing applies to both the data elements and computed measure score. Examples of reliability testing for data elements include, but are not limited to: inter-rater/abstractor or intra-rater/abstractor studies; internal consistency for multi-item scales; test-retest for survey items. Reliability testing of the measure score addresses precision of measurement (e.g., signal-to-noise).

11. Validity testing applies to both the data elements and computed measure score. Validity testing of data elements typically analyzes agreement with another authoritative source of the same information. Examples of validity testing of the measure score include, but are not limited to: testing hypotheses that the measures scores indicate quality of care, e.g., measure scores are different for groups known to have differences in quality assessed by another valid quality measure or method; correlation of measure scores with another valid indicator of quality for the specific topic; or relationship to conceptually related measures (e.g., scores on process measures to scores on outcome measures). Face validity of the measure score as a quality indicator may be adequate if accomplished through a systematic and transparent process, by identified experts, and explicitly addresses whether performance scores resulting from the measure as specified can be used to distinguish good from poor quality.

12. Examples of evidence that an exclusion distorts measure results include, but are not limited to: frequency of occurrence, variability of exclusions across providers, and sensitivity analyses with and without the exclusion.
13. Patient preference is not a clinical exception to eligibility and can be influenced by provider interventions.

14. Risk factors that influence outcomes should not be specified as exclusions
15. With large enough sample sizes, small differences that are statistically significant may or may not be practically or clinically meaningful. The substantive question may be, for example, whether a statistically significant difference of one percentage point in the percentage of patients who received smoking cessation counseling (e.g., 74 percent v. 75 percent) is clinically meaningful; or whether a statistically significant difference of $25 in cost for an episode of care (e.g., $5,000 v. $5,025) is practically meaningful. Measures with overall less-than-optimal performance may not demonstrate much variability across providers.

1. DATA/SAMPLE USED FOR ALL TESTING OF THIS MEASURE

Often the same data are used for all aspects of measure testing. In an effort to eliminate duplication, the first five questions apply to all measure testing. If there are differences by aspect of testing,(e.g., reliability vs. validity) be sure to indicate the specific differences in question 1.7.

1.1. What type of data was used for testing? (*Check all the sources of data identified in the measure specifications and data used for testing the measure. Testing must be provided for all the sources of data specified and intended for measure implementation.* ***If different data sources are used for the numerator and denominator, indicate N [numerator] or D [denominator] after the checkbox.***)

Measure Specified to Use Data From: (***must be consistent with data sources entered in S.23***)	**Measure Tested with Data From:**
☐ abstracted from paper record	☐ abstracted from paper record
☐ administrative claims	☐ administrative claims
☒ clinical database/registry	☒ clinical database/registry
☐ abstracted from electronic health record	☐ abstracted from electronic health record

☐ eMeasure (HQMF) implemented in EHRs	☐ eMeasure (HQMF) implemented in EHRs
☐ other: Click here to describe	☐ other: Click here to describe

1.2. If an existing dataset was used, identify the specific dataset (*the dataset used for testing must be consistent with the measure specifications for target population and healthcare entities being measured; e.g., Medicare Part A claims, Medicaid claims, other commercial insurance, nursing home MDS, home health OASIS, clinical registry*).

The primary analysis was conducted at the level of the individual provider and included all patients with coronary artery disease (CAD) cared for by that provider and captured in the PINNACLE Registry during the one-year study period. The PINNACLE Registry systematically maps each practice's Electronic Health Record to the data elements required for the Registry, with careful validation of the translation process prior to enrollment. Data from the registry are reported back to the practices on a quarterly basis for quality improvement and are available for CMS reporting. Using these data, we were able to calculate the number of patients who should have received antiplatelet therapy, or a clinically, evidence-based reason not to use antiplatelet therapy was documented. This means that every patient in that provider's practice is included. For this measure, providers with less than 10 eligible patient encounters during the study period were excluded, since performance estimates are unstable with such small numbers. All other cases from all practices and providers were included. We included all visits for each patient in these analyses and meeting the performance measure on any single visit within the year met the criterion for this measure.

1.3. What are the dates of the data used in testing? The primary analysis included encounters between 01/01/2014-12/31/2014. Additionally, we used data from 01/01/2013 thru 12/31/2013 for temporal comparison.

1.4. What levels of analysis were tested? (*testing must be provided for <u>all</u> the levels specified and intended for measure implementation, e.g., individual clinician, hospital, health plan*)

Measure Specified to Measure Performance of: (***must be consistent with levels entered in item S.26***)	**Measure Tested at Level of:**
☒ individual clinician	☒ individual clinician
☐ group/practice	☐ group/practice
☐ hospital/facility/agency	☐ hospital/facility/agency
☐ health plan	☐ health plan
☐ other: Click here to describe	☐ other: Click here to describe

1.5. How many and which <u>measured entities</u> were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of measured entities included in the analysis (e.g., size, location, type); if a sample was used, describe how entities were selected for inclusion in the sample*)

<u>2013</u>

2,407 providers met the minimum number of eligible patients (10) for inclusion in the reliability analysis. The average number of eligible patients for providers included is 425.2 for a total of 1,023,530 patients. The range of number of patients for providers included is from 10 to 2,834. As described above, providers with fewer than 10 eligible patient encounters during the study period were excluded.

The unit of analysis for this measure is the provider. A description of the providers studied for the 2013 calendar year is shown below:

	Total **n = 2407**
Provider gender	
(1) Male	1923 (80.0%)
(2) Female	482 (20.0%)
Missing (.)	2
Provider categories	
NP/PA	258 (10.9%)
MD/DO	2061 (86.9%)
RN/nurses	52 (2.2%)
Missing (.)	36
Region	
(1) Northeast	305 (12.7%)
(2) Midwest	698 (29.0%)
(3) South	956 (39.7%)
(4) West	448 (18.6%)

2014

2,248 providers met the minimum number of eligible patients (10) for inclusion in the reliability analysis. The average number of eligible patients for providers included is 427.0 for a total of 959,792 patients. The range of numbers of patients for providers included is from 10 to 2,649. As described above, providers with fewer than 10 eligible patient encounters during the study period were excluded.

The unit of analysis for this measure is the provider. A description of the providers studied for the 2014 calendar year is shown below:

	Total **n = 2248**

	Total
	n = 2248
Provider gender	
(1) Male	1784 (79.4%)
(2) Female	464 (20.6%)
Provider categories	
NP/PA	250 (11.3%)
MD/DO	1915 (86.7%)
RN/nurses	44 (2.0%)
Missing (.)	39
Region	
(1) Northeast	257 (11.4%)
(2) Midwest	640 (28.5%)
(3) South	905 (40.3%)
(4) West	446 (19.8%)

1.6. How many and which <u>patients</u> were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of patients included in the analysis (e.g., age, sex, race, diagnosis); if a sample was used, describe how patients were selected for inclusion in the sample*)

<u>2013</u>

There are a total of 1,023,530 patients included in the temporal comparison that were treated in 2013. Patients' characteristics are provided below:

	Total
	n = 1023530
Race	
(1) White	502521 (92.0%)
(2) Black	31466 (5.8%)
(3) Other	12014 (2.2%)
Missing (.)	170072
Insurance	
(0) No insurance	1381 (1.0%)
(1) Private	100517 (69.9%)
(2) Medicare	40963 (28.5%)
(3) Medicaid	182 (0.1%)
(4) Other	820 (0.6%)
Missing (.)	154582
Age	
18 to <60	197507 (19.3%)
60 to <70	285197 (27.9%)
70 to <80	320245 (31.3%)
80 to 114	220581 (21.6%)

	Total n = 1023530
Sex (1) Male (2) Female Missing (.)	 637419 (62.4%) 384062 (37.6%) 1918
BMI (kg/m2) Missing	30.6 ± 9.0 231647
Diabetes Mellitus	288906 (28.9%)
Hypertension	807299 (85.4%)
Atrial Fibrillation/Flutter	217128 (22.7%)
Heart Failure	239885 (24.5%)
Peripheral Arterial Disease	139911 (16.1%)
Stroke/TIA	40229 (6.1%)
Myocardial Infarction	261043 (30.3%)

2014

There are a total of 959,792 patients included in the primary analysis (2014). See below for details on patient characteristics.

	Total n = 959792
Race (1) White (2) Black (3) Other Missing (.)	 428912 (92.9%) 23387 (5.1%) 9331 (2.0%) 158682
Insurance (0) No insurance (1) Private (2) Medicare (3) Medicaid (4) Other Missing (.)	 528 (0.4%) 99826 (81.6%) 21467 (17.6%) 177 (0.1%) 284 (0.2%) 158102
Age 18 to <60 60 to <70 70 to <80 80 to 114	 179194 (18.7%) 265376 (27.6%) 306202 (31.9%) 209020 (21.8%)
Sex (1) Male (2) Female Missing (.)	 599619 (62.6%) 357647 (37.4%) 2248

	Total
	n = 959792
BMI (kg/m2) Missing	30.7 ± 8.9 189212
Diabetes Mellitus	265083 (29.4%)
Hypertension	724628 (86.1%)
Atrial Fibrillation/Flutter	210886 (23.9%)
Heart Failure	233017 (26.1%)
Peripheral Arterial Disease	136158 (16.3%)
Stroke/TIA	40536 (6.2%)
Myocardial Infarction	238396 (29.3%)

1.7. If there are differences in the data or sample used for different aspects of testing (e.g., reliability, validity, exclusions, risk adjustment), identify how the data or sample are different for each aspect of testing reported below.

The dataset described above was used for all aspects of testing.

1.8 What were the patient-level sociodemographic (SDS) variables that were available and analyzed in the data or sample used? For example, patient-reported data (e.g., income, education, language), proxy variables when SDS data are not collected from each patient (e.g. census tract), or patient community characteristics (e.g. percent vacant housing, crime rate).

We do not currently collect any of the SDS variables examples listed above. As is noted in other sections of this testing form we do collect data on race as well as insurance type.

2a2. RELIABILITY TESTING

***Note**: If accuracy/correctness (validity) of data elements was empirically tested, separate reliability testing of data elements is not required – in 2a2.1 check critical data elements; in 2a2.2 enter "see section 2b2 for validity testing of data elements"; and skip 2a2.3 and 2a2.4.*

2a2.1. What level of reliability testing was conducted? (*may be one or both levels*)

☐ **Critical data elements used in the measure** (*e.g., inter-abstractor reliability; data element reliability must address ALL critical data elements*)

☒ **Performance measure score** (e.g., *signal-to-noise analysis*)

2a2.2. For each level checked above, describe the method of reliability testing and what it tests (*describe the steps—do not just name a method; what type of error does it test; what statistical analysis was used*)

Reliability of the computed measure score was measured as the ratio of signal to noise. The signal in this case is the proportion of the variability in measured performance that can be explained by real differences in physician performance. Reliability at the level of the specific physician is given by:

Reliability = Variance (physician-to-physician) / [Variance (physician-to-physician) + Variance (physician-specific-error], where the latter represents the within-physician estimate of our error in assessing their 'true' performance. Thus, the reliability estimate is the ratio of the physician-to-physician variance divided by the sum of the physician-to-physician variance plus the error variance specific to a physician. A reliability of zero implies that all the variability in a measure is attributable to measurement error. A reliability of one implies that all the variability is attributable to real differences in physician performance.

Reliability testing was performed by using a beta-binomial model. The beta-binomial model assumes the physician performance score is a binomial random variable conditional on the physician's true value that comes from the beta distribution. The beta distribution is usually defined by two parameters, alpha and beta. Alpha and beta can be thought of as intermediate calculations to get to the needed variance estimates.

Reliability is estimated at five different distributions of providers' patient volumes: at the minimum number of quality reporting events for the measure; at the mean number of quality reporting events per physician; and at the 25th, 50th and 75th percentiles of the number of quality reporting events.

2a2.3. For each level of testing checked above, what were the statistical results from reliability testing? (e.*g., percent agreement and kappa for the critical data elements; distribution of reliability statistics from a signal-to-noise analysis*)

2013 – In 2013, the signal-noise ratios are shown below:

Description	Number of Patients	Signal-to-Noise Ratio
Minimum	10	0.994
25th percentile	188	0.998
50th percentile	368	0.998
75th percentile	586	0.999
Average	426	0.998

2014 – In 2014, the signal-noise ratios are shown below:

Description	Number of Patients	Signal-to-Noise Ratio
Minimum	10	0.995
25th percentile	204	0.998
50th percentile	376	0.998
75th percentile	578	0.999
Average	427	0.998

2a2.4 What is your interpretation of the results in terms of demonstrating reliability? (i.*e., what do the results mean and what are the norms for the test conducted?*)

For this measure the reliability was very high and was similar for 2013 and 2014, supporting the reproducibility of these estimates across years. At the minimum number of patient visits required (>10) the average reliability was 0.994 and 0.986 for 2013 and 2014, respectively. For providers with the median number of patient encounters, the reliability was even higher, with 0.998 for both years. Given that a reliability of 0.70 is generally considered a minimum threshold for acceptability, and 0.80 is considered very good reliability, these data suggest that the measure is exceedingly good at describing true differences across physicians.

2b2. VALIDITY TESTING

2b2.1. What level of validity testing was conducted? (*may be one or both levels*)

☐ **Critical data elements** (*data element validity must address ALL critical data elements*)

☒ **Performance measure score**

☐ **Empirical validity testing**

☒ **Systematic assessment of face validity of <u>performance measure score</u> as an indicator** of quality or resource use (*i.e., is an accurate reflection of performance on quality or resource use and can distinguish good from poor performance*)

2b2.2. For each level of testing checked above, describe the method of validity testing and what it tests (*describe the steps—do not just name a method; what was tested, e.g., accuracy of data elements compared to authoritative source, relationship to another measure as expected; what statistical analysis was used)*

Content validity for this measure was assessed by expert work group members during the development process. Additional input on the content validity of draft measures was established through a 30-day public comment period and concurrent formal peer review process. All comments received were reviewed by the expert work group and the measures were adjusted as needed. Additionally, the measure underwent review and approval by the Board of Trustees of the ACC and the Science Advisory and Coordinating Committee of the AHA, as well as review and voting by the PCPI membership. Members of the expert work group that developed the measure included: Bruce Abramowitz, MD, FACC (interventional cardiology; measure implementation), Karen Alexander, MD (cardiology; geriatrics), Craig T. Beam, CRE (patient representative), Robert O. Bonow, MD, MACC, FAHA, FACP (cardiology), Jill S. Burkiewicz, PharmD, BCPS (pharmacy); Michael Crouch, MD, MSPH (family medicine), David C. Goff, Jr., MD, PhD, FAHA, FACP (internal medicine), Richard Hellman, MD, FACP, FACE (endocrinology), Thomas James, III, FACP, FAAP (health plan representative), Marjorie L. King, MD, FACC, MAACVPR (cardiology; cardiac rehabilitation), Edison A. Machado, Jr., MD, MBA (measure implementation), Eduardo Ortiz, MD, MPH (guideline development), Michael O'Toole, MD (cardiology; electrophysiology; measure implementation), Stephen D. Persell, MD, MPH (internal medicine; measure implementation), Jesse M. Pines, MD, MBA, MSCE, FAAEM (emergency medicine), Frank J. Rybicki, MD, PhD (radiology), Lawrence B. Sadwin (patient representative), Joanna D. Sikkema, MSN, ANP-BC, FAHA (cardiology), Peter K. Smith, MD (thoracic surgery), Patrick J. Torcson, MD, FACP, MMM (hospital medicine), John B. Wong MD, FACP (internal medicine).

Construct validity was difficult to establish because there has not been an independent audit of these data. However, it is important to note that an independent audit would merely involve an abstractor reviewing the

same medical record from which PINNACLE directly abstracts its data and, given the identical source of the data, any error observed would either be due to the auditor incorrectly abstracting the data from the EHR or PINNACLE incorrectly mapping the data elements from the EHR. To address the latter, we conduct detailed analyses to insure that this does not happen and quarantine (i.e. not report) data that fails our addition Data Quality Review process. Validity of measure data elements in PINNACLE is routinely evaluated on a quarterly basis as part of the standard data extraction and analytic data set creation process. First, all relevant data elements are reviewed at the record level to ensure that individual data values are valid; any invalid values are set to missing. Next, the *distribution* of each data element is reviewed, aggregating both across practices and across calendar quarters within each practice, to identify outliers, suspicious patterns and/or systematic changes in the prevalence of the data element that may suggest data mapping errors or unanticipated changes in definitions, coding consistency, data completeness, etc. Identification of suspicious data includes both statistical criteria, using quality control charts with rigorous definitions of "out of control" rates, and manual clinical review of each distribution for plausibility. Records that are flagged as suspicious by these criteria are quarantined and excluded from analysis and reporting. In 2013 the rate of records not passing the quality evaluation was 1.9% and in 2014 it was 2.1%. Feedback reports are generated to facilitate investigation of data issues at the practice level to verify accuracy of abstraction and to remap elements whose definitions or recording have changed.

Face validity of the measure score was systematically assessed as follows:

After the measure was fully specified, members of two existing committees, one at the ACC and one at AHA, with expertise in in general cardiology, interventional cardiology, heart failure, electrophysiology and quality improvement, outcomes research, informatics and performance measurement, who were not involved in development of the measure, were asked to review the measure specifications and rate their agreement with the following statement:

"The scores obtained from the measure as specified will provide an accurate reflection of quality and can be used to distinguish good and poor quality."

The respondents recorded their rating on a scale of 1-5, where 1= Strongly Disagree; 3=Neither Agree nor Disagree; 5= Strongly Agree

Forty Two (42) members completed the survey and provided a mean importance rating of 4.26, with 83.3% agreeing with the use of the measure for quality assessment.

2b2.3. What were the statistical results from validity testing? (*e.g., correlation; t-test*)

We believe that the processes used to extract data from the exact source from which any abstraction process done manually would use (the EHR), and our thorough data quality review, provide strong evidence for the validity of this measure.

The results of the expert panel rating of the validity statement were as follows:

N = 42; Mean rating = 4.26 and 83.3% of respondents either agree or strongly agree that this measure can accurately distinguish good and poor quality.

Frequency Distribution of Ratings
1 - <2> (Strongly Disagree)
2 - <3>
3 - <2> (Neither Agree nor Disagree)
4 - <10>
5 - <25> (Strongly Agree)

2b2.4. What is your interpretation of the results in terms of demonstrating validity? (i.*e., what do the results mean and what are the norms for the test conducted?*)

The measure was judged to have high face validity by both its clinical importance and by the group of experts asked to rate it. The majority of experts agreed that the measure as specified will provide an accurate reflection of quality and can be used to distinguish good and poor quality. Importantly, as a process measure, the strong association of treatment with improved survival and reduced myocardial infarction rates provide strong validity for this measure as a mechanism to insure that strong clinical evidence is being translated to routine clinical care.

2b3. EXCLUSIONS ANALYSIS
NA ☐ no exclusions — *skip to section 2b4*

2b3.1. Describe the method of testing exclusions and what it tests (*describe the steps—do not just name a method; what was tested, e.g., whether exclusions affect overall performance scores; what statistical analysis was used*)

Since not all patients with CAD will meet the guideline recommendations for antiplatelet therapy, exclusions in this measure are intended to remove patients for whom antiplatelet therapy may not be appropriate. We divide these into two categories: Exclusions and Exceptions. Exclusions arise when patients who are included in the initial patient or eligible population for the measure set do not meet the denominator criteria specific to the intervention required by the numerator. Exclusions are absolute and apply to all patients and therefore are not part of clinical judgment within a measure. Specific exclusions should be derived from evidence-based guidelines. Exceptions are not absolute, and are based on clinical judgment and individual patient characteristics, thus patients with such contraindications represent circumstances where the clinicians balanced the risks and benefits and felt that, in a given situation, the benefits outweighed the risks and chose to treat the patient. These patients are therefore included in both the numerator and denominator of the measure. In contrast, the exceptions are clearly documented reasons to not treat the patient and are removed from the denominator of the population.

Exclusions in this measure:

- Documented medical, patient, or system reason for not on aspirin or clopidogrel or patients were on warfarin.

2b3.2. What were the statistical results from testing exclusions? (*include overall number and percentage of individuals excluded, frequency distribution of exclusions across measured entities, and impact on performance measure scores*)

The Exceptions for each year are provided below:

2013: 3.1% (n=74) of the providers do not have exceptions in the denominator. Among 2,333 providers who do have exceptions, the exclusion rate ranges from 0.2% to 35.3%, mean is 6.0%. Of those patients removed from the measure, 0.72% were removed due to a medical reason, 9.47% were removed for a patient reason, 1.48% were removed for a system reason, 0.30% were removed due to multiple reasons, and 88.03% were removed due to patients who were on warfarin or another thienopyridine that is not included in this measure (e.g. prasugrel or ticagrelor) and the physician felt that the addition of aspirin or a clopidogrel provided an increased risk of bleeding with minimal benefits in the prevention of recurrent cardiovascular events.

2014: 2.5% (n=56) of the providers do not have exceptions in the denominator. Among 2,192 providers who do have exceptions, the exclusion rate ranges from 0.3% to 27.4%, mean is 5.8%. Of those patients removed from the measure, 0.80% were removed due to a medical reason, 9.52% were removed for a patient reason, 1.88% were removed for a system reason, 0.31% were removed due to multiple reasons, and 87.50% were removed due to concomitant medications that either provide anti-platelet or systemic anti-coagulation.

2b3.3. What is your interpretation of the results in terms of demonstrating that exclusions are needed to prevent unfair distortion of performance results? (*i.e., the value outweighs the burden of increased data collection and analysis. Note: **If patient preference is an exclusion**, the measure must be specified so that the effect on the performance score is transparent, e.g., scores with and without exclusion*)

We do not view any concerns with exclusions or exceptions for this measure. While the majority of exceptions are due to patient reasons and these might be 'gameable' by clinicians, we recognize the bleeding and bruising are very frequent side effects of anti-platelet treatment (see Amin et al, *J Am Coll Cardiol* 2013; 2013;61(21):2130-8) and that clinicians who think enough about this decision process to document an exclusion are likely providing excellent, patient-centered care.

2b4. RISK ADJUSTMENT/STRATIFICATION FOR OUTCOME OR RESOURCE USE MEASURES
If not an intermediate or health outcome, or PRO-PM, or resource use measure, skip to section 2b5.

2b4.1. What method of controlling for differences in case mix is used?
☒ **No risk adjustment or stratification**
☐ **Statistical risk model with** Click here to enter number of factors **risk factors**
☐ **Stratification by** Click here to enter number of categories **risk categories**
☐ **Other,** Click here to enter description

2b4.2. If an outcome or resource use measure is not risk adjusted or stratified, provide rationale and analyses to demonstrate that controlling for differences in patient characteristics (case mix) is not needed to achieve fair comparisons across measured entities.

2b4.3. Describe the conceptual/clinical and statistical methods and criteria used to select patient factors (clinical factors or sociodemographic factors) used in the statistical risk model or for stratification by risk (*e.g., potential factors identified in the literature and/or expert panel; regression analysis; statistical significance of p<0.10; correlation of x or higher; patient factors should be present at the start of care*)

2b4.4a. What were the statistical results of the analyses used to select risk factors?

2b4.4b. Describe the analyses and interpretation resulting in the decision to select SDS factors (e.g. prevalence of the factor across measured entities, empirical association with the outcome, contribution of unique variation in the outcome, assessment of between-unit effects and within-unit effects)

2b4.5. Describe the method of testing/analysis used to develop and validate the adequacy of the statistical model or stratification approach (*describe the steps—do not just name a method; what statistical analysis was used*)

Provide the statistical results from testing the approach to controlling for differences in patient characteristics (case mix) below.
If stratified, skip to 2b4.9

2b4.6. Statistical Risk Model Discrimination Statistics (*e.g., c-statistic, R-squared*)**:**

2b4.7. Statistical Risk Model Calibration Statistics (*e.g., Hosmer-Lemeshow statistic*):

2b4.8. Statistical Risk Model Calibration – Risk decile plots or calibration curves:

2b4.9. Results of Risk Stratification Analysis:

2b4.10. What is your interpretation of the results in terms of demonstrating adequacy of controlling for differences in patient characteristics (case mix)? (i.*e., what do the results mean and what are the norms for the test conducted*)

2b4.11. Optional Additional Testing for Risk Adjustment (*not required, but would provide additional support of adequacy of risk model, e.g., testing of risk model in another data set; sensitivity analysis for missing data; other methods that were assessed*)

2b5. IDENTIFICATION OF STATISTICALLY SIGNIFICANT & MEANINGFUL DIFFERENCES IN PERFORMANCE

2b5.1. Describe the method for determining if statistically significant and clinically/practically meaningful differences in performance measure scores among the measured entities can be identified (*describe the steps—do not just name a method; what statistical analysis was used? Do not just repeat the information provided related to performance gap in 1b)*

We examined variation in provider performance on this measure based on sex, age, race and a number of other patient factors to identify variations. The findings are represented for 2013 and 2014 respectively.

2013

label	# of providers	# of patients	Minimum	Lower Quartile	Mean	Upper Quartile	Maximum	Quartile Range	Std Dev

2b5.2. What were the statistical results from testing the ability to identify statistically significant and/or clinically/practically meaningful differences in performance measure scores across measured entities?

(e.g., *number and percentage of entities with scores that were statistically significantly different from mean or some benchmark, different from expected; how was meaningful difference defined*)

2013

Overall mean performance on this measure is 86.2%, with a standard deviation of 10.5%. The minimum score equals 0.00%, while the maximum score equals 100.00%. The interquartile score is equal to 10.3%.

2,407 providers were measured, and the patient study sample equals 1,023,530. 62.4% of the sample is male. 92.0% of the sample is white, 5.8% is black, and 2.2 % identified as "other." The sample reached across all US regions, with 12.7% of providers in the Northeast, 29.0% of providers in the Midwest, 39.7% of providers in the South, and 18.6% of providers in the West.

# of providers	Minimum	Lower Quartile	Mean	Upper Quartile	Maximum	Quartile Range	Std Dev
2407	0.00%	82.6%	86.2%	92.9%	100%	10.3%	10.5%

	Mean
Decile 1	62.6%
Decile 2	77.7%
Decile 3	82.6%
Decile 4	85.5%
Decile 5	87.6%
Decile 6	89.5%
Decile 7	91.2%
Decile 8	93.0%
Decile 9	94.9%
Decile 10	97.6%

2014

Overall mean performance on this measure is 86.3%, with a standard deviation of 9.49%. The minimum score equals 0.00%, while the maximum score equals 100.00%. The interquartile score is equal to 10.2%.

2,248 providers were measured, and the patient study sample equals 959,792. 62.6% of the sample is male. 92.9% of the sample is white, 5.1% is black, and 2.0% identified as "other." The sample reached across all US regions, with 11.4% of providers in the Northeast, 28.5% of providers in the Midwest, 40.3% of providers in the South, and 19.8% of providers in the West.

# of providers	Minimum	Lower Quartile	Mean	Upper Quartile	Maximum	Quartile Range	Std Dev
2248	10.0%	82.6%	86.3%	92.8%	100%	10.2%	9.49%

	Mean
Decile 1	65.4%
Decile 2	77.8%
Decile 3	82.4%
Decile 4	85.1%
Decile 5	87.3%
Decile 6	89.2%
Decile 7	91.0%
Decile 8	92.8%
Decile 9	94.7%
Decile 10	97.4%

2b5.3. What is your interpretation of the results in terms of demonstrating the ability to identify statistically significant and/or clinically/practically meaningful differences in performance across measured entities? (i.*e., what do the results mean in terms of statistical and meaningful differences?*)

2013: A small amount of variability was noted among providers. The performance-met rate range was 0-100% with the inter-quartile range being 82.6% to 92.9%. This yielded a Median Rate Ratio of 1.11 (1.10, 1.11). The Median Rate Ratio measures the variation across providers for statistically 'identical' patients and suggests that a patient presenting to 1 provider, as opposed to another, would, on average, be 11% more likely to be treated with an anti-platelet agent.

2014: A small amount of variability was also noted among providers in 2014. The performance-met rate range was 10-100% with the inter-quartile range being 83% to 93%. This yielded a Median Rate Ratio of 1.09 (1.09, 1.10).

2b6. COMPARABILITY OF PERFORMANCE SCORES WHEN MORE THAN ONE SET OF SPECIFICATIONS

If only one set of specifications, this section can be skipped.

Note: *This item is directed to measures that are risk-adjusted (with or without SDS factors)* ***OR*** *to measures with more than one set of specifications/instructions (e.g., one set of specifications for how to identify and compute the measure from medical record abstraction and a different set of specifications for claims or eMeasures). It does not apply to measures that use more than one source of data in one set of specifications/instructions (e.g., claims data to identify the denominator and medical record abstraction for the numerator).* ***Comparability is not required when comparing performance scores with and without SDS factors in the risk adjustment model. However, if comparability is not demonstrated for measures with***

more than one set of specifications/instructions, the different specifications (e.g., for medical records vs. claims) should be submitted as separate measures.

2b6.1. Describe the method of testing conducted to compare performance scores for the same entities across the different data sources/specifications (*describe the steps—do not just name a method; what statistical analysis was used*)

2b6.2. What were the statistical results from testing comparability of performance scores for the same entities when using different data sources/specifications? (*e.g., correlation, rank order*)

2b6.3. What is your interpretation of the results in terms of the differences in performance measure scores for the same entities across the different data sources/specifications? (i.*e., what do the results mean and what are the norms for the test conducted*)

2b7. MISSING DATA ANALYSIS AND MINIMIZING BIAS

2b7.1. Describe the method of testing conducted to identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias (*describe the steps—do not just name a method; what statistical analysis was used*)

In PINNACLE missing values are interpreted as "no" for most variables. It is challenging to distinguish real missing versus "No." Therefore, we are assuming that missing documentation of antiplatelet indicates a failure to meet the measure. It is possible that a provider may not have documented antiplatelet therapy use in their EMR system, perhaps if it was provided by another provider in a different healthcare system. However, we believe that this is unlikely and that it is still incumbent upon a provider to clearly document all the medications that a patient is taking, particularly antiplatelet for CAD patients.

2b7.2. What is the overall frequency of missing data, the distribution of missing data across providers, and the results from testing related to missing data? (*e.g., results of sensitivity analysis of the effect of various rules for missing data/nonresponse; if no empirical sensitivity analysis, identify the approaches for handling missing data that were considered and pros and cons of each*)

Given our assumptions, noted above, we did not conduct an empirical analysis of frequency or distribution of missing data. For this measure, missing data is reported as a quality failure.

2b7.3. What is your interpretation of the results in terms of demonstrating that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias**?** (i.*e., what do the results mean in terms of supporting the selected approach for missing data and what are the norms for the test conducted; if no empirical analysis, provide rationale for the selected approach for missing data*)

We do not believe any biases are introduced in the assessing of individual physician performance and continued endorsement of this measure would lead to improved care.

3. Feasibility

Extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

3a. Byproduct of Care Processes

For clinical measures, the required data elements are routinely generated and used during care delivery (e.g., blood pressure, lab test, diagnosis, medication order).

3a.1. **Data Elements Generated as Byproduct of Care Processes.**

Generated or collected by and used by healthcare personnel during the provision of care (e.g., blood pressure, lab value, diagnosis, depression score), Coded by someone other than person obtaining original information (e.g., DRG, ICD-9 codes on claims)

If other:

3b. Electronic Sources

The required data elements are available in electronic health records or other electronic sources. If the required data are not in electronic health records or existing electronic sources, a credible, near-term path to electronic collection is specified.

3b.1. **To what extent are the specified data elements available electronically in defined fields?** *(i.e., data elements that are needed to compute the performance measure score are in defined, computer-readable fields)*

ALL data elements are in defined fields in electronic clinical data (e.g., clinical registry, nursing home MDS, home health OASIS)

3b.2. **If ALL the data elements needed to compute the performance measure score are not from electronic sources, specify a credible, near-term path to electronic capture, OR provide a rationale for using other than electronic sources.**

3b.3. **If this is an eMeasure, provide a summary of the feasibility assessment in an attached file or make available at a measure-specific URL.**

Attachment:

3c. Data Collection Strategy

Demonstration that the data collection strategy (e.g., source, timing, frequency, sampling, patient confidentiality, costs associated with fees/licensing of proprietary measures) can be implemented (e.g., already in operational use, or testing demonstrates that it is ready to put into operational use). For eMeasures, a feasibility assessment addresses the data elements and measure logic and demonstrates the eMeasure can be implemented or feasibility concerns can be adequately addressed.

3c.1. **Describe what you have learned/modified as a result of testing and/or operational use of the measure regarding data collection, availability of data, missing data, timing and frequency of data collection, sampling, patient confidentiality, time and cost of data collection, other feasibility/implementation issues.**

IF a PRO-PM, consider implications for both individuals providing PROM data (patients, service recipients, respondents) and those whose performance is being measured.

Demonstration that the data collection strategy (e.g., source, timing, frequency, sampling, patient confidentiality, costs associated with fees/licensing of proprietary measures) can be implemented (e.g., already in operational use, or testing demonstrates that it is ready to put into operational use).

3c.2. **Describe any fees, licensing, or other requirements to use any aspect of the measure as specified** *(e.g., value/code set, risk model, programming code, algorithm)*.

Limited proprietary coding is contained in the measure specifications for convenience. Users of the proprietary code sets should obtain all necessary licenses from the owners of these code sets. The AMA, the ACC, the AHA, the PCPI and its members disclaim all liability for use or accuracy of any Current Procedural Terminology (CPT®) or other coding contained in the specifications. CPT® contained in the measures specifications is copyright 2004-2015 American Medical Association.

4. Usability and Use

Extent to which potential audiences (e.g., consumers, purchasers, providers, policy makers) are using or could use performance results for both accountability and performance improvement to achieve the goal of high-quality, efficient healthcare for individuals or populations.

4a. Accountability and Transparency

Performance results are used in at least one accountability application within three years after initial endorsement and are publicly reported within six years after initial endorsement (or the data on performance results are available). If not in use at the time of initial endorsement, then a credible plan for implementation within the specified timeframes is provided.

4.1. Current and Planned Use

NQF-endorsed measures are expected to be used in at least one accountability application within 3 years and publicly reported within 6 years of initial endorsement in addition to performance improvement.

Planned	Current Use (for current use provide URL)
Public Reporting Quality Improvement (Internal to the specific organization)	Payment Program Physician Quality Reporting System http://www.cms.gov/Medicare/Quality-Initiatives-Patient-Assessment- Regulatory and Accreditation Programs Physician Quality Reporting System http://www.cms.gov/Medicare/Quality-Initiatives-Patient-Assessment- Quality Improvement with Benchmarking (external benchmarking to multiple organizations) ACC Pinnacle Registry URL: http://www.ncdr.com/webncdr/pinnacle/

4a.1. For each CURRENT use, checked above, provide:

- Name of program and sponsor
- Purpose
- Geographic area and number and percentage of accountable entities and patients included

PINNACLE Registry (URL: http://www.ncdr.com/webncdr/pinnacle/)
In 2008, the American College of Cardiology Foundation launched the PINNACLE program (Formerly known as the Improving Continuous Cardiac Care or IC3). The PINNACLE Registry® continues to grow rapidly, with more than 3446 providers representing almost 960 unique office locations across the U.S submitting data to the registry. As of March 2015, the registry has more than 19.8 million patient encounter records representing approximately 4.85 million patients. PINNACLE assists practices in understanding and improving care through the production and distribution of quarterly performance reports. These reports, covering all valid patient encounters, detail adherence to 28 cardiovascular clinical measures at the physician, location, and practice levels across coronary artery disease, hypertension, heart failure and atrial fibrillation.

PQRS Qualified Clinical Data Registry:
In addition to the current use for quality improvement with benchmarking in the PINNACLE registry, the measure will be reported to CMS by the registry as part of PQRS in 2015 as a Qualified Clinical Data Registry. Pinnacle did submit data for 2014 for QCDR purposes to CMS. Eligible professionals will be considered to have satisfactorily participated in PQRS if they submit quality measures data or results to CMS via a qualified clinical data registry. CMS does have plans to eventually publicly report QCDR data.

CAD: Antiplatelet Therapy
Physician Quality Reporting System (Centers for Medicare and Medicaid Services):
PQRS is a national reporting program that uses a combination of incentive payments and payment adjustments to promote

reporting of quality information by eligible professionals (EPs). The program provides an incentive payment to practices with Eps (identified on claims by their individual National Provider Identifier [NPI] and Tax Identification Number [TIN]). EPs satisfactorily report data on quality measures for covered Physician Fee Schedule (PFS) services furnished to Medicare Part B Fee-for-Service (FFS) beneficiaries (including Railroad Retirement Board and Medicare Secondary Payer). Beginning in 2015, the program also applies a payment adjustment to EPs who do not satisfactorily report data on quality measures for covered professional services. Source: http://www.cms.gov/Medicare/Quality-Initiatives-Patient-Assessment-Instruments/PQRS/index.html It is our understanding that CMS is also planning to move towards publicly reporting physician data via Physician Compare.

4a.2. **If not currently publicly reported OR used in at least one other accountability application (e.g., payment program, certification, licensing) what are the reasons?** (*e.g., Do policies or actions of the developer/steward or accountable entities restrict access to performance results or impede implementation?*)
We are continuously seeking opportunities to advocate for expanded use of this measure in government or other programs, including those intended for accountability or public reporting. The ACC, AHA and PCPI do not have any policies that would restrict access to the performance measure specifications or results or that would impede implementation of the measure for any application.

4a.3. **If not currently publicly reported OR used in at least one other accountability application, provide a credible plan for implementation within the expected timeframes -- any accountability application within 3 years and publicly reported within 6 years of initial endorsement.** (*Credible plan includes the specific program, purpose, intended audience, and timeline for implementing the measure within the specified timeframes. A plan for accountability applications addresses mechanisms for data aggregation and reporting.*)
As described above, it is our understanding that CMS is also planning to move towards publicly reporting physician data via Physician Compare.

Also, although the measure is currently in use, we are continuously seeking opportunities to advocate for expanded use of this measure in government or other programs, including those intended for accountability or public reporting.

4b. Improvement

Progress toward achieving the goal of high-quality, efficient healthcare for individuals or populations is demonstrated. If not in use for performance improvement at the time of initial endorsement, then a credible rationale describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.

4b.1. **Progress on Improvement. (Not required for initial endorsement unless available.)**
Performance results on this measure (current and over time) should be provided in 1b.2 and 1b.4. Discuss:

- **Progress (trends in performance results, number and percentage of people receiving high-quality healthcare)**
- **Geographic area and number and percentage of accountable entities and patients included**

The mean performance rates from the Pinnacle registry was 86.2% in 2013 and 86.3% in 2014.

In 2013, 2,407 providers were measured, and the patient study sample equals 1,023,530. In 2014, 2,248 providers were measured, and the patient study sample equaled 959,792. The statistical significance of these results was not analyzed.

While the ACC and AHA creates measures with an ultimate goal of improving the quality of care, measurement is a mechanism to drive improvement but does not equate with improvement. Measurement can help identify opportunities for improvement with actual improvement requiring making changes to health care processes and structure. In order to promote improvement, quality measurement systems need to provide feedback to front-line clinical staff in as close to real time as possible and at the point of care whenever possible. (1)

1. Conway PH, Mostashari F, Clancy C. The future of quality measurement for improvement and accountability. JAMA. 2013 Jun 5;309(21):2215-6.

4b.2. **If no improvement was demonstrated, what are the reasons? If not in use for performance improvement at the time of initial endorsement, provide a credible rationale that describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.**

Not Applicable.

4c. Unintended Consequences

The benefits of the performance measure in facilitating progress toward achieving high-quality, efficient healthcare for individuals or populations outweigh evidence of unintended negative consequences to individuals or populations (if such evidence exists).

4c.1. **Were any unintended negative consequences to individuals or populations identified during testing; OR has evidence of unintended negative consequences to individuals or populations been reported since implementation? If so, identify the negative unintended consequences and describe how benefits outweigh them or actions taken to mitigate them.**

We are not aware of any unintended consequences at this time, but we continuously monitor for them.

5. Comparison to Related or Competing Measures

If a measure meets the above criteria and there are endorsed or new related measures (either the same measure focus or the same target population) or competing measures (both the same measure focus and the same target population), the measures are compared to address harmonization and/or selection of the best measure.

5. Relation to Other NQF-endorsed Measures

Are there related measures (conceptually, either same measure focus or target population) or competing measures (conceptually both the same measure focus and same target population)? If yes, list the NQF # and title of all related and/or competing measures.

Yes

5.1a. **List of related or competing measures (selected from NQF-endorsed measures)**

0465 : Perioperative Anti-platelet Therapy for Patients undergoing Carotid Endarterectomy

5.1b. **If related or competing measures are not NQF endorsed please indicate measure title and steward.**

5a. Harmonization

The measure specifications are harmonized with related measures;

OR

The differences in specifications are justified

5a.1. **If this measure conceptually addresses EITHER the same measure focus OR the same target population as NQF-endorsed measure(s):**

Are the measure specifications completely harmonized?

No

5a.2. **If the measure specifications are not completely harmonized, identify the differences, rationale, and impact on interpretability and data collection burden.**

See 5b.1 for more detailed response due to lack of character spaces in this section.

5b. Competing Measures

The measure is superior to competing measures (e.g., is a more valid or efficient way to measure);

OR

Multiple measures are justified.

5b.1. **If this measure conceptually addresses both the same measure focus and the same target population as NQF-endorsed measure(s):**

Describe why this measure is superior to competing measures (e.g., a more valid or efficient way to measure quality); OR provide a rationale for the additive value of endorsing an additional measure. (Provide analyses when possible.)

Measure 0067 looks at whether ASA or clopidogrel where prescribed during a 12 month measurement period. Meanwhile, the two

existing NQF endorsed measures (#0465 and #0964) focused on whether the medications were prescribed prior to discharge or prior to surgery.

Specifically, Measure #0465 (Perioperative Antiplatelet Therapy for patients undergoing Carotid Endaroretomy) focuses on inpatient who were provided ASA or clopidogrel within 48 hours prior to surgery and prescribed this medication at hospital discharge. Measure #0067 looks at whether ASA or clopidogrel was prescribed during the 12 month measurement period. Both measures allow for medical exceptions.

In the case of Measure 0964 (Therapy with aspirin, P2Y12 inhibitor, and statin at discharge following PCI in eligible patients), this measure is also an inpatient measure and focuses on sosley PCI eligible patients who had ASA or P2y12 and statins prescribed prior to discharge. Measure 0067 looks at whether ASA or clopidogrel was prescribed during the 12 month measurement period. Both measures allow for medical exceptions.

Measures #0465 and #0964 address a different patient demographic and focuses on inpatient prescribed of ASA or Clopidogrel.

Appendix

A.1 Supplemental materials may be provided in an appendix. All supplemental materials (such as data collection instrument or methodology reports) should be organized in one file with a table of contents or bookmarks. If material pertains to a specific submission form number, that should be indicated. Requested information should be provided in the submission form and required attachments. There is no guarantee that supplemental materials will be reviewed.

Additional Information

Ad.1 **Workgroup/Expert Panel involved in measure development**
Provide a list of sponsoring organizations and workgroup/panel members' names and organizations. Describe the members' role in measure development.
Bruce Abramowitz, MD, FACC (interventional cardiology; measure implementation)
Karen Alexander, MD (cardiology; geriatrics)
Craig T. Beam, CRE (patient representative)
Robert O. Bonow, MD, MACC, FAHA, FACP (cardiology)
Jill S. Burkiewicz, PharmD, BCPS (pharmacy)
Michael Crouch, MD, MSPH (family medicine)
David C. Goff, Jr., MD, PhD, FAHA, FACP (internal medicine)
Richard Hellman, MD, FACP, FACE (endocrinology)
Thomas James, III, FACP, FAAP (health plan representative)
Marjorie L. King, MD, FACC, MAACVPR (cardiology; cardiac rehabilitation)
Edison A. Machado, Jr., MD, MBA (measure implementation)
Eduardo Ortiz, MD, MPH (guideline development)
Michael O'Toole, MD (cardiology; electrophysiology; measure implementation)
Stephen D. Persell, MD, MPH (internal medicine; measure implementation)
Jesse M. Pines, MD, MBA, MSCE, FAAEM (emergency medicine)
Frank J. Rybicki, MD, PhD (radiology)

Lawrence B. Sadwin (patient representative)
Joanna D. Sikkema, MSN, ANP-BC, FAHA (cardiology)
Peter K. Smith, MD (thoracic surgery)
Patrick J. Torcson, MD, FACP, MMM (hospital medicine)
John B. Wong MD, FACP (internal medicine)

ACC/AHA/ AMA PCPI measures are developed through cross-specialty, multi-disciplinary work groups. All medical specialties and other health care professional disciplines participating in patient care for the clinical condition or topic under study must be equal contributors to the measure development process. In addition, the ACC/AHA/AMA PCPI strive to include on its work groups individuals representing the perspectives of patients, consumers, private health plans, and employers. This broad-based approach to measure development ensures buy-in on the measures from all stakeholders and minimizes bias toward any individual specialty or stakeholder group. All work groups have at least two co-chairs who have relevant clinical and/or measure development expertise and who are responsible for ensuring that consensus is achieved and that all perspectives are voiced.

Measure Developer/Steward Updates and Ongoing Maintenance
Ad.2 **Year the measure was first released:** 2003
Ad.3 **Month and Year of most recent revision:** 01, 2011
Ad.4 **What is your frequency for review/update of this measure?** On average, every 3 years or as new evidence becomes available that materially affects the measures.
Ad.5 **When is the next scheduled review/update for this measure?** 12, 2016

Ad.7 **Disclaimers:** This Physician Performance Measurement Set (PPMS) and related data specifications were developed by the Physician Consortium for Performance Improvement (the Consortium) including the American College of Cardiology (ACC), the American Heart Association (AHA) and the American Medical Association (AMA) to facilitate quality improvement activities by physicians. The performance measures contained in this PPMS are not clinical guidelines and do not establish a standard of medical care, and have not been tested for all potential applications. This PPMS is intended to assist physicians to enhance quality of care and is not intended for comparing individual physicians to each other or for individual physician accountability by comparing physician performance against the measure or guideline.

Ad.8 **Additional Information/Comments:** The ACCF, AHA, and PCPI have a formal measurement review process that stipulates regular (usually on a three-year cycle, when feasible) review of the measures. The process can also be activated if there is a major change in scientific evidence, results from testing or other implementation issues are noted that materially affect the integrity of the measure.

MEASURE WORKSHEET

This document summarizes the evaluation of the measure as it progresses through NQF's Consensus Development Process (CDP). The information submitted by measure developers/stewards is included after the Brief Measure Information, Preliminary Analysis, and Pre-meeting Public and Member Comments sections.

To navigate the links in the worksheet: Ctrl + click link to go to the link; ALT + LEFT ARROW to return

Brief Measure Information

NQF #: 0068
Measure Title: Ischemic Vascular Disease (IVD): Use of Aspirin or Another Antiplatelet
Measure Steward: National Committee for Quality Assurance
Brief Description of Measure: The percentage of patients 18 years of age and older who were discharged from an inpatient setting with an acute myocardial infarction (AMI), coronary artery bypass graft (CABG) or percutaneous coronary intervention (PCI) during the 12 months prior to the measurement year, or who had a diagnosis of ischemic vascular disease (IVD) during the measurement year and the year prior to the measurement year and who had documentation of routine use of aspirin or another antiplatelet during the measurement year.
Developer Rationale: This measure aims to improve the quality of care for patients with established cardiovascular disease by assessing whether or not they received aspirin or another antiplatelet medication during the measurement year. Antiplatelet medications, such as aspirin and clopidogrel, are drugs that inhibit platelets from clumping together and forming clots. Their use in the secondary prevention of cardiovascular events is well-established. In patients who are at high risk because they already have atherosclerotic cardiovascular disease, antiplatelet therapy reduces the yearly risk of serious vascular events (MI, stroke, death) by about twenty-five percent. Antiplatelet agents also have a beneficial effect in reducing all-cause mortality and fatal cardiovascular events in patients with peripheral arterial disease.

Numerator Statement: Patients who had documentation of routine use of aspirin or another antiplatelet during the measurement year.
Denominator Statement: Patients 18 years or older by the end of the measurement year discharged from an inpatient setting with an AMI, CABG, or PCI during the 12 months prior to the measurement year or who had a diagnosis of IVD during both the measurement year and the year prior to the measurement year.
Denominator Exclusions: Patients who had documentation of use of anticoagulant medications during the measurement year.

Measure Type: Process
Data Source: Administrative claims, Electronic Clinical Data, Electronic Clinical Data : Electronic Health Record, Paper Medical Records
Level of Analysis: Clinician : Group/Practice, Clinician : Individual
Is this an eMeasure? ☐ **Yes** ☒ **No** **If Yes, was it re-specified from a previously endorsed measure?** ☐ **Yes** ☐ **No**

The measure is included in CMS' Electronic Health Record Incentive Program Stage 2 and ACO Shared Savings Program. An eMeasure was submitted for endorsement review.

Is this a MAINTENANCE measure submission? ☒ Yes ☐ No, this is a NEW measure submission.
For a MAINTENANCE, what is the Original Endorsement Date: 8/10/09 Most Recent Endorsement Date: 1/18/12

Previous Measure Evaluation - Public & Member Comments, Developer Responses & Steering Committee Recommendations from (Cardiology Project 2010):

Public & Member Comments included:
• Competing measures contain differences with respect to data collection methods, applicable settings, and exclusion criteria; however, it's important that the Steering Committee continue to work with developers of measures #0068, #0067, #0075 to determine the feasibility of harmonizing specifications of these measures where appropriate.
• Favor composite measure 0076 over the individual measures.
• Add BRILINTA (ticagrelor) to the list of oral anti-platelet agents.

• Encourage the measure developer to commit to develop an all-or-nothing composite for its IVD process measures in the near term.
Developer Response:
• Inclusion of Brilinta will be reviewed during our routine measure update process which includes review by our pharmacy panel.
Steering Committee:
• Urged the developers to work toward harmonization of the measures.

Preliminary Analysis

The preliminary analysis was developed in response to recommendations from NQF's Consensus Task Force and measurement stakeholders as a way to enhance and streamline the measures evaluation and voting processes. The preliminary analysis will help to guide the Standing Committee evaluation of each measure by summarizing the measure developer submission, guide measure evaluation discussion, and identify topic areas for additional input. **NQF staff would like to stress that the preliminary analysis is intended to be used as a guide to facilitate the Committee's discussion and evaluation.**

Criteria 1: Importance to Measure and Report

1a. Evidence

1a. Evidence. The evidence requirements for a *process* measure is that it is based on a systematic review (SR) and grading of the body of empirical evidence where the specific focus of the evidence matches what is being measured.

The developer provides the following evidence for this process measure:

- This is a clinician level measure that calculates the % of patients 18 years of age and older who were discharged from an inpatient setting with an acute myocardial infarction (AMI), coronary artery bypass graft (CABG) or percutaneous coronary intervention (PCI) during the 12 months prior to the measurement year, or who had a diagnosis of ischemic vascular disease (IVD) during the measurement year and the year prior to the measurement year and who had documentation of routine use of aspirin or another antiplatelet during the measurement year in a clinician office/clinic.
- The developer provides 4 separate guidelines with 10 guideline statements for the use of aspirin or another antiplatelet in patients diagnosed with cardiovascular disease but does not provide the QQC for the clinical guidelines. Per NQF criteria, they reference one seminal systematic review cited in the guidelines that summarizes the body of evidence supporting the recommendations.
- The developer provides decision logic from secondary prevention to outcome for the use of aspirin or another antiplatelet medication in reducing the risk of having an AMI, stroke, vascular complication or dying in patients with cardiovascular disease and peripheral artery disease.

Questions for the Committee:

- *For process measures:*
  - *Is the evidence directly applicable to the process of care being measured?*
  - *Is the process of care proximal and closely related to desired outcomes?*
- *For possible exception to the evidence criteria:*
  - *Are there, or could there be, performance measures of a related health outcome, OR evidence-based intermediate clinical outcomes, intervention/treatment?*
  - *Is there evidence of a systematic assessment of expert opinion beyond those involved in developing the measure?*
  - *Does the SC agree that it is acceptable (or beneficial) to hold providers accountable without empiric evidence?*

1b. Gap in Care/Opportunity for Improvement and 1b. Disparities

1b. Performance Gap. The performance gap requirements include demonstrating quality problems and opportunity for improvement.

- The developer provides data from NCQA's Heart/Stroke Recognition Program and CMS' PQRS:

Performance Data from NCQA's Heart/Stroke Recognition Program (HSRP) – Individual Clinician Level

YEAR	N	MEAN	ST DEV	10TH	25TH	50TH	75TH	90TH	Interquartile Range
2012	755	65%	24%	38%	44%	59%	89%	97%	45%
2013	659	84%	20%	50%	83%	91%	97%	100%	14%

CMS PHYSICIAN QUALITY REPORTING SYSTEM (PQRS)

YEAR	N	MEAN
2010	4491	75%
2011	8167	80%
2012	18291	55%
2013	17935	64%

- The developer does not provide sample characteristics or volumes. No data on disparities from the measure is provided, though the prevalence of heart disease, stroke, and peripheral arterial disease (PAD) based on sex, age, and race are provided. The developer also cites a study that found blacks are less likely than whites to use aspirin (29% vs. 44%, p = 0.008). Another study found that PAD patients with lower SES are less likely to receive antiplatelet and statin therapy.

- ***Questions for the Committee:***
  - *The PQRS performance declines significantly from 2011 and 2012, while volumes significantly increased? Did a change in the measure or program impact the performance? Similar declines were noted in 2012 to 2013 in HSRP*
  - *Is there a gap in care that warrants a national performance measure?*
  - *Should this measure be indicated as disparities sensitive?*

1c. Priority

1c. High Priority (previously "High Impact") requires measures to address national health goal/priority or a demonstrated high-impact aspect of care.

- *Beginning in 2015, priority is no longer an NQF measure evaluation criterion.*

Committee pre-evaluation comments

Criteria 1: Importance to Measure and Report (including 1a, 1b, 1c)

1. ***Committee's Overview Comments***:
   - High rating for evidence. QQC provided, and high quality for guidelines and systematic review. Evidence applies directly to process.
   - As this is a process measure it is required to have a systematic review. This measure has clinical guidelines with supportive statements with 1A strength of the statements in the guideline, as well as a systematic review of 287 studies including 135,000 patients. I feel this measure has sufficient evidence to support the measure focus.

1a. ***Committee's Comments on Evidence to Support Measure Focus:***
- High rating for evidence. QQC provided, and high quality for guidelines and systematic review. Evidence applies directly to process.
- The evidence relates directly to the process measured which is routine use of aspirin or another antiplatelet. Recommend rating as HIGH

1b. ***Committee's Comments on Performance Gap:***
- Some performance gap noted, though data confusing with poorer performance when volume increased. No disparities related to measure noted, but a couple studies note both racial and SES disparities.
- Concerns exist in CMS PQRS that the N is increasing but the mean % decreases from 2010 through 2013. The NCQA heart stroke recognition program individual clinician level demonstrates increase in % reporting, but decrease in N reporting.
- There is no performance data on disparities, but it appears according to evidence that there are disparities, including black vs white and lower SES. In addition, specific diseases may not be receiving appropriate care (e.g. PAD)

1c. ***Committee's Comments on Composite Performance Measure:***
- Not Applicable

Criteria 2: Scientific Acceptability of Measure Properties

2a. Reliability

2a1. Reliability Specifications

2a1. Specifications requires the measure, as specified, to produce consistent (reliable) and credible (valid) results about the quality of care when implemented.

- Data sources to calculate performance include administrative claims, electronic clinical data, EHR, and paper medical records. ICD-9, ICD-10, CPT, HCPCS, and UBREV (billing codes). An ICD-9 to ICD-10 conversion methodology is not provided.
- Eligible patients identified by either event or diagnosis. If identified by event (MI, CABG, PCI), the event must occur during the year prior to the measurement year. However, if identified by diagnosis of IVD then must have had diagnosis during both the measurement year and the year prior to the measurement year.
- At a minimum 'documentation' is defined as a note in the MR indicating dates when aspirin or other antiplatelet was prescribed or documentation of prescription from another treating physician.
- Developer states since last maintenance the following changes to the measure have been made:
    - Changed "antithrombotic" to "antiplatelet" throughout the measure specification to more closely align with measure intent, which is to assess the use of aspirin or other antiplatelet medications in patients with ischemic vascular disease.
    - Added exclusion for patients on anticoagulant therapy based on feedback from measurement advisory panels.

Questions for the Committee:

- *Are all the data elements clearly defined? Are all appropriate codes included?*
- *Is the logic or calculation algorithm clear?*
- *Is it likely this measure can be consistently implemented?*

2a2. Reliability Testing Testing attachment

2a2. Reliability testing demonstrates if the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise enough to distinguish differences in performance across providers.

- Reliability testing for this measure was conducted at the level of the performance measure score, using the data source and level of analysis specified. The primary analysis was conducted at the level of the individual provider and included 659 clinicians (35 eligible patients per clinician; total = 23,065 patients) who participated in NCQA's Heart/Stroke Program (HSRP) in 2013.
- The sampling methodology for reliability testing included provider established abstraction start date, and selecting 35 consecutive regressive patients who meet age, IVD diagnostic, patient duration with provider, and timing parameters for face-to-face visits.
- A signal-to-noise analysis using the beta-binomial model was conducted. This type of analysis, which is appropriate for the measure, quantifies the amount of variation in performance that is due to differences between providers (as opposed to differences that are due to random measurement error). The method results in a reliability statistic for each clinician.
- Overall reliability for this measure based on data submitted by 659 clinicians is 0.88. A reliability of 0.70 is generally considered a minimum threshold for acceptability, and 0.80 is considered very good reliability.

Questions for the Committee:

- *Specific questions on the method and results of reliability testing.*

- *Is the test sample adequate to generalize for widespread implementation?*
- *Do the results demonstrate sufficient reliability so that differences in performance can be identified?*

2b. Validity

2b1. Validity: Specifications

2b1. Validity Specifications. This section should determine if the measure specifications are consistent with the evidence.

- The clinical practice guidelines and body of evidence supporting this measure recommend the use of aspirin or other antiplatelets as secondary preventive treatment in patients with established cardiovascular disease.

Question for the Committee:

- *Are the specifications consistent with the evidence?*

2b2. Validity testing

2b2. Validity Testing should demonstrate the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality.

- Systematic assessment of face validity consists of a four step standardized process called the HEDIS measure life cycle. The steps include identifying areas of interest/gaps in care, a literature review, measure development, field testing, public comment, and ongoing evaluation.
- The developers state this measure was tested for face validity with two expert panels, Cardiovascular Measurement Advisory Panel (8 physicians, 1 nurse) and NCQA's Clinical Programs Committee (17 members).
- The developer does not provide statistical results from validity testing but does state that the multiple NCQA panels agreed that the measure, as specified, accurately differentiates quality across clinicians.

Questions for the Committee:

- *Is the test sample adequate to generalize for widespread implementation?*
- *Do the results demonstrate sufficient validity so that conclusions about quality can be made?*
- *Do you agree that the score from this measure as specified is an indicator of quality?*
- *Other specific question of the validity testing?*

2b3-2b7. Threats to Validity

2b3. Exclusions:

- The developer states that prior to 2015 the measure did not have any exclusions. However, developer stated since last maintenance added exclusion for patients on anticoagulant therapy based on feedback from measurement advisory.
- No statistical testing results on the impact of adding the exclusion of patients on anticoagulant therapy provided.

Questions for the Committee:

- *Are the exclusions consistent with the evidence?*
- *Are any patients or patient groups inappropriately excluded from the measure?*
- *Are the exclusions/exceptions of sufficient frequency and variation across providers to be needed (and outweigh the data collection burden)?*

2b4. Risk adjustment:

- This process measure is not risk adjusted or stratified.

2b5. Meaningful difference:

- A box plot with 2012 and 2013 data is included with # of clinicians, average, lowest/highest rate but the developer only provides SD, percentiles, IQR and interpretation of the 2013 data.
- The overall mean performance on this measure is 84% (SD = 20%) for 2013.
- There is a statistically significant difference (14%) in performance between clinicians in the 25th and 75th percentiles. The gap is significantly higher (50%) between the 10th and 90th percentiles.
- The developers expect clinicians outside of the Heart/Stroke Recognition Program (HSRP) to show wider variation in performance.

Question for the Committee:

- *Does this measure identify meaningful differences about quality?*

2b6. Comparability of data sources/methods:

- This measure submission includes the claims and registry submission for the measure, and not the eMeasure specifications for the EHR Incentive Program and ACO Shared Savings Programs. Therefore, not comparability of data sources is available.

Question for the Committee:

Does performance across data sources for non-eMeasures and eMeasures of the same measure differ?

2b7. Missing Data

- The developer states that this measure is collected with a complete sample, therefore no missing data on this measure.

Question for the Committee:

- *Does the developer have data demonstrating how many patients were excluded due to missing data?*

Committee pre-evaluation comments

Criteria 2: Scientific Acceptability of Measure Properties (including all 2a, 2b, and 2d)

2a1. &2b1.: ***Committee's Comments on Reliability-Specifications:***

- Measure specifications are clearly defined and consistent with the evidence. Measure likely to be implemented consistently.
- The data elements are clearly defined and the evidence clearly supports this measure.

2a2.: ***Committee's Comments on Reliability-Testing:***

- Reliability testing was done through beta-binomial model measuring signal-to-noise ratio, and the results demonstrated high reliability analysis. High rating.
- The developers have done an excellent job of revising the numerator and the denominator by changing anitcoagulant in numerator to antiplatelet, and have added very appropriate and thorough exclusions that are consistent with the evidence. One concern is the number of patients who experience atrial fibrillation and are placed on anticoagulants for this who may be post PCI, CABG, MI... they would all be excluded from this measure?
- The exclusions are of sufficient frequency across providers.
- The reliability score (.88) is high suggesting sufficient signal strength to discriminate performance between entities

2b1.: ***Committee's Comments on Validity-Specifications***:

- Measure specifications are clearly defined and consistent with the evidence. Measure likely to be implemented consistently.
- None

2b2.: ***Committee's Comments on Validity-Testing:***

- Face validity done, and results indicate a majority percentage believe measure can accurately distinguish good and poor quality. No statistical results of validity testing provided. Overall moderate validity.
- Empirical validity testing was not performed, but face validity of performance measure score was performed with 2 expert panels: one with 9 members (8 physicians, one nurse) and one with 17 members.
- This is not the optimal method of validity testing.

2b3-7.: ***Committee's Comments on Threats to Validity:***

- Exceptions noted. No apparent threats, but meaningful differences are noted in clinician performance. No risk adjustment done.
- According to the box plot provided by the developers of the heart stroke recognition program from 2012 and 2013 there is a 14% gap between first 1/4 and 3/4 percentiles but a 50% gap between 10 and 90%...indicating meaningful differences in performance. This indicates clinicians outside of HSRP program would probably demonstrate a larger variation.

2d.: ***Committee's Comments on Composite Performance Measure:***

- Not Applicable

Criterion 3. Feasibility

3. Feasibility is the extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

- The data source includes administrative claims, electronic clinical data, EHR, and paper medical records and readily available data occurring during patient care.
- The developer states that some data elements are in electronic sources but to allow for widespread reporting across health care practices, this measure is collected through multiple data sources including paper medical records.
- The developers do not provide specific information on the operational use of the measure but do state that clinicians participating in NCQA's Heart/Stroke Recognition Program have no difficulty collecting, interpreting, and reporting this measure. Additionally, the developers have received positive feedback on the use of this measure in the PQRS program.
- The developers encourage broad public use and dissemination of the measure and agreed that noncommercial uses do not require the consent. Practice use is not considered commercial use.

Questions for the Committee:

- *Are the required data elements routinely generated and used during care delivery?*
- *Are the required data elements available in electronic form, e.g., EHR or other electronic sources?*
- *Is the data collection strategy ready to be put into operational use?*
- *If an eMeasure, does the eMeasure Feasibility Score Card demonstrate acceptable feasibility in multiple EHR systems and sites?*

Committee pre-evaluation comments

Criteria 3: Feasibility

3.: ***Committee's Comments on Feasibility:***

- Data collection obtained through administrative claims, EHRs, and other sources. No data collection barriers identified. No assessments of costs or abstraction time done. Moderate to high feasibility.
- The data elements are routinely generated and used during care delivery and could easily be captured in electronic form.

Criterion 4: Usability and Use

4. Usability and Use evaluate the extent to which audiences (e.g., consumers, purchasers, providers, policymakers) use or could use performance results for both accountability and performance improvement activities.

- The measure is publicly reported in PQRS; it is also used in CMS' EHR Incentive Program (Meaningful Use), ACO Shared Savings Program, and NCQA's Heart/Stroke Recognition Program (HSRP).

- In 2014 the Measure Applications Partnership (MAP) Clinician Workgroup supported this measure for the Physician Compare and Value-Based Payment Modifier Programs because the measure promotes alignment across programs, settings, and public- and private-sector efforts. Included in a MAP family of measures. Address program goals/requirements. The measure was previously supported by Clinician Workgroup for inclusion in Physician Compare and VBPM for clinician group reporting.

Questions for the Committee (as appropriate) *:*

- *Is the measure publicly reported?*
- *For maintenance measures – is the measure used in at least one accountability application?*
- *How can the performance results be used to further the goal of high-quality, efficient healthcare?*
- *Do the benefits of the measure outweigh any potential unintended consequences?*

Committee pre-evaluation comments

Criteria 4: Usability and Use

4.: ***Committee's Comments on Usability and Use:***

- Measure is currently implemented by CMS in PQRS, EHR Incentive Program, and Medicare Shared Savings Program. High usability.
- Currently used in PQRS with CMS and in NCQAs heart stroke recognition program

Criterion 5: Related and Competing Measures

- List any related or competing measures based on harmonization protocol.
- Summarize any harmonization efforts, i.e., responses from the developers regarding harmonization.
- Briefly summarize next steps according to protocol
- 0067 : Chronic Stable Coronary Artery Disease: Antiplatelet Therapy
- 0076 : Optimal Vascular Care
- 0142 : Aspirin prescribed at discharge for AMI
- 2452 :Percutaneous Coronary Intervention (PCI): Post-Procedural Optimal Medical Therapy
- 0964 :Therapy with Aspirin, P2Y12 Inhibitor, and Statin at Discharge Following PCI in Eligible Patients
- 0465: Perioperative Anti-platelet Therapy for Patients undergoing Carotid Endarterectomy

Pre-meeting public and member comments

-

NATIONAL QUALITY FORUM—Evidence (subcriterion 1a)

Measure Number (*if previously endorsed*)**:** 0068

Measure Title: Ischemic Vascular Disease (IVD): Use of Aspirin or Another Antiplatelet

IF the measure is a component in a composite performance measure, provide the title of the Composite Measure here: Click here to enter composite measure #/ title

Date of Submission: 6/30/2015

Instructions

- *For composite performance measures:*
  - *A separate evidence form is required for each component measure unless several components were studied together.*
  - *If a component measure is submitted as an individual performance measure, attach the evidence form to the individual measure submission.*
- Respond to all questions as instructed with answers immediately following the question. All information needed to demonstrate meeting the evidence subcriterion (1a) must be in this form. An appendix of *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 10 pages (*incudes questions/instructions*; minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the evidence for this measure meets NQF's evaluation criteria.

1a. Evidence to Support the Measure Focus

The measure focus is evidence-based, demonstrated as follows:

- Health outcome: [3] a rationale supports the relationship of the health outcome to processes or structures of care. Applies to patient-reported outcomes (PRO), including health-related quality of life/functional status, symptom/symptom burden, experience with care, health-related behavior.
- Intermediate clinical outcome: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured intermediate clinical outcome leads to a desired health outcome.
- Process: [5] a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured process leads to a desired health outcome.
- Structure: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured structure leads to a desired health outcome.
- Efficiency: [6] evidence not required for the resource use component.

Notes

3. Generally, rare event outcomes do not provide adequate information for improvement or discrimination; however, serious reportable events that are compared to zero are appropriate outcomes for public reporting and quality improvement.

4. The preferred systems for grading the evidence are the U.S. Preventive Services Task Force (USPSTF) grading definitions and methods, or Grading of Recommendations, Assessment, Development and Evaluation (GRADE) guidelines.

5. Clinical care processes typically include multiple steps: assess → identify problem/potential problem → choose/plan intervention (with patient input) → provide intervention → evaluate impact on health status. If the measure focus is one step in such a multistep process, the step with the strongest evidence for the link to the desired outcome should be selected as the focus of measurement. Note: A measure focused only on collecting PROM data is not a PRO-PM.

6. Measures of efficiency combine the concepts of resource use and quality (see NQF's Measurement Framework: Evaluating Efficiency Across Episodes of Care; AQA Principles of Efficiency Measures).

1a.1.This is a measure of: (*should be consistent with type of measure entered in De.1*)

Outcome

☐ Health outcome: Click here to name the health outcome

☐Patient-reported outcome (PRO): Click here to name the PRO

PROs include HRQoL/functional status, symptom/symptom burden, experience with care, health-related behaviors

☐ Intermediate clinical outcome (*e.g., lab value*): Click here to name the intermediate outcome

☒ Process: Routine use of aspirin or another antiplatelet

☐ Structure: Click here to name the structure

☐ Other: Click here to name what is being measured

HEALTH OUTCOME/PRO PERFORMANCE MEASURE *If not a health outcome or PRO, skip to 1a.3*

1a.2. Briefly state or diagram the path between the health outcome (or PRO) and the healthcare structures, processes, interventions, or services that influence it.

1a.2.1. State the rationale supporting the relationship between the health outcome (or PRO) to at least one healthcare structure, process, intervention, or service (*i.e., influence on outcome/PRO*).

Note: For health outcome/PRO performance measures, no further information is required; however, you may provide evidence for any of the structures, processes, interventions, or service identified above.

INTERMEDIATE OUTCOME, PROCESS, OR STRUCTURE PERFORMANCE MEASURE

1a.3. Briefly state or diagram the path between structure, process, intermediate outcome, and health outcomes. Include all the steps between the measure focus and the health outcome.

Patient 18 years of age or older >>>> Diagnosed with cardiovascular disease (either through having an event like an AMI, CABG, or PCI or by having a diagnosis consistent with ischemic vascular disease in the outpatient setting) >>>> Health provider discusses benefits of antiplatelet therapy with patient >>>> Health care provider prescribes aspirin or another antiplatelet >>>> Patient uses antiplatelet medication routinely >>>> Patient has significant reduction in risk of having an AMI, stroke, vascular complication, or dying.

1a.3.1. What is the source of the systematic review of the body of evidence that supports the performance measure?

☒ Clinical Practice Guideline recommendation – ***complete sections 1a.4, and 1a.7***

☐ US Preventive Services Task Force Recommendation – ***complete sections 1a.5 and 1a.7***

☒ Other systematic review and grading of the body of evidence (*e.g., Cochrane Collaboration, AHRQ Evidence Practice Center*) – ***complete sections 1a.6 and 1a.7***

☐ Other – ***complete section 1a.8***

Please complete the sections indicated above for the source of evidence. You may skip the sections that do not apply.

1a.4. CLINICAL PRACTICE GUIDELINE RECOMMENDATION

1a.4.1. Guideline citation (*including date*) and **URL for guideline** (*if available online*):

Smith SC Jr, Benjamin EJ, Bonow RO, Braun LT, Creager MA, Franklin BA, Gibbons RJ, Grundy SM, Hiratzka LF, Jones DW, Lloyd-Jones DM, Minissian M, Mosca L, Peterson ED, Sacco RL, Spertus J, Stein JH, Taubert KA. AHA/ACCF secondary prevention and risk reduction therapy for patients with coronary and other atherosclerotic vascular disease: 2011 update: a guideline from the American Heart Association and American College of Cardiology Foundation. 1a.4.2. Identify guideline recommendation number and/or page number and **quote verbatim, the specific guideline recommendation**.

AHA/ACCF Secondary Prevention and Risk Reduction Therapy for Patients with Coronary and Other Atherosclerotic Vascular Disease: 2011 Update

Page Number	Recommendation	Verbatim Quote
3	1	Aspirin 75–162 mg daily is recommended in all patients with coronary artery disease unless contraindicated. (Level of Evidence: A) • Clopidogrel 75 mg daily is recommended as an alternative for patients who are intolerant of or allergic to aspirin. (Level of Evidence: B) Class I
3	2	A P2Y12 receptor antagonist in combination with aspirin is indicated in patients after ACS or PCI with stent placement. (Level of Evidence: A) • For patients receiving a bare-metal stent or drug-eluting stent during PCI for ACS, clopidogrel 75 mg daily, prasugrel 10 mg daily, or ticagrelor 90 mg twice daily should be given for at least 12 months. (Level of Evidence: A) Class I
4	3	For patients undergoing coronary artery bypass grafting, aspirin should be started within 6 hours after surgery to reduce saphenous vein graft closure. Dosing regimens ranging from 100 to 325 mg daily for 1 year appear to be efficacious. (Level of Evidence: A) Class I

Page Number	Recommendation	Verbatim Quote
4	4	In patients with extracranial carotid or vertebral atherosclerosis who have had ischemic stroke or TIA, treatment with aspirin alone (75–325 mg daily), clopidogrel alone (75 mg daily), or the combination of aspirin plus extended-release dipyridamole (25 mg and 200 mg twice daily, respectively) should be started and continued. (Level of Evidence: B) Class I
4	5	For patients with symptomatic atherosclerotic peripheral artery disease of the lower extremity, antiplatelet therapy with aspirin (75–325 mg daily) or clopidogrel (75 mg daily) should be started and continued. (Level of Evidence: A) Class I
4	6	Antiplatelet therapy is recommended in preference to anticoagulant therapy with warfarin or other vitamin K antagonists to treat patients with atherosclerosis. (Level of Evidence: A) Class I

Guidelines for the Prevention of Stroke in Patients with Stroke and Transient Ischemic Attack: 2014

Page Number	Recommendation	Verbatim Quote
2198	1	For patients with noncardioembolic ischemic stroke or TIA, the use of antiplatelet agents rather than oral anticoagulation is recommended to reduce the risk of recurrent stroke and other cardiovascular events (Class I; Level of Evidence A).
2198	2	Aspirin (50–325 mg/d) monotherapy (Class I; Level of Evidence A) or the combination of aspirin 25 mg and extended-release dipyridamole 200 mg twice daily (Class I; Level of Evidence B) is indicated as initial therapy after TIA or ischemic stroke for prevention of future stroke. (Revised recommendation)
2198	3	Clopidogrel (75 mg) monotherapy is a reasonable option for secondary prevention of stroke in place of aspirin or combination aspirin/dipyridamole (Class IIa; Level of Evidence B). This recommendation also applies to patients who are allergic to aspirin.
2199	4	For patients with noncardioembolic ischemic stroke or TIA, the use of antiplatelet agents rather than oral anticoagulation is recommended to reduce the risk of recurrent stroke and other cardiovascular events (Class I; Level of Evidence A).

1a.4.3. Grade assigned to the quoted recommendation <u>with definition</u> of the grade:

AHA/ACCF Secondary Prevention and Risk Reduction Therapy for Patients with Coronary and Other Atherosclerotic Vascular Disease: 2011 Update

Recommendation	Grade	Definition
1-6	Class I	Benefit >>> Risk Procedure/Treatment SHOULD be performed/administered

Guidelines for the Prevention of Stroke in Patients with Stroke and Transient Ischemic Attack: 2014

Recommendation	Grade	Definition
1, 2, 4	Class I	Benefit >>> Risk Procedure/Treatment SHOULD be performed/administered
3	Class IIa	Benefit >> Risk Additional studies with focused objectives needed IT IS REASONABLE to perform procedure/administer treatment

1a.4.4. Provide all other grades and associated definitions for recommendations in the grading system. (*Note: If separate grades for the strength of the evidence, report them in section 1a.7.*)

Grade	Definition
Class IIb	Benefit ≥ Risk Additional studies with broad objectives needed; additional registry data would be helpful Procedure/Treatment MAY BE CONSIDERED
Class III – No Benefit	No Benefit Procedure/Test -Not helpful Treatment – No proven benefit
Class III - Harm	Harm Procedure/Test – Excess cost without benefit or harmful Treatment – Harmful to patients

1a.4.5. Citation and URL for methodology for grading recommendations (*if different from 1a.4.1*)**:**

Both guidelines cited in 1a.4.1 use the same methodology for grading recommendations.

1a.4.6. If guideline is evidence-based (rather than expert opinion), are the details of the quantity, quality, and consistency of the body of evidence available (e.g., evidence tables)?

☐ Yes → ***complete section 1a.7***

☒ No → ***report on another systematic review of the evidence in sections 1a.6 and 1a.7; if another review does not exist, provide what is known from the guideline review of evidence in 1a.7***

1a.5. UNITED STATES PREVENTIVE SERVICES TASK FORCE RECOMMENDATION

1a.5.1. Recommendation citation (*including date*) and **URL for recommendation** (*if available online*):

1a.5.2. Identify recommendation number and/or page number and **quote verbatim, the specific recommendation**.

1a.5.3. Grade assigned to the quoted recommendation with definition of the grade:

1a.5.4. Provide all other grades and associated definitions for recommendations in the grading system. (*Note: the grading system for the evidence should be reported in section 1a.7.*)

1a.5.5. Citation and URL for methodology for grading recommendations (*if different from 1a.5.1*)**:**

Complete section 1a.7

1a.6. OTHER SYSTEMATIC REVIEW OF THE BODY OF EVIDENCE

1a.6.1. Citation (*including date*) and **URL** (*if available online*):

Both clinical guidelines cited in 1a.4.1 cover a much broader topic area (i.e., secondary prevention) than just antiplatelet therapy and do not discuss in detail the evidence review process used for each antiplatelet therapy recommendation. They do, however, provide a grade of the evidence for each of the recommendations and cite multiple studies, other guidelines, and systematic reviews supporting those recommendations. Therefore, to answer the questions in 1a.7, we are using the evidence grades provided in the guidelines and referencing one seminal systematic review cited in the guidelines that summarizes the body of evidence supporting the recommendations.

- Antithrombotic Trialists' Collaboration Collaborative meta-analysis of randomised trials of antiplatelet therapy for prevention of death, myocardial infarction, and stroke in high risk patients. BMJ. 2002;324:71–86.

  http://www.bmj.com/content/324/7329/71.long

1a.6.2. Citation and URL for methodology for evidence review and grading (*if different from 1a.6.1*)**:**

Both guidelines cited in 1a.4.1 use the same methodology for grading evidence.

Complete section 1a.7

1a.7. FINDINGS FROM SYSTEMATIC REVIEW OF BODY OF THE EVIDENCE SUPPORTING THE MEASURE

If more than one systematic review of the evidence is identified above, you may choose to summarize the one (or more) for which the best information is available to provide a summary of the quantity, quality, and consistency of the body of evidence. Be sure to identify which review is the basis of the responses in this section and if more than one, provide a separate response for each review.

1a.7.1. What was the specific structure, treatment, intervention, service, or intermediate outcome addressed in the evidence review?

Antithrombotic Trialists' Collaboration Meta-Analysis

This meta-analysis of randomized trials sought to determine the effects of antiplatelet therapy among patients at high risk of occlusive vascular events and studied non-fatal myocardial infarctions, non-fatal stroke (subdivided into intracranial hemorrhages and strokes of ischemic or unknown etiology), and vascular death as main outcomes.

1a.7.2. Grade assigned for the quality of the quoted evidence with definition of the grade:

AHA/ACCF Secondary Prevention and Risk Reduction Therapy for Patients with Coronary and Other Atherosclerotic Vascular Disease: 2011 Update

Recommendation	Grade	Definition
1-3, 5, 6	Level A	Multiple populations evaluated* Data derived from multiple randomized clinical trials or meta-analyses
4, sub-bullet of recommendation 1	Level B	Limited populations evaluated* Data derived from a single randomized trial or nonrandomized studies

* Data available from clinical trials or registries about the usefulness/efficacy in different subpopulations, such as sex, age, history of diabetes, history of prior myocardial infarction, history of heart failure, and prior aspirin use.

Guidelines for the Prevention of Stroke in Patients with Stroke and Transient Ischemic Attack: 2014

Recommendation	Grade	Definition
1, 4	Level A	Multiple populations evaluated* Data derived from multiple randomized clinical trials or

		meta-analyses
2, 3	Level B	Limited populations evaluated* Data derived from a single randomized trial or nonrandomized studies

* Data available from clinical trials or registries about the usefulness/efficacy in different subpopulations, such as sex, age, history of diabetes, history of prior myocardial infarction, history of heart failure, and prior aspirin use.

1a.7.3. Provide all other grades and associated definitions for strength of the evidence in the grading system.

Grade	Definition
Level C	Very limited populations evaluated* Only consensus opinion of experts, case studies, or standar of care

*Data available from clinical trials or registries about the usefulness/efficacy in different subpopulations, such as sex, age, history of diabetes, history of prior myocardial infarction, history of heart failure, and prior aspirin use.

1a.7.4. What is the time period covered by the body of evidence? (*provide the date range, e.g., 1990-2010*).
Date range: Click here to enter date range

The antiplatelet recommendations from the 2011 ACC/AHA Secondary Prevention Guidelines and the 2014 AHA/ASA Stroke Prevention Guidelines cite studies, systematic reviews, and other guidelines as recent as 2013 and dating back to 1978. It should be noted that the search parameters described by some of the systematic reviews did not include clear date ranges (e.g., "all studies published by 1997") so the body of evidence potentially goes back further.

QUANTITY AND QUALITY OF BODY OF EVIDENCE

1a.7.5. How many and what type of study designs are included in the body of evidence? (*e.g., 3 randomized controlled trials and 1 observational study*)

The body of evidence supporting antiplatelet therapy as secondary preventive treatment in patients with established cardiovascular disease is comprised of many (>100) studies, meta-analyses, and practice guidelines.

The Antithrombotic Trialists' Collaboration (ATT Collaboration) ultimately included 287 studies involving 135,000 patients in comparisons of antiplatelet therapy versus control and 77,000 in comparisons of different antiplatelet regimens to make their conclusions. The ATT Collaboration Meta-Analysis reviewed randomized trials of an antiplatelet regimen versus control or of one antiplatelet regimen versus another in high risk patients (with acute or previous vascular disease or some other predisposing condition) from which results were available before September 1997. Trials had to use a method of randomization that precluded prior knowledge of the next treatment to be allocated and comparisons had to be un-confounded—that is, have study groups that differed only in terms of antiplatelet regimen.

1a.7.6. What is the overall quality of evidence <u>across studies</u> in the body of evidence? (*discuss the certainty or confidence in the estimates of effect particularly in relation to study factors such as design flaws, imprecision due to small numbers, indirectness of studies to the measure focus or target population*)

The ATT Collaboration found sufficient quality of evidence across the studies included in their analysis to support the use of antiplatelet therapy as secondary preventive treatment in patient with established cardiovascular disease. Antiplatelet therapy clearly reduced the incidence of non-fatal myocardial infarctions, non-fatal stroke, or vascular death.

ESTIMATES OF BENEFIT AND CONSISTENCY ACROSS STUDIES IN BODY OF EVIDENCE

1a.7.7. What are the estimates of benefit—magnitude and direction of effect on outcome(s) <u>across studies</u> in the body of evidence? (*e.g., ranges of percentages or odds ratios for improvement/ decline across studies, results of meta-analysis, and statistical significance*)

Aspirin or other oral antiplatelet drugs are protective in most types of patients at increased risk of occlusive vascular events, including those with an acute myocardial infarction or ischemic stroke, unstable or stable angina, previous myocardial infarction, stroke or cerebral ischemia, peripheral arterial disease, or atrial fibrillation. Overall, among these high risk patients, allocation to antiplatelet therapy reduced the combined outcome of any serious vascular event by about one quarter; non-fatal myocardial infarction was reduced by one third, non-fatal stroke by one quarter, and vascular mortality by one sixth (with no apparent adverse effect on other deaths). Absolute reductions in the risk of having a serious vascular event were 36 per 1000 treated for two years among patients with previous myocardial infarction; 38 per 1000 patients treated for one month among patients with acute myocardial infarction; 36 per 1000 treated for two years among those with previous stroke or transient ischemic attack; 9 per 1000 treated for three weeks among those with acute stroke; and 22 per 1000 treated for two years among other high risk patients (with separately significant results for those with stable angina ($P = 0.0005$), peripheral arterial disease ($P = 0.004$), and atrial fibrillation ($P = 0.01$)). In each of these high risk categories, the absolute benefits substantially outweighed the absolute risks of major extracranial bleeding.

Aspirin was the most widely studied antiplatelet drug, with doses of 75-150 mg daily at least as effective as higher daily doses. The effects of doses lower than 75 mg daily were less certain. Clopidogrel reduced serious vascular events by 10% compared with aspirin, which was similar to the 12% reduction observed with its analogue ticlopidine. Addition of dipyridamole to aspirin produced no significant further reduction in vascular events compared with aspirin alone. Among patients at high risk of immediate coronary occlusion, short term addition of an intravenous glycoprotein IIb/IIIa antagonist to aspirin prevented a further 20 vascular events per 1000 ($P < 0.0001$) but caused 23 major (but rarely fatal) extracranial bleeds per 1000.

1a.7.8. What harms were studied and how do they affect the net benefit (benefits over harms)?

Because all antiplatelet drugs interfere with normal blood clotting, the most common side effect or risk associated with using them is bleeding. Bleeding risks range from the very minor, such as nose bleeds, to major, life-threatening events such as bleeding into the brain.

In addition to the main outcomes of non-fatal myocardial infarctions, non-fatal stroke (subdivided into intracranial hemorrhages and strokes of ischemic or unknown etiology), and vascular death, the ATT Collaboration Meta-Analysis also studied extracranial bleeding as a potential harm. The benefits of antiplatelet therapy were found to far exceed that harm (as well as the others) in patients at an increased risk of occlusive vascular events.

UPDATE TO THE SYSTEMATIC REVIEW(S) OF THE BODY OF EVIDENCE

1a.7.9. If new studies have been conducted since the systematic review of the body of evidence, provide for <u>each</u> new study: 1) citation, 2) description, 3) results, 4) impact on conclusions of systematic review.

Since the publication of the 2002 ATT Collaboration Meta-Analysis, there have been many (>100) studies and systematic reviews focused on the use of antiplatelet therapy as secondary prevention, none of which conflict with the ATT Collaboration findings.

1a.8 OTHER SOURCE OF EVIDENCE

If source of evidence is NOT from a clinical practice guideline, USPSTF, or systematic review, please describe the evidence on which you are basing the performance measure.

1a.8.1 What process was used to identify the evidence?

1a.8.2. Provide the citation and summary for each piece of evidence.

1. Evidence, Performance Gap, Priority – Importance to Measure and Report
Extent to which the specific measure focus is evidence-based, important to making significant gains in healthcare quality, and improving health outcomes for a specific high-priority (high-impact) aspect of healthcare where there is variation in or overall less-than-optimal performance. ***Measures must be judged to meet all subcriteria to pass this criterion and be evaluated against the remaining criteria.***
1a. Evidence to Support the Measure Focus – See attached Evidence Submission Form Final_Evidence_Form_0068_IVD_Aspirin.docx
1b. Performance Gap Demonstration of quality problems and opportunity for improvement, i.e., data demonstrating: • considerable variation, or overall less-than-optimal performance, in the quality of care across providers; and/or • disparities in care across population groups. 1b.1. **Briefly explain the rationale for this measure** *(e.g., the benefits or improvements in quality envisioned by use of this measure)* This measure aims to improve the quality of care for patients with established cardiovascular disease by assessing whether or not they received aspirin or another antiplatelet medication during the measurement year. Antiplatelet medications, such as aspirin and clopidogrel, are drugs that inhibit platelets from clumping together and forming clots. Their use in the secondary prevention of cardiovascular events is well-established. In patients who are at high risk because they already have atherosclerotic cardiovascular disease, antiplatelet therapy reduces the yearly risk of serious vascular events (MI, stroke, death) by about twenty-five percent.

Antiplatelet agents also have a beneficial effect in reducing all-cause mortality and fatal cardiovascular events in patients with peripheral arterial disease.

1b.2. Provide performance scores on the measure as specified (current and over time) at the specified level of analysis. *(This is required for endorsement maintenance. Include mean, std dev, min, max, interquartile range, scores by decile. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities included). This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*

NCQA HEART/STROKE RECOGNITION PROGRAM

The data references are extracted from NCQA's Heart/Stroke Recognition Program reflecting the most recent years of reporting for this measure. Below is a description of the total number of clinicians (N) submitting data for this measure. The figure N represents the total number of individual clinicians reporting data. Performance data is summarized by the mean, standard deviation, performance percentiles (10th, 25th, 50th, 75th and 90th percentile) and the interquartile range.

Performance Data from NCQA's Heart/Stroke Recognition Program – Individual Clinician Level

YEAR	N	MEAN	ST DEV	10TH	25TH	50TH	75TH	90TH	Interquartile Range
2012	755	65%	24%	38%	44%	59%	89%	97%	45%
2013	659	84%	20%	50%	83%	91%	97%	100%	14%

CMS PHYSICIAN QUALITY REPORTING SYSTEM (PQRS)

The following PQRS data available from CMS includes mean performance for program years 2010-2013. Note that the figure N here represents the total number of eligible professionals reporting data each year for the IVD: Use of Aspirin or Another Antiplatelet measure.

YEAR	N	MEAN
2010	4491	75%
2011	8167	80%
2012	18291	55%
2013	17935	64%

1b.3. If no or limited performance data on the measure as specified is reported in 1b2, then provide a summary of data from the literature that indicates opportunity for improvement or overall less than optimal performance on the specific focus of measurement.

N/A

1b.4. Provide disparities data from the measure as specified (current and over time) by population group, e.g., by race/ethnicity, gender, age, insurance status, socioeconomic status, and/or disability. *(This is required for endorsement maintenance. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities include.) This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*

See response in question 1b.5

1b.5. If no or limited data on disparities from the measure as specified is reported in 1b4, then provide a summary of data from the literature that addresses disparities in care on the specific focus of measurement. Include citations.

Heart disease is the leading cause of death for people of most ethnicities in the United States, including African Americans, Hispanics, and whites. For American Indians or Alaska Natives and Asians or Pacific Islanders, heart disease is the second leading cause of death (CDC, 2015). Non-Hispanic black adults are at least 50% more likely to die of heart disease or stroke prematurely (i.e., before age 75 years) than their non-Hispanic white counterparts (CDC, 2013). Black women and men are more likely to die before age 75 as a result of coronary heart disease (CHD) than white women and men (rates of death are 37.9%, 61.5%, 19.4%, and 41.5%, respectively) (CDC, 2011). Racial and age-related disparities also exist in rates of recurrent MI or fatal CHD within 5 years of a first MI. Of those who have a first MI, the percentage with a recurrent event is as follows: at 45 to 64 years of age, 14% of white men, 18% of white women, 22% of black men, and 28% of black women; at =65 years of age, 21% of white men and women, 33% of black men, and 26% of black women (Mozaffarian et al., 2015).

According to data from the 2013 Behavioral Risk Factor Surveillance System (BRFSS), 2.7% of men and 2.7% of women =18 years of age had a history of stroke; 2.5% of non-Hispanic whites, 4.0% of non-Hispanic blacks, 1.3% of Asian/Pacific Islanders, 2.3% of Hispanics (of any race), 4.6% of American Indian/Alaska Natives, and 4.6% of other races or multiracial people had a history of stroke. Over the time period 2006 to 2010, data from BRFSS show that the overall self-reported stroke prevalence did not change. Older adults, blacks, people with lower levels of education, and people living in the southeastern United States had higher stroke

prevalence (BRFSS, 2013).

With regard to peripheral arterial disease (PAD), the highest prevalence has been observed among elderly people, non-Hispanic blacks, and women (Mozaffarian et al., 2015). The 2011 overall any-mention age-adjusted death rate for PAD was 18.1 per 100,000. Any-mention death rates in males were 21.6 for whites, 24.7 for blacks, 8.8 for Asians or Pacific Islanders, and 16.7 for American Indians or Alaska Natives. In females, rates were 15.7 for whites, 18.3 for blacks, 6.9 for Asians or Pacific Islanders, and 13.0 for American Indians or Alaska Natives (NCHS, 2011).

There are limited studies examining the use and adherence of aspirin because pharmacy claims do not include aspirins and other "over-the-counter" drugs. However, a 2010 study using in-home interviews of 3,005 community-residing individuals, ages 57–85 years, found that blacks are less likely than whites to use aspirin (29% vs. 44%, p = 0.008). After controlling for age, gender, comorbidity, socioeconomic status, and access to care factors, racial/ethnic disparities persisted. In particular, black participants at the highest risk of having a cardiovascular event were less likely than their white counterparts to use aspirin (odd ratio 0.61, CI 0.37–0.98) (Qato et al., 2010).

Using data from the American College of Cardiology's PINNACLE Registry, researchers examined the association between socioeconomic status (SES) and guidelines-based treatment with anti-platelet and statin medications and found that PAD patients with lower SES are less likely to receive antiplatelet and statin therapy. The practice site at which patients received care largely explained the observed SES differences in treatment with guideline-recommended secondary prevention medications. Future efforts to reduce treatment disparities in these vulnerable populations should target systems improvement at practices serving high proportions of patients with low SES. (Subherwal et al., 2013).

1c. High Priority (previously referred to as High Impact)

The measure addresses:

- a specific national health goal/priority identified by DHHS or the National Priorities Partnership convened by NQF; OR
- a demonstrated high-priority (high-impact) aspect of healthcare (e.g., affects large numbers of patients and/or has a substantial impact for a smaller population; leading cause of morbidity/mortality; high resource use (current and/or future); severity of illness; and severity of patient/societal consequences of poor quality).

1c.1. **Demonstrated high priority aspect of healthcare**
Affects large numbers, A leading cause of morbidity/mortality, High resource use
1c.2. **If Other:**

1c.3. **Provide epidemiologic or resource use data that demonstrates the measure addresses a high priority aspect of healthcare. List citations in 1c.4.**
Cardiovascular disease, including stroke, is the leading cause of death in the United States. More than 85 million American adults have one or more types of cardiovascular disease. Specifically, more than 15 million adults (20 years and older) have coronary heart disease (CHD), over 8 million adults have angina, more than 7 million adults have had a myocardial infarction (MI), over 6 million adults have had a stroke, and nearly 7 million adults 40 years of age and older have peripheral artery disease (Mozaffarian et al., 2015). It is estimated that by 2030 more than 43 percent of Americans will have a form of cardiovascular disease (Heidenreich et al., 2011).

In 2011, the total cost of cardiovascular disease and stroke in the United States was estimated to be $320 billion. This total includes direct costs such as the cost of physicians and other health professionals, hospital services, prescribed medications and home health care, as well as indirect costs due to loss of productivity from premature mortality (Mozaffarian et al., 2015). By 2030, direct medical costs for cardiovascular disease are projected to increase to nearly $918 billion (Heidenreich, 2011).

Antiplatelet medications, such as aspirin and clopidogrel, are drugs that inhibit platelets from clumping together and forming clots. Their use in the secondary prevention of cardiovascular events is well established. In patients who are at high risk because they already have occlusive cardiovascular disease, long-term antiplatelet therapy reduces the yearly risk of serious vascular events (MI, stroke, death) by about twenty-five percent (Antiplatelet Trialists´ Collaboration, 1994; 2002; 2009). A more recent systematic review of the literature confirmed the benefits of antiplatelet therapy in reducing death from cardiovascular causes, MI, or stroke (Cheng, 2013). Antiplatelet agents also have a beneficial effect in reducing all-cause mortality and fatal cardiovascular events in patients with peripheral arterial disease (Wong et al., 2011).

1c.5. **If a PRO-PM (e.g. HRQoL/functional status, symptom/burden, experience with care, health-related behaviors), provide evidence that the target population values the measured PRO and finds it meaningful.** *(Describe how and from whom their input was obtained.)*

2. Reliability and Validity—Scientific Acceptability of Measure Properties

Extent to which the measure, as specified, produces consistent (reliable) and credible (valid) results about the quality of care when implemented. ***Measures must be judged to meet the subcriteria for both reliability and validity to pass this criterion and be evaluated against the remaining criteria.***

2a.1. Specifications The measure is well defined and precisely specified so it can be implemented consistently within and across organizations and allows for comparability. eMeasures should be specified in the Health Quality Measures Format (HQMF) and the Quality Data Model (QDM).

De.5. **Subject/Topic Area** *(check all the areas that apply):*
Cardiovascular, Cardiovascular : Acute Myocardial Infarction, Cardiovascular : Ischemic Heart Disease, Coronary Artery Disease, Cardiovascular : Percutaneous Coronary Intervention (PCI), Prevention

De.6. **Cross Cutting Areas** *(check all the areas that apply):*

S.1. **Measure-specific Web Page** *(Provide a URL link to a web page specific for this measure that contains current detailed specifications including code lists, risk model details, and supplemental materials. Do not enter a URL linking to a home page or to general information.)*
http://www.ncqa.org/tabid/59/Default.aspx

S.2a. **If this is an eMeasure**, HQMF specifications must be attached. Attach the zipped output from the eMeasure authoring tool (MAT) - if the MAT was not used, contact staff. (Use the specification fields in this online form for the plain-language description of the specifications)
This is not an eMeasure **Attachment:**

S.2b. **Data Dictionary, Code Table, or Value Sets** *(and risk model codes and coefficients when applicable) must be attached. (Excel or csv file in the suggested format preferred - if not, contact staff)*
Attachment **Attachment:** 0068_IVD_Value_Sets_Final.xlsx

S.3. **For endorsement maintenance**, please briefly describe any changes to the measure specifications since last endorsement date and explain the reasons.
Since this measure last underwent endorsement maintenance, we revised the measure in the following ways:

-Changed “antithrombotic” to “antiplatelet” throughout the measure specification to more closely align with measure intent, which is to assess the use of aspirin or other antiplatelet medications in patients with ischemic vascular disease.

-Added exclusion for patients on anticoagulant therapy based on feedback from measurement advisory panels.

S.4. **Numerator Statement** *(Brief, narrative description of the measure focus or what is being measured about the target population, i.e., cases from the target population with the target process, condition, event, or outcome)*
IF an OUTCOME MEASURE, state the outcome being measured. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
Patients who had documentation of routine use of aspirin or another antiplatelet during the measurement year.

S.5. **Time Period for Data** *(What is the time period in which data will be aggregated for the measure, e.g., 12 mo, 3 years, look back to August for flu vaccination? Note if there are different time periods for the numerator and denominator.)*
Numerator: The measurement year (12 month period).
Denominator: The measurement year and the year prior to the measurement year (24 month period).

S.6. **Numerator Details** *(All information required to identify and calculate the cases from the target population with the target process, condition, event, or outcome such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
IF an OUTCOME MEASURE, describe how the observed outcome is identified/counted. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
ADMINISTRATIVE

Patients who had documentation of routine use of aspirin or another antiplatelet during the measurement year.

Refer to Table IVD-E to identify medications for oral anti-platelet therapy.

ORAL ANTI-PLATELET THERAPIES (TABLE IVD-E)
PRESCRIPTIONS
- Aspirin
- Clopidogrel
- Aspirin-dipyridamole
- Prasugrel
- Ticagrelor
- Ticlopidine

MEDICAL RECORD
Patients who had documentation of routine use of aspirin or another antiplatelet during the measurement year.

At a minimum, documentation in the medical record must include a note indicating the date when aspirin or another antiplatelet was prescribed or documentation of prescription from another treating physician.

S.7. **Denominator Statement** *(Brief, narrative description of the target population being measured)*
Patients 18 years or older by the end of the measurement year discharged from an inpatient setting with an AMI, CABG, or PCI during the 12 months prior to the measurement year or who had a diagnosis of IVD during both the measurement year and the year prior to the measurement year.

S.8. **Target Population Category** *(Check all the populations for which the measure is specified and tested if any):*
Populations at Risk

S.9. **Denominator Details** *(All information required to identify and calculate the target population/denominator such as definitions, specific data collection items/responses , code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
ADMINISTRATIVE

Patients are identified for the eligible population in two ways: by event or by diagnosis. The organization must use both methods to identify the eligible population, but a patient only needs to be identified by one method to be included in the measure.

Event. Any of the following during the year prior to the measurement year meet criteria:
- MI. Discharged from an inpatient setting with an MI (MI Value Set)*. Use both facility and professional claims to identify MI.
-CABG. Discharged from an inpatient setting with a CABG (CABG Value Set)*. Use both facility and professional claims to identify CABG.
-PCI. Patients who had a PCI (PCI Value Set)* in any setting.

Diagnosis. Patients who meet at least one of the following criteria during both the measurement year and the year prior to the measurement year. Criteria need not be the same across both years.
-At least one outpatient visit (Outpatient Value Set)* with an IVD diagnosis (IVD Value Set)*, or
-At least one acute inpatient encounter (Acute Inpatient Value Set)* with an IVD diagnosis (IVD Value Set)*.

*Due to the extensive volume of codes associated with identifying the denominator for this measure, we are attaching a separate file with code value sets. See code value sets located in question S.2b.

MEDICAL RECORD
Documentation of IVD in the medical record includes:
- IVD
- Ischemic heart disease
- Angina
- Coronary atherosclerosis
- Coronary artery occlusion

- Cardiovascular disease
- Occlusion or stenosis of precerebral arteries (including basilar, carotid and vertebral arteries)
- Atherosclerosis of renal artery
- Atherosclerosis of native arteries of the extremities
- Chronic total occlusion of artery of the extremities
- Arterial embolism and thrombosis
- Atheroembolism.

Note: Use paper logs, patient registries or electronic medical records (EMRs) to identify the denominator, then use the medical record to confirm patient eligibility.

S.10. **Denominator Exclusions** *(Brief narrative description of exclusions from the target population)*
Patients who had documentation of use of anticoagulant medications during the measurement year.

S.11. **Denominator Exclusion Details** *(All information required to identify and calculate exclusions from the denominator such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
Patients who had documentation of use of anticoagulant medications during the measurement year.

ANTICOAGULANT MEDICATIONS
- Apixaban
- Argatroban
- Bivalirudin
- Dabigatran
- Dalteparin
- Desirudin
- Edoxaban
- Enoxaparin
- Fondaparinux
- Heparin
- Lepirudin
- Rivaroxaban
- Tinzaparin
- Warfarin

S.12. **Stratification Details/Variables** *(All information required to stratify the measure results including the stratification variables, definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format with at S.2b)*
N/A

S.13. **Risk Adjustment Type** (Select type. Provide specifications for risk stratification in S.12 and for statistical model in S.14-15)
No risk adjustment or risk stratification
If other:

S.14. **Identify the statistical risk model method and variables** *(Name the statistical method - e.g., logistic regression and list all the risk factor variables. Note - risk model development and testing should be addressed with measure testing under Scientific Acceptability)*
N/A

S.15. **Detailed risk model specifications** *(must be in attached data dictionary/code list Excel or csv file. Also indicate if available at measure-specific URL identified in S.1.)*
Note: Risk model details (including coefficients, equations, codes with descriptors, definitions), should be provided on a separate worksheet in the suggested format in the Excel or csv file with data dictionary/code lists at S.2b.

S.15a. **Detailed risk model specifications** (*if not provided in excel or csv file at S.2b*)

S.16. **Type of score:**
Rate/proportion
If other:

S.17. **Interpretation of Score** *(Classifies interpretation of score according to whether better quality is associated with a higher score, a lower score, a score falling within a defined interval, or a passing score)*
Better quality = Higher score

S.18. **Calculation Algorithm/Measure Logic** *(Describe the calculation of the measure score as an ordered sequence of steps including identifying the target population; exclusions; cases meeting the target process, condition, event, or outcome; aggregating data; risk adjustment; etc.)*
Step 1: Determine the denominator
Patients 18 years of age or older by the end of the measurement year AND who were discharged from an inpatient setting for an AMI, CABG or PCI during the 12 months prior to the measurement year or who had a diagnosis of IVD during both the measurement year and the year prior to the measurement year.

Step 2: Exclude patients who meet the exclusion criteria
Patients on anticoagulant therapy.

Step 3: Determine the numerator
Patients who had documentation of routine use of aspirin or another antiplatelet during the measurement year.

Step 4: Calculate the rate by dividing the numerator (Step 3) by the denominator (after exclusions) (Step 2).

S.19. **Calculation Algorithm/Measure Logic Diagram URL or Attachment** *(You also may provide a diagram of the Calculation Algorithm/Measure Logic described above at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
No diagram provided

S.20. **Sampling** *(If measure is based on a sample, provide instructions for obtaining the sample and guidance on minimum sample size.)*
IF a PRO-PM, identify whether (and how) proxy responses are allowed.
N/A

S.21. **Survey/Patient-reported data** *(If measure is based on a survey, provide instructions for conducting the survey and guidance on minimum response rate.)*
IF a PRO-PM, specify calculation of response rates to be reported with performance measure results.

S.22. **Missing data** (specify how missing data are handled, e.g., imputation, delete case.)
Required for Composites and PRO-PMs.

S.23. **Data Source** *(Check ONLY the sources for which the measure is SPECIFIED AND TESTED).*
If other, please describe in S.24.
Administrative claims, Electronic Clinical Data, Electronic Clinical Data : Electronic Health Record, Paper Medical Records

S.24. **Data Source or Collection Instrument** *(Identify the specific data source/data collection instrument e.g. name of database, clinical registry, collection instrument, etc.)*
IF a PRO-PM, identify the specific PROM(s); and standard methods, modes, and languages of administration.
N/A

S.25. **Data Source or Collection Instrument** *(available at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
No data collection instrument provided

S.26. **Level of Analysis** *(Check ONLY the levels of analysis for which the measure is SPECIFIED AND TESTED)*
Clinician : Group/Practice, Clinician : Individual

S.27. **Care Setting** *(Check ONLY the settings for which the measure is SPECIFIED AND TESTED)*
Ambulatory Care : Clinician Office/Clinic
If other:

S.28. **COMPOSITE Performance Measure** - Additional Specifications *(Use this section as needed for aggregation and weighting rules, or calculation of individual performance measures if not individually endorsed.)*
N/A

2a. Reliability – See attached Measure Testing Submission Form
2b. Validity – See attached Measure Testing Submission Form
Final_Testing_Form_0068_IVD_Aspirin-635712772001794970.docx

NATIONAL QUALITY FORUM—Measure Testing (subcriteria 2a2, 2b2-2b7)

Measure Number (*if previously endorsed*)**:** 0068
Measure Title: Ischemic Vascular Disease (IVD): Use of Aspirin or Another Antiplatelet
Date of Submission: 6/30/2015
Type of Measure:

☐ Composite – ***STOP – use composite testing form***	☐ Outcome (*including PRO-PM*)
☐ Cost/resource	☒ Process
☐ Efficiency	☐ Structure

Instructions

- Measures must be tested for all the data sources and levels of analyses that are specified. ***If there is more than one set of data specifications or more than one level of analysis, contact NQF staff*** about how to present all the testing information in one form.
- **For all measures, sections 1, 2a2, 2b2, 2b3, and 2b5 must be completed.**
- **For outcome and resource use measures**, section **2b4** also must be completed.
- If specified for **multiple data sources/sets of specificaitons** (e.g., claims and EHRs), section **2b6** also must be completed.
- Respond to all questions as instructed with answers immediately following the question. All information on testing to demonstrate meeting the subcriteria for reliability (2a2) and validity (2b2-2b6) must be in this form. An appendix for *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 20 pages (*incuding questions/instructions;* minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.
- For information on the most updated guidance on how to address sociodemographic variables and testing in this form refer to the release notes for version 6.6 of the Measure Testing Attachment.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the testing results for this measure meet NQF's evaluation criteria for testing.

2a2. Reliability testing [10] demonstrates the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise. For **PRO-PMs and composite performance measures**, reliability should be demonstrated for the computed performance score.

2b2. Validity testing [11] demonstrates that the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality. For **PRO-PMs and composite performance measures**, validity should be demonstrated for the computed performance score.

2b3. Exclusions are supported by the clinical evidence; otherwise, they are supported by evidence of sufficient frequency of occurrence so that results are distorted without the exclusion; [12]

AND

If patient preference (e.g., informed decisionmaking) is a basis for exclusion, there must be evidence that the exclusion impacts performance on the measure; in such cases, the measure must be specified so that the information about patient preference and the effect on the measure is transparent (e.g., numerator category computed separately, denominator exclusion category computed separately). [13]

2b4. For outcome measures and other measures when indicated (e.g., resource use):

- **an evidence-based risk-adjustment strategy** (e.g., risk models, risk stratification) is specified; is based on patient factors (including clinical and sociodemographic factors) that influence the measured outcome and are present at start of care; [14,15] and has demonstrated adequate discrimination and calibration

OR

- rationale/data support no risk adjustment/ stratification.

2b5. Data analysis of computed measure scores demonstrates that methods for scoring and analysis of the specified measure allow for **identification of statistically significant and practically/clinically meaningful** [16] **differences in performance**;

OR

there is evidence of overall less-than-optimal performance.

2b6. If multiple data sources/methods are specified, there is demonstration they produce comparable results.

2b7. For **eMeasures, composites, and PRO-PMs** (or other measures susceptible to missing data), analyses identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias.

Notes

10. Reliability testing applies to both the data elements and computed measure score. Examples of reliability testing for data elements include, but are not limited to: inter-rater/abstractor or intra-rater/abstractor studies; internal consistency for multi-item scales; test-retest for survey items. Reliability testing of the measure score addresses precision of measurement (e.g., signal-to-noise).

11. Validity testing applies to both the data elements and computed measure score. Validity testing of data elements typically analyzes agreement with another authoritative source of the same information. Examples of validity testing of the measure score include, but are not limited to: testing hypotheses that the measures scores indicate quality of care, e.g., measure scores are different for groups known to have differences in quality assessed by another valid quality measure or method; correlation of measure scores with another valid indicator of quality for the specific topic; or relationship to conceptually related measures (e.g., scores on process measures to scores on outcome measures). Face validity of the measure score as a quality indicator may be adequate if accomplished through a systematic and transparent process, by identified experts, and explicitly addresses

whether performance scores resulting from the measure as specified can be used to distinguish good from poor quality.

12. Examples of evidence that an exclusion distorts measure results include, but are not limited to: frequency of occurrence, variability of exclusions across providers, and sensitivity analyses with and without the exclusion.
13. Patient preference is not a clinical exception to eligibility and can be influenced by provider interventions.

14. Risk factors that influence outcomes should not be specified as exclusions
15. With large enough sample sizes, small differences that are statistically significant may or may not be practically or clinically meaningful. The substantive question may be, for example, whether a statistically significant difference of one percentage point in the percentage of patients who received smoking cessation counseling (e.g., 74 percent v. 75 percent) is clinically meaningful; or whether a statistically significant difference of $25 in cost for an episode of care (e.g., $5,000 v. $5,025) is practically meaningful. Measures with overall less-than-optimal performance may not demonstrate much variability across providers.

1. DATA/SAMPLE USED FOR ALL TESTING OF THIS MEASURE
Often the same data are used for all aspects of measure testing. In an effort to eliminate duplication, the first five questions apply to all measure testing. If there are differences by aspect of testing,(e.g., reliability vs. validity) be sure to indicate the specific differences in question 1.7.

1.1. What type of data was used for testing? (*Check all the sources of data identified in the measure specifications and data used for testing the measure. Testing must be provided for all the sources of data specified and intended for measure implementation.* ***If different data sources are used for the numerator and denominator, indicate N [numerator] or D [denominator] after the checkbox.***)

Measure Specified to Use Data From: (***must be consistent with data sources entered in S.23***)	**Measure Tested with Data From:**
☒ abstracted from paper record	☒ abstracted from paper record
☒ administrative claims	☒ administrative claims
☐ clinical database/registry	☐ clinical database/registry
☒ abstracted from electronic health record	☒ abstracted from electronic health record
☐ eMeasure (HQMF) implemented in EHRs	☐ eMeasure (HQMF) implemented in EHRs
☐ other: Click here to describe	☐ other: Click here to describe

1.2. If an existing dataset was used, identify the specific dataset (*the dataset used for testing must be consistent with the measure specifications for target population and healthcare entities being measured; e.g., Medicare Part A claims, Medicaid claims, other commercial insurance, nursing home MDS, home health OASIS, clinical registry*).
N/A

1.3. What are the dates of the data used in testing?
Testing of reliability of the performance measure score with beta binomial was performed with data from measurement year 2013.

1.4. What levels of analysis were tested? (*testing must be provided for all the levels specified and intended for measure implementation, e.g., individual clinician, hospital, health plan*)

Measure Specified to Measure Performance of:	**Measure Tested at Level of:**

(*must be consistent with levels entered in item S.26*)	
☒ individual clinician	☒ individual clinician
☒ group/practice	☒ group/practice
☐ hospital/facility/agency	☐ hospital/facility/agency
☐ health plan	☐ health plan
☐ other: Click here to describe	☐ other: Click here to describe

1.5. How many and which measured entities were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of measured entities included in the analysis (e.g., size, location, type); if a sample was used, describe how entities were selected for inclusion in the sample*)

ENTITIES INCLUDED FOR MEASURE SCORE RELIABILTY TESTING
Measure score reliability was calculated from NCQA's Heart/Stroke Recognition Program (HSRP) that included 659 clinicians who voluntarily participate in the program The HSRP recognizes clinicians and group practices for the delivery of quality ambulatory care to persons with cardiovascular disease.

SYSTEMATIC ASSESSMENT OF FACE VALIDITY
This measure was tested for face validity with two expert panels. See additional information: Ad.1. Workgroup/Expert Panel in Measure Development for names and affiliation of expert panels:

1. Cardiovascular Measurement Advisory Panel includes eight physicians and one nurse with expertise in cardiovascular health and quality measurement.
2. NCQA's Clinical Programs Committee (CPC) oversees the evolution of NCQA's recognition programs and related measures including the Diabetes Recognition Program, the Heart/Stroke Recognition Program, the Patient Centered Medical Home and Patient-Centered Specialty Practice Recognition Program, among others. The CPC includes representation by purchasers, consumers, health plans, health care providers and policy makers. This panel is made up of 15 members. The CPC is organized and managed by NCQA and reports to the NCQA Board of Directors and is responsible for advising NCQA staff on the development and maintenance of clinical recognition programs. CPC members reflect the diversity of constituencies that performance measurement serves; some bring other perspectives and additional expertise in quality management and the science of measurement.

1.6. How many and which patients were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of patients included in the analysis (e.g., age, sex, race, diagnosis); if a sample was used, describe how patients were selected for inclusion in the sample*)

HEART/STROKE RECOGNITION PROGRAM
Clinicians submitting data to the Heart Stroke Recognition Program establish a start date for abstraction and working consecutively backward from that date, identify 35 patients who had office visits and meet three eligibility criteria:

1. 18 years of age or older
2. Diagnosis of ischemic vascular disease (e.g., coronary artery disease, stroke, peripheral arterial disease, etc.) for at least 12 months
3. Under the care of the applicant clinician or group practice for IVD for at least 12 months. This is defined by documentation of a face-to-face visit for IVD care between the clinician and the patient that pre-dates the most recent IVD visit by at least 12 months.

Clinicians report clinical data relevant to the HSRP measures from the 35 patient records that met the eligibility criteria to NCQA for review. In 2013, a total of 659 clinicians submitted data on approximately 23065 patients.

1.7. If there are differences in the data or sample used for different aspects of testing (e.g., reliability, validity, exclusions, risk adjustment), identify how the data or sample are different for each aspect of testing reported below.

Reliability of this measure was tested using date from 2013. Validity was tested through a systematic assessment of face validity. We have described the composition of the expert panels that assessed face validity in the data sample questions above.

1.8 What were the patient-level sociodemographic (SDS) variables that were available and analyzed in the data or sample used? For example, patient-reported data (e.g., income, education, language), proxy variables when SDS data are not collected from each patient (e.g. census tract), or patient community characteristics (e.g. percent vacant housing, crime rate).
N/A

2a2. RELIABILITY TESTING
Note: *If accuracy/correctness (validity) of data elements was empirically tested, separate reliability testing of data elements is not required – in 2a2.1 check critical data elements; in 2a2.2 enter "see section 2b2 for validity testing of data elements"; and skip 2a2.3 and 2a2.4.*

2a2.1. What level of reliability testing was conducted? (*may be one or both levels*)
☐ **Critical data elements used in the measure** (*e.g., inter-abstractor reliability; data element reliability must address ALL critical data elements*)
☒ **Performance measure score** (e.g., *signal-to-noise analysis*)

2a2.2. For each level checked above, describe the method of reliability testing and what it tests (*describe the steps—do not just name a method; what type of error does it test; what statistical analysis was used*)

METHOD FOR PERFORMANCE MEASURE SCORE RELIABILITY TESTING (BETA-BINOMIAL):
In order to assess measure precision in the context of the observed variability across accountable entities, we utilized the reliability estimate proposed by Adams (2009). The following is quoted from the tutorial which focused on provider-level assessment, "Reliability is a key metric of the suitability of a measure for [provider] profiling because it describes how well one can confidently distinguish the performance of one physician from another. Conceptually, it is the ratio of signal to noise. The signal in this case is the proportion of the variability in measured performance that can be explained by real differences in performance. There are three main drivers of reliability: sample size, differences between physicians, and measurement error. At the physician level, sample size can be increased by increasing the number of patients in the physician's data as well as increasing the number of measures per patient."

The beta-binomial approach accounts for the non-normal distribution of performance within and across accountable entities. Reliability scores vary from 0.0 to 1.0. A score of zero implies that all variation is attributed to measurement error (noise or the individual accountable entity variance) whereas a reliability of 1.0 implies that all variation is caused by a real difference in performance across accountable entities.

Adams, J. L. The Reliability of Provider Profiling: A Tutorial. Santa Monica, California: RAND Corporation. TR-653-NCQA, 2009

2a2.3. For each level of testing checked above, what were the statistical results from reliability testing? (e.g., *percent agreement and kappa for the critical data elements; distribution of reliability statistics from a signal-to-noise analysis*)

Below, we present available statistics from data submitted by 659 clinicians in the Heart/Stroke Recognition Program for the IVD: Use of Aspirin or Another Antiplatelet measure.

Overall Reliability	10th Percentile-90th Percentile
0.88	0.82-1.00

2a2.4 What is your interpretation of the results in terms of demonstrating reliability? (i.e., *what do the results mean and what are the norms for the test conducted?*)
PERFORMANCE MEASURE SCORE (BETA BINOMIAL)
Reliability scores can vary from 0.0 to 1.0. A score of zero implies that all variation is attributed to measurement error (noise) whereas a reliability of 1.0 implies that all variation is caused by a real difference in performance (signal). Generally, a minimum reliability score of 0.7 is used to indicate sufficient signal strength to discriminate performance between accountable entities.

Testing suggests that this measure has strong overall reliability at 0.88. The 10th-90th percentile distribution of physician level reliability on the rates in this measure show the vast majority of physicians met or exceeded the minimally accepted threshold of 0.7, and the majority of them exceeded 0.8. Strong reliability is demonstrated since majority of variances is due to signal and not to noise.

2b2. VALIDITY TESTING
2b2.1. What level of validity testing was conducted? (*may be one or both levels*)
☐ **Critical data elements** (*data element validity must address ALL critical data elements*)
☒ **Performance measure score**
☐ **Empirical validity testing**
☒ **Systematic assessment of face validity of performance measure score as an indicator** of quality or resource use (*i.e., is an accurate reflection of performance on quality or resource use and can distinguish good from poor performance*)

2b2.2. For each level of testing checked above, describe the method of validity testing and what it tests (*describe the steps—do not just name a method; what was tested, e.g., accuracy of data elements compared to authoritative source, relationship to another measure as expected; what statistical analysis was used)*

SYSTEMATIC ASSESSMENT OF FACE VALIDITY
Method of Assessing Face Validity: NCQA has identified and refined measure management into a standardized process called the HEDIS measure life cycle.

STEP 1: NCQA staff identifies areas of interest or gaps in care. Clinical expert panels (MAPs—whose members are authorities on clinical priorities for measurement) participate in this process. Once topics are identified, a literature review is conducted to find supporting documentation on their importance, scientific soundness and feasibility. This information is gathered into a work-up format. The work-up is vetted by NCQA's Measurement Advisory Panels (MAPs) and the Clinical Programs Committee (CPC), as well as other panels as necessary.

STEP 2: Development ensures that measures are fully defined and tested before the organization collects them. MAPs participate in this process by helping identify the best measures for assessing health care performance in clinical areas identified in the topic selection phase. Development includes the following tasks: (1) Prepare a detailed conceptual and operational work-up that includes a testing proposal and (2) Collaborate with practices or health plans to conduct field-tests that assess the feasibility and validity of potential measures. NCQA uses testing results and proposed final specifications to determine if the measure will move forward to Public Comment.

STEP 3: Public Comment is a 30-day period of review that allows interested parties to offer feedback to NCQA about new measures or about changes to existing measures. NCQA MAPs and technical panels consider all comments and advise NCQA staff on appropriate recommendations. New measures and changes to existing measures approved by the CPC and NCQAs Board of Directors will be included in the next recognition program year.

STEP 4: Evaluation is the ongoing review of a measure's performance and recommendations for its modification or retirement. Every measure is reviewed for reevaluation at least every three years. NCQA staff continually monitors the performance of publicly reported measures. Statistical analysis, audit result review and user comments through NCQA's Policy Clarification Support portal contribute to measure refinement during re-evaluation. Information derived from analyzing the performance of existing measures is used to improve development of the next generation of measures.

Each year, NCQA prioritizes measures for re-evaluation and selected measures are researched for changes in clinical guidelines or in the health care delivery systems, and the results from previous years are analyzed. Measure work-ups are updated with new information gathered from the literature review, and the appropriate MAPs review the work-ups and the previous year's data. If necessary, the measure specification may be updated or the measure may be recommended for retirement. The CPC reviews recommendations from the evaluation process and approves or rejects the recommendation. If approved, the change is included in the next year's measure set.

Expert Participation

The IVD: Use of Aspirin or Another Antiplatelet was tested for face validity with two expert panels. Updated guidelines from the American Heart Association, the American College of Cardiology, and the American Stroke Association were also strong authoritative sources in re-evaluating the IVD: Use of Aspirin or Another Antiplatelet measure.

We list each panel here. See additional information: Ad.1. Workgroup/Expert Panel in Measure Development for names and affiliation of expert panels:

1. Cardiovascular Measurement Advisory Panel includes eight physicians and one nurse with expertise in cardiovascular health and quality measurement.
2. NCQA's Clinical Programs Committee (CPC) oversees the evolution of NCQA's recognition programs and related measures including the Diabetes Recognition Program, the Heart/Stroke Recognition Program, the Patient Centered Medical Home and Patient-Centered Specialty Practice Recognition Program, among others. The CPC includes representation by purchasers, consumers, health plans, health care providers and policy makers. This panel is made up of 17 members. The CPC is organized and managed by NCQA and reports to the NCQA Board of Directors and is responsible for advising NCQA staff on the development and maintenance of clinical recognition programs. CPC members reflect the diversity of constituencies that performance measurement serves; some bring other perspectives and additional expertise in quality management and the science of measurement.

2b2.3. What were the statistical results from validity testing? (*e.g., correlation; t-test*)

N/A

2b2.4. What is your interpretation of the results in terms of demonstrating validity? (i.*e., what do the results mean and what are the norms for the test conducted?*)

SYSTEMATIC ASSESSMENT OF FACE VALIDITY
The results indicate that the multiple NCQA panels concluded with good agreement that the measure, as specified accurately differentiates quality across clinicians and group practices. Our interpretation of these results is that IVD: Use of Aspirin or Another Antiplatelet measure is a valid and necessary quality metric.

2b3. EXCLUSIONS ANALYSIS
NA ☒ no exclusions — *skip to section 2b4*

2b3.1. Describe the method of testing exclusions and what it tests (*describe the steps—do not just name a method; what was tested, e.g., whether exclusions affect overall performance scores; what statistical analysis was used*)

Prior to 2015, the IVD: Use of Aspirin or Another Antiplatelet measure did not have any exclusions.

2b3.2. What were the statistical results from testing exclusions? (*include overall number and percentage of individuals excluded, frequency distribution of exclusions across measured entities, and impact on performance measure scores*)
N/A
2b3.3. What is your interpretation of the results in terms of demonstrating that exclusions are needed to prevent unfair distortion of performance results? (*i.e., the value outweighs the burden of increased data collection and analysis. Note: **If patient preference is an exclusion**, the measure must be specified so that the effect on the performance score is transparent, e.g., scores with and without exclusion*)
N/A

2b4. RISK ADJUSTMENT/STRATIFICATION FOR OUTCOME OR RESOURCE USE MEASURES
If not an intermediate or health outcome, or PRO-PM, or resource use measure, skip to section 2b5.

2b4.1. What method of controlling for differences in case mix is used?
☒ **No risk adjustment or stratification**
☐ **Statistical risk model with** Click here to enter number of factors **risk factors**
☐ **Stratification by** Click here to enter number of categories **risk categories**
☐ **Other,** Click here to enter description

2b4.2. If an outcome or resource use measure is not risk adjusted or stratified, provide rationale and analyses to demonstrate that controlling for differences in patient characteristics (case mix) is not needed to achieve fair comparisons across measured entities.

2b4.3. Describe the conceptual/clinical and statistical methods and criteria used to select patient factors (clinical factors or sociodemographic factors) used in the statistical risk model or for stratification by risk (*e.g., potential factors identified in the literature and/or expert panel; regression analysis; statistical significance of p<0.10; correlation of x or higher; patient factors should be present at the start of care*)

2b4.4a. What were the statistical results of the analyses used to select risk factors?

2b4.4b. Describe the analyses and interpretation resulting in the decision to select SDS factors (e.g. prevalence of the factor across measured entities, empirical association with the outcome, contribution of unique variation in the outcome, assessment of between-unit effects and within-unit effects)

2b4.5. Describe the method of testing/analysis used to develop and validate the adequacy of the statistical model or stratification approach (*describe the steps—do not just name a method; what statistical analysis was used*)

Provide the statistical results from testing the approach to controlling for differences in patient characteristics (case mix) below.
If stratified, skip to 2b4.9

2b4.6. Statistical Risk Model Discrimination Statistics (*e.g., c-statistic, R-squared*)**:**

2b4.7. Statistical Risk Model Calibration Statistics (*e.g., Hosmer-Lemeshow statistic*):

2b4.8. Statistical Risk Model Calibration – Risk decile plots or calibration curves:

2b4.9. Results of Risk Stratification Analysis:

2b4.10. What is your interpretation of the results in terms of demonstrating adequacy of controlling for differences in patient characteristics (case mix)? (i.*e., what do the results mean and what are the norms for the test conducted*)

2b4.11. Optional Additional Testing for Risk Adjustment (*not required, but would provide additional support of adequacy of risk model, e.g., testing of risk model in another data set; sensitivity analysis for missing data; other methods that were assessed*)

2b5. IDENTIFICATION OF STATISTICALLY SIGNIFICANT & MEANINGFUL DIFFERENCES IN PERFORMANCE

2b5.1. Describe the method for determining if statistically significant and clinically/practically meaningful differences in performance measure scores among the measured entities can be identified (*describe the steps—do not just name a method; what statistical analysis was used? Do not just repeat the information provided related to performance gap in 1b)*

To demonstrate meaningful differences in performance, NCQA calculates an inter-quartile range (IQR) for each indicator. The IQR provides a measure of the dispersion of performance. The IQR can be interpreted as the difference between the 25th and 75th percentile on a measure. To determine if this difference is statistically significant, NCQA calculates an independent sample t-test of the performance difference between two randomly selected entities (e.g., physicians, clinicians, plans) at the 25th and 75th percentile. The t-test method calculates a testing statistic based on the sample size, performance rate, and standardized error of each entity. The test statistic is then compared against a normal distribution. If the p value of the test statistic is less than .05, then the two entities' performance is significantly different from each other. Using this method, we compared the performance rates of two randomly selected physicians, one in the 25th percentile and another in the 75th percentile of performance. We used these two physicians as examples of measured entities. However, the method can be used for comparison of any two measured entities.

2b5.2. What were the statistical results from testing the ability to identify statistically significant and/or clinically/practically meaningful differences in performance measure scores across measured entities? (e.g., *number and percentage of entities with scores that were statistically significantly different from mean or some benchmark, different from expected; how was meaningful difference defined*)

Variation in Performance Across Physicians in the Heart/Stroke Recognition Program

Year	N	Mean	SD	10th	25th	50th	75th	90th	IQR	p-value
2013	659	84%	20%	50%	83%	91%	97%	100%	14%	<0.05

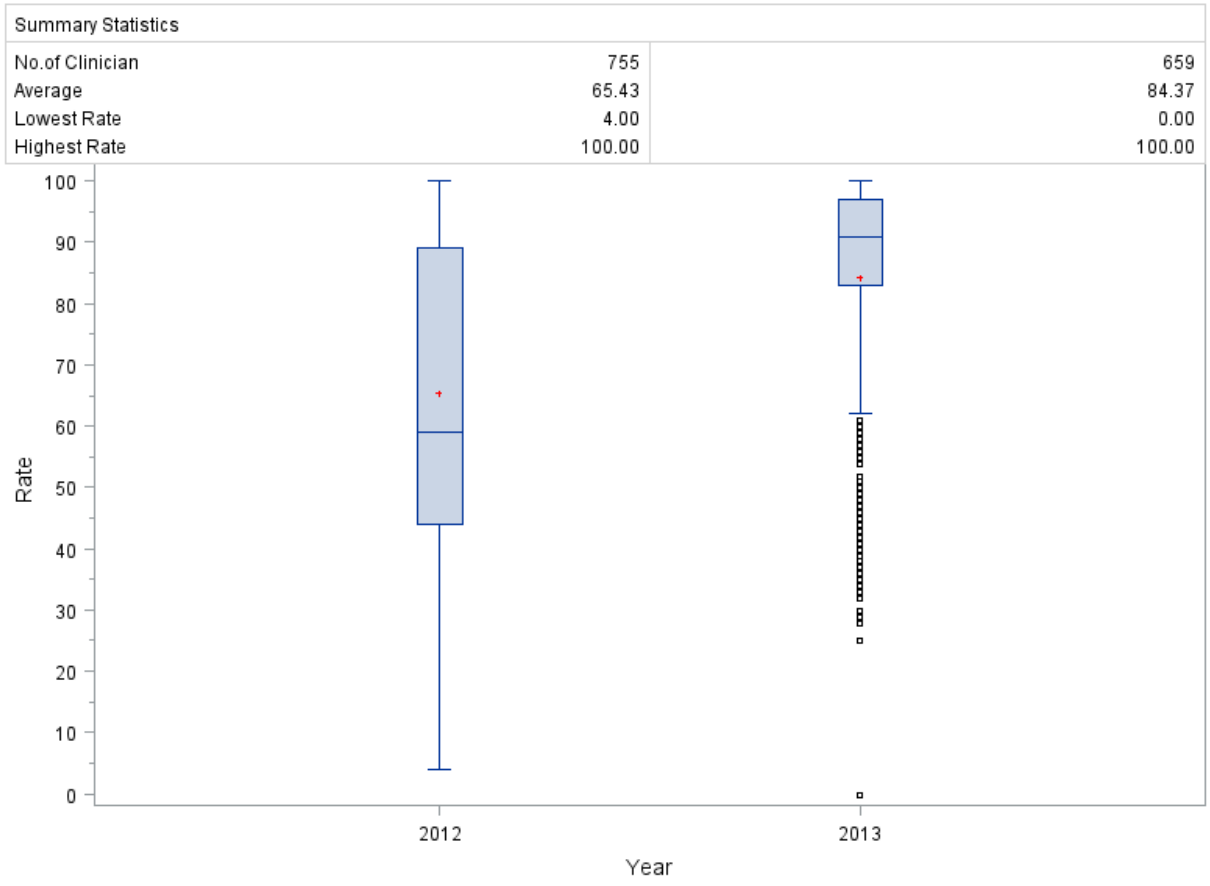
N = total number of physicians reporting data for recognition

IQR: Interquartile range

p-value: p-value of independent samples t-test comparing physicians at the 25th percentile to physicians at the 75th percentile

A box plot of the Heart/Stroke Recognition Program (HSRP) data from 2012 and 2013 is included below for your reference. The HSRP includes physicians who voluntarily submit data on a sample of 35 ischemic vascular disease patients. Please note the title of the measure changed to "Use of Aspirin or Another Antiplatelet" in 2015.

Ischemic Vascular Disease (IVD): Use of Aspirin or another Antithrombotic from 2012-2013 Clinician level



2b5.3. What is your interpretation of the results in terms of demonstrating the ability to identify statistically significant and/or clinically/practically meaningful differences in performance across

measured entities? (i.*e., what do the results mean in terms of statistical and meaningful differences?*)

The results indicate there is a 14% gap in performance between physicians in the 25th and 75th percentiles and the difference is statistically significant. There is also a 50% gap in performance between the 10th and 90th percentiles. Overall, results suggest there are meaningful differences in performance and there is an opportunity for improvement. We would expect performance of clinicians outside of the HSRP program to show wider variation.

2b6. COMPARABILITY OF PERFORMANCE SCORES WHEN MORE THAN ONE SET OF SPECIFICATIONS

If only one set of specifications, this section can be skipped.

Note: *This criterion is directed to measures with more than one set of specifications/instructions (e.g., one set of specifications for how to identify and compute the measure from medical record abstraction and a different set of specifications for claims or eMeasures). It does not apply to measures that use more than one source of data in one set of specifications/instructions (e.g., claims data to identify the denominator and medical record abstraction for the numerator).* ***If comparability is not demonstrated, the different specifications should be submitted as separate measures.***

2b6.1. Describe the method of testing conducted to demonstrate comparability of performance scores for the same entities across the different data sources/specifications (*describe the steps—do not just name a method; what statistical analysis was used*)
N/A

2b6.2. What were the statistical results from testing comparability of performance scores for the same entities when using different data sources/specifications? (*e.g., correlation, rank order*)
N/A

2b6.3. What is your interpretation of the results in terms of demonstrating comparability of performance measure scores for the same entities across the different data sources/specifications? (i.*e., what do the results mean and what are the norms for the test conducted*)
N/A

2b7. MISSING DATA ANALYSIS AND MINIMIZING BIAS

2b7.1. Describe the method of testing conducted to identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias (*describe the steps—do not just name a method; what statistical analysis was used*)
This measure is collected with a complete sample, there is no missing data on this measure.

2b7.2. What is the overall frequency of missing data, the distribution of missing data across providers, and the results from testing related to missing data? (*e.g., results of sensitivity analysis of the effect of various rules for missing data/nonresponse; if no empirical sensitivity analysis, identify the approaches for handling missing data that were considered and pros and cons of each*)
This measure is collected with a complete sample, there is no missing data on this measure.

2b7.3. What is your interpretation of the results in terms of demonstrating that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how

the specified handling of missing data minimizes bias**?** (i.*e., what do the results mean in terms of supporting the selected approach for missing data and what are the norms for the test conducted; if no empirical analysis, provide rationale for the selected approach for missing data*)
This measure is collected with a complete sample, there is no missing data on this measure.

3. Feasibility

Extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

3a. Byproduct of Care Processes

For clinical measures, the required data elements are routinely generated and used during care delivery (e.g., blood pressure, lab test, diagnosis, medication order).

3a.1. **Data Elements Generated as Byproduct of Care Processes.**
Generated or collected by and used by healthcare personnel during the provision of care (e.g., blood pressure, lab value, diagnosis, depression score), Coded by someone other than person obtaining original information (e.g., DRG, ICD-9 codes on claims), Abstracted from a record by someone other than person obtaining original information (e.g., chart abstraction for quality measure or registry)
If other:

3b. Electronic Sources

The required data elements are available in electronic health records or other electronic sources. If the required data are not in electronic health records or existing electronic sources, a credible, near-term path to electronic collection is specified.

3b.1. **To what extent are the specified data elements available electronically in defined fields?** *(i.e., data elements that are needed to compute the performance measure score are in defined, computer-readable fields)*
Some data elements are in defined fields in electronic sources

3b.2. **If ALL the data elements needed to compute the performance measure score are not from electronic sources, specify a credible, near-term path to electronic capture, OR provide a rationale for using other than electronic sources.**
To allow for widespread reporting across health care practices, this measure is collected through multiple data sources (administrative data, electronic clinical data, and paper records). We anticipate as electronic health records become more widespread, the reliance on paper record review will decrease.

3b.3. **If this is an eMeasure, provide a summary of the feasibility assessment in an attached file or make available at a measure-specific URL.**
Attachment:

3c. Data Collection Strategy

Demonstration that the data collection strategy (e.g., source, timing, frequency, sampling, patient confidentiality, costs associated with fees/licensing of proprietary measures) can be implemented (e.g., already in operational use, or testing demonstrates that it is ready to put into operational use). For eMeasures, a feasibility assessment addresses the data elements and measure logic and demonstrates the eMeasure can be implemented or feasibility concerns can be adequately addressed.

3c.1. **Describe what you have learned/modified as a result of testing and/or operational use of the measure regarding data collection, availability of data, missing data, timing and frequency of data collection, sampling, patient confidentiality, time and cost of data collection, other feasibility/implementation issues.**
IF a PRO-PM, consider implications for both individuals providing PROM data (patients, service recipients, respondents) and those whose performance is being measured.
We have found that physicians participating in NCQA's Heart/Stroke Recognition Program have no difficulty collecting, interpreting and reporting the data for this measure. We receive constant feedback from the field during our reviews which helps us strengthen the program. We have received positive feedback on the use of this measure in the CMS PQRS program and few questions have been raised by participating clinicians to the CMS vendor.

3c.2. **Describe any fees, licensing, or other requirements to use any aspect of the measure as specified** *(e.g., value/code set, risk model, programming code, algorithm)*.

Broad public use and dissemination of this measure is encouraged. NCQA has agreed with NQF that noncommercial uses do not require the consent of the measure developer. Use by health care physicians in connection with their own practices is not commercial use. Commercial use of a measure requires the prior written consent of NCQA. As used herein, "commercial use" refers to any sale, license or distribution of a measure for commercial gain, or incorporation of a measure into any product or service that is sold, licensed or distributed for commercial gain, even if there is no actual charge for inclusion of the measure.

4. Usability and Use

Extent to which potential audiences (e.g., consumers, purchasers, providers, policy makers) are using or could use performance results for both accountability and performance improvement to achieve the goal of high-quality, efficient healthcare for individuals or populations.

4a. Accountability and Transparency

Performance results are used in at least one accountability application within three years after initial endorsement and are publicly reported within six years after initial endorsement (or the data on performance results are available). If not in use at the time of initial endorsement, then a credible plan for implementation within the specified timeframes is provided.

4.1. Current and Planned Use

NQF-endorsed measures are expected to be used in at least one accountability application within 3 years and publicly reported within 6 years of initial endorsement in addition to performance improvement.

Planned	Current Use (for current use provide URL)
	Public Reporting CMS Physician Quality Reporting System (PQRS) http://www.cms.gov/Medicare/Quality-Initiatives-Patient-Assessment-Instruments/PQRS/ Payment Program CMS EHR Incentive Program (Meaningful Use) http://www.cms.gov/Regulations-and-Guidance/Legislation/EHRIncentivePrograms/index.html Regulatory and Accreditation Programs CMS ACO Shared Savings Program http://www.cms.gov/Medicare/Medicare-Fee-for-Service-Payment/sharedsavingsprogram/Quality_Measures_Standards.html Professional Certification or Recognition Program NCQA Heart/Stroke Recognition Program http://www.ncqa.org/tabid/140/Default.aspx

4a.1. For each CURRENT use, checked above, provide:

- Name of program and sponsor
- Purpose
- Geographic area and number and percentage of accountable entities and patients included

CMS PHYSICIAN QUALITY REPORTING SYSTEM: This measure is used in the Physician Quality Reporting System (PQRS) which is a reporting program that uses a combination of incentive payments and payment adjustments to promote reporting of quality information by eligible professionals (EPs). PQRS is a voluntary individual reporting program that provides an incentive payment to identified eligible professionals who satisfactorily report data on quality measures for covered Physician Fee Schedule (PFS) services furnished to Medicare Part B beneficiaries (including Railroad Retirement Board and Medicare Secondary Payer). Medicare Part C–Medicare Advantage beneficiaries are not included in claims-based reporting of individual measures or measures groups.
CMS EHR INCENTIVE PROGRAM (MEANINGFUL USE): The Medicare and Medicaid Electronic Health Care Record (EHR) Incentive Programs provide incentive payments to eligible professionals, eligible hospitals, and critical access hospitals (CAHs) as they adopt, implement, upgrade or demonstrate meaningful use of certified EHR technology.
CMS ACO SHARED SAVINGS PROGRAM: The Medicare Shared Savings Program (Shared Savings Program) was established by section

3022 of the Affordable Care Act. The Shared Savings Program is a key component of the Medicare delivery system reform initiatives included in the Affordable Care Act and is a new approach to the delivery of health care. Congress created the Shared Savings Program to facilitate coordination and cooperation among providers to improve the quality of care for Medicare Fee-For-Service (FFS) beneficiaries and reduce unnecessary costs. Eligible providers, hospitals, and suppliers may participate in the Shared Savings Program by creating or participating in an Accountable Care Organization (ACO).
HEART/STROKE RECOGNITION PROGRAM: This measure is used in NCQA's Heart Stroke Recognition Program (HSRP) that assesses clinician performance on key quality measures that are based on national evidence-based guidelines for secondary prevention of cardiovascular disease and stroke. The program includes the following measures: blood pressure control, use of aspirin or another antiplatelet, and smoking status and cessation advice or treatment. The HSRP Recognition provides assurance that clinicians are providing high quality, evidenced–based care for their CVD and stroke patients. Eligible clinicians abstract data from the charts or EHRs of CVD/stroke patients (35 patients for a single applicant) and submit this information to NCQA for review.

4a.2. **If not currently publicly reported OR used in at least one other accountability application (e.g., payment program, certification, licensing) what are the reasons?** (*e.g., Do policies or actions of the developer/steward or accountable entities restrict access to performance results or impede implementation?*)
N/A

4a.3. **If not currently publicly reported OR used in at least one other accountability application, provide a credible plan for implementation within the expected timeframes -- any accountability application within 3 years and publicly reported within 6 years of initial endorsement.** (*Credible plan includes the specific program, purpose, intended audience, and timeline for implementing the measure within the specified timeframes. A plan for accountability applications addresses mechanisms for data aggregation and reporting.*)
N/A

4b. Improvement

Progress toward achieving the goal of high-quality, efficient healthcare for individuals or populations is demonstrated. If not in use for performance improvement at the time of initial endorsement, then a credible rationale describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.

4b.1. **Progress on Improvement. (Not required for initial endorsement unless available.)**
Performance results on this measure (current and over time) should be provided in 1b.2 and 1b.4. Discuss:

- **Progress (trends in performance results, number and percentage of people receiving high-quality healthcare)**
- **Geographic area and number and percentage of accountable entities and patients included**

Refer to data in 1b.2.

HEART/STROKE RECOGNITION PROGRAM
From 2012 to 2013, mean performance increased from 65% to 84%. It should also be noted that performance in each percentile also greatly increased from 2012 to 2013.

PQRS
From 2010 to 2011, mean performance increased from 75% to 80% but then dropped to 55% in 2012. This drop may be due to the sharp increase in the number of providers voluntarily reporting on this measure for the first time in 2012 and not yet progressing up the learning curve. The following year in 2013, mean performance increased to 64%.

4b.2. **If no improvement was demonstrated, what are the reasons? If not in use for performance improvement at the time of initial endorsement, provide a credible rationale that describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.**
N/A

4c. Unintended Consequences

The benefits of the performance measure in facilitating progress toward achieving high-quality, efficient healthcare for individuals or populations outweigh evidence of unintended negative consequences to individuals or populations (if such evidence exists).

4c.1. **Were any unintended negative consequences to individuals or populations identified during testing; OR has evidence of unintended negative consequences to individuals or populations been reported since implementation? If so, identify the negative unintended consequences and describe how benefits outweigh them or actions taken to mitigate them.**
We have not identified unintended negative consequences to individuals during the testing and long-standing use of this measure.

5. Comparison to Related or Competing Measures

If a measure meets the above criteria and there are endorsed or new related measures (either the same measure focus or the same target population) or competing measures (both the same measure focus and the same target population), the measures are compared to address harmonization and/or selection of the best measure.

5. Relation to Other NQF-endorsed Measures
Are there related measures (conceptually, either same measure focus or target population) or competing measures (conceptually both the same measure focus and same target population)? If yes, list the NQF # and title of all related and/or competing measures.
Yes

5.1a. **List of related or competing measures (selected from NQF-endorsed measures)**
0067 : Chronic Stable Coronary Artery Disease: Antiplatelet Therapy
0076 : Optimal Vascular Care
0142 : Aspirin prescribed at discharge for AMI

5.1b. **If related or competing measures are not NQF endorsed please indicate measure title and steward.**
N/A

5a. Harmonization

The measure specifications are harmonized with related measures;
OR
The differences in specifications are justified

5a.1. **If this measure conceptually addresses EITHER the same measure focus OR the same target population as NQF-endorsed measure(s):**
Are the measure specifications completely harmonized?
No

5a.2. **If the measure specifications are not completely harmonized, identify the differences, rationale, and impact on interpretability and data collection burden.**
DUE TO THE TEXT LIMIT IN THIS SECTION – WE ARE PROVIDING OUR ANSWER FOR 5a.2 IN SECTION 5b.1.

5b. Competing Measures

The measure is superior to competing measures (e.g., is a more valid or efficient way to measure);
OR
Multiple measures are justified.

5b.1. **If this measure conceptually addresses both the same measure focus and the same target population as NQF-endorsed measure(s):**
Describe why this measure is superior to competing measures (e.g., a more valid or efficient way to measure quality); OR provide a rationale for the additive value of endorsing an additional measure. (Provide analyses when possible.)
ANSWER FOR SECTION 5a.2

Our current measure, NQF 0068 – Ischemic Vascular Disease (IVD): Use of Aspirin or Another Antiplatelet, assesses the percentage of patients 18 years of age and older who were discharged from an inpatient setting with an acute myocardial infarction (AMI), coronary artery bypass graft (CABG) or percutaneous coronary intervention (PCI) during the 12 months prior to the measurement year, AND patients who had a diagnosis of ischemic vascular disease (IVD) during the measurement year and the year prior to the measurement year, who had documentation of the routine use of aspirin or another antiplatelet during the measurement year. NQF 0068 uses administrative claims, electronic clinical data, electronic health record data, and paper medical records from the ambulatory care setting, providing a wide array of options for how data can be collected and reported.

The following is a description of the differences and the impact on interpretability and data collection burden between NQF 0068 and each related measure listed in 5.1a:

NQF 0142 – ASPIRIN PRESCRIBED AT DISCHARGE FOR AMI
This measure assesses the percentage of AMI patients, 18 years and older, who are prescribed aspirin at hospital discharge. The measure population only includes patients who have had an AMI, whereas NQF 0068 includes patients who have had an AMI, CABG or PCI procedure, and patients who have diagnoses consistent with ischemic vascular disease. NQF 0142 focuses only on aspirin prescribed at discharge while NQF 0068 focuses on documentation of the use of any antiplatelet medication during the measurement year. NQF 0142 is a facility-level measure that uses administrative claims and paper medical records from the inpatient setting; NQF 0068 is a physician-level measure that uses administrative claims, electronic clinical data, electronic health record data, and paper medical records from the ambulatory care setting.

There is no impact on interpretability of publically-reported rates or added burden of data collection because the focus of each measure is different, the accountable entity is different and the data for each measure is collected from different data sources by different entities. Additionally, both use value sets of codes to identify patients with AMI that do not conflict.

NQF 0067 – CHRONIC STABLE CORONARY ARTERY DISEASE: ANTIPLATELET THERAPY
This measure assesses the percentage of patients aged 18 years and older with a diagnosis of coronary artery disease (CAD) who were seen by a physician within a 12-month period and who were prescribed aspirin or clopidogrel. The focus of this measure is very similar to NQF 0068 in that it assesses the routine use of antiplatelet therapy in a twelve-month period for patients with CAD. However, NQF 0068 includes more antiplatelet medications than just aspirin or clopidogrel and includes a broader population of patients with cardiovascular disease than just those with CAD.

Although NQF 0067 and NQF 0068 are both physician-level measures that are specified to collect data from administrative claims, electronic clinical data, electronic health record data, and paper medical records from the ambulatory care setting, the impact on interpretability of publically-reported rates or added burden of data collection should be minimal because NQF 0067 is currently only reported through registry data. Additionally, NQF 0067 is focused on only on patients with CAD, while NQF 0068 is focused on a broader population of patients with cardiovascular disease who would benefit from the use of antiplatelet medications.

NQF 0076 – OPTIMAL VASCULAR CARE
This composite measure assesses the percentage of adult patients ages 18 to 75 who have ischemic vascular disease with optimally-managed modifiable risk factors (blood pressure, tobacco-free status, daily aspirin use) at their most recent visit with a physician during the measurement year. While the focus populations for NQF 0076 and NQF 0068 are very similar, NQF 0076 is a composite that includes assessment of blood pressure control and tobacco use status. NQF 0068 assesses the routine use of aspirin or other antiplatelet medications while NQF 0076 focuses only on aspirin use. NQF 0076 does not use administrative claims though it does use electronic clinical data, electronic health record data, and paper medical records from the ambulatory care setting, which is similar to NQF 0068.

Despite the similarities, there should be minimal impact on interpretability of publically-reported rates or added burden of data collection between the two measures since NQF 0076 is a composite of multiple indicators while NQF 0068 is focused only on antiplatelet therapy.

NQF 2452 – PERCUTANEOUS CORONARY INTERVENTION (PCI): POST-PROCEDURAL OPTIMAL MEDICAL THERAPY (NOTE: UNABLE TO SELECT IN 5.a1)
NQF 2452 is a composite measure that assesses the percentage of patients undergoing PCI who receive prescriptions for all medications (aspirin, P2Y12 and statins) for which they are eligible for at discharge. The measure population for NQF 2452 is patients undergoing PCI while NQF 0068 includes patient who have had an AMI, CABG or PCI procedure, and patients who have diagnoses consistent with ischemic vascular disease. NQF 2452 assesses the prescription of aspirin, P2Y12 agents, and statins at discharge; NQF 0068 assesses documentation of use of antiplatelet medications during the measurement year. NQF 2452 is a physician-level measure that uses data from registries while NQF 0068 is a physician-level measure that uses administrative claims, electronic clinical data, electronic health record data, and paper medical records from the ambulatory care setting.

There is no impact on interpretability of publically-reported rates or added burden of data collection because the focus of each measure is different and the data for each measure is collected from different data sources by different entities.

NQF 0964 – THERAPY WITH ASPIRIN, P2Y12 INHIBITOR, AND STATIN AT DISCHARGE FOLLOWING PCI IN ELIGIBLE PATIENTS (NOTE: UNABLE TO SELECT IN 5.a1)
NQF 0964 is a composite measure that assesses the percentage of patients undergoing PCI who receive prescriptions for all medications (aspirin, P2Y12 and statins) for which they are eligible for at discharge. The measure population for NQF 0964 is patients

undergoing PCI while NQF 0068 includes patient who have had an AMI, CABG or PCI procedure, and patients who have diagnoses consistent with ischemic vascular disease. NQF 0964 assesses the prescription of aspirin, P2Y12 agents, and statins at discharge; NQF 0068 assesses documentation of use of antiplatelet medications during the measurement year. NQF 0964 is a facility-level measure that uses data from registries while NQF 0068 is a physician-level measure that uses administrative claims, electronic clinical data, electronic health record data, and paper medical records from the ambulatory care setting.

There is no impact on interpretability of publically-reported rates or added burden of data collection because the focus of each measure is different, the accountable entity is different and the data for each measure is collected from different data sources by different entities.

ANSWER FOR SECTION 5b.1

Our current measure, NQF 0068, has a long history of use and is implemented in four national programs: PQRS, EHR Incentive Program, CMS ACO Shared Savings Program, and the Heart/Stroke Recognition Program.

Appendix

A.1 Supplemental materials may be provided in an appendix. All supplemental materials (such as data collection instrument or methodology reports) should be organized in one file with a table of contents or bookmarks. If material pertains to a specific submission form number, that should be indicated. Requested information should be provided in the submission form and required attachments. There is no guarantee that supplemental materials will be reviewed.

All commercial uses must be approved by NCQA and are subject to a license at the discretion of NCQA. © 2012 by the National Committee for Quality Assurance.

MEASURE WORKSHEET

This document summarizes the evaluation of the measure as it progresses through NQF's Consensus Development Process (CDP). The information submitted by measure developers/stewards is included after the Brief Measure Information, Preliminary Analysis, and Pre-meeting Public and Member Comments sections.

Brief Measure Information

NQF #: 0070
De.2. **Measure Title:** Coronary Artery Disease (CAD): Beta-Blocker Therapy-Prior Myocardial Infarction (MI) or Left Ventricular Systolic Dysfunction (LVEF <40%)
Co.1.1. **Measure Steward:** AMA-convened Physician Consortium for Performance Improvement
De.3. **Brief Description of Measure:** Percentage of patients aged 18 years and older with a diagnosis of coronary artery disease seen within a 12 month period who also have a prior MI or a current or prior LVEF <40% who were prescribed beta-blocker therapy
1b.1. **Developer Rationale:** For patients with coronary artery disease (CAD), beta-blockers are recommended for 3 years after myocardial infarction or acute coronary syndrome. Beta-blockers, particularly carvedilol, metoprolol succinate, or bisoprolol which have been shown to reduce risk of death, are recommended indefinitely for patients with CAD and LV systolic dysfunction. These agents have proven efficacy in reducing angina onset and improving the ischemic threshold during exercise. In patients who have suffered an MI, beta-blockers significantly reduce deaths and recurrent MIs. (1) Nonadherence to cardioprotective medications is prevalent among outpatients with CAD and can be associated with a broad range of adverse outcomes, including all-cause and cardiovascular mortality, cardiovascular hospitalizations, and the need for revascularization procedures.(2) This measure is intended to promote beta-blocker usage in select patients with CAD.

S.4. **Numerator Statement:** Patients who were prescribed beta-blocker therapy
S.7. **Denominator Statement:** All patients aged 18 years and older with a diagnosis of coronary artery disease seen within a 12 month period who also have a prior MI (within the past 3 years) or a current or prior LVEF <40%
S.10. **Denominator Exclusions:** Documentation of medical reason(s) for not prescribing beta-blocker therapy (eg, allergy, intolerance, other medical reasons)

Documentation of patient reason(s) for not prescribing beta-blocker therapy (eg, patient declined, other patient reasons)
Documentation of system reason(s) for not prescribing beta-blocker therapy (eg, other reasons attributable to the health care system)

De.1. **Measure Type:**
S.23. **Data Source:** Electronic Clinical Data, Electronic Clinical Data : Electronic Health Record, Electronic Clinical Data : Registry
S.26. **Level of Analysis:** Clinician : Group/Practice, Clinician : Individual
Is this an eMeasure? ☒ **Yes** ☐ **No** **If Yes, was it re-specified from a previously endorsed measure?** ☒ **Yes** ☐ **No**

This measure is submitted as a Registry measure & an eMeasure.

Is this a MAINTENANCE measure submission? ☒ **Yes** ☐ **No, this is a NEW measure submission.**

For a MAINTENANCE, what is the Original Endorsement Date: 1/10/09 **Most Recent Endorsement Date:** 1/18/12

Previous Measure Evaluation - Public & Member Comments, Developer Responses & Steering Committee Recommendations from (Cardiology Project 2010):

Public and Member Comments:

- Measure 0071 requires pharmacy data which is not available to clinicians. A clinician-level measure is needed for this process of care. Greater use of low-cost generic medications from discount pharmacies may not be captured in the pharmacy data collection.

Steering Committee: The Committee agreed these issues have merit and re-voted on recommending the measure: Y=8 , N=4 to recommend both 0070 and 0071

Preliminary Analysis

The preliminary analysis was developed in response to recommendations from NQF's Consensus Task Force and measurement stakeholders as a way to enhance and streamline the measures evaluation and voting processes. The preliminary analysis will help to guide the Standing Committee evaluation of each measure by summarizing the measure developer submission, guide measure evaluation discussion, and identify topic areas for additional input. **NQF staff would like to stress that the preliminary analysis is intended to be used as a guide to facilitate the Committee's discussion and evaluation.**

Criteria 1: Importance to Measure and Report

1a. Evidence

1a. Evidence. The evidence requirements for a *process* measure is that it is based on a systematic review (SR) and grading of the body of empirical evidence (including a quantity, quality and consistency assessment) where the evidence focus matches what is being measured, and leads to a desired health outcome.

- This clinician-level process *registry* and *eMeasure* calculates the percentage of patients aged 18 years and older with a diagnosis of coronary artery disease seen within a 12-month period who also have a prior MI or a current or prior LVEF <40% who were prescribed beta-blocker therapy. Three beta-blockers may be prescribed for patients with LVEF <40%, and all beta-blockers may be prescribed for patients with a prior MI.
- The developer provide the 2012 ACCF/AHA/ACP/AATS/PCNA/SCAI/STS for the guideline for the diagnosis and management of patients with stable ischemic heart disease, using the 2010ACCF/AHA guideline methodology to grade the guideline, (Class I, Level of Evidence: B) for patients with normal LVSD and a previous MI (Class I, Level of Evidence: A) for patients with LVEF < 40%. The guideline data represents patient care from 1996-2009.
- For patients with normal LVSD and a previous MI 3 articles support the recommendation, including 2 systematic reviews & an observational study. For patients with LVEF < 40%, 5 articles are provided including 3 RCTs, 1 meta-analysis of RCTs, and 1 comparative analysis of RCTs. The quality of the articles is not provided. Beta-blockade side effects are discussed as measures harms are noted. An analysis of 75 additional articles since the guideline is also provided.
- A decision logic diagram is provided for beta-blockades to reduce death risk and angina onset, reduce recurrent MIs for patients with previous MIs, and improve ischemic thresholds during exercise.

Questions for the Committee:

- *For process measures:*
  - *Is the evidence directly applicable to the process of care being measured?*
  - *Is the process of care proximal and closely related to desired outcomes?*
- *For possible exception to the evidence criteria:*
  - *Are there, or could there be, performance measures of a related health outcome, OR evidence-based intermediate clinical outcomes, intervention/treatment?*
  - *Is there evidence of a systematic assessment of expert opinion beyond those involved in developing the*

measure?

- *Does the SC agree that it is acceptable (or beneficial) to hold providers accountable without empiric evidence?*

1b. Gap in Care/Opportunity for Improvement and 1b. Disparities

1b. Performance Gap. The performance gap requirements include demonstrating quality problems and opportunity for improvement.

- The developer provides average performance data from 2013 PQRS Experience Report which is consistent with 2008-2010 NCDR PINNACLE Registry Data of nearly 90,000 eligible patients:
  - 2010: 71.4%
  - 2011: 82.1%
  - 2012: 69.9%
  - 2013: 74.2% (2013 Small Group Practice Exception Rate: 2.0%)
- PQRS Group Practice Reporting Option (GPRO) Registry reporting volumes are not provided. The developers state that PQRS is a voluntary reporting program. Performance data is not provided from the eMeasure.
- No data on disparities was provided, though the disparities literature finds similar rates between blacks & whites, and genders. Uninsured patients were less likely to receive beta-blockades, though no differences were noted between public and private insurance recipients.

Questions for the Committee:

- *Is there a gap in care that warrants a national performance measure?*
- *If no disparities information is provided, are you aware of evidence that disparities exist in this area of healthcare?*
- *Should this measure be indicated as disparities sensitive?*

1c. Priority

1c. High Priority (previously "High Impact") requires measures to address national health goal/priority or a demonstrated high-impact aspect of care.

- *Beginning in 2015, priority is no longer an NQF measure evaluation criterion.*

Committee pre-evaluation comments

Criteria 1: Importance to Measure and Report (including 1a, 1b, 1c)

1. ***Committee's Overview Comments***:
   - None.

1a. ***Committee's Comments on Evidence to Support Measure Focus:***

- The evidence is strong

1b. ***Committee's Comments on Performance Gap:***

- Performance gap remains with 2013 data only hitting 74%

1c. ***Committee's Comments on Composite Performance Measure:***

- Not Applicable

Criteria 2: Scientific Acceptability of Measure Properties

2a. Reliability

2a1. Reliability Specifications

2a1. Specifications requires the measure, as specified, to produce consistent (reliable) and credible (valid) results about the quality of care when implemented.

- This process measure assess the percentage of patients aged 18 years and older with a diagnosis of coronary artery disease seen within a 12 month period who also have a prior MI or a current or prior LVEF <40% who were prescribed

beta-blocker therapy.

- The developer submits 2 specifications for the measure: Registry & eMeasure. ICD-9 & ICD-10 codes are included, though the ICD-10 conversion methodology is not discussed. In both sets of specifications, the logic is unambiguous. Higher scores equal better quality.
- All eMeasure specifications and values sets meet current NQF technical requirements and are provided on Sharepoint for SC review.
- The measure is intended for use in an office visit, outpatient consultation, nursing facility, long-term care residential facility, home health and provider interaction during the measurement period.
- The developer includes arrhythmia, hypotension, asthma, bradycardia, atrioventricular block and cardiac pacer in Situ as exclusions in the eMeasure specification for both populations (MI within prior 3 years & LVEF <40%), though not in the Registry specification.
- The developer states that exceptions should only be considered when the numerator activity was not performed, that they are not uniformly relevant across measures, and that there must be a clear rationale to permit an exception for a medical, patient, or system reason. In the provided value sets, broadly defined and inappropriate patient, medical and system reason denominator exclusions include but are not limited to: medical reason: 216952002 failure in dosage (event), patient reason: 224187001 variable income (finding) & 266966009 family illness (situation), system reason:266756008 medical care unavailable (situation).
- The eMeasure and Registry Calculation Algorithm are clear, though the denominator details for the Registry specification state a minimum of 2 visits are needed to determine an established patient-provider relationship. Two visits should be included in the description and denominator statement to provide consistent measure calculation. The developer should also clarify if the 2 visits occurred at any time of within the measurement period. Two visits are included in the eMeasure.
- Provider interactions are listed as encounters in the value set spreadsheet and in the eMeasure specifications that include both face-to-face visits and non-face-to-face communications. The developer is encouraged to provide reasoning for inclusion, and clarify if all provider interactions are included in the denominator definition for a patient encounter.
- In addition to critical data element testing, the developer submitted pre-testing from the Measure Authoring Tool within the Bonnie Output that tests eMeasure logic. The measure logic successfully validated through the Bonnie Output.
- The measure is not risk adjusted and SDS variables were not captured for the measure. The developer encourages users to provide collect data and stratify results by race, ethnicity, administrative sex, and payer consistent with CMS' Measures Management System Blueprint and recent national recommendations put forth by the IOM and NQF.

Questions for the Committee:

- *Are all the data elements clearly defined? Are all appropriate codes included?*
- *Is the logic or calculation algorithm clear?*
- *Is it likely this measure can be consistently implemented?*

2a2. Reliability Testing Testing attachment

2a2. Reliability testing demonstrates if the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise enough to distinguish differences in performance across providers.

GPRO Registry Testing

- The developer tested reliability at the performance measure score level, using a beta-binomial model in a signal-to-noise analysis, to differentiate the true differences between measured entities (the signal) from random measurement error (the noise). A value of 0 indicates that all variation is due to measurement error and a value of 1 indicates that all variation is due to real differences in performance (for this measure, between providers). A value of 0.7 is often regarded as a minimum acceptable reliability value.
- A sample 1,724 (41.8%) of 4,124 physicians reported the measure Results showed the average number of quality reporting events for physicians included is 61.0 and reliability was 0.92 (high reliability). For the program required minimum of 10 quality reporting events, the reliability was 0.65 (moderate reliability).

- A missing data assessment was not performed. The developer states data missing from denominator excludes the patient from the measure, while missing numerator data counts as a measure "fail".

eMeasure Testing

- Critical data element (Validity against the Gold Standard) was conducted. Per NQF criteria, if empirical validity testing was performed of patient-level data, the rating from validity testing of patient-level data elements should be used. The developer provides simple agreement results for critical data element validity. Comparison of the values for several data elements (electronic extracted vs. data abstracted) using EHR data was conducted and could satisfy the data element reliability criterion (Algorithm box 3; validity testing results described in 2b.2 below). Results were provided for most, but not all, critical data elements. Percent agreement statistics were presented; however, percent agreement does not adjust for agreement due to chance, and should not be used alone to demonstrate reliability.
- Ideally, implementation of an eMeasure can be considered an automated process, and therefore the calculations will be consistent.
- In addition to critical data element testing, the developer submitted pre-testing from the Measure Authoring Tool within the Bonnie Output that tests eMeasure logic and performance calculation. This testing does use "live" EHR patients, though NQF currently accepts Bonnie Output pre-testing when EHR testing was not provided. Results in the 55 "pre-test" patients demonstrated 100% performance in identifying both expected and actual initial patient population, denominator, denominator exclusions, numerator, and denominator exceptions, with 82% of all possible data elements covered in the pre-test sample.
- For both specifications, a missing data assessment was not performed. The developer states data missing from denominator excludes the patient from the measure, while missing numerator data counts as a measure "fail".

Questions for the Committee (as appropriate):

- *Is the test sample adequate to generalize for widespread implementation?*
- *Do the results demonstrate sufficient reliability so that differences in performance can be identified?*

2b. Validity

2b1. Validity: Specifications

2b1. Validity Specifications. This section should determine if the measure specifications are consistent with the evidence.

- Exclusions for arrhythmia, hypotension, asthma, bradycardia, atrioventricular block and cardiac pacer in Situ as exclusions are included in the eMeasure specification, but not in the Registry specifications.
- The evidence indicates that Acute Coronary Syndrome (ACS) is also appropriate for beta-blockades, which seem to appear in the provided value set conditions though not in the measure specifications.

Question for the Committee:

- *Are the specifications consistent with the evidence?*

2b2. Validity testing

2b2. Validity Testing should demonstrate the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality.

GPRO Registry Testing

- The developer provided face validity results using 12 members of the PCPI Measure Advisory Committee (MAC) with a mean rating of 4.17 and 91.7% of respondents either agree or strongly agree the measure is able to distinguish good and poor quality using a 1-5 Likert, highest score was 5. The MAC is independent of the measure developer experts.

eMeasure Testing

- The developer provided critical data element (Validity against the Gold Standard) was conducted. Per NQF criteria, if empirical validity testing was performed of patient-level data, this rating will also be used for reliability testing. Data elements included patient age, visit, problem list, or medical history of CAD, those who met the denominator

population.

- The developers provide simple agreement for the 134 patients sampled via automated EHR review. Of the sample, 111 patients (82.8%) were detected that met the numerator criteria. Performance on the measure was calculated to be 90.3% through comparison of automated and manual EHR review. When manual abstraction was added to the automated EHR review, agreement increased to 124 patients detected (92.5%). Additional statistical testing was not provided.
- Data element validity testing was conducting by comparing, for several data elements, the values obtained from electronic extraction from 1 EHR to those obtained from those abstracted from the EHR by an abstractor. Simple agreement was provided for most, but not all, critical data elements. However, simple agreement does not adjust for agreement due to chance and thus should not be used alone to demonstrate validity; sensitivity/specificity statistics are preferred for demonstrating data element validity. Percentage agreement values were relatively high for most data elements considered. It appears that only one abstractor was utilized, which is acceptable for testing validity against the gold standard in an EHR.
- In addition to critical data element testing, the developer submitted pre-testing from the Measure Authoring Tool within the Bonnie Output that also tests eMeasure performance calculation. This testing does use "live" EHR patients, though NQF currently accepts Bonnie Output pre-testing when EHR testing was not provided. Results in the 55 "pre-test" patients demonstrated 100% agreement for identifying both expected and actual initial patient population, denominator, denominator exclusions, numerator, and denominator exceptions. Testing characteristics are provided for the 55 "pre-test" patients, with 82% of the of data elements concepts included in the Initial Patient Population (IPP), Denominator, Numerator and Denominator Exceptions.

Questions for the Committee:

- *Is the test sample adequate to generalize for widespread implementation?*
- *Do the results demonstrate sufficient validity so that conclusions about quality can be made?*
- *Do you agree that the score from this measure as specified is an indicator of quality?*
- *Other specific question of the validity testing?*

2b3-2b7. Threats to Validity

2b3. Exclusions/Exceptions:

GPRO Registry Testing

- Broad patient, medical & system reasons quality codes are reported for the Registry specification, with 4,291 exceptions reported from 1,724 physicians, with 2.5 exceptions reported per physician, and an overall exception rate of 3.9%. The timeframe for the frequencies and variability across providers is not provided.

eMeasure Testing

- An exception analysis of 2,717 exceptions show 2,292 (84.4%) exceptions were medical reasons for not prescribing beta blocker therapy, 347 (12.8%) exceptions were patient reasons and 78 (2.9%) were system reasons.
- Exclusions for arrhythmia, hypotension, asthma, bradycardia, atrioventricular block and cardiac pacer in Situ as exclusions are included in the eMeasure specification, but not in the Registry specifications. These do not appear in the exception analysis.

Questions for the Committee:

- *Are the exclusions consistent with the evidence?*
- *Are any patients or patient groups inappropriately excluded from the measure?*
- *Are the exclusions/exceptions of sufficient frequency and variation across providers to be needed (and outweigh the data collection burden)?*

2b4. Risk adjustment:

- This measure is not risk adjusted.

2b5. Meaningful difference:

- Meaningful difference data for the Registry measure is provided.
- Meaningful difference data for the eMeasure was not provided by the developer, as the eMeasure testing data used fictitious "pre-test" patients, though higher performance and detection rates were noted in eMeasure validity testing with EHR & manual reviews, than in EHR-only reviews.

Question for the Committee:

- *Does this measure identify meaningful differences about quality?*

2b6. Comparability of data sources/methods:

- NQF criteria require a comparability assessment of data sources/methods, such as with multiple specifications for the same measure. This was not provided by the developer, as the eMeasure testing data used fictitious "pre-test" patients.
- For validity testing of the eMeasure, developers did find higher performance & detection rates for the records abstracted with EHR & manual reviews, than EHR-only reviews.

2b7. Missing Data

- A missing data assessment was not performed.

Committee pre-evaluation comments

Criteria 2: Scientific Acceptability of Measure Properties (including all 2a, 2b, and 2d)

2a1. &2b1.: ***Committee's Comments on Reliability-Specifications:***

- Measure specifications meet criteria and seem straightforward

2a2.: ***Committee's Comments on Reliability-Testing:***

- Signal to noice analysis is said to have a minimal acceptable reliability value of 0.7 and with a minimum of 10 reporting events, the reliability is only 0.65, but overall was 0.92.

2b1.: ***Committee's Comments on Validity-Specifications***:

- ACS is not included, rather just AMI, but I am fine with that.

2b2.: ***Committee's Comments on Validity-Testing:***

- Results in the 55 "pre-test" patients demonstrated 100% agreement for identifying both expected and actual initial patient population, denominator, denominator exclusions, numerator, and denominator exceptions. Testing characteristics are provided for the 55 "pre-test" patients, with 82% of the of data elements concepts included in the Initial Patient Population (IPP), Denominator, Numerator and Denominator Exceptions.

2b3-7.: ***Committee's Comments on Threats to Validity:***

- Patient level does not get assessed in this e-measure so and it is tested with limited numbers of "pre-test" patients so it is hard to assess meaningful difference or comparability of data sources.

2d.: ***Committee's Comments on Composite Performance Measure:***

- Not Applicable

Criterion 3. Feasibility

3. Feasibility is the extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

GPRO Registry Testing

- For both Registry & eMeasures, data elements are collected by and used by healthcare personnel during provisions of care (BP, lab values), codes by someone other than the person obtaining the information (billing), and abstracted by someone other personnel (quality staff). All data elements are in electronic fields.
- The measure is specified for Clinician : Group/Practice, Clinician : Individual use.
- In the eMeasure Feasibility Scorecard, the developer states all data elements score "3" on a scale of 1 – 3 (3 the highest) for current and future use. The developer should clarify if this includes ICD-10, SNOMED-CT & RxNorm codes

for the eMeasure for all data elements. The EHR product(s) & number of EHRs used in the eMeasure Feasibility Scorecard is not reported. NQF requires a Feasibility Scorecard from more than one EHR.

Questions for the Committee:

- *Are the required data elements routinely generated and used during care delivery?*
- *Are the required data elements available in electronic form, e.g., EHR or other electronic sources?*
- *Is the data collection strategy ready to be put into operational use?*
- *If an eMeasure, does the eMeasure Feasibility Score Card demonstrate acceptable feasibility in multiple EHR systems and sites?*

Committee pre-evaluation comments

Criteria 3: Feasibility

3.: ***Committee's Comments on Feasibility:***

- There was not a feasibility scorecard from more than one EHR reported, as per NQF requirements.

Criterion 4: Usability and Use

4. Usability and Use evaluate the extent to which audiences (e.g., consumers, purchasers, providers, policymakers) use or could use performance results for both accountability and performance improvement activities.

- The developer provides the following information on measure use
  - Public Reporting - Physician Quality Reporting System (PQRS)
  - Payment Program - Meaningful Use Stage 2 (EHR Incentive Program)
  - Quality Improvement with Benchmarking (external benchmarking to multiple organizations)- Pinnacle Registry
- The developer states no unintended consequences have been noted, though they monitor for identification and mitigation continuously.
- In 2014 the Measure Applications Partnership (MAP) Clinician Workgroup did not support the measure for the Physician Compare and Value-Based Payment Modifier Programs because the measure does not adequately address any current needs of the program preferring other outcome measures that address coronary artery disease. In 2015, the Clinician Workgroup did not support narrow-focused, process measures for MSSP.

Questions for the Committee:

- *Is the measure publicly reported?*
- *For maintenance measures – is the measure used in at least one accountability application?*
- *How can the performance results be used to further the goal of high-quality, efficient healthcare?*
- *Do the benefits of the measure outweigh any potential unintended consequences?*

Committee pre-evaluation comments

Criteria 4: Usability and Use

4.: ***Committee's Comments on Usability and Use:***

- Physician compare, value based modifier program and MSSP all do not support the use of this measure.

Criterion 5: Related and Competing Measures

- 0071: Persistence of Beta-Blocker Treatment After a Heart Attack
- 0083: Heart Failure (HF): Beta-Blocker Therapy for Left Ventricular Systolic Dysfunction (LVSD).

The developer states the specifications are harmonized to the extent possible. As a result, the denominator specifications for the measures differ where needed based on the differing patient populations.

Pre-meeting public and member comments

-

NATIONAL QUALITY FORUM—Evidence (subcriterion 1a)

Measure Number (*if previously endorsed*)**:** 0070

Measure Title: Coronary Artery Disease (CAD): Beta-Blocker Therapy-Prior Myocardial Infarction (MI) or Left Ventricular Systolic Dysfunction (LVEF <40%)

IF the measure is a component in a composite performance measure, provide the title of the Composite Measure here: Click here to enter composite measure #/ title

Date of Submission: 6/30/2015

Instructions

- *For composite performance measures:*
  - *A separate evidence form is required for each component measure unless several components were studied together.*
  - *If a component measure is submitted as an individual performance measure, attach the evidence form to the individual measure submission.*
- Respond to all questions as instructed with answers immediately following the question. All information needed to demonstrate meeting the evidence subcriterion (1a) must be in this form. An appendix of *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 10 pages (*incudes questions/instructions*; minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the evidence for this measure meets NQF's evaluation criteria.

1a. Evidence to Support the Measure Focus

The measure focus is evidence-based, demonstrated as follows:

- Health outcome: [3] a rationale supports the relationship of the health outcome to processes or structures of care. Applies to patient-reported outcomes (PRO), including health-related quality of life/functional status, symptom/symptom burden, experience with care, health-related behavior.
- Intermediate clinical outcome: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured intermediate clinical outcome leads to a desired health outcome.
- Process: [5] a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured process leads to a desired health outcome.
- Structure: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured structure leads to a desired health outcome.

- Efficiency: [6] evidence not required for the resource use component.

Notes

3. Generally, rare event outcomes do not provide adequate information for improvement or discrimination; however, serious reportable events that are compared to zero are appropriate outcomes for public reporting and quality improvement.

4. The preferred systems for grading the evidence are the U.S. Preventive Services Task Force (USPSTF) grading definitions and methods, or Grading of Recommendations, Assessment, Development and Evaluation (GRADE) guidelines.

5. Clinical care processes typically include multiple steps: assess → identify problem/potential problem → choose/plan intervention (with patient input) → provide intervention → evaluate impact on health status. If the measure focus is one step in such a multistep process, the step with the strongest evidence for the link to the desired outcome should be selected as the focus of measurement. Note: A measure focused only on collecting PROM data is not a PRO-PM.

6. Measures of efficiency combine the concepts of resource use and quality (see NQF's Measurement Framework: Evaluating Efficiency Across Episodes of Care; AQA Principles of Efficiency Measures).

1a.1.This is a measure of: (*should be consistent with type of measure entered in De.1*)

Outcome

☐ Health outcome: Click here to name the health outcome

☐Patient-reported outcome (PRO): Click here to name the PRO

PROs include HRQoL/functional status, symptom/symptom burden, experience with care, health-related behaviors

☐ Intermediate clinical outcome (*e.g., lab value*): Click here to name the intermediate outcome

☒ Process: Beta-Blocker Therapy for CAD patients with Prior Myocardial Infarction (MI) or Left Ventricular Systolic Dysfunction (LVEF <40%)

☐ Structure: Click here to name the structure

☐ Other: Click here to name what is being measured

HEALTH OUTCOME/PRO PERFORMANCE MEASURE *If not a health outcome or PRO, skip to 1a.3*

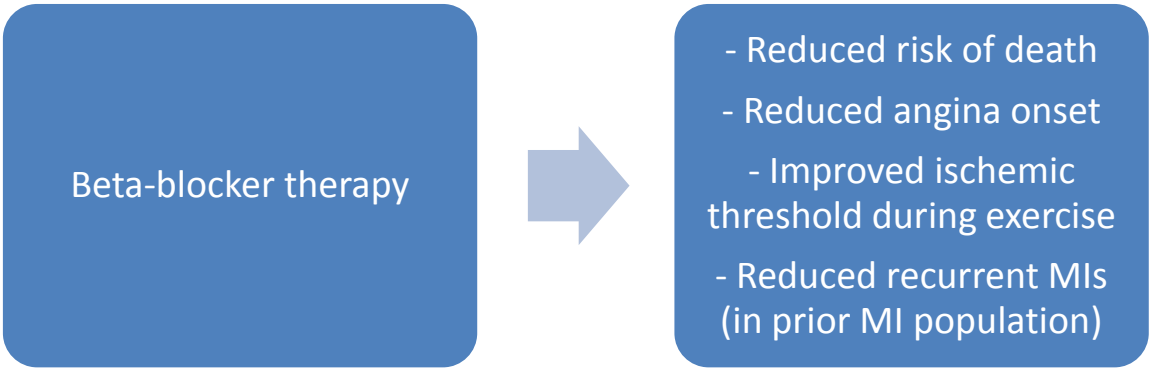
1a.2. Briefly state or diagram the path between the health outcome (or PRO) and the healthcare structures, processes, interventions, or services that influence it.

1a.2.1. State the rationale supporting the relationship between the health outcome (or PRO) to at least one healthcare structure, process, intervention, or service (*i.e., influence on outcome/PRO*).

Note: For health outcome/PRO performance measures, no further information is required; however, you may provide evidence for any of the structures, processes, interventions, or service identified above.

INTERMEDIATE OUTCOME, PROCESS, OR STRUCTURE PERFORMANCE MEASURE

1a.3. Briefly state or diagram the path between structure, process, intermediate outcome, and health outcomes. Include all the steps between the measure focus and the health outcome.



1a.3.1. What is the source of the systematic review of the body of evidence that supports the performance measure?

☒ Clinical Practice Guideline recommendation – ***complete sections 1a.4, and 1a.7***

☐ US Preventive Services Task Force Recommendation – ***complete sections 1a.5 and 1a.7***

☐ Other systematic review and grading of the body of evidence (*e.g., Cochrane Collaboration, AHRQ Evidence Practice Center*) – ***complete sections 1a.6 and 1a.7***

☐ Other – ***complete section 1a.8***

Please complete the sections indicated above for the source of evidence. You may skip the sections that do not apply.

1a.4. CLINICAL PRACTICE GUIDELINE RECOMMENDATION

1a.4.1. Guideline citation (*including date*) and **URL for guideline** (*if available online*):

Fihn SD, Gardin JM, Abrams J, et al. 2012 ACCF/AHA/ACP/AATS/PCNA/SCAI/STS guideline for the diagnosis and management of patients with stable ischemic heart disease: a report of the American College of Cardiology Foundation/American Heart Association Task Force on Practice Guidelines, American Association for Thoracic Surgery, Preventive Cardiovascular Nurses Association, Society for Cardiovascular Angiography and Interventions, and Society of Thoracic Surgeons. J Am Coll Cardiol 2012;60:e44-164.

Available at: http://content.onlinejacc.org/article.aspx?articleid=1391404

1a.4.2. Identify guideline recommendation number and/or page number and **quote verbatim, the specific guideline recommendation**.

4.4.2.2. BETA-BLOCKER THERAPY:

Beta-blocker therapy should be started and continued for 3 years in all patients with normal LV function after MI or ACS. (Class I, Level of Evidence: B)

Beta-blocker therapy should be used in all patients with LV systolic dysfunction (EF ≤40%) with heart failure or prior MI, unless contraindicated. (Use should be limited to carvedilol, metoprolol succinate,

or bisoprolol, which have been shown to reduce risk of death.) (Class I, Level of Evidence: A)

1a.4.3. Grade assigned to the quoted recommendation with definition of the grade:

Both recommendation statements included in section 1a.4.2 have been assigned a Class I recommendation. Class I recommendations refer to " Conditions for which there is evidence and/or general agreement that a given procedure or treatment is beneficial, useful, and effective."

1a.4.4. Provide all other grades and associated definitions for recommendations in the grading system. (*Note: If separate grades for the strength of the evidence, report them in section 1a.7.*)

ACCF/AHA guideline methodology categorizes indications as class I, II, or III on the basis of a multifactorial assessment of risk and expected efficacy viewed in the context of current knowledge and the relative strength of this knowledge. These classes summarize the recommendations for procedures or treatments as follows and noted in the table below:

Class I: Conditions for which there is evidence and/or general agreement that a given procedure or treatment is useful and effective.

Class II: Conditions for which there is conflicting evidence and/or a divergence of opinion about the usefulness/efficacy of a procedure or treatment.

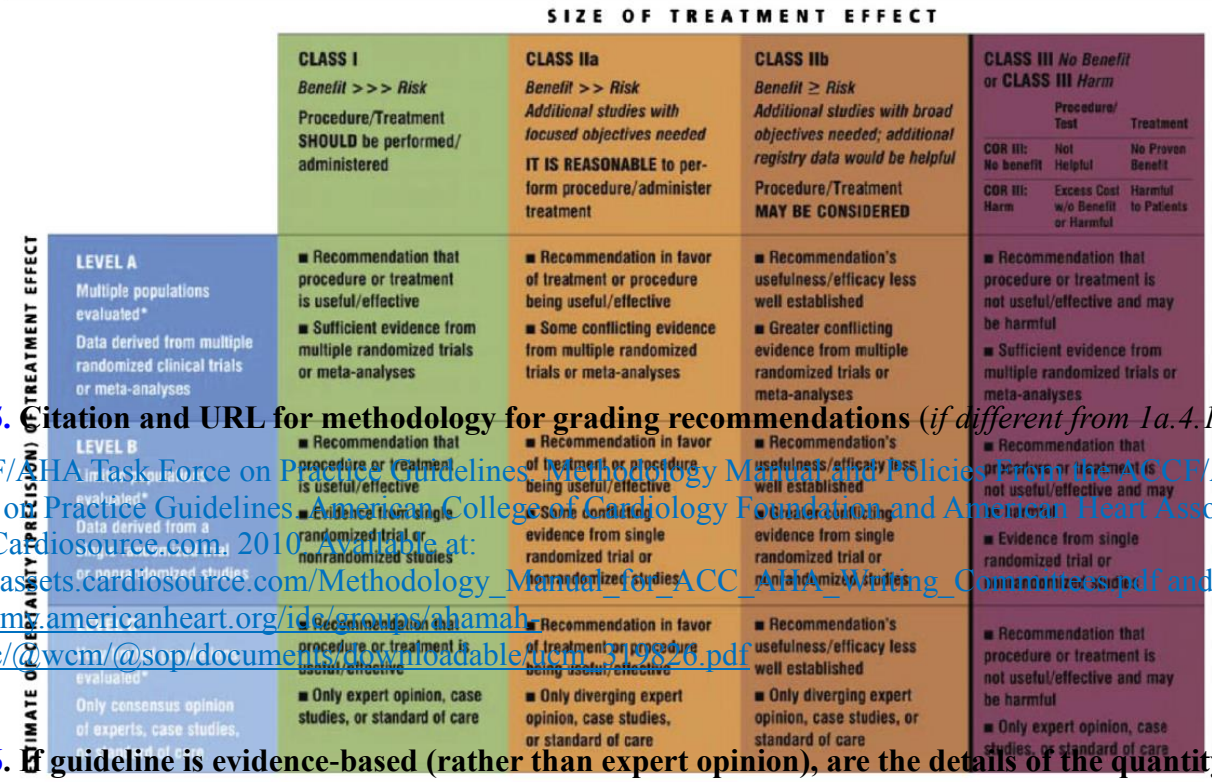
- IIa: Weight of evidence/opinion is in favor of usefulness/efficacy
- IIb: Usefulness/efficacy is less well established by evidence/opinion.

Class III: Conditions for which there is evidence and/or general agreement that the procedure/treatment is not useful/effective e and in some cases may be harmful.

- No Benefit- Procedure/Test not helpful or Treatment w/o established proven benefit
- Harm- Procedure/Test leads to excess cost w/o benefit or is harmful, and or Treatment is harmful

Additional detail regarding the classification of recommendation and level of evidence is provided in the following table.

Table 1. Applying Classification of Recommendation and Level of Evidence



1a.4.5. Citation and URL for methodology for grading recommendations (*if different from 1a.4.1*)**:**

1a.4.6. If guideline is evidence-based (rather than expert opinion), are the details of the quantity, quality, and consistency of the body of evidence available (e.g., evidence tables)?

☐ Yes → ***complete section 1a.7***

☒ No → ***report on another systematic review of the evidence in sections 1a.6 and 1a.7; if another review does not exist, provide what is known from the guideline review of evidence in 1a.7***

1a.5. UNITED STATES PREVENTIVE SERVICES TASK FORCE RECOMMENDATION

1a.5.1. Recommendation citation (*including date*) and **URL for recommendation** (*if available online*):

1a.5.2. Identify recommendation number and/or page number and **quote verbatim, the specific recommendation**.

1a.5.3. Grade assigned to the quoted recommendation with definition of the grade:

1a.5.4. Provide all other grades and associated definitions for recommendations in the grading system.
(*Note: the grading system for the evidence should be reported in section 1a.7.*)

1a.5.5. Citation and URL for methodology for grading recommendations (*if different from 1a.5.1*)**:**

Complete section 1a.7

1a.6. OTHER SYSTEMATIC REVIEW OF THE BODY OF EVIDENCE

1a.6.1. Citation (*including date*) and **URL** (*if available online*):

1a.6.2. Citation and URL for methodology for evidence review and grading (*if different from 1a.6.1*)**:**

Complete section 1a.7

1a.7. FINDINGS FROM SYSTEMATIC REVIEW OF BODY OF THE EVIDENCE SUPPORTING THE MEASURE

If more than one systematic review of the evidence is identified above, you may choose to summarize the one (or more) for which the best information is available to provide a summary of the quantity, quality, and consistency of the body of evidence. Be sure to identify which review is the basis of the responses in this section and if more than one, provide a separate response for each review.

1a.7.1. What was the specific structure, treatment, intervention, service, or intermediate outcome addressed in the evidence review?

The section of the guideline which includes the recommendations referenced in 1a4.2. pertains to the use of beta-blocker therapy in patients with stable ischemic heart disease

1a.7.2. Grade assigned for the quality of the quoted evidence with definition of the grade:

The guideline recommendations refer to 2 distinct patient populations address by the measure – 1) patients with a prior (resolved) (within the past 3 years) myocardial infarction and 2) patients with left ventricular systolic dysfunction (LVEF <40%). For the prior MI population, the weight of the evidence in support of the recommendation is rated as Level B. Level B evidence refers to "Data derived from a single randomized trial, or nonrandomized studies." For the LVSD population, the weight of the evidence in support of the recommendation is rated as Level A. Level A evidence refers to "Data derived from multiple randomized clinical trials or meta-analyses."

1a.7.3. Provide all other grades and associated definitions for strength of the evidence in the grading system.

Levels A and B are described in 1a.7.2. Level C evidence refers to "Only consensus opinion of experts, case studies, or standard-of-care." Additional details and information about the evidence rating scheme can also be seen in 1a.4.2. and 1a.4.3.

1a.7.4. What is the time period covered by the body of evidence? (*provide the date range, e.g., 1990-2010*).
Date range: 1996-2009

QUANTITY AND QUALITY OF BODY OF EVIDENCE

1a.7.5. How many and what type of study designs are included in the body of evidence? (*e.g., 3 randomized controlled trials and 1 observational study*)

Information regarding the total number of studies and type of study designs included in the body of evidence is not available.

However, for the prior MI population: the guideline cites 3 articles in support of the recommendation statement. They include 2 systematic reviews including 33 and 82 randomized controlled trials, respectively, dating back to 1980. The third article was an observational study.

For the LVSD population: the guideline cites 5 articles in support of the recommendation statement. They include 3 randomized controlled trials, 1 meta-analysis of randomized controlled trials and 1 comparative analysis of randomized controlled trials.

1a.7.6. What is the overall quality of evidence <u>across studies</u> in the body of evidence? (*discuss the certainty or confidence in the estimates of effect particularly in relation to study factors such as design flaws, imprecision due to small numbers, indirectness of studies to the measure focus or target population*)

Information regarding the overall quality of evidence across studies is not available.

ESTIMATES OF BENEFIT AND CONSISTENCY ACROSS STUDIES IN BODY OF EVIDENCE

1a.7.7. What are the estimates of benefit—magnitude and direction of effect on outcome(s) <u>across studies</u> in the body of evidence? (*e.g., ranges of percentages or odds ratios for improvement/ decline across studies, results of meta-analysis, and statistical significance*)

The guideline does not include an overall estimate of benefit from the body of evidence. However, they do include the following summary information regarding the benefits of beta-blocker therapy, "Decreases in the rate–BP product, AV nodal conduction, and myocardial contractility from beta blockers reduce myocardial oxygen demand, counteracting beta-receptor activity and contributing to a reduction in angina onset, with improvement in the ischemic threshold during exercise and in symptoms. These agents significantly reduce deaths and recurrent MIs in patients who have suffered a MI and are especially effective when a STEMI is complicated by persistent or recurrent ischemia or tachyarrhythmias early after the onset of infarction."

1a.7.8. What harms were studied and how do they affect the net benefit (benefits over harms)?

The guideline describes the principle adverse effects of beta blockers as fatigue, exercise intolerance, lethargy, insomnia, nightmares, and impotence.

UPDATE TO THE SYSTEMATIC REVIEW(S) OF THE BODY OF EVIDENCE

1a.7.9. If new studies have been conducted since the systematic review of the body of evidence, provide for <u>each</u> new study: 1) citation, 2) description, 3) results, 4) impact on conclusions of systematic review.

The guidelines reviewed and incorporated relevant new clinical trials published in peer-reviewed journals and articles through December 2011. A Medical Subject Headings (MeSH®) was conducted using the terms "Adrenergic beta-Antagonists"[Mesh] AND "Coronary Artery Disease"[Mesh] to identify articles published after 2011, resulting in 75 articles.

The articles that are most relevant to the focus of the body of evidence are described below.

1. Citation: Bangalore S1, Steg G, Deedwania P, Crowley K, Eagle KA, Goto S, Ohman EM, Cannon CP, Smith SC, Zeymer U, Hoffman EB, Messerli FH, Bhatt DL; REACH Registry Investigators. β-Blocker use and clinical outcomes in stable outpatients with and without coronary artery disease. JAMA. 2012 Oct 3;308(13):1340-9. doi: 10.1001/jama.2012.12559.

Description: Longitudinal, observational study of patients in the Reduction of Atherothrombosis for Continued Health (REACH) registry who were divided into 3 cohorts: known prior MI (n = 14,043), known CAD without MI (n = 12,012), or those with CAD risk factors only (n = 18,653) to assess the association of β-blocker use with cardiovascular events in stable patients with a prior history of MI, in those with CAD but no history of MI, and in those with only risk factors for CAD.

Results: With a median follow-up of 44 months (interquartile range, 35-45 months), event rates were not significantly different in patients with β-blocker use compared with those without β-blocker use for any of the outcomes tested, even in the prior MI cohort (489 [16.93%] vs 532 [18.60%], respectively; hazard ratio [HR], 0.90 [95% CI, 0.79-1.03]; P = .14). In the CAD without MI cohort, the associated event rates were not significantly different in those with β-blocker use for the primary outcome (391 [12.94%]) vs without β-blocker use (405 [13.55%]) (HR, 0.92 [95% CI, 0.79-1.08]; P = .31), with higher rates for the secondary outcome (1101 [30.59%] vs 1002 [27.84%]; odds ratio [OR], 1.14 [95% CI, 1.03-1.27]; P = .01) and for the tertiary outcome of hospitalization (870 [24.17%] vs 773 [21.48%]; OR, 1.17 [95% CI, 1.04-1.30]; P = .01). In the cohort with CAD risk factors only, the event rates were higher for the primary outcome with β-blocker use (467 [14.22%]) vs without β-blocker use (403 [12.11%]) (HR, 1.18 [95% CI, 1.02-1.36]; P = .02), for the secondary outcome (870 [22.01%] vs 797 [20.17%]; OR, 1.12 [95% CI, 1.00-1.24]; P = .04) but not for the tertiary outcomes of MI (89 [2.82%] vs 68 [2.00%]; HR, 1.36 [95% CI, 0.97-1.90]; P = .08) and stroke (210 [6.55%] vs 168 [5.12%]; HR, 1.22 [95% CI, 0.99-1.52]; P = .06). However, in those with recent MI (≤1 year), β-blocker use was associated with a lower incidence of the secondary outcome (OR, 0.77 [95% CI, 0.64-0.92]).

Conclusion: Although this observational study found that the use of β-blockers in the populations studied was not associated with a lower risk of composite cardiovascular events, the article received several letters which highlighted 2 primary concerns: 1) the use of an observational study to assess the effectiveness of a drug when large RCTs and meta-analyses already have shown its effectiveness and 2) the study did not distinguish among different types of beta-blockers. As the measure developer, we would wait until an updated systematic review of the body of evidence is conducted which can confirm or refute the findings of the study taking into account the full body of evidence available.

1a.8 OTHER SOURCE OF EVIDENCE

If source of evidence is NOT from a clinical practice guideline, USPSTF, or systematic review, please describe the evidence on which you are basing the performance measure.

1a.8.1 What process was used to identify the evidence?

1a.8.2. Provide the citation and summary for each piece of evidence.

1. Evidence, Performance Gap, Priority – Importance to Measure and Report

Extent to which the specific measure focus is evidence-based, important to making significant gains in healthcare quality, and improving health outcomes for a specific high-priority (high-impact) aspect of healthcare where there is variation in or overall less-than-optimal performance. ***Measures must be judged to meet all subcriteria to pass this criterion and be evaluated against the remaining criteria.***

1a. Evidence to Support the Measure Focus – See attached Evidence Submission Form
evidence_attachment_CAD_BB.docx

1b. Performance Gap

Demonstration of quality problems and opportunity for improvement, i.e., data demonstrating:

- considerable variation, or overall less-than-optimal performance, in the quality of care across providers; and/or
- disparities in care across population groups.

1b.1. **Briefly explain the rationale for this measure** *(e.g., the benefits or improvements in quality envisioned by use of this measure)*
For patients with coronary artery disease (CAD), beta-blockers are recommended for 3 years after myocardial infarction or acute coronary syndrome. Beta-blockers, particularly carvedilol, metoprolol succinate, or bisoprolol which have been shown to reduce risk of death, are recommended indefinitely for patients with CAD and LV systolic dysfunction. These agents have proven efficacy in reducing angina onset and improving the ischemic threshold during exercise. In patients who have suffered an MI, beta-blockers significantly reduce deaths and recurrent MIs. (1) Nonadherence to cardioprotective medications is prevalent among outpatients with CAD and can be associated with a broad range of adverse outcomes, including all-cause and cardiovascular mortality, cardiovascular hospitalizations, and the need for revascularization procedures.(2) This measure is intended to promote beta-blocker usage in select patients with CAD.

ACC/AHA 2002 guideline update for the management of patients with chronic stable angina: a report of the American College of Cardiology/American Heart Association Task Force on Practice Guidelines (Committee to Update the 1999 Guidelines for the Management of Patients with Chronic Stable Angina). 2002. Available at: www.acc.org/clinical/guidelines/stable/stable.pdf

1b.2. **Provide performance scores on the measure as specified (current and over time) at the specified level of analysis.** *(This is required for endorsement maintenance. Include mean, std dev, min, max, interquartile range, scores by decile. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities included). This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*
2013 PQRS Experience Report
2013 is the most recent year for which PQRS Experience Report measure data is available. The average performance rates on Coronary Artery Disease (CAD): Beta-Blocker Therapy-Prior Myocardial Infarction (MI) or Left Ventricular Systolic Dysfunction (LVEF <40%) over the last several years are as follows:

2010: 71.4%
2011: 82.1%
2012: 69.9%
2013: 74.2%

2013 Small Group Practice Exception Rate: 2.0%

It is important to note that PQRS was a voluntary reporting program, with approximately 51% of eligible professionals participating using any reporting option in 2013, and performance rates may not be nationally representative.
Reference: Center for Medicare and Medicaid Services. 2013 Reporting Experience Including Trends (2007-2014). Available: http://www.cms.gov/Medicare/Quality-Initiatives-Patient-Assessment-Instruments/PQRS/AnalysisAndPayment.html

1b.3. If no or limited performance data on the measure as specified is reported in 1b2, then provide a summary of data from the literature that indicates opportunity for improvement or overall less than optimal performance on the specific focus of measurement.
Suboptimal rates of beta-blocker prescriptions among patients with CAD indicated by PQRS data are further evidenced by several recent studies.

Maddox and colleagues analyzed data from 2008 through 2010 from the NCDR® PINNACLE Registry®, a national outpatient cardiology practice registry, to assess practice variation of secondary prevention medication prescription among CAD patients. Among eligible patients, beta-blockers were prescribed in 73.3% (63,800/86,999) at their index clinic visit. After inclusion of all visits among eligible patients occurring within the year following the index visit, the rates increased to 77.3%. Among practices, the median prescription rate of beta-blockers for eligible patients at their index clinic visit was 78.4% (range 35.2-100%) and 79.4% (range 46.2-100%) after inclusion of all visits among eligible patients occurring within the year following the index visit.(1)

An earlier study by Chan and colleagues analyzed 2008-9 data from the Pinnacle registry and found slightly higher rates (86.4%) of beta-blocker prescription among CAD patients following an MI. It's important to note that the Chan et al. study examined compliance rates with performance measures among the first 14,000 outpatients enrolled in the PINNACE program as compared to the Maddox et al study which included a larger and more heterogeneous patient and practice population.(2)

References:

Variations in coronary artery disease secondary prevention prescriptions among outpatient cardiology practices: insights from the NCDR (National Cardiovascular Data Registry). J Am Coll Cardiol. 2014 Feb 18;63(6):539-46. doi: 10.1016/j.jacc.2013.09.053. Epub 2013 Oct 30.

2. Chan PS, Oetgen WJ, Buchanan D, et al. Cardiac performance measure compliance in outpatients: the American College of Cardiology and National Cardiovascular Data Registry´s PINNACLE (Practice Innovation And Clinical Excellence) program. J. Am. Coll. Cardiol. 2010; 56(1):8–14.

1b.4. Provide disparities data from the measure as specified (current and over time) by population group, e.g., by race/ethnicity, gender, age, insurance status, socioeconomic status, and/or disability. *(This is required for endorsement maintenance. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities include.) This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*
While this measure is included in several federal reporting programs, those programs have not yet made disparities data available for us to analyze and report.

1b.5. If no or limited data on disparities from the measure as specified is reported in 1b4, then provide a summary of data from the literature that addresses disparities in care on the specific focus of measurement. Include citations.
The Chan et al. article cited above conducted a secondary analysis of PINNACLE data for select performance measures to examine whether compliance rates differed by race or sex. The authors found that compliance rates were similar between black and white patients and men and women for all 4 CAD performance measures (including beta-blocker therapy after MI). (1)

A separate analysis was completed using PINNACLE data from 2009 to compare treatment rates by insurance status for 5 quality-of-care indicators for CAD care related to medication treatment. Uninsured patients were less likely to receive ß-blocker therapy after MI as compared with those who had private health insurance (73.3% vs. 80.5%; unadjusted RR=0.91; 95% CI, 0.87-0.95; P<0.001). There were no meaningful differences in treatment rates between patients with public and private insurance. (2)

1c. High Priority (previously referred to as High Impact)

The measure addresses:

- a specific national health goal/priority identified by DHHS or the National Priorities Partnership convened by NQF; OR
- a demonstrated high-priority (high-impact) aspect of healthcare (e.g., affects large numbers of patients and/or has a substantial impact for a smaller population; leading cause of morbidity/mortality; high resource use (current and/or future); severity of illness; and severity of patient/societal consequences of poor quality).

1c.1. **Demonstrated high priority aspect of healthcare**

Affects large numbers, A leading cause of morbidity/mortality, High resource use, Patient/societal consequences of poor quality, Severity of illness

1c.2. **If Other:**

1c.3. **Provide epidemiologic or resource use data that demonstrates the measure addresses a high priority aspect of healthcare. List citations in 1c.4.**

Heart disease is the leading cause of death for both men and women in the United States and coronary heart disease is the most common type of heart disease.(1) According to the American Heart Association's 2015 Heart Disease and Stroke Statistics, coronary heart disease alone caused ˜1 of every 7 deaths in the United States in 2011. In 2011, close to 400,000 Americans died of coronary heart disease. Each year, an estimated ˜635 000 Americans have a new coronary attack (defined as first hospitalized myocardial infarction or coronary heart disease death) and ˜300 000 have a recurrent attack. It is estimated that an additional 155 000 silent first myocardial infarctions occur each year. Approximately every 34 seconds, 1 American has a coronary event, and approximately every 1 minute 24 seconds, an American will die of one.(2)

1c.4. **Citations for data demonstrating high priority provided in 1a.3**

1. CDC, NCHS. Underlying Cause of Death 1999-2013 on CDC WONDER Online Database, released 2015. Data are from the Multiple Cause of Death Files, 1999-2013, as compiled from data provided by the 57 vital statistics jurisdictions through the Vital Statistics Cooperative Program.
2. Mozaffarian D, Benjamin EJ, Go AS, et al.; on behalf of the American Heart Association Statistics Committee and Stroke Statistics Subcommittee. Heart disease and stroke statistics—2015 update: a report from the American Heart Association. Circulation. 2015;131:e29–e322.

1c.5. **If a PRO-PM (e.g. HRQoL/functional status, symptom/burden, experience with care, health-related behaviors), provide evidence that the target population values the measured PRO and finds it meaningful.** *(Describe how and from whom their input was obtained.)*

2. Reliability and Validity—Scientific Acceptability of Measure Properties

Extent to which the measure, as specified, produces consistent (reliable) and credible (valid) results about the quality of care when implemented. ***Measures must be judged to meet the subcriteria for both reliability and validity to pass this criterion and be evaluated against the remaining criteria.***

2a.1. Specifications The measure is well defined and precisely specified so it can be implemented consistently within and across organizations and allows for comparability. eMeasures should be specified in the Health Quality Measures Format (HQMF) and the Quality Data Model (QDM).

De.5. **Subject/Topic Area** *(check all the areas that apply):*

Cardiovascular, Cardiovascular : Ischemic Heart Disease, Coronary Artery Disease

De.6. **Cross Cutting Areas** *(check all the areas that apply):*

S.1. **Measure-specific Web Page** *(Provide a URL link to a web page specific for this measure that contains current detailed specifications including code lists, risk model details, and supplemental materials. Do not enter a URL linking to a home page or to general information.)*
The measure specifications are included as an attachment with this submission. Additional measure details may be found at:http://www.cms.gov/Regulations-and-Guidance/Legislation/EHRIncentivePrograms/eCQM_Library.html Value sets at https://vsac.nlm.nih.gov

S.2a. **If this is an eMeasure**, HQMF specifications must be attached. Attach the zipped output from the eMeasure authoring tool (MAT) - if the MAT was not used, contact staff. (Use the specification fields in this online form for the plain-language description of the specifications)
This is an eMeasure **Attachment:** EP_CMS145v4_NQF0070_CAD_BB.zip

S.2b. **Data Dictionary, Code Table, or Value Sets** *(and risk model codes and coefficients when applicable) must be attached. (Excel or csv file in the suggested format preferred - if not, contact staff)*
Attachment **Attachment:** 0070_AMAPCPI_CAD-BB_ValueSets_June2015.xlsx

S.3. **For endorsement maintenance**, please briefly describe any changes to the measure specifications since last endorsement date and explain the reasons.
Supporting guidelines and coding value sets included in the measure are reviewed on an annual basis. The measure and specifications have been updated to align with the 2012 ACCF/AHA/ACP/AATS/PCNA/SCAI/STS Guideline for the Diagnosis and Management of Patients With Stable Ischemic Heart Disease which now recommends the use of beta-blocker therapy for 3 years following MI or ACS as opposed to indefinite use as previously recommended. Additional limited changes have been incorporated during the annual update process to adhere to current eCQM industry standards while preserving the original measure intent.

S.4. **Numerator Statement** *(Brief, narrative description of the measure focus or what is being measured about the target population, i.e., cases from the target population with the target process, condition, event, or outcome)*
IF an OUTCOME MEASURE, state the outcome being measured. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
Patients who were prescribed beta-blocker therapy

S.5. **Time Period for Data** *(What is the time period in which data will be aggregated for the measure, e.g., 12 mo, 3 years, look back to August for flu vaccination? Note if there are different time periods for the numerator and denominator.)*
Once during the 12 consecutive month measurement period

S.6. **Numerator Details** *(All information required to identify and calculate the cases from the target population with the target process, condition, event, or outcome such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
IF an OUTCOME MEASURE, describe how the observed outcome is identified/counted. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
For EHR:
HQMF eMeasure developed and is included in this submission.

For Registry:
Option 1 – for patients with LVEF < 40%:
Definitions:
Prescribed- May include prescription given to the patient for beta-blocker therapy at one or more visits in the measurement period OR patient already taking beta-blocker therapy as documented in current medication list.
Beta-blocker Therapy- For patients with prior LVEF < 40%, beta-blocker therapy includes the following: bisoprolol, carvedilol, or sustained release metoprolol succinate.

Report Quality Data Code, G9189: Beta-blocker therapy prescribed or currently being taken

Option 2 – for patients with prior MI:
Definitions:

Prescribed- May include prescription given to the patient for beta-blocker therapy at one or more visits in the measurement period OR patient already taking beta-blocker therapy as documented in current medication list.
Beta-blocker Therapy- For patients with prior MI, beta-blocker therapy includes any agent within the beta-blocker drug class. As of 2014, no recommendations or evidence are cited in current stable ischemic heart disease guidelines for preferential use of specific agents.

Report CPT Category II Code, 4008F: Beta-blocker therapy prescribed or currently being taken

S.7. **Denominator Statement** *(Brief, narrative description of the target population being measured)*
All patients aged 18 years and older with a diagnosis of coronary artery disease seen within a 12 month period who also have a prior MI (within the past 3 years) or a current or prior LVEF <40%

S.8. **Target Population Category** *(Check all the populations for which the measure is specified and tested if any):*

S.9. **Denominator Details** *(All information required to identify and calculate the target population/denominator such as definitions, specific data collection items/responses , code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
For EHR:
HQMF eMeasure developed and is included in this submission.

DENOMINATOR DEFINITION:
LVEF < 40% corresponds to qualitative documentation of moderate dysfunction or severe dysfunction.

Prior Myocardial Infarction (MI) for denominator 2 is limited to those occurring within the past 3 years.

DENOMINATOR NOTES:
The requirement of "Count >=2 of Encounter, Performed" is to establish that the eligible professional has an existing relationship with the patient.

For Registry:
Option 1 -- for patients with LVEF < 40%:
Patient aged >= 18 years
AND
Diagnosis for coronary artery disease (ICD-9-CM) [for use 1/1/2015-9/30/2015]: 411.0, 411.1, 411.81, 411.89, 413.0, 413.1, 413.9, 414.00, 414.01, 414.02, 414.03, 414.04, 414.05, 414.06, 414.07, 414.2, 414.3, 414.8, 414.9, V45.81, V45.82

AND
Two Denominator Eligible Visits

S.10. Denominator Exclusions *(Brief narrative description of exclusions from the target population)*
Documentation of medical reason(s) for not prescribing beta-blocker therapy (eg, allergy, intolerance, other medical reasons)
Documentation of patient reason(s) for not prescribing beta-blocker therapy (eg, patient declined, other patient reasons)
Documentation of system reason(s) for not prescribing beta-blocker therapy (eg, other reasons attributable to the health care system)

S.11. Denominator Exclusion Details *(All information required to identify and calculate exclusions from the denominator such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
Exceptions are used to remove a patient from the denominator of a performance measure when the patient does not receive a therapy or service AND that therapy or service would not be appropriate due to patient-specific reasons. The patient would otherwise meet the denominator criteria. Exceptions are not absolute, and are based on clinical judgment, individual patient characteristics, or patient preferences. This measure was developed using the PCPI exception methodology which uses three categories of reasons for which a patient may be removed from the denominator of an individual measure.

These measure exception categories are not uniformly relevant across all measures; for each measure, there must be a clear rationale to permit an exception for a medical, patient, or system reason. Examples are provided in the measure exception language of instances that may constitute an exception and are intended to serve as a guide to clinicians. For this measure, exceptions may include medical reason(s) (eg, allergy, intolerance, other medical reasons), patient reason(s) (eg, patient declined, other patient reasons) or system reason(s) for not prescribing beta-blocker therapy (eg, other reasons attributable to the health care system).

Where examples of exceptions are included in the measure language, value sets for these examples are developed and included in the eSpecifications. Although this methodology does not require the external reporting of more detailed exception data, the PCPI recommends that physicians document the specific reasons for exception in patients' medical records for purposes of optimal patient management and audit-readiness. The PCPI also advocates the systematic review and analysis of each physician's exceptions data to identify practice patterns and opportunities for quality improvement.

Additional details by data source are as follows:
For EHR:
HQMF eMeasure developed and is included in this submission.

For Registry:

Option 1 -- for patients with LVEF < 40%:
Report Quality Data Code, G9190: Documentation of medical reason(s) for not prescribing beta-blocker therapy (eg, allergy, intolerance, other medical reasons)

Report Quality Data Code, G9191: Documentation of patient reason(s) for not prescribing beta-blocker therapy (eg, patient declined, other patient reasons)

Report Quality Data Code, G9192 : Documentation of system reason(s) for not prescribing beta-blocker therapy (eg, other reasons attributable to the health care system)

Option 2 – for patients with prior MI:
Append a modifier to CPT Category II Code:
4008F-1P : Documentation of medical reason(s) for not prescribing beta-blocker therapy (eg, allergy, intolerance, other medical reasons)

4008F-2P : Documentation of patient reason(s) for not prescribing beta-blocker therapy (eg, patient declined, other patient reasons)

4008F-3P : Documentation of system reason(s) for not prescribing beta-blocker therapy (eg, other reasons attributable to the health care system)

S.12. Stratification Details/Variables *(All information required to stratify the measure results including the stratification variables, definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format with at S.2b)*
Consistent with CMS' Measures Management System Blueprint and recent national recommendations put forth by the IOM and NQF to standardize the collection of race and ethnicity data, we encourage the results of this measure to be stratified by race, ethnicity, administrative sex, and payer and have included these variables as recommended data elements to be collected.

S.13. Risk Adjustment Type (Select type. Provide specifications for risk stratification in S.12 and for statistical model in S.14-15)
No risk adjustment or risk stratification
If other:

S.14. Identify the statistical risk model method and variables *(Name the statistical method - e.g., logistic regression and list all the risk factor variables. Note - risk model development and testing should be addressed with measure testing under Scientific Acceptability)*
No risk adjustment or risk stratification

S.15. Detailed risk model specifications *(must be in attached data dictionary/code list Excel or csv file. Also indicate if available at measure-specific URL identified in S.1.)*
Note: Risk model details (including coefficients, equations, codes with descriptors, definitions), should be provided on a separate worksheet in the suggested format in the Excel or csv file with data dictionary/code lists at S.2b.
Provided in response box S.15a

S.15a. Detailed risk model specifications (*if not provided in excel or csv file at S.2b*)
No risk adjustment or risk stratification

S.16. Type of score:
Rate/proportion
If other:

S.17. Interpretation of Score *(Classifies interpretation of score according to whether better quality is associated with a higher score, a lower score, a score falling within a defined interval, or a passing score)*
Better quality = Higher score

S.18. Calculation Algorithm/Measure Logic *(Describe the calculation of the measure score as an ordered sequence of steps including identifying the target population; exclusions; cases meeting the target process, condition, event, or outcome; aggregating data; risk adjustment; etc.)*
To calculate performance rates:

1. Find the patients who meet the initial population (ie, the general group of patients that a set of performance measures is designed to address).
2. From the patients within the initial population criteria, find the patients who qualify for the denominator (ie, the specific group of patients for inclusion in a specific performance measure based on defined criteria). Note: in some cases the initial population and denominator are identical.
3. From the patients within the denominator, find the patients who meet the numerator criteria (ie, the group of patients in the denominator for whom a process or outcome of care occurs). Validate that the number of patients in the numerator is less than or equal to the number of patients in the denominator
4. From the patients who did not meet the numerator criteria, determine if the provider has documented that the patient meets any criteria for exception when denominator exceptions have been specified [for this measure: medical reason(s) (eg, allergy, intolerance, other medical reasons), patient reason(s) (eg, patient declined, other patient reasons) or system reason(s) for not prescribing beta-blocker therapy (eg, other reasons attributable to the health care system).] If the patient meets any exception criteria, they should be removed from the denominator for performance calculation. --Although the exception cases are removed from the denominator population for the performance calculation, the exception rate (ie, percentage with valid exceptions) should be calculated and reported along with performance rates to track variations in care and highlight possible areas of focus for QI.

If the patient does not meet the numerator and a valid exception is not present, this case represents a quality failure.

S.19. Calculation Algorithm/Measure Logic Diagram URL or Attachment *(You also may provide a diagram of the Calculation Algorithm/Measure Logic described above at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
No diagram provided

S.20. Sampling *(If measure is based on a sample, provide instructions for obtaining the sample and guidance on minimum sample size.)*
IF a PRO-PM, identify whether (and how) proxy responses are allowed.
Not applicable. The measure is not based on a sample.

S.21. Survey/Patient-reported data *(If measure is based on a survey, provide instructions for conducting the survey and guidance on minimum response rate.)*
IF a PRO-PM, specify calculation of response rates to be reported with performance measure results.
Not applicable. The measure is not based on a survey.

S.22. Missing data (specify how missing data are handled, e.g., imputation, delete case.)
Required for Composites and PRO-PMs.
Patient eligibility is determined by a set of defined criteria relevant to a particular measure. If data required to determine patient eligibility are missing, those patients/cases would be ineligible for inclusion in the denominator and therefore the patient/case would be deleted.

If data required to determine if a denominator eligible patient qualifies for the numerator (or has a valid exclusion/exception) are missing, this case would represent a quality failure.

S.23. Data Source *(Check ONLY the sources for which the measure is SPECIFIED AND TESTED).*
If other, please describe in S.24.
Electronic Clinical Data, Electronic Clinical Data : Electronic Health Record, Electronic Clinical Data : Registry

S.24. Data Source or Collection Instrument *(Identify the specific data source/data collection instrument e.g. name of database, clinical registry, collection instrument, etc.)*
IF a PRO-PM, identify the specific PROM(s); and standard methods, modes, and languages of administration.
Not applicable.

S.25. Data Source or Collection Instrument *(available at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
No data collection instrument provided

S.26. Level of Analysis *(Check ONLY the levels of analysis for which the measure is SPECIFIED AND TESTED)*
Clinician : Group/Practice, Clinician : Individual

S.27. **Care Setting** *(Check ONLY the settings for which the measure is SPECIFIED AND TESTED)* Ambulatory Care : Clinician Office/Clinic, Home Health, Other, Post Acute/Long Term Care Facility : Long Term Acute Care Hospital, Post Acute/Long Term Care Facility : Nursing Home/Skilled Nursing Facility If other: Domiciliary
S.28. **COMPOSITE Performance Measure** - Additional Specifications *(Use this section as needed for aggregation and weighting rules, or calculation of individual performance measures if not individually endorsed.)*
2a. Reliability – See attached Measure Testing Submission Form **2b. Validity – See attached Measure Testing Submission Form** NQF_0070_Coronary_Artery_Disease_-CAD-_-_Beta_Blocker_Therapy_Prior_to_MI_or_LVSD_Testing_Attachment.docx

NATIONAL QUALITY FORUM—Measure Testing (subcriteria 2a2, 2b2-2b6)

Measure Title: CoronaryArtery Disease – Beta Blocker Therapy Prior to MI or LVSD
Date of Submission: Click here to enter a date

Type of Measure:

☐ Composite – ***STOP – use composite testing form***	☐ Outcome (*including PRO-PM*)
☐ Cost/resource	☑ Process
☐ Efficiency	☐ Structure

Instructions

- Measures must be tested for all the data sources and levels of analyses that are specified. ***If there is more than one set of data specifications or more than one level of analysis, contact NQF staff*** about how to present all the testing information in one form.
- **For all measures, sections 1, 2a2, 2b2, 2b3, and 2b5 must be completed.**
- **For outcome and resource use measures**, section **2b4** also must be completed.
- If specified for **multiple data sources/sets of specifications** (e.g., claims and EHRs), section **2b6** also must be completed.
- Respond to all questions as instructed with answers immediately following the question. All information on testing to demonstrate meeting the subcriteria for reliability (2a2) and validity (2b2-2b6) must be in this form. An appendix for *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 20 pages (*incuding questions/instructions;* minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the testing results for this measure meet NQF's evaluation criteria for testing.

2a2. Reliability testing [10] demonstrates the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise.

2b2. Validity testing [11] demonstrates that the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality.

2b3. Exclusions are supported by the clinical evidence; otherwise, they are supported by evidence of sufficient frequency of occurrence so that results are distorted without the exclusion; [12]

AND

If patient preference (e.g., informed decision making) is a basis for exclusion, there must be evidence that the exclusion impacts performance on the measure; in such cases, the measure must be specified so that the information about patient preference and the effect on the measure is transparent (e.g., numerator category computed separately, denominator exclusion category computed separately). [13]

2b4. For outcome measures and other measures when indicated (e.g., resource use):

- **an evidence-based risk-adjustment strategy** (e.g., risk models, risk stratification) is specified; is based on patient factors that influence the measured outcome (but not factors related to disparities in care or the quality of care) and are present at start of care; [14,15] and has demonstrated adequate discrimination and calibration

OR

- rationale/data support no risk adjustment/ stratification.

2b5. Data analysis of computed measure scores demonstrates that methods for scoring and analysis of the specified measure allow for **identification of statistically significant and practically/clinically meaningful** [16] **differences in performance**;

OR

there is evidence of overall less-than-optimal performance.

2b6. If multiple data sources/methods are specified, there is demonstration they produce comparable results.

Notes

10. Reliability testing applies to both the data elements and computed measure score. Examples of reliability testing for data elements include, but are not limited to: inter-rater/abstractor or intra-rater/abstractor studies; internal consistency for multi-item scales; test-retest for survey items. Reliability testing of the measure score addresses precision of measurement (e.g., signal-to-noise).

11. Validity testing applies to both the data elements and computed measure score. Validity testing of data elements typically analyzes agreement with another authoritative source of the same information. Examples of validity testing of the measure score include, but are not limited to: testing hypotheses that the measures scores indicate quality of care, e.g., measure scores are different for groups known to have differences in quality assessed by another valid quality measure or method; correlation of measure scores with another valid indicator of quality for the specific topic; or relationship to conceptually related measures (e.g., scores on process measures to scores on outcome measures). Face validity of the measure score as a quality indicator may be adequate if accomplished through a systematic and transparent process, by identified experts, and explicitly addresses whether performance scores resulting from the measure as specified can be used to distinguish good from poor quality.

12. Examples of evidence that an exclusion distorts measure results include, but are not limited to: frequency of occurrence, variability of exclusions across providers, and sensitivity analyses with and without the exclusion.

13. Patient preference is not a clinical exception to eligibility and can be influenced by provider interventions.

14. Risk factors that influence outcomes should not be specified as exclusions.

15. Risk models should not obscure disparities in care for populations by including factors that are associated with differences/inequalities in care, such as race, socioeconomic status, or gender (e.g., poorer treatment outcomes of African American men with prostate cancer or inequalities in treatment for CVD risk factors between men and women). It is preferable to stratify measures by race and socioeconomic status rather than to adjust out the differences.

16. With large enough sample sizes, small differences that are statistically significant may or may not be practically or clinically meaningful. The substantive question may be, for example, whether a statistically significant difference of one percentage point in the percentage of patients who received smoking cessation counseling (e.g., 74 percent v. 75 percent) is clinically meaningful; or whether a statistically significant difference of $25 in cost for an episode of care (e.g., $5,000 v. $5,025) is practically meaningful. Measures with overall less-than-optimal performance may not demonstrate much variability across providers.

1. DATA/SAMPLE USED FOR ALL TESTING OF THIS MEASURE

Often the same data are used for all aspects of measure testing. In an effort to eliminate duplication, the first five questions apply to all measure testing. If there are differences by aspect of testing,(e.g., reliability vs. validity) be sure to indicate the specific differences in question 1.7.

1.1. What type of data was used for testing? (*Check all the sources of data identified in the measure specifications and data used for testing the measure. Testing must be provided for all the sources of data specified and intended for measure implementation.* ***If different data sources are used for the numerator and denominator, indicate N [numerator] or D [denominator] after the checkbox.***)

Measure Specified to Use Data From: (***must be consistent with data sources entered in S.23***)	**Measure Tested with Data From:**
☐ abstracted from paper record	☐ abstracted from paper record
☐ administrative claims	☐ administrative claims
☑ clinical database/registry	☑ clinical database/registry
☑ abstracted from electronic health record	☑ abstracted from electronic health record
☑ eMeasure (HQMF) implemented in EHRs	☑ eMeasure (HQMF) implemented in EHRs
☐ other: Click here to describe	☐ other: Click here to describe

1.2. If an existing dataset was used, identify the specific dataset (*the dataset used for testing must be consistent with the measure specifications for target population and healthcare entities being measured; e.g., Medicare Part A claims, Medicaid claims, other commercial insurance, nursing home MDS, home health OASIS, clinical registry*).

Data 1 (EHR - Validity Against the Gold Standard)

The data source is EHR data.

Bonnie Patient Test Deck

As a supplement to the EHR reliability testing performed on this measure, a deck of patient test cases have been developed and a summary of the details has been included as part of the feasibility attachment in section 3b.3 of the measure submission form.

Data 2 (GPRO Registry)

The data source is the Centers for Medicare & Medicaid Service (CMS) PQRS GPRO database.

Data 3 (EHR – Exceptions Analysis)

The data source is EHR data.

1.3. What are the dates of the data used in testing?

Data 1 (EHR - Validity Against the Gold Standard)

The data are collected from patients sampled from 2004.

Data 2 (GPRO Registry)

The data are for the time period January 2013 – December 31, 2013 and cover the entire United States.

Data 3 (EHR – Exceptions Analysis)

The data are collected from patients sampled in 2009.

1.4. What levels of analysis were tested? (*testing must be provided for all the levels specified and intended for measure implementation, e.g., individual clinician, hospital, health plan*)

Measure Specified to Measure Performance of: (***must be consistent with levels entered in item S.26***)	**Measure Tested at Level of:**
☑ individual clinician	☑ individual clinician
☑ group/practice	☑ group/practice
☐ hospital/facility/agency	☐ hospital/facility/agency
☐ health plan	☐ health plan
☐ other: Click here to describe	☐ other: Click here to describe

1.5. How many and which measured entities were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of measured entities included in the*

analysis (e.g., size, location, type); if a sample was used, describe how entities were selected for inclusion in the sample)

Data 1 (EHR - Validity Against the Gold Standard)

The data sample came from an academic general internal medicine clinic with several years of experience using a commercial EHR. The clinic employs 40 full or part-time internal medicine physicians and provides more than 41,000 patient visits annually.

Data 2 (GPRO Registry)

The total number of physicians reporting on this measure is 4,124. Of those, 1,724 physicians had all the required data elements and met the minimum number of quality reporting events (10) for inclusion in the reliability analysis. For this measure, 41.8 percent of physicians are included in the analysis, and the average number of quality reporting events is 61.0 for a total of 105,124 events. The range of quality reporting events for 1,724 physicians included is from 1398 to 10. The average number of quality reporting events for the remaining 58.2 percent of physicians who aren't included is 3.6.

Data 3 (EHR – Exceptions Analysis)

The data sampled came from 5 physician offices using 5 different EHR systems.

1.6. How many and which patients were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of patients included in the analysis (e.g., age, sex, race, diagnosis); if a sample was used, describe how patients were selected for inclusion in the sample*)

Data 1 (EHR - Validity Against the Gold Standard)

The sample consisted of approximately 134 charts for a total of 134 eligible patients. One trained investigator reviewed the 134 charts. The patients were selected using random sampling.

Data 2 (GPRO Registry)

There were 105,124 patients included in this testing and analysis. These were the patients that were associated with physicians who had 10 or more patients eligible for this measure.

Data 3 (EHR – Exceptions Analysis)

The sample consisted of approximately 2,717 eligible patients.

1.7. If there are differences in the data or sample used for different aspects of testing (e.g., reliability, validity, exclusions, risk adjustment), identify how the data or sample are different for each aspect of testing reported below.

Data 1 (EHR - Validity Against the Gold Standard)

The data sample was used for the purposes of reliability and validity testing.

Data 2 (GPRO Registry)

The same data sample from each data source was used for reliability testing and exceptions analysis.

Face Validity (Data 2)

After the measure was fully specified, an expert panel of 12 members was asked to rate their agreement with the following statement:

The scores obtained from the measure as specified will provide an accurate reflection of quality and can be used to distinguish good and poor quality.

Data 3 (EHR – Exceptions Analysis)

The data sample was used for the exception analysis only.

1.8. What were the patient-level sociodemographic (SDS) variables that were available and analyzed in the data or sample used? For example, patient-reported data (e.g., income, education, language), proxy variables when SDS data are not collected from each patient (e.g. census tract), or patient community characteristics (e.g. percent vacant housing, crime rate).

Data 1 (EHR - Validity Against the Gold Standard)

Patient-level sociodemographic (SDS) variables were not analyzed in this project.

Data 2 (GPRO Registry)

This was not captured as part of the testing.

Data 3 (EHR – Exceptions Analysis)

This was not captured as part of the testing.

2a2. RELIABILITY TESTING

***Note**: If accuracy/correctness (validity) of data elements was empirically tested, separate reliability testing of data elements is not required – in 2a2.1 check critical data elements; in 2a2.2 enter "see section 2b2 for validity testing of data elements"; and skip 2a2.3 and 2a2.4.*

2a2.1. What level of reliability testing was conducted? (*may be one or both levels*)
☑ **Critical data elements used in the measure** (*e.g., inter-abstractor reliability; data element reliability must address ALL critical data elements*)
☑ **Performance measure score** (e.g., *signal-to-noise analysis*)

2a2.2. For each level checked above, describe the method of reliability testing and what it tests (*describe the steps—do not just name a method; what type of error does it test; what statistical analysis was used*)

Data 1 (EHR - Validity Against the Gold Standard)

See 2b2.2 for Validity Against the Gold Standard Results

Data 2 (GPRO Registry / Signal-to-Noise Reliability)

Reliability of the computed measure score was measured as the ratio of signal to noise. The signal in this case is the proportion of the variability in measured performance that can be explained by real differences in physician performance. Reliability at the level of the specific physician is given by:

Reliability = Variance (physician-to-physician) / [Variance (physician-to-physician) + Variance (physician-specific-error]

Reliability is the ratio of the physician-to-physician variance divided by the sum of the physician-to-physician variance plus the error variance specific to a physician. A reliability of zero implies that all the variability in a measure is attributable to measurement error. A reliability of one implies that all the variability is attributable to real differences in physician performance.

Reliability testing was performed by using a beta-binomial model. The beta-binomial model assumes the physician performance score is a binomial random variable conditional on the physician's true value that comes from the beta distribution. The beta distribution is usually defined by two parameters, alpha and beta. Alpha and beta can be thought of as intermediate calculations to get to the needed variance estimates.

Reliability is estimated at two different points, at the minimum number of quality reporting events for the measure and at the mean number of quality reporting events per physician.

2a2.3. For each level checked above, what were the statistical results from reliability testing? (e.*g., percent agreement and kappa for the critical data elements; distribution of reliability statistics from a signal-to-noise analysis*)

Data 1 (EHR - Validity Against the Gold Standard)

See 2b2.3 for Validity Against the Gold Standard Results

Data 2 (GPRO Registry)

For this measure, the reliability at the minimum level of quality reporting events (10) was 0.65. The average number of quality reporting events for physicians included is 61.0. The reliability at the average number of quality reporting events was 0.92.

2a2.4 What is your interpretation of the results in terms of demonstrating reliability? (i.*e., what do the results mean and what are the norms for the test conducted?*)

Data 1 (EHR - Validity Against the Gold Standard)

See 2b2.4 for Validity Against the Gold Standard Results

Data 2 (GPRO Registry)

This measure has moderate reliability when evaluated at the minimum level of quality reporting events and high reliability at the average number of quality events.

2b2. VALIDITY TESTING

2b2.1. What level of validity testing was conducted? (*may be one or both levels*)

☑ **Critical data elements** (*data element validity must address ALL critical data elements*)

☑ **Performance measure score**

☐ **Empirical validity testing**

☑ **Systematic assessment of face validity of performance measure score as an indicator** of quality or resource use (*i.e., is an accurate reflection of performance on quality or resource use and can distinguish good from poor performance*)

2b2.2. For each level checked above, describe the method of validity testing and what it tests (*describe the steps—do not just name a method; what was tested, e.g., accuracy of data elements compared to authoritative source, relationship to another measure as expected; what statistical analysis was used)*

Data 1 (EHR - Validity Against the Gold Standard)

Data abstracted from randomly sampled patient records were used to evaluate parallel forms reliability for the measure. Charts for abstraction were selected for patients aged 18 years and older with a visit, problem list, or medical history diagnosis of CAD.

Data 2 (GPRO Registry) Face Validity

Face validity of the measure score as an indicator of quality was systematically assessed as follows.

After the measure was fully specified, the expert panel was asked to rate their agreement with the following statement:

The scores obtained from the measure as specified will provide an accurate reflection of quality and can be used to distinguish good and poor quality.

Scale 1-5, where 1= Strongly Disagree; 3= Neither Agree nor Disagree; 5= Strongly Agree

2b2.3. What were the statistical results from validity testing? (*e.g., correlation; t-test*)

Data 1 (EHR - Validity Against the Gold Standard)

Of the 134 patients sampled via automated EHR review, 111 patients (82.8%) that met the numerator criteria were detected. Performance on the measure was calculated to be 90.3% through comparison of automated and manual EHR review.

Face Validity (Data 2)

Our expert panel included 12 members. Panel members were comprised of experts from the AMA-PCPI Measure Advisory Committee. The list of expert panel members is as follows:

Amy Sanders, MD, MS

David Seidenwurm, MD

Dianne V. Jewell, PT, DPT, PhD, CCS, FAACVPR

Janet Sullivan, MD
John Easa, MD, FIPP

Joseph P. Drozda, Jr., MD, FACC

Mark Metersky, MD

Martha J. Radford, MD, FACC, FAHA

Michael O'Dell, MD, MS, MSHA, FAAFP

Richard Bankowitz, MD, MBA, FACP

Scott T. MacDonald, MD

Shannon Sims, MD, PhD

2b2.4. What is your interpretation of the results in terms of demonstrating validity? (i.*e., what do the results mean and what are the norms for the test conducted?*)

Data 1 (EHR - Validity Against the Gold Standard)

Discrepancies between performance measures based on EHR automated review alone and those based on automated review plus manual reviews were due to two types of misclassification: failure to correctly identify performance of quality measures among true, eligible patients; and failure to correctly exclude patients. Upon further analysis, the differences between automated review alone and automated plus manual reviews were 10 patients (7.5%).

Face Validity (Data 2)

The results of the expert panel rating of the validity statement were as follows: N = 12; Mean rating = 4.17 and 91.7% of respondents either agree or strongly agree that this measure can accurately distinguish good and poor quality.

Frequency Distribution of Ratings

1 – 1 response (Strongly Disagree)

2 – 0 responses

3 – 0 responses (Neither Agree nor Disagree)

4 – 6 responses

5 – 5 responses (Strongly Agree)

2b3. EXCLUSIONS ANALYSIS

NA no exclusions — *skip to section 2b4*

2b3.1. Describe the method of testing exclusions and what it tests (*describe the steps—do not just name a method; what was tested, e.g., whether exclusions affect overall performance scores; what statistical analysis was used*)

Data 1 (EHR - Validity Against the Gold Standard)

This data sample was not used to test exclusions.

Data 2 (GPRO Registry)

With the information available from the PQRS Registry, we are unable to determine the type of exception reported. However, the exceptions data captured were analyzed to determine frequency and variability across providers.

Data 3 (EHR – Exceptions Analysis)

Exceptions included documentation of medical reason(s), patient reason(s) and system reason(s) for not prescribing beta-blocker therapy. Exceptions were analyzed for frequency and variability across providers.

2b3.2. What were the statistical results from testing exclusions? (*include overall number and percentage of individuals excluded, frequency distribution of exclusions across measured entities, and impact on performance measure scores*)

Data 1 (EHR - Validity Against the Gold Standard)

This data sample was not used to test exclusions.

Data 2 (GPRO Registry)

Amongst the 1,724 physicians with the minimum (10) number of quality reporting events, there were a total of 4,291 exceptions reported. The average number of exceptions per physician in this sample is 2.5. The overall exception rate is 3.9%.

Data 3 (EHR – Exceptions Analysis)

Review of the 2,717 exceptions revealed that 2,292 (84.4%) exceptions were medical reasons for not prescribing beta blocker therapy, 347 (12.8%) exceptions were patient reasons and 78 (2.9%) were system reasons.

2b3.3. What is your interpretation of the results in terms of demonstrating that exclusions are needed to prevent unfair distortion of performance results? (*i.e., the value outweighs the burden of increased data collection and analysis. Note: **If patient preference is an exclusion**, the measure must be specified so that the effect on the performance score is transparent, e.g., scores with and without exclusion*)

Exceptions are necessary to account for those situations when it is not medically appropriate to prescribe beta blocker therapy. Exceptions are discretionary and the methodology used for measure exception categories are not uniformly relevant across all measures; for this measure, there is a clear rationale to permit an exception for medical, patient or system reasons. Rather than specifying an exhaustive list of explicit medical, patient or system reasons for exception for each measure, the measure developer relies on clinicians to link the exception with a specific reason for the decision not to prescribe beta blocker therapy required by the measure.

Some have indicated concerns with exception reporting including the potential for physicians to inappropriately exclude patients to enhance their performance statistics. Research has indicated that levels of exception reporting occur infrequently and are generally valid (Doran et al., 2008), (Kmetik et al., 2011). Furthermore, exception reporting has been found to have substantial benefits: "it is precise, it increases acceptance of [pay for performance] programs by physicians, and it ameliorates perverse incentives to refuse care to "difficult" patients." (Doran et al., 2008).

Although this methodology does not require the external reporting of more detailed exception data, the measure developer recommends that physicians document the specific reasons for exception in patients' medical records for purposes of optimal patient management and audit-readiness. We also advocate for the systematic review and analysis of each physician's exceptions data to identify practice patterns and opportunities for quality improvement.

Without exceptions, the performance rate would not accurately reflect the true performance of that physician. This would result in an increase in performance failures and false negatives. The additional value of increased data collection of capturing an exception greatly outweighs the reporting burden.

2b4. RISK ADJUSTMENT/STRATIFICATION FOR OUTCOME OR RESOURCE USE MEASURES
If not an intermediate or health outcome, or PRO-PM, or resource use measure, skip to section 2b5.

2b4.1. What method of controlling for differences in case mix is used?

☑ **No risk adjustment or stratification**

☐ **Statistical risk model with** Click here to enter number of factors **risk factors**

☐ **Stratification by** Click here to enter number of categories **risk categories**

☐ **Other,** Click here to enter description

2b4.2. If an outcome or resource use measure is not risk adjusted or stratified, provide rationale and analyses to demonstrate that controlling for differences in patient characteristics (case mix) is not needed to achieve fair comparisons across measured entities.

Not applicable

2b4.3. Describe the conceptual/clinical and statistical methods and criteria used to select patient factors used in the statistical risk model or for stratification by risk (*e.g., potential factors identified in the literature and/or expert panel; regression analysis; statistical significance of p<0.10; correlation of x or higher; patient factors should be present at the start of care and not related to disparities*)

Not applicable

2b4.4a. What were the statistical results of the analyses used to select risk factors?

Not applicable

2b4.4b. Describe the method of testing/analysis used to develop and validate the adequacy of the statistical model or stratification approach *(describe the steps – do not just name a method; what statistical analysis was used)*

Not applicable

2b4.5. Describe the method of testing/analysis used to develop and validate the adequacy of the statistical model or stratification approach (*describe the steps—do not just name a method; what statistical analysis was used*)

Provide the statistical results from testing the approach to controlling for differences in patient characteristics (case mix) below.
if stratified, skip to 2b4.9

Not applicable

2b4.6. Statistical Risk Model Discrimination Statistics (*e.g., c-statistic, R-squared*)**:**

Not applicable

2b4.7. Statistical Risk Model Calibration Statistics (*e.g., Hosmer-Lemeshow statistic*):

Not applicable

2b4.8. Statistical Risk Model Calibration – Risk decile plots or calibration curves:

Not applicable

2b4.9. Results of Risk Stratification Analysis:

Not applicable

2b4.10. What is your interpretation of the results in terms of demonstrating adequacy of controlling for differences in patient characteristics (case mix)? (i.*e., what do the results mean and what are the norms for the test conducted*)

Not applicable

***2b4.11. Optional Additional Testing for Risk Adjustment** (*not required, but would provide additional support of adequacy of risk model, e.g., testing of risk model in another data set; sensitivity analysis for missing data; other methods*)

Not applicable

2b5. IDENTIFICATION OF STATISTICALLY SIGNIFICANT & MEANINGFUL DIFFERENCES IN PERFORMANCE

2b5.1. Describe the method for determining if statistically significant and clinically/practically meaningful differences in performance measure scores among the measured entities can be identified (*describe the steps—do not just name a method; what statistical analysis was used? Do not just repeat the information provided related to performance gap in 1b)*

Data 1 (EHR - Validity Against the Gold Standard)

This data sample was not used to test for meaningful differences in performance across providers or practice sites.

Data 2 (GPRO Registry)

Measures of central tendency, variability, and dispersion were calculated.

2b5.2. What were the statistical results from testing the ability to identify statistically significant and/or clinically/practically meaningful differences in performance measure scores across measured entities? (e.g., *number and percentage of entities with scores that were statistically significantly different from mean or some benchmark, different from expected; how was meaningful difference defined*)

Data 1 (EHR - Validity Against the Gold Standard)

This data sample was not used to test for meaningful differences in performance across providers or practice sites.

Data 2 (GPRO Registry)

Based on the sample of 1,724 included physicians, the mean performance rate is 0.74, the median performance rate is 0.78 and the mode is 1.00. The standard deviation is 0.20. The range of the performance rate is 1.0, with a minimum rate of 0.00 and a maximum rate of 1.00. The interquartile range is 0.23 (0.65 - 0.88).

2b5.3. What is your interpretation of the results in terms of demonstrating the ability to identify statistically significant and/or clinically/practically meaningful differences in performance across measured entities? (i.*e., what do the results mean in terms of statistical and meaningful differences?*)

Data 1 (EHR - Validity Against the Gold Standard)

This data sample was not used to test for meaningful differences in performance across providers or practice sites.

Data 2 (GPRO Registry)

The range of performance from 0.00 to 1.00 suggests there's clinically meaningful variation across physicians' performance.

2b6. COMPARABILITY OF PERFORMANCE SCORES WHEN MORE THAN ONE SET OF SPECIFICATIONS

If only one set of specifications, this section can be skipped.

Note: *This criterion is directed to measures with more than one set of specifications/instructions (e.g., one set of specifications for how to identify and compute the measure from medical record abstraction and a different set of specifications for claims or eMeasures). It does not apply to measures that use more than one source of data in one set of specifications/instructions (e.g., claims data to identify the denominator and medical record abstraction for the numerator).* ***If comparability is not demonstrated, the different specifications should be submitted as separate measures.***

2b6.1. Describe the method of testing conducted to demonstrate comparability of performance scores for the same entities across the different data sources/specifications (*describe the steps—do not just name a method; what statistical analysis was used*)

This test was not performed for this measure.

2b6.2. What were the statistical results from testing comparability of performance scores for the same entities when using different data sources/specifications? (*e.g., correlation, rank order*)

This test was not performed for this measure.

2b6.3. What is your interpretation of the results in terms of demonstrating comparability of performance measure scores for the same entities across the different data sources/specifications? (i.*e., what do the results mean and what are the norms for the test conducted*)

This test was not performed for this measure.

2b7. MISSING DATA ANALYSIS AND MINIMIZING BIAS

2b7.1. Describe the method of testing conducted to identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias (describe the steps – do not just name a method; what statistical analysis was used)

Data are not available to complete this testing.

2b7.2. What is the overall frequency of missing data, the distribution of missing data across providers, and the results from testing related to missing data? (e.g., results of sensitivity analysis of the effect of various rules for missing data/nonresponse; if no empirical sensitivity analysis, identify the approaches for handling missing data that were considered and pros and cons of each)

Data are not available to complete this testing.

2b7.3. What is your interpretation of the results in terms of demonstrating that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias? (i.e., what do the results mean in terms of supporting the selected approach for missing data and what are the norms for the test conducted; if no empirical analysis, provide rationale for the selected approach for missing data)

Data are not available to complete this testing.

3. Feasibility
Extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.
3a. Byproduct of Care Processes For clinical measures, the required data elements are routinely generated and used during care delivery (e.g., blood pressure, lab test, diagnosis, medication order).

3a.1. **Data Elements Generated as Byproduct of Care Processes.**
Generated or collected by and used by healthcare personnel during the provision of care (e.g., blood pressure, lab value, diagnosis, depression score), Coded by someone other than person obtaining original information (e.g., DRG, ICD-9 codes on claims), Abstracted from a record by someone other than person obtaining original information (e.g., chart abstraction for quality measure or registry)
If other:

3b. Electronic Sources

The required data elements are available in electronic health records or other electronic sources. If the required data are not in electronic health records or existing electronic sources, a credible, near-term path to electronic collection is specified.

3b.1. **To what extent are the specified data elements available electronically in defined fields?** *(i.e., data elements that are needed to compute the performance measure score are in defined, computer-readable fields)*
ALL data elements are in defined fields in electronic health records (EHRs)

3b.2. **If ALL the data elements needed to compute the performance measure score are not from electronic sources, specify a credible, near-term path to electronic capture, OR provide a rationale for using other than electronic sources.**

3b.3. **If this is an eMeasure, provide a summary of the feasibility assessment in an attached file or make available at a measure-specific URL.**
Attachment **Attachment:** NQF_0070_Feasibility_Scorecard_Bonnie_Output_Screen_Shots_Revised.pdf

3c. Data Collection Strategy

Demonstration that the data collection strategy (e.g., source, timing, frequency, sampling, patient confidentiality, costs associated with fees/licensing of proprietary measures) can be implemented (e.g., already in operational use, or testing demonstrates that it is ready to put into operational use). For eMeasures, a feasibility assessment addresses the data elements and measure logic and demonstrates the eMeasure can be implemented or feasibility concerns can be adequately addressed.

3c.1. **Describe what you have learned/modified as a result of testing and/or operational use of the measure regarding data collection, availability of data, missing data, timing and frequency of data collection, sampling, patient confidentiality, time and cost of data collection, other feasibility/implementation issues.**
IF a PRO-PM, consider implications for both individuals providing PROM data (patients, service recipients, respondents) and those whose performance is being measured.
We have not identified any areas of concern or made any modifications as a result of testing and operational use of the measure in relation to data collection, availability of data, missing data, timing and frequency of data collection, sampling, patient confidentiality, time and cost of data collection, and other feasibility issues unless otherwise noted.

3c.2. **Describe any fees, licensing, or other requirements to use any aspect of the measure as specified** *(e.g., value/code set, risk model, programming code, algorithm)*.
The Measures, while copyrighted, can be reproduced and distributed, without modification, for noncommercial purposes, eg, use by health care providers in connection with their practices. Commercial uses of the Measures require a license agreement between the user and the AMA, (on behalf of the PCPI), ACC or AHA.
Limited proprietary coding is contained in the Measure specifications for convenience. Users of the proprietary code sets should obtain all necessary licenses from the owners of these code sets.

4. Usability and Use

Extent to which potential audiences (e.g., consumers, purchasers, providers, policy makers) are using or could use performance results for both accountability and performance improvement to achieve the goal of high-quality, efficient healthcare for individuals or populations.

4a. Accountability and Transparency

Performance results are used in at least one accountability application within three years after initial endorsement and are publicly reported within six years after initial endorsement (or the data on performance results are available). If not in use at the time of initial endorsement, then a credible plan for implementation within the specified timeframes is provided.

4.1. Current and Planned Use

NQF-endorsed measures are expected to be used in at least one accountability application within 3 years and publicly reported within 6 years of initial endorsement in addition to performance improvement.

Planned	Current Use (for current use provide URL)
	Public Reporting Physician Quality Reporting System (PQRS) http://www.cms.gov/Medicare/Quality-Initiatives-Patient-Assessment-Instruments/PQRS/MeasuresCodes.html Payment Program Meaningful Use Stage 2 (EHR Incentive Program) http://www.cms.gov/Regulations-and-Guidance/Legislation/EHRIncentivePrograms/eCQM_Library.html Quality Improvement with Benchmarking (external benchmarking to multiple organizations) Pinnacle Registry http://cvquality.acc.org/en/NCDR-Home/Registries/Outpatient-Registries.aspx

4a.1. For each CURRENT use, checked above, provide:

- Name of program and sponsor
- Purpose
- Geographic area and number and percentage of accountable entities and patients included

1. Physician Quality Reporting System (PQRS) – Sponsored by the Centers for Medicare and Medicaid Services (CMS)
PQRS is a national reporting program that uses a combination of incentive payments and payment adjustments to promote reporting of quality information by eligible professionals (EPs). The program provides an incentive payment to practices with EPs (identified on claims by their individual National Provider Identifier [NPI] and Tax Identification Number [TIN]). EPs satisfactorily report data on quality measures for covered Physician Fee Schedule (PFS) services furnished to Medicare Part B Fee-for-Service (FFS) beneficiaries (including Railroad Retirement Board and Medicare Secondary Payer). Beginning in 2015, the program also applies a payment adjustment to EPs who do not satisfactorily report data on quality measures for covered professional services. Source: http://www.cms.gov/Medicare/Quality-Initiatives-Patient-Assessment-Instruments/PQRS/index.html. It is our understanding that CMS is also planning to move towards publicly reporting physician data via Physician Compare.

2. Meaningful Use Stage 2 (EHR Incentive Program) – Sponsored by the Centers for Medicare and Medicaid Services (CMS)
The Medicare and Medicaid EHR Incentive Programs provide incentive payments to eligible professionals, eligible hospitals, and critical access hospitals (CAHs) as they adopt, implement, upgrade or demonstrate meaningful use of certified EHR technology. Eligibility for incentive payments for the "meaningful use" of certified EHR technology is established if all program requirements are met, including successful implementation and reporting of program measures, which include this measure, to demonstrate meaningful use of EHR technology.

3. PINNACLE Registry (URL: http://cvquality.acc.org/en/NCDR-Home/Registries/Outpatient-Registries.aspx)
The PINNACLE Registry® is cardiology´s largest outpatient quality improvement registry, capturing data on coronary artery disease, hypertension, heart failure and atrial fibrillation. The PINNACLE Registry® continues to grow rapidly, with more than 2400 providers representing almost 800 unique office locations across the U.S submitting data to the registry as of the fourth quarter of 2013. As of the fourth quarter of 2013, the registry has more than 13 million patient encounter records. PINNACLE assists practices in understanding and improving care through the production and distribution of quarterly performance reports. These reports, covering all valid patient encounters, detail adherence to 28 cardiovascular clinical measures at the physician, location, and practice levels across coronary artery disease, hypertension, heart failure and atrial fibrillation. All jointly developed ACC/AHA/PCPI performance measures for these topics are reported by the registry.

4a.2. If not currently publicly reported OR used in at least one other accountability application (e.g., payment program, certification, licensing) what are the reasons? (*e.g., Do policies or actions of the developer/steward or accountable entities restrict access to performance results or impede implementation?*)
We support the expanded use of this measure in government or other programs, including those intended for accountability or public reporting. The ACC, AHA and PCPI do not have any policies that would restrict access to the performance measure

specifications or results or that would impede implementation of the measure for any application. We would welcome its implementation in emerging applications such as accountable care organizations (ACO), Medicare Advantage insurance plans or health plans selling on the new insurance marketplace.

4a.3. **If not currently publicly reported OR used in at least one other accountability application, provide a credible plan for implementation within the expected timeframes -- any accountability application within 3 years and publicly reported within 6 years of initial endorsement.** (*Credible plan includes the specific program, purpose, intended audience, and timeline for implementing the measure within the specified timeframes. A plan for accountability applications addresses mechanisms for data aggregation and reporting.*)

As described above, it is our understanding that CMS is also planning to move towards publicly reporting physician data via Physician Compare. Also, although the measure is currently in use, we support expanded use of this measure in government or other programs, including those intended for accountability or public reporting.

4b. Improvement

Progress toward achieving the goal of high-quality, efficient healthcare for individuals or populations is demonstrated. If not in use for performance improvement at the time of initial endorsement, then a credible rationale describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.

4b.1. **Progress on Improvement. (Not required for initial endorsement unless available.)**

Performance results on this measure (current and over time) should be provided in 1b.2 and 1b.4. Discuss:

- **Progress (trends in performance results, number and percentage of people receiving high-quality healthcare)**
- **Geographic area and number and percentage of accountable entities and patients included**

2013 PQRS Experience Report

2013 is the most recent year for which PQRS Experience Report measure data is available. The average performance rates on Coronary Artery Disease (CAD): Beta-Blocker Therapy-Prior Myocardial Infarction (MI) or Left Ventricular Systolic Dysfunction (LVEF <40%) over the last several years are as follows:

2010: 71.4%
2011: 82.1%
2012: 69.9%
2013: 74.2%

2013 Small Group Practice Exception Rate: 2.0%

It is important to note that PQRS was a voluntary reporting program, with approximately 51% of eligible professionals participating using any reporting option in 2013, and performance rates may not be nationally representative.

Reference: Center for Medicare and Medicaid Services. 2013 Reporting Experience Including Trends (2007-2014). Available: http://www.cms.gov/Medicare/Quality-Initiatives-Patient-Assessment-Instruments/PQRS/AnalysisAndPayment.html

4b.2. **If no improvement was demonstrated, what are the reasons? If not in use for performance improvement at the time of initial endorsement, provide a credible rationale that describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.**

While we create measures with an ultimate goal of improving the quality of care, measurement is a mechanism to drive improvement but does not equate with improvement. Measurement can help identify opportunities for improvement with actual improvement requiring making changes to health care processes and structure. In order to promote improvement, quality measurement systems need to provide feedback to front-line clinical staff in as close to real time as possible and at the point of care whenever possible. (1)

1. Conway PH, Mostashari F, Clancy C. The future of quality measurement for improvement and accountability. JAMA. 2013 Jun 5;309(21):2215-6.

4c. Unintended Consequences

The benefits of the performance measure in facilitating progress toward achieving high-quality, efficient healthcare for individuals or populations outweigh evidence of unintended negative consequences to individuals or populations (if such evidence exists).

4c.1. **Were any unintended negative consequences to individuals or populations identified during testing; OR has evidence of unintended negative consequences to individuals or populations been reported since implementation? If so, identify the negative**

unintended consequences and describe how benefits outweigh them or actions taken to mitigate them.
We are not aware of any unintended consequences at this time, but we take unintended consequences very seriously and therefore continuously monitor to identify actions that can be taken to mitigate them.

5. Comparison to Related or Competing Measures

If a measure meets the above criteria and there are endorsed or new related measures (either the same measure focus or the same target population) or competing measures (both the same measure focus and the same target population), the measures are compared to address harmonization and/or selection of the best measure.

5. Relation to Other NQF-endorsed Measures
Are there related measures (conceptually, either same measure focus or target population) or competing measures (conceptually both the same measure focus and same target population)? If yes, list the NQF # and title of all related and/or competing measures.
Yes

5.1a. **List of related or competing measures (selected from NQF-endorsed measures)**
0071 : Persistence of Beta-Blocker Treatment After a Heart Attack
0083 : Heart Failure (HF): Beta-Blocker Therapy for Left Ventricular Systolic Dysfunction (LVSD)

5.1b. **If related or competing measures are not NQF endorsed please indicate measure title and steward.**

5a. Harmonization

The measure specifications are harmonized with related measures;
OR
The differences in specifications are justified

5a.1. **If this measure conceptually addresses EITHER the same measure focus OR the same target population as NQF-endorsed measure(s):**
Are the measure specifications completely harmonized?
No

5a.2. **If the measure specifications are not completely harmonized, identify the differences, rationale, and impact on interpretability and data collection burden.**
Measure 0070 addresses a patient population of patients with CAD and either a recent prior MI or LVSD. This patient population is also covered in part by the following NQF-endorsed measures: NQF 0071: Persistence of Beta-Blocker Treatment After a Heart Attack and NQF 0083: Heart Failure (HF): Beta-Blocker Therapy for Left Ventricular Systolic Dysfunction (LVSD). The specifications are harmonized to the extent possible. As a result, the denominator specifications for the measures differ where needed based on the differing patient populations.

5b. Competing Measures

The measure is superior to competing measures (e.g., is a more valid or efficient way to measure);
OR
Multiple measures are justified.

5b.1. **If this measure conceptually addresses both the same measure focus and the same target population as NQF-endorsed measure(s):**
Describe why this measure is superior to competing measures (e.g., a more valid or efficient way to measure quality); OR provide a rationale for the additive value of endorsing an additional measure. (Provide analyses when possible.)

Appendix

A.1 Supplemental materials may be provided in an appendix. All supplemental materials (such as data collection instrument or

methodology reports) should be organized in one file with a table of contents or bookmarks. If material pertains to a specific submission form number, that should be indicated. Requested information should be provided in the submission form and required attachments. There is no guarantee that supplemental materials will be reviewed.

Additional Information

Ad.1 **Workgroup/Expert Panel involved in measure development**

Provide a list of sponsoring organizations and workgroup/panel members' names and organizations. Describe the members' role in measure development.

Work Group members:
Joseph Drozda, MD, FACC (Co-Chair) (cardiology; methodology)
Joseph V. Messer, MD, MACC, FAHA (Co-Chair) (cardiology)
John Spertus, MD, FACC, FAHA (Co-Chair) (cardiology)
Bruce Abramowitz, MD, FACC (interventional cardiology; measure implementation)
Karen Alexander, MD, FACC (cardiology; geriatrics)
Craig T. Beam, CRE (patient representative)
Robert O. Bonow, MD, MACC, FAHA, FACP (cardiology)
Jill S. Burkiewicz, PharmD, BCPS (pharmacy)
Michael Crouch, MD, MSPH (family medicine)
David C. Goff, Jr., MD, PhD, FAHA, FACP (internal medicine)
Richard Hellman, MD, FACP, FACE (endocrinology)
Thomas James, III, FACP, FAAP (health plan representative)
Marjorie L. King, MD, FACC, MAACVPR (cardiology; cardiac rehabilitation)
Edison A. Machado, Jr., MD, MBA (measure implementation)
Eduardo Ortiz, MD, MPH (internal medicine; guideline development)
Michael O'Toole, MD, FACC (cardiology; electrophysiology; measure implementation)
Stephen D. Persell, MD, MPH (internal medicine; measure implementation)
Jesse M. Pines, MD, MBA, MSCE, FAAEM (emergency medicine)
Frank J. Rybicki, MD, PhD (radiology)
Lawrence B. Sadwin (patient representative)
Joanna D. Sikkema, MSN, ANP-BC, FAHA (cardiology)
Peter K. Smith, MD (thoracic surgery)
Patrick J. Torcson, MD, FACP, MMM (hospital medicine)
John B. Wong MD, FACP (internal medicine)

ACCF, AHA, and PCPI measures are developed through cross-specialty, multi-disciplinary work groups. All medical specialties and other health care professional disciplines participating in patient care for the clinical condition or topic under study are invited to participate as equal contributors to the measure development process. In addition, the ACCF, AHA and PCPI strive to include on their work groups individuals representing the perspectives of patients, consumers, private health plans, and employers. This broad-based approach to measure development ensures buy-in on the measures from all stakeholders and minimizes bias toward any individual specialty or stakeholder group. All work groups have at least two co-chairs who have relevant clinical and/or measure development expertise and who are responsible for ensuring that consensus is achieved and that all perspectives are voiced.

Measure Developer/Steward Updates and Ongoing Maintenance

Ad.2 **Year the measure was first released:** 2003
Ad.3 **Month and Year of most recent revision:** 12, 2014
Ad.4 **What is your frequency for review/update of this measure?** Supporting guidelines and specifications for this measure are reviewed on an annual basis.

MEASURE WORKSHEET

This document summarizes the evaluation of the measure as it progresses through NQF's Consensus Development Process (CDP). The information submitted by measure developers/stewards is included after the Brief Measure Information, Preliminary Analysis, and Pre-meeting Public and Member Comments sections.

To navigate the links in the worksheet: Ctrl + click link to go to the link; ALT + LEFT ARROW to return

Brief Measure Information

NQF #: 0071
Measure Title: Persistence of Beta-Blocker Treatment After a Heart Attack
Measure Steward: National Committee for Quality Assurance
Brief Description of Measure: The percentage of patients 18 years of age and older during the measurement year who were hospitalized and discharged from July 1 of the year prior to the measurement year to June 30 of the measurement year with a diagnosis of acute myocardial infarction (AMI) and who received persistent beta-blocker treatment for six months after discharge.
Developer Rationale: This measure addresses the appropriate clinical management of a person who has experienced an AMI. Persistent beta-blocker treatment after a heart attack reduces the risk of mortality, reduces the risk and severity of reinfarction, and improves the preservation of the left ventricular function.

Numerator Statement: Patients who had a 180-day course of treatment with beta-blockers post discharge.
Denominator Statement: Patients 18 years of age and older as of December 31 of the measurement year who were hospitalized and discharged from July 1 of the year prior to the measurement year to June 30 of the measurement year with diagnosis of AMI. See question S.9 Denominator Details for methods to identify patients who qualify for the denominator.
Denominator Exclusions: Exclude from the denominator, hospitalizations in which the patient was transferred directly to a nonacute care facility for any diagnosis.

Exclude patients who are identified as having an intolerance or allergy to beta-blocker therapy. Any of the following anytime during the patient's history through the end of the continuous enrollment period meet criteria:
- Asthma (Asthma Value Set).
- COPD (COPD Value Set).
- Obstructive chronic bronchitis (Obstructive Chronic Bronchitis Value Set).
- Chronic respiratory conditions due to fumes and vapors (Chronic Respiratory Conditions Due to Fumes/Vapors Value Set).
- Hypotension, heart block >1 degree or sinus bradycardia (Beta-Blocker Contraindications Value Set).
- A medication dispensing event indicative of a history of asthma (Table PBH-D).
- Intolerance or allergy to beta-blocker therapy.

Measure Type: Intermediate Clinical Outcome
Data Source: Administrative claims, Electronic Clinical Data, Electronic Clinical Data : Pharmacy
Level of Analysis: Health Plan, Integrated Delivery System
Is this an eMeasure? ☐ **Yes** ☒ **No** **If Yes, was it re-specified from a previously endorsed measure?** ☐ **Yes** ☐

Is this a MAINTENANCE measure submission? ☒ **Yes** ☐ **No, this is a NEW measure submission.**
For a MAINTENANCE, what is the Original Endorsement Date: Aug 10, 2009 **Most Recent Endorsement Date:** Jan 18, 2012

Previous Measure Evaluation - Public & Member Comments, Developer Responses & Steering Committee Recommendations from (Cardiology Project 2010):

Public and Member Comments included:
- The facility can evaluate whether the patient has the resources to comply with medication recommendations and when available refer them to low-cost resources when they do not. The patient though is responsible for compliance. The facility and physicians can only control whether or not the beta-blocker treatment is prescribed.
- Support endorsement of this measure given a significant gap in performance.

Developer Response:
- The improvement in patient outcomes occurs only if the patients take the medication.

Clinicians can greatly influence patient compliance.
Steering Committee: Agree with developer's response.

Preliminary Analysis

The preliminary analysis was developed in response to recommendations from NQF's Consensus Task Force and measurement stakeholders as a way to enhance and streamline the measures evaluation and voting processes. The preliminary analysis will help to guide the Standing Committee evaluation of each measure by summarizing the measure developer submission, guide measure evaluation discussion, and identify topic areas for additional input. **NQF staff would like to stress that the preliminary analysis is intended to be used as a guide to facilitate the Committee's discussion and evaluation.**

Criteria 1: Importance to Measure and Report

1a. Evidence

1a. Evidence. The evidence requirements for an *intermediate clinical outcome* measure is that it is based on a systematic review (SR) and grading of the body of empirical evidence where the specific focus of the evidence matches what is being measured. Per NQF's submission criteria, this medication adherence measure is an *intermediate clinical outcomes* measure, rather than a process measure as defined by the developer.

The developer provides the following evidence for this intermediate clinical outcome measure:

- This is a health plan/integrated delivery system intermediate clinical outcome measure that calculates the percentage of patients 18 years of age and older during the measurement year who were hospitalized and discharged from July 1 of the year prior to the measurement year to June 30 of the measurement year with a diagnosis of acute myocardial infarction (AMI) and who received persistent beta-blocker treatment for six months after discharge. The developer does not describe the methodology for determining the 75% threshold of 180.
- The developer provides 2 clinical practice guidelines with 3 guideline statements for the persistent use of beta-blockers in patients diagnosed with AMI. Grading is provided for each guideline statement including for beta blockades during and after hospitalization for a STEMI a Class I/Level B, for beta-blockades in HF patients after Non-STEMI/ACS hospitalization Class I/Level C, and beta-blockades for patients with normal LVF Class IIa/Level C. They also provided a 1966-1997 seminal systematic review summarizing the quantity, quality and consistency of the evidence, and supporting the recommendations with findings, with Levels B and C "Estimate of Certainty (Precision) of Treatment".
- The developer provides decision logic from secondary prevention to intermediate clinical outcome for the persistent use of beta-blockers in reducing the risk of mortality, risk and severity of re-infarction and improving the preservation of the left ventricular function with patients with AMI.

Questions for the Committee:
- *Is the evidence directly applicable to the process of care being measured?*
- *Is the process of care proximal and closely related to desired outcomes?*
- *Does the SC agree with the methodology for determining the 75% threshold for receiving beta blockades?*

1b. Gap in Care/Opportunity for Improvement and 1b. Disparities

1b. Performance Gap. The performance gap requirements include demonstrating quality problems and opportunity for improvement.

- The developer provides data from Commercial health plans, Medicare, and Medicaid in the tables below. No additional information is provided on the number or characteristics of the patients included in these data.

  Commercial (HMO and PPO Combined)

YEAR	N	MEAN	ST DEV	10th	25th	50TH	75th	90th	IQ
2012	250	79%	8%	68%	73%	79%	84%	84%	11%
2013	252	81%	8%	71%	77%	82%	87%	91%	10%
2014	253	83%	7%	73%	78%	82%	88%	91%	10%

Medicaid

YEAR	N	MEAN	ST DEV	10th	25th	50TH	75th	90th	IQ
2012	54	80%	10%	67%	73%	83%	88%	91%	15%
2013	64	82%	9%	71%	78%	83%	88%	91%	10%
2014	75	84%	10%	72%	80%	86%	91%	95%	11%

Medicare

YEAR	N	MEAN	ST DEV	10th	25th	50TH	75th	90th	IQ
2012	255	87%	6%	79%	84%	88%	91%	94%	7%
2013	269	89%	6%	81%	85%	90%	93%	95%	8%
2014	269	90%	6%	83%	87%	91%	94%	96%	7%

N= # of health plans

- A review of the performance data provided appears to demonstrate similar commercial and Medicaid rates, and higher Medicare rates, with all rates increasing annually. Further explanation of the performance data characteristics and findings is not provided.
- The developer summarizes data from the literature on the prevalence of heart disease, medication adherence among MI survivors by disability, status, race/ethnicity, and income for all Medicare fee-for-service beneficiaries and the impact of employment status on rates of CHD/stroke.
- The developer states they do not collect performance data stratified by race, ethnicity, or language, though other HEDIS measure sets are available for stratified by demographic variables, such as race/ethnicity or socioeconomic status, in order to assess the presence of health care disparities.

Questions for the Committee:

- *Is there a gap in care that warrants a national performance measure?*
- *If no disparities information is provided, are you aware of evidence that disparities exist in this area of healthcare?*
- *Should this measure be indicated as disparities sensitive?*

1c. Priority

1c. High Priority (previously "High Impact") requires measures to address national health goal/priority or a demonstrated high-impact aspect of care.

- *Beginning in 2015, priority is no longer an NQF measure evaluation criterion.*

Committee pre-evaluation comments

Criteria 1: Importance to Measure and Report (including 1a, 1b, 1c)

1. ***Committee's Overview Comments***:
   - Moderate rating for evidence. QQC provided, with grades B and C quality for guidelines and systematic review. Additional, more recent evidence supports SR. Evidence applies directly to process.
   - This is an intermediate clinical outcome measure regarding prescription of beta blockers for 180 days post discharge from acute MI. the rationale is that persistent beta blocker treatment after an MI will reduce the risk of mortality, reduce the risk and severity of reinfarction and improve the preservation of LV function The evidence provided is from two clinical guidelines: one on management of STEMI and one on management of NONSTEMI. The STEMI guideline is graded level B that Beta blockers should be continued during and after hospitalization for all patients...but does not discuss reinfarction rates or outcomes. The actual guideline says the benefit of beta blockers for secondary prevention has been established in numerous trials conducted in the prereperfusion era and appears to be greatest for patients with MI complicated by HF, LV dysfunction or ventricular arrhythmias....long term duration not been prospectively addressed. Do NOT feel evidence supports the measure NONSTEMI guidelines...graded as level C THEREFORE would rate as Insufficient Evidence with exception

1a. ***Committee's Comments on Evidence to Support Measure Focus:***

- Moderate rating for evidence. QQC provided, with grades B and C quality for guidelines and systematic review.

Additional, more recent evidence supports SR. Evidence applies directly to process.
- Other systematic review: FREEMANTLE systematic review is old 1999 Insufficient evidence with exception

1b. ***Committee's Comments on Performance Gap:***
- Minimal performance gap noted, particularly in Medicare population. No disparities related to measure noted, though some data on indirect proxies.
- There is no statistical data to demonstrate gap in care but there is evidence that there is a disparities issue. This appears to be a disparities sensitive measure

1c. ***Committee's Comments on Composite Performance Measure:***
- Not Applicable

Criteria 2: Scientific Acceptability of Measure Properties

2a. Reliability

2a1. Reliability Specifications

2a1. Specifications requires the measure, as specified, to produce consistent (reliable) and credible (valid) results about the quality of care when implemented.
- Data sources include administrative claims and electronic clinical data including pharmacy claims.
- ICD-9, ICD-10, UBREV, and UBTOB (type of billing) codes are provided for the numerator and denominator that is readily available from administrative claims data.
- "Persistent" beta-blocker treatment is defined as at least 75% (135 days) of six months (180 days) of filled prescriptions post hospital discharge. The developer permits "allowed gap days", though further explanation is not provided.
- Beta-blockers used to calculate the numerator are provided.
- Definitions for transfers and readmissions are provided.
- Patients who are direct transfers to non-acute facilities are excluded, as well as those with intolerance and/or allergy to beta-blocker excluded (e.g. asthma, COPD, hypotension); value sets provided including medications used to identify asthma. Patients excluded for asthma are defined with diagnostic and medication codes. This structure is not similarly utilized for other pulmonary conditions in the exclusions.
- Changes to the measure since last endorsement are not provided, rather categorized as "not significant" by the developer.

Questions for the Committee:
- *Are all the data elements clearly defined? Are all appropriate codes included?*
- *Is the logic or calculation algorithm clear?*
- *Is it likely this measure can be consistently implemented?*

2a2. Reliability Testing Testing attachment

2a2. Reliability testing demonstrates if the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise enough to distinguish differences in performance across providers.

- Reliability testing for this measure was conducted at the level of the performance measure score, using the data source and level of analysis specified. The primary analysis was conducted at the health plan level and stratified by product line (253 Commercial plans, 75 Medicaid plans and 269 Medicare plans) and includes all health plans submitting data to NCQA for HEDIS in 2013.
- A signal-to-noise analysis using the beta-binomial model was conducted. This type of analysis, which is appropriate for the measure, quantifies the amount of variation in performance that is due to differences between providers (as opposed to differences that are due to random measurement error). The method results

in a reliability statistic for each health plan.

- Overall reliability (likely the average reliability for plans in each stratum) for this measure is based on data submitted from 253 commercial plans, 75 Medicaid plans, and 269 Medicare plans is between 0.78 and 0.81. A reliability of 0.70 is generally considered a minimum threshold for acceptability.

Questions for the Committee:

- *Is the test sample adequate to generalize for widespread implementation?*
- *Do the results demonstrate sufficient reliability so that differences in performance can be identified?*

2b. Validity

2b1. Validity: Specifications

2b1. Validity Specifications. This section should determine if the measure specifications are consistent with the evidence.

- The clinical practice guidelines supporting this measure recommend the persistent use of beta-blockers in patients with AMI.
- "Persistent" beta-blocker treatment is defined as at least 75% (135 days) of six months (180 days) of filled prescriptions post hospital discharge. The timeframe for determining "persistent" use and "allowed gap days", are not provided.
- The developers outline a seven step ICD-9 to ICD-10 conversion process.

Question for the Committee:

- *Are the specifications consistent with the evidence?*

2b2. Validity testing

2b2. Validity Testing should demonstrate the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality.

- Construct validity was tested by exploring whether Persistence of Beta-Blocker Treatment after a Heart Attack (#0071) correlated with 3 medication measures using a Person correlation test. The developers used the same reliability testing data source for validity testing. Developers hypothesize that plans that do well in managing patients with AMI will also do well in managing patients with other conditions. Results of the correlation analysis suggest that results for this measure are moderately and statistically significantly correlated with results from the diabetes and cardiovascular disease cholesterol control measures and COPD medication measure, confirming the construct validity hypotheses.
- Systematic assessment of face validity consists of a six step standardized process called the HEDIS measure life cycle. The steps include identifying areas of interest/gaps in care, a literature review, measure development, public comment, data collection and ongoing evaluation.
- The developers state this measure was tested for face validity with three expert panels, Cardiovascular Measurement Advisory Panel (8 physicians, 1 nurse), Technical measurement Advisory Panel (12 members) and NCQA's Clinical Programs Committee (17 members). The developer does not provide statistical results from validity testing but does state that the multiple NCQA panels agreed that the measure, as specified, accurately assesses persistence of beta blocker use for at-risk patients in health plans.
- The measure is not risk adjusted and SDS factors were not assessed for use in the measure.

Questions for the Committee:

- *Is the test sample adequate to generalize for widespread implementation?*
- *Do the results demonstrate sufficient validity so that conclusions about quality can be made?*
- *Do you agree that the score from this measure as specified is an indicator of quality?*

2b3-2b7. Threats to Validity

2b3. Exclusions:

- This measure excludes hospitalizations in which the patient was transferred directly to a non-acute care facility for any diagnosis, patients with asthma (diagnosis or medications), COPD, obstructive chronic bronchitis, hypotension/heart block >1 degree or sinus bradycardia, and patients who are identified as having an intolerance or allergy to beta-blocker therapy.
- The developer states there are no exclusions in 2b3, which is inconsistent with information provided in S.10 and S.11
- The developer does not provide information on exclusions testing and analysis.

Questions for the Committee:

- *Are the exclusions consistent with the evidence?*
- *Are any patients or patient groups inappropriately excluded from the measure?*
- *Are the exclusions/exceptions of sufficient frequency and variation across providers to be needed (and outweigh the data collection burden)?*

2b4. Risk adjustment:

- This intermediate clinical outcome measure is not risk adjusted.

Questions for the Committee:

- *Do you agree with the developer that risk adjustment is not necessary for this measure?*

2b5. Meaningful difference:

- The overall mean performance on this measure is 83% (SD = 7%) for the commercial health plans, 84% (SD=10%) for Medicaid and 90% (SD=6%) for Medicare for 2014.
- The difference between 25th and 75th percentile is statistically significant for all product lines (Commercial, Medicaid, and Medicare). The largest performance gap (11%) is in Medicaid plans. Overall, results suggest there are meaningful differences in performance and there is an opportunity for improvement.

Question for the Committee:

- *Does this measure identify meaningful differences about quality?*

2b6. Comparability of data sources/methods:

- N/A

2b7. Missing Data

- The developer states that this measure is collected with a complete sample, there is no missing data on this measure.

Committee pre-evaluation comments

Criteria 2: Scientific Acceptability of Measure Properties (including all 2a, 2b, and 2d)

2a1. &2b1.: ***Committee's Comments on Reliability-Specifications:***

- Measure specifications are clearly defined and consistent with the evidence. Measure likely to be implemented consistently. Methodology for determining "persistence" explained, but no definition of "allowed gap days."
- Denominator: concerned if there is actually a way to determine all AMIs. What if the MI goes on for CABG or Stent. Is their diagnosis now Stent or MI? Will the denominator capture these AMIs? High reliability testing reported (.81)

2a2.: ***Committee's Comments on Reliability-Testing:***

- Reliability testing was done through beta-binomial model measuring signal-to-noise ratio, and the results demonstrated moderate reliability.
- Overall .78-.81 yes

2b1.: ***Committee's Comments on Validity-Specifications***:

- Measure specifications are clearly defined and consistent with the evidence. Measure likely to be implemented consistently. Methodology for determining "persistence" explained, but no definition of "allowed gap days."

- Expert panel determined this was valid, empirical testing demonstrated a moderate correlation with other measures including comprehensive diabetes care, cholesterol management and phamacotherapy with COPD exacerbation

2b2.: ***Committee's Comments on Validity-Testing:***

- Both construct and face validity done. Construct validity done through Pearson correlation testing and results indicate moderate and statistically significant correlation. Face validity also done through three expert panels and all unanimously supported measure. No statistical results of face validity testing provided. Overall moderate validity.
- Mostly expert panel determined this was valid

2b3-7.: ***Committee's Comments on Threats to Validity:***

- Exclusions noted, though inconsistency in application. No apparent threats, but meaningful differences are noted in clinician performance. No risk adjustment done.
- According to the boxplots there is a 7-11% gap in performance between first quartile and third quartile. Largest gap is in Medicaid plans. there are meaningful differences, but small

2d.: ***Committee's Comments on Composite Performance Measure:***

- Not Applicable

Criterion 3. Feasibility

3. Feasibility is the extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

- The data source includes administrative claims, electronic clinical data, including pharmacy claims and readily available data occurring during patient care. All data elements are in defined fields in electronic claims.
- The developers do not provide specific information on the operational use of the measure; instead they outline the HEDIS Compliance Audit process to verify that HEDIS specifications are met. In addition to the audit, NCQA provides a system that allows for 'real-time' feedback from measure users.

Questions for the Committee:

- *Are the required data elements routinely generated and used during care delivery?*
- *Are the required data elements available in electronic form, e.g., EHR or other electronic sources?*
- *Is the data collection strategy ready to be put into operational use?*

Committee pre-evaluation comments

Criteria 3: Feasibility

3.: ***Committee's Comments on Feasibility:***

- Data collection obtained through administrative claims, EHRs, and other sources. No data collection barriers identified. No assessments of costs or abstraction time done. Moderate to high feasibility.
- Data from electronic clinical data, pharmacy and administrative claims. Could be put to operational use, but caution regarding denominator and identifying individuals with AMI.

Criterion 4: Usability and Use

4. Usability and Use evaluate the extent to which audiences (e.g., consumers, purchasers, providers, policymakers) use or could use performance results for both accountability and performance improvement activities.

- This measure is publicly reported in NCQA's Quality Compass and Annual State of Health Care Quality. It is also

used in scoring for accreditation of Medicare Advantage Health Plans.
- The developer reports performance improvements over the past 3 years ~ 2% annually for Medicare, Medicaid and commercial plans, and no unintended consequences were identified from measure use.

Questions for the Committee:
- *Is the measure publicly reported?*
- *Is the measure used in at least one accountability application?*
- *How can the performance results be used to further the goal of high-quality, efficient healthcare?*
- *Do the benefits of the measure outweigh any potential unintended consequences?*

Committee pre-evaluation comments
Criteria 4: Usability and Use

4.: ***Committee's Comments on Usability and Use:***
- Measure is currently reported publically through NCQA Health Plan Rankings, Accreditation, and Quality Compass. High usability.
- Benefits outweigh unintended consequences at this time. Publicly reported on Quality Compass and Annual State of health care quality

Criterion 5: Related and Competing Measures

- 0070 : Coronary Artery Disease (CAD): Beta-Blocker Therapy-Prior Myocardial Infarction (MI) or Left Ventricular Systolic Dysfunction
- The developer states that the differences between measures 0071 and 0070 do not have an impact on interpretability of publically reported rates, or the burden of data collection, because all data for both measures are collected from different data sources by different entities.

Pre-meeting public and member comments

-

NATIONAL QUALITY FORUM—Evidence (subcriterion 1a)

Measure Number (*if previously endorsed*)**:** 0071

Measure Title: Persistence of Beta-Blocker Treatment After a Heart Attack

IF the measure is a component in a composite performance measure, provide the title of the Composite Measure here: Click here to enter composite measure #/ title

Date of Submission: 6/30/2015

Instructions
- *For composite performance measures:*
  - *A separate evidence form is required for each component measure unless several components were studied together.*

- *If a component measure is submitted as an individual performance measure, attach the evidence form to the individual measure submission.*

- Respond to all questions as instructed with answers immediately following the question. All information needed to demonstrate meeting the evidence subcriterion (1a) must be in this form. An appendix of *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 10 pages (*includes questions/instructions*; minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the evidence for this measure meets NQF's evaluation criteria.

1a. Evidence to Support the Measure Focus

The measure focus is evidence-based, demonstrated as follows:

- Health outcome: [3] a rationale supports the relationship of the health outcome to processes or structures of care. Applies to patient-reported outcomes (PRO), including health-related quality of life/functional status, symptom/symptom burden, experience with care, health-related behavior.
- Intermediate clinical outcome: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured intermediate clinical outcome leads to a desired health outcome.
- Process: [5] a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured process leads to a desired health outcome.
- Structure: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured structure leads to a desired health outcome.
- Efficiency: [6] evidence not required for the resource use component.

Notes

3. Generally, rare event outcomes do not provide adequate information for improvement or discrimination; however, serious reportable events that are compared to zero are appropriate outcomes for public reporting and quality improvement.

4. The preferred systems for grading the evidence are the U.S. Preventive Services Task Force (USPSTF) grading definitions and methods, or Grading of Recommendations, Assessment, Development and Evaluation (GRADE) guidelines.

5. Clinical care processes typically include multiple steps: assess → identify problem/potential problem → choose/plan intervention (with patient input) → provide intervention → evaluate impact on health status. If the measure focus is one step in such a multistep process, the step with the strongest evidence for the link to the desired outcome should be selected as the focus of measurement. Note: A measure focused only on collecting PROM data is not a PRO-PM.

6. Measures of efficiency combine the concepts of resource use and quality (see NQF's Measurement Framework: Evaluating Efficiency Across Episodes of Care; AQA Principles of Efficiency Measures).

1a.1.This is a measure of: (*should be consistent with type of measure entered in De.1*)

Outcome

☐ Health outcome: Click here to name the health outcome

☐Patient-reported outcome (PRO): Click here to name the PRO

PROs include HRQoL/functional status, symptom/symptom burden, experience with care, health-related behaviors

☒ Intermediate clinical outcome (*e.g., lab value*): A 180-day course of treatment with beta-blockers

☐ Process:

☐ Structure: Click here to name the structure

☐ Other: Click here to name what is being measured

HEALTH OUTCOME/PRO PERFORMANCE MEASURE *If not a health outcome or PRO, skip to 1a.3*

1a.2. Briefly state or diagram the path between the health outcome (or PRO) and the healthcare structures, processes, interventions, or services that influence it.

N/A

1a.2.1. State the rationale supporting the relationship between the health outcome (or PRO) to at least one healthcare structure, process, intervention, or service (*i.e., influence on outcome/PRO*).

N/A

Note: For health outcome/PRO performance measures, no further information is required; however, you may provide evidence for any of the structures, processes, interventions, or service identified above.

INTERMEDIATE OUTCOME, PROCESS, OR STRUCTURE PERFORMANCE MEASURE

1a.3. Briefly state or diagram the path between structure, process, intermediate outcome, and health outcomes. Include all the steps between the measure focus and the health outcome.

Patient 18 years of age and older is hospitalized>>> Health care provider diagnoses patient with acute myocardial infarction (AMI)>>> Health care provider and patient discuss the risk and benefits of beta-blocker therapy post discharge>>> Patient is dispensed a 180-day course of treatment with beta-blockers>>> Persistent beta-blocker use in patient's treatment reduces the risk of mortality, reduces the risk and severity of reinfarction, and improves the preservation of the left ventricular function>>> Improvement in quality of life and functioning for patient (Desired outcome).

1a.3.1. What is the source of the systematic review of the body of evidence that supports the performance measure?

☒ Clinical Practice Guideline recommendation – ***complete sections 1a.4, and 1a.7***

☐ US Preventive Services Task Force Recommendation – ***complete sections 1a.5 and 1a.7***

☐ Other systematic review and grading of the body of evidence (*e.g., Cochrane Collaboration, AHRQ Evidence Practice Center*) – ***complete sections 1a.6 and 1a.7***

☐ Other – ***complete section 1a.8***

Please complete the sections indicated above for the source of evidence. You may skip the sections that do not apply.

1a.4. CLINICAL PRACTICE GUIDELINE RECOMMENDATION

1a.4.1. Guideline citation (*including date*) and **URL for guideline** (*if available online*):

ST-Elevation Myocardial Infarction (STEMI) Guideline:

O'Gara PT, Kushner FG, Ascheim DD, et al. 2013 ACCF/AHA Guideline for the Management of ST-Elevation Myocardial Infarction : A Report of the American College of Cardiology Foundation/American Heart Association Task Force on Practice Guidelines. J Am Coll Cardiol. 2013;61(4):e78-e140. doi:10.1016/j.jacc.2012.11.019

- URL: http://content.onlinejacc.org/article.aspx?articleid=1486115

Non-ST Elevation Myocardial Infarction (NSTEMI) Guideline:

Amsterdam EA, Wenger NK, Brindis RG, et al. 2014 AHA/ACC Guideline for the Management of Patients With Non–ST-Elevation Acute Coronary Syndromes: Executive Summary: A Report of the American College of Cardiology/American Heart Association Task Force on Practice Guidelines. J Am Coll Cardiol. 2014;64(24):2645-2687. doi:10.1016/j.jacc.2014.09.016.

- URL: http://content.onlinejacc.org/article.aspx?articleid=1910085&resultClick=3

1a.4.2. Identify guideline recommendation number and/or page number and **quote verbatim, the specific guideline recommendation**.

Guideline	Recommendation	Verbatim Quote	Estimate of Certainty (Precision) of Treatment	Size of Treatment Effect
STEMI Guideline	1	"Beta blockers should be continued during and after hospitalization for all patients with STEMI and with no contradictions to their use."	Level B	Class I
NSTEMI GUIDELINE	2	"In patients with concomitant NSTE-ACS [non-ST-elevation acute coronary syndrome], stabilized HF [heart failure], and reduced systolic function, it is recommended to continue beta blocker therapy with 1 of the 3 drugs proven to reduce mortality in patients with HF: sustained-release metoprolol succinate, carvedilol, or bosoprolol."	Level C	Class I
NSTEMI GUIDELINE	3	"It is reasonable to continue beta blocker therapy in patients with normal LV [left ventricular] function with NSTE-ACS"	Level C	Class lla

1a.4.3. Grade assigned to the quoted recommendation <u>with definition</u> of the grade:

Both STEMI and NSTEMI guidelines use the same grading system.

Guideline	Recommendation	Size of Treatment	Definition of Class

		Effect (Grade)	
STEMI	1	Class I	Benefit > > > Risk Procedure/Treatment SHOULD be performed/administered
NSTEMI	2	Class I	Benefit > > > Risk Procedure/Treatment SHOULD be performed/administered
NSTEMI	3	Class IIa	Benefit > > Risk Additional studies with focused objective needed **IT IS REASONABLE** to perform procedure/administer treatment

1a.4.4. Provide all other grades and associated definitions for recommendations in the grading system. (*Note: If separate grades for the strength of the evidence, report them in section 1a.7.*)

Size of Treatment Effect (Grade)	Definition of Class
Class IIb	Benefit ≥ Risk Additional studies with broad objectives needed; additional registry data would be helpful Procedure/Treatment **MAY BE CONSIDERED**
Class III- No benefit	No Benefit Procedure/Test- Not Helpful Treatment- No proven benefit
Class III - Harm	Harm Procedure/Test – Excess cost without benefit or harmful Treatment- Harmful to patients

1a.4.5. Citation and URL for methodology for grading recommendations (*if different from 1a.4.1*)**:**

Both guidelines cited in 1a.4.1 use the same methodology for grading recommendations.

1a.4.6. If guideline is evidence-based (rather than expert opinion), are the details of the quantity, quality, and consistency of the body of evidence available (e.g., evidence tables)?

☐ Yes → ***complete section 1a.7***

☒ No → ***report on another systematic review of the evidence in sections 1a.6 and 1a.7; if another review does not exist, provide what is known from the guideline review of evidence in 1a.7***

1a.5. UNITED STATES PREVENTIVE SERVICES TASK FORCE RECOMMENDATION

1a.5.1. Recommendation citation (*including date*) and **URL for recommendation** (*if available online*):

1a.5.2. Identify recommendation number and/or page number and **quote verbatim, the specific recommendation**.

1a.5.3. Grade assigned to the quoted recommendation with definition of the grade:

1a.5.4. Provide all other grades and associated definitions for recommendations in the grading system. (*Note: the grading system for the evidence should be reported in section 1a.7.*)

1a.5.5. Citation and URL for methodology for grading recommendations (*if different from 1a.5.1*)**:**

Complete section 1a.7

1a.6. OTHER SYSTEMATIC REVIEW OF THE BODY OF EVIDENCE

1a.6.1. Citation (*including date*) and **URL** (*if available online*):

Both guidelines used to support this measure cover a much wider topic area than just secondary prevention of myocardioal infarction with persistent beta-blocker therapy treatment and do not discuss in detail the evidence review process for each recommendation supporting the persistence of beta-blocker treatment after heart attack measure. They do, however, provide a grade of evidence for each of the recommendations and cite systematic reviews supporting those recommendations. Therefore, to answer the questions in 1a.7, we are using the evidence grades the guidelines provide and referencing one seminal systematic review cited in the guidelines that summarizes the body of evidence supporting the recommendations.

- Freemantle N, Cleland J, Young P, Mason J, Harrison J. Beta blockade after myocardial infarction: systematic review and meta regression analysis. BMJ. 1999;318:1730–1737.

http://www.ncbi.nlm.nih.gov/pubmed/10381708

1a.6.2. Citation and URL for methodology for evidence review and grading (*if different from 1a.6.1*)**:**

Both guidelines cited in 1a.4.1 use the same methodology for grading evidence.

Complete section 1a.7

1a.7. FINDINGS FROM SYSTEMATIC REVIEW OF BODY OF THE EVIDENCE SUPPORTING THE MEASURE

If more than one systematic review of the evidence is identified above, you may choose to summarize the one (or more) for which the best information is available to provide a summary of the quantity, quality, and consistency of the body of evidence. Be sure to identify which review is the basis of the responses in this section and if more than one, provide a separate response for each review.

1a.7.1. What was the specific structure, treatment, intervention, service, or intermediate outcome addressed in the evidence review?

The evidence for this measure focuses on the importance of beta blocker therapy in long-term secondary prevention of acute myocardial infarction (AMI). It is important to note that a systematic evidence review completed by Freemantle et al., in 1999 supports and is referenced by both STEMI and NSTEMI guidelines.

Freemantle et al. assessed the effectiveness of beta-blockers in longer-term secondary prevention of AMI using randomized controlled trials (RCTs). The review focused on RCTs that compared beta-blockers to placebo.

1a.7.2. Grade assigned for the quality of the quoted evidence with definition of the grade:

Guideline	Recommendation	Estimate of Certainty (Precision) of Treatment	Definition of Level:
STEMI Guideline	**1**	**B**	Limited populations evaluated* Data derived from a single randomized trial or nonrandomized studies
NSTEMI Guideline	**2**	**C**	Very limited populations* Only consensus opinion of experts, case

			studies, or standard of care
NSTEMI Guideline	**3**	**C**	Very limited populations* Only consensus opinion of experts, case studies, or standard of care

*Data available from clinical trials or registries about the usefulness/efficacy in different subpopulations, such as sex, age, history of diabetes, history of prior myocardial infarction, history of heart failure, and prior aspirin use.

1a.7.3. Provide all other grades and associated definitions for strength of the evidence in the grading system.

Estimate of Certainty (Percision) of Treatment	Definition of Level:
A	Multiple populations evaluated* Data derived from multiple randomized clinical trials or meta-analyses

*Data available from clinical trials or registries about the usefulness/efficacy in different subpopulations, such as sex, age, history of diabetes, history of prior myocardial infarction, history of heart failure, and prior aspirin use.

1a.7.4. What is the time period covered by the body of evidence? (*provide the date range, e.g., 1990-2010*). Date range:

It should be noted that the body of evidence supporting the guideline recommendations is much broader and includes more recent evidence than the evidence used in the Freemantle et al. systematic review which includes studies published from 1966-1997.

QUANTITY AND QUALITY OF BODY OF EVIDENCE

1a.7.5. How many and what type of study designs are included in the body of evidence? (*e.g., 3 randomized controlled trials and 1 observational study*)

There are 31 long-term randomized controlled trials included in the systematic evidence review by Freemantle et al. (1999), which supports the STEMI and NSTEMI guideline recommendations regarding persistent beta-blocker treatment after heart attack.

1a.7.6. What is the overall quality of evidence <u>across studies</u> in the body of evidence? (*discuss the certainty or confidence in the estimates of effect particularly in relation to study factors such as design flaws, imprecision due to small numbers, indirectness of studies to the measure focus or target population*)

The Freemantle et al. systematic evidence review rated the quality of studies as reasonably high, with adequate follow-up achieved in many trials.

ESTIMATES OF BENEFIT AND CONSISTENCY ACROSS STUDIES IN BODY OF EVIDENCE

1a.7.7. What are the estimates of benefit—magnitude and direction of effect on outcome(s) <u>across studies</u> in the body of evidence? (*e.g., ranges of percentages or odds ratios for improvement/decline across studies, results of meta-analysis, and statistical significance*)

Considerable evidence supports the routine long term use of beta blockers in patients who have had a myocardial infarction, with substantial benefits in terms of reduced mortality and morbidity.

Freemantle et al., use a random effects approach in long term trials for incidence of risk difference to estimate to normalized annual reduction in mortality across trials. This approach suggests an annual reduction of 1.2 deaths in 100 patients treated with beta-blockers after myocardial infarction; that is about 84 patients will require treatment for 1 year to avoid one death. A similar approach was used to estimate the effects of treatment on reinfarction, although only 21 of the 34 comparisons provided data on reinfarction, resulting in wider confidence intervals and the potential for reporting bias. This analysis suggests an annual reduction in reinfarction of 0.9 events every 100 (0.3 to 1.6); that is about 107 patients would require treatment of 1 year to avoid one non-fatal reinfarction. There was a 23% reduction in the odds of death in long term trials (95% confidence interval 15% to 31%).

1a.7.8. What harms were studied and how do they affect the net benefit (benefits over harms)?

The guidelines and systematic review provide extremely limited findings regarding harm associated with persistent beta blocker treatment after a heart attack. Freemantle et al., studied withdrawal from treatment for both active treatment and placebo groups. The trials reported that dizziness, depression, cold extremitites, and fatigue were only marginally more common in the treatment than control groups. This supports the fact that the benefits of beta-blocker treatment significantly outweigh the minor treatment harms.

UPDATE TO THE SYSTEMATIC REVIEW(S) OF THE BODY OF EVIDENCE

1a.7.9. If new studies have been conducted since the systematic review of the body of evidence, provide for <u>each</u> new study: 1) citation, 2) description, 3) results, 4) impact on conclusions of systematic review.

There have been many (>100) studies examining the use of beta blockers in patients who have had an MI since the publication of the systematic reviews used to generate the STEMI and NSTEMI guidelines. An article published in 2012 by Bangalore et al., confirms that beta-blockers remain the standard of care after a myocardial infarction. This study also references the findings from the Freemantle et al., systematic review used to support the recommendations for our measure.

Bangalore S, Steg G, Deedwania P, et al. β-Blocker Use and Clinical Outcomes in Stable Outpatients With and Without Coronary Artery Disease. *JAMA.* 2012;308(13):1340-1349. doi:10.1001/jama.2012.12559.

1a.8 OTHER SOURCE OF EVIDENCE

If source of evidence is NOT from a clinical practice guideline, USPSTF, or systematic review, please describe the evidence on which you are basing the performance measure.

1a.8.1 What process was used to identify the evidence?

1a.8.2. Provide the citation and summary for each piece of evidence.

1. Evidence, Performance Gap, Priority – Importance to Measure and Report

Extent to which the specific measure focus is evidence-based, important to making significant gains in healthcare quality, and improving health outcomes for a specific high-priority (high-impact) aspect of healthcare where there is variation in or overall less-than-optimal performance. ***Measures must be judged to meet all subcriteria to pass this criterion and be evaluated against the remaining criteria.***

1a. Evidence to Support the Measure Focus – See attached Evidence Submission Form
FINAL_Evidence_Form_0071_PBH.docx

1b. Performance Gap

Demonstration of quality problems and opportunity for improvement, i.e., data demonstrating:

- considerable variation, or overall less-than-optimal performance, in the quality of care across providers; and/or
- disparities in care across population groups.

1b.1. **Briefly explain the rationale for this measure** *(e.g., the benefits or improvements in quality envisioned by use of this measure)*
This measure addresses the appropriate clinical management of a person who has experienced an AMI. Persistent beta-blocker treatment after a heart attack reduces the risk of mortality, reduces the risk and severity of reinfarction, and improves the preservation of the left ventricular function.

1b.2. **Provide performance scores on the measure as specified (current and over time) at the specified level of analysis.** *(This is required for endorsement maintenance. Include mean, std dev, min, max, interquartile range, scores by decile. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities included). This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*
The following data are extracted from HEDIS data collection and reflect the most recent years of measurement for this measure. Performance data is summarized at the health plan level and summarized by the mean, standard deviation, performance percentiles (10th, 25th, 50th, 75th and 90th percentile) and the interquartile range. Data is stratified by year and product line (i.e. commercial, Medicare, Medicaid, HMO and PPO) at the health plan level.

Persistence of Beta-Blocker Treatment After a Heart Attack

N=Number of Health Plans

Commercial (HMO and PPO Combined)
YEAR|N|MEAN|ST DEV|10TH| 25TH| 50TH|75TH|90TH|Interquartile Range
2012|250|79%|8%|68%|73%|79%|84%|89%|11%
2013|252|81%|8%|71%|77%|82%|87%|91%|10%
2014|253|83%|7%|73%|78%|82%|88%|91% |10%

Medicaid

2012|255|87%|6%|79%|84%|88%|91%|94%|7%
2013|269|89%|6%|81%|85%|90%|93%|95%|8%
2014|269|90%|6%|83%|87%|91%|94%|96%|7%

1b.3. **If no or limited performance data on the measure as specified is reported in 1b2, then provide a summary of data from the literature that indicates opportunity for improvement or overall less than optimal performance on the specific focus of measurement.**
N/A

1b.4. **Provide disparities data from the measure as specified (current and over time) by population group, e.g., by race/ethnicity, gender, age, insurance status, socioeconomic status, and/or disability.** *(This is required for endorsement maintenance. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities include.) This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*
HEDIS data are stratified by type of insurance (e.g. commercial, Medicaid, Medicare). NCQA does not currently collect performance data stratified by race, ethnicity, or language. Escarce et al. have described in detail the difficulty of collecting valid data on race, ethnicity and language at the health plan level (Escarce, 2011). While not specified in the measure, this measure can also be stratified by demographic variables, such as race/ethnicity or socioeconomic status, in order to assess the presence of health care disparities. The HEDIS Health Plan Measure Set contains two measures that can assist with stratification to assess health care disparities. The Race/Ethnicity Diversity of Membership and the Language Diversity of Membership measures were designed to promote standardized methods for collecting these data and follow Office of Management and Budget and Institute of Medicine guidelines for collecting and categorizing race/ethnicity and language data. In addition, NCQA's Multicultural Health Care Distinction Program outlines standards for collecting, storing and using race/ethnicity and language data to assess health care disparities. Based on extensive work by NCQA to understand how to promote culturally and linguistically appropriate services among plans and providers, we have many examples of how health plans have used HEDIS measures to design quality improvement programs to decrease disparities in care.

Escarce JJ, Carreon R, Veselovskiy G, Lawson EG. Collection of Race and Ethnicity Data by Health plans has Grown Substantially, but opportunities Remain to Expand Efforts. Health Affairs (Millwood) 2011; 30(10):1984-91.
http://www.ncbi.nlm.nih.gov/pubmed/21976343

1b.5. **If no or limited data on disparities from the measure as specified is reported in 1b4, then provide a summary of data from the literature that addresses disparities in care on the specific focus of measurement. Include citations.**
Heart disease is the leading cause of death for people of most ethnicities in the United States, including African Americans, Hispanics, and whites. For American Indians or Alaska Natives and Asians or Pacific Islanders, heart disease is the second leading cause of death (CDC, 2015). Non-Hispanic black adults are at least 50% more likely to die of heart disease or stroke prematurely (i.e., before age 75 years) than their non-Hispanic white counterparts (CDC, 2013). Black women and men are more likely to die before age 75 as a result of coronary heart disease (CHD) than white women and men (rates of death are 37.9%, 61.5%, 19.4%, and 41.5%, respectively) (CDC, 2011). Racial and age-related disparities also exist in rates of recurrent MI or fatal CHD within 5 years of a first MI. Of those who have a first MI, the percentage with a recurrent event is as follows: at 45 to 64 years of age, 14% of white men, 18% of white women, 22% of black men, and 28% of black women; at =65 years of age, 21% of white men and women, 33% of black men, and 26% of black women (Mozaffarian et al., 2015).

A 2012 study by Zhang et al. compared medication adherence among MI survivors by disability, status, race/ethnicity, and income for all Medicare fee-for-service beneficiaries discharged post-MI in 2008. Among the disabled who were taking beta-blockers, the percentage of beneficiaries with good adherence for 6-month adherence was highest for Whites at 67% and lowest for Blacks at 52% with Asians, Hispanics, and Native Americans ranging in between. (Zhang et al., 2012). Moreover, 1 year adherence rates among beneficiaries were 68%, 66%, 61%, 58%, and 57% for Whites, Asians, Hispanics, Native Americans and Backs respectively. A comparison by income showed that among dual eligibles, Black beneficiaries were less likely to have good adherence compared to White beneficiaries at both 6 months and 1-year post-MI (Zhang et al., 2012).

The CDC analyzed data from 2008-2012 to identify if employment status had an impact on rates of CHD/stroke. The results of this analysis showed that 1.9% of employed adults aged <55 years reported a history of CHD/stroke, compared with 2.5% of unemployed adults looking for work, and 6.3% of adults not in the labor force. Workers employed in service and blue collar occupations were more likely than those in white collar occupations to report a history of CHD/stroke (Luckhaupt, 2014).

1c. High Priority (previously referred to as High Impact)

The measure addresses:

- a specific national health goal/priority identified by DHHS or the National Priorities Partnership convened by NQF; OR
- a demonstrated high-priority (high-impact) aspect of healthcare (e.g., affects large numbers of patients and/or has a substantial impact for a smaller population; leading cause of morbidity/mortality; high resource use (current and/or future); severity of illness; and severity of patient/societal consequences of poor quality).

1c.1. Demonstrated high priority aspect of healthcare

Affects large numbers, A leading cause of morbidity/mortality, High resource use

1c.2. If Other:

1c.3. Provide epidemiologic or resource use data that demonstrates the measure addresses a high priority aspect of healthcare. List citations in 1c.4.

Heart disease is the leading cause of death in the United States (CDC, 2015). Approximately every 34 seconds, someone in the United States has a heart attack, and approximately every 90 seconds, an American dies of one (Mozaffarian, et al., 2015). Every year an estimated 735,000 Americans have a heart attack. Of these, 210,000 have had at least one prior heart attack, while the remaining 525,000 have their first heart attack (Mozaffarian, et al., 2015). About 15% of people who have a heart attack will die from it (Mozaffarian, et al., 2015). High blood pressure, high cholesterol and smoking can lead to heart disease and heart attack. Nearly half of Americans adults have one or more of these risk factors (CDC, 2011).

The estimated annual costs for cardiovascular disease (CVD) and stroke in the United States for 2011 was $320.1 billion. This figure includes $195.6 billion for in direct costs and $124.5 billion in indirect costs from lost future productivity. CVD costs more than any other diagnostic group (Mozaffarian, et al., 2015).

Beta-blocker treatment decreases the likelihood of sudden cardiac death (Kezerashivili, 2012).
Beta-blockers are heart medications that work, in part, by lowering the heart rate, which reduces the amount of force on the heart and blood vessels (AHA, 2013). Treatment with beta-blockers after a heart attack can help reduce blood pressure (AHA, 2014). Around 70% of people who have a heart attack also have high blood pressure (Mozaffarian, et al., 2015). Although beta blockers can reduce chest pain and decrease the likelihood of a future heart attack, only 52% of heart-attack patients adhere to their beta-blocker treatment at 180 days post discharge. (AHA, 2015. Kramer, et al 2006).

1c.5. **If a PRO-PM (e.g. HRQoL/functional status, symptom/burden, experience with care, health-related behaviors), provide evidence that the target population values the measured PRO and finds it meaningful.** *(Describe how and from whom their input was obtained.)*

2. Reliability and Validity—Scientific Acceptability of Measure Properties

Extent to which the measure, as specified, produces consistent (reliable) and credible (valid) results about the quality of care when implemented. ***Measures must be judged to meet the subcriteria for both reliability and validity to pass this criterion and be evaluated against the remaining criteria.***

2a.1. Specifications The measure is well defined and precisely specified so it can be implemented consistently within and across organizations and allows for comparability. eMeasures should be specified in the Health Quality Measures Format (HQMF) and the Quality Data Model (QDM).

De.5. **Subject/Topic Area** *(check all the areas that apply):*
Cardiovascular, Cardiovascular : Acute Myocardial Infarction, Prevention

De.6. **Cross Cutting Areas** *(check all the areas that apply):*
Prevention

S.1. **Measure-specific Web Page** *(Provide a URL link to a web page specific for this measure that contains current detailed specifications including code lists, risk model details, and supplemental materials. Do not enter a URL linking to a home page or to general information.)*
http://www.ncqa.org/tabid/59/Default.aspx

S.2a. **If this is an eMeasure**, HQMF specifications must be attached. Attach the zipped output from the eMeasure authoring tool (MAT) - if the MAT was not used, contact staff. (Use the specification fields in this online form for the plain-language description of the specifications)
This is not an eMeasure **Attachment:**

S.2b. **Data Dictionary, Code Table, or Value Sets** *(and risk model codes and coefficients when applicable) must be attached. (Excel or csv file in the suggested format preferred - if not, contact staff)*
Attachment **Attachment:** 0071_PBH_Value_Sets_Final.xlsx

S.3. **For endorsement maintenance**, please briefly describe any changes to the measure specifications since last endorsement date

and explain the reasons.
There are no significant changes to the measure specification since the last endorsement maintenance completed on January 18, 2012.

S.4. **Numerator Statement** *(Brief, narrative description of the measure focus or what is being measured about the target population, i.e., cases from the target population with the target process, condition, event, or outcome)*
IF an OUTCOME MEASURE, state the outcome being measured. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
Patients who had a 180-day course of treatment with beta-blockers post discharge.

S.5. **Time Period for Data** *(What is the time period in which data will be aggregated for the measure, e.g., 12 mo, 3 years, look back to August for flu vaccination? Note if there are different time periods for the numerator and denominator.)*
Numerator: 12 month measurement period (calendar year) plus a 6 month look back period.
Denominator: A 12 month period beginning on July 1 of the year prior to the measurement year through June 30 of the measurement year.

S.6. **Numerator Details** *(All information required to identify and calculate the cases from the target population with the target process, condition, event, or outcome such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
IF an OUTCOME MEASURE, describe how the observed outcome is identified/counted. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
ADMINISTRATIVE
Patients who had a 180-day course of treatment with beta-blockers post-discharge. Post discharge refers to patients discharged from an acute inpatient setting with an AMI (AMI Value Set) from July 1 of the year prior to the measurement year through June 30 of the measurement year.

In order to identify patients with "persistent" beta-blocker treatment, identify all patients in the denominator population whose dispensed days supply is =135 days in the 180-day measurement interval. The measure defines persistence of treatment as at least 75 percent of the days supply filled.

To determine continuity of treatment during the 180-day period, identify all prescriptions filled within the 180-day measurement interval, and add the number of allowed gap days (up to 45 days) to the number of treatment days for a maximum of 180 days (i.e., 135 treatment days + 45 gap days = 180 days).

To account for patients who are on beta-blockers prior to admission, factor those prescriptions into adherence rates if the actual treatment days fall within the 180-day measurement interval.

DEFINITIONS
Treatment days (days covered) - The actual number of calendar days covered with prescriptions within the specified 180-day measurement interval (i.e., a prescription of a 90-day supply dispensed on the 100th day will have 80 days counted in the 180-day interval).

180-day measurement interval - The 180 day period that includes the discharge date and the 179 days after discharge.

TABLE PBH-B BETA-BLOCKER MEDICATIONS
DESCRIPTION / PRESCRIPTION
Noncardioselective beta-blockers / Carvedilol; Labetalol; Nadolol; Penbutolol; Pindolol; Propranolol; Timlol; Sotalol
Cardioselective beta-blockers / Acebutolol; Atenolol; Betaxolol; Bisoprolol; Metoprolol; Nebivolol
Antihypertensive combinations / Atenolol-chlorthalidone; Bendroflumethiazide-nadolol; Bisoprolol-hydrochlorothiazide; Hydrochlorothiazide-metoprolol; Hydrochlorothiazide-propranolol

S.7. **Denominator Statement** *(Brief, narrative description of the target population being measured)*
Patients 18 years of age and older as of December 31 of the measurement year who were hospitalized and discharged from July 1 of the year prior to the measurement year to June 30 of the measurement year with diagnosis of AMI. See question S.9 Denominator Details for methods to identify patients who qualify for the denominator.

S.8. **Target Population Category** *(Check all the populations for which the measure is specified and tested if any):*

Populations at Risk

S.9. **Denominator Details** *(All information required to identify and calculate the target population/denominator such as definitions, specific data collection items/responses , code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
Patients discharged from an acute inpatient setting with an AMI (AMI Value Set) from July 1 of the year prior to the measurement year through June 30 of the measurement year.

Use only facility claims to identify denominator events (including readmissions or direct transfers). Do not use professional claims.

If a patient has more than one episode of AMI from July 1 of the year prior to the measurement year through June 30 of the measurement year, only include the first discharge.

Transfers to acute facilities: Include hospitalizations in which the patient was transferred directly to another acute inpatient facility for any diagnosis. Count the discharge from the subsequent acute inpatient facility, not the initial discharge. The discharge date from the facility to which the patient was transferred must occur on or before
June 30 of the measurement year.

Transfers to nonacute facilities. Exclude from the denominator, hospitalizations in which the patient was transferred directly to a nonacute care facility for any diagnosis.

Readmissions: If the patient was readmitted to an acute or nonacute care facility for any diagnosis, include the patient in the denominator and use the discharge date from the original hospitalization.

Due to the extensive volume of codes associated with identifying the denominator for this measure, we are attaching a separate file with code value sets. See code value sets located in question S.2b.

S.10. **Denominator Exclusions** *(Brief narrative description of exclusions from the target population)*
Exclude from the denominator, hospitalizations in which the patient was transferred directly to a nonacute care facility for any diagnosis.

Exclude patients who are identified as having an intolerance or allergy to beta-blocker therapy. Any of the following anytime during the patient's history through the end of the continuous enrollment period meet criteria:
- Asthma (Asthma Value Set).
- COPD (COPD Value Set).
- Obstructive chronic bronchitis (Obstructive Chronic Bronchitis Value Set).
- Chronic respiratory conditions due to fumes and vapors (Chronic Respiratory Conditions Due to Fumes/Vapors Value Set).
- Hypotension, heart block >1 degree or sinus bradycardia (Beta-Blocker Contraindications Value Set).
- A medication dispensing event indicative of a history of asthma (Table PBH-D).
- Intolerance or allergy to beta-blocker therapy.

S.11. **Denominator Exclusion Details** *(All information required to identify and calculate exclusions from the denominator such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
MEDICATIONS TO IDENTIFY EXCLUSIONS (History of Asthma)
DESCRIPTION / PRESCRIPTION
Bronchodilator combinations / Albuterol-ipratropium; Budesonide-formoterol; Fluticasone-salmeterol; Mometasone-formoterol
Inhaled corticosteroids / Beclomethasone; Budesonide; Ciclesonide; Flunisolide; Fluticasone; Fluticasone CFC free; Mometasone; Triamcinolone

Due to the extensive volume of codes associated with identifying denominator exclusions for this measure we are attaching a separate file with code value sets (except for medications to identify patients with a history of asthma). See code value sets located in question S.2b.

S.12. **Stratification Details/Variables** *(All information required to stratify the measure results including the stratification variables, definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format with at S.2b)*

N/A

S.13. **Risk Adjustment Type** (Select type. Provide specifications for risk stratification in S.12 and for statistical model in S.14-15)
No risk adjustment or risk stratification
If other:

S.14. **Identify the statistical risk model method and variables** *(Name the statistical method - e.g., logistic regression and list all the risk factor variables. Note - risk model development and testing should be addressed with measure testing under Scientific Acceptability)*
N/A

S.15. **Detailed risk model specifications** *(must be in attached data dictionary/code list Excel or csv file. Also indicate if available at measure-specific URL identified in S.1.)*
Note: Risk model details (including coefficients, equations, codes with descriptors, definitions), should be provided on a separate worksheet in the suggested format in the Excel or csv file with data dictionary/code lists at S.2b.

S.15a. **Detailed risk model specifications** (*if not provided in excel or csv file at S.2b*)

S.16. **Type of score:**
Rate/proportion
If other:

S.17. **Interpretation of Score** *(Classifies interpretation of score according to whether better quality is associated with a higher score, a lower score, a score falling within a defined interval, or a passing score)*
Better quality = Higher score

S.18. **Calculation Algorithm/Measure Logic** *(Describe the calculation of the measure score as an ordered sequence of steps including identifying the target population; exclusions; cases meeting the target process, condition, event, or outcome; aggregating data; risk adjustment; etc.)*
STEP 1. Determine the eligible population. To do so, identify patients who meet all specified criteria.
-AGES: 18 years and older as of December 31 of the measurement year.
-EVENT/DIAGNOSIS: Identify patients who were discharged from an acute setting with an AMI (AMI Value Set) from July 1 of the year prior to the measurement year through June 30 of the measurement year. Use only facility claims.
STEP 2: Exclude patients who meet the exclusions criteria. SEE S.10 AND S.11 FOR DENOMINATOR EXCLUSION CRITERIA AND DETAILS.
STEP 3: Determine the number of patients in the eligible population who were given a 180-day course of treatment with beta blockers post discharge.
STEP 4: Identify patients whose dispensed days supply is = 135 days in the 180-day measurement interval
STEP 5: Calculate the rate by dividing the numerator (Step 4) by the denominator (after exclusions) (Step 2).

S.19. **Calculation Algorithm/Measure Logic Diagram URL or Attachment** *(You also may provide a diagram of the Calculation Algorithm/Measure Logic described above at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
No diagram provided

S.20. **Sampling** *(If measure is based on a sample, provide instructions for obtaining the sample and guidance on minimum sample size.)*
IF a PRO-PM, identify whether (and how) proxy responses are allowed.
N/A

S.21. **Survey/Patient-reported data** *(If measure is based on a survey, provide instructions for conducting the survey and guidance on minimum response rate.)*
IF a PRO-PM, specify calculation of response rates to be reported with performance measure results.
N/A

S.22. **Missing data** (specify how missing data are handled, e.g., imputation, delete case.)
Required for Composites and PRO-PMs.

N/A

S.23. **Data Source** *(Check ONLY the sources for which the measure is SPECIFIED AND TESTED).*
If other, please describe in S.24.
Administrative claims, Electronic Clinical Data, Electronic Clinical Data : Pharmacy

S.24. **Data Source or Collection Instrument** *(Identify the specific data source/data collection instrument e.g. name of database, clinical registry, collection instrument, etc.)*
IF a PRO-PM, identify the specific PROM(s); and standard methods, modes, and languages of administration.
This measure is based on administrative claims collected in the course of providing care to health plan members. NCQA collects the Healthcare Effectiveness Data and Information Set (HEDIS) data for this measure directly from Health Management Organizations and Preferred Organizations via NCQA's online data submission system.

S.25. **Data Source or Collection Instrument** *(available at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
No data collection instrument provided

S.26. **Level of Analysis** *(Check ONLY the levels of analysis for which the measure is SPECIFIED AND TESTED)*
Health Plan, Integrated Delivery System

S.27. **Care Setting** *(Check ONLY the settings for which the measure is SPECIFIED AND TESTED)*
Ambulatory Care : Clinician Office/Clinic
If other:

S.28. **COMPOSITE Performance Measure** - Additional Specifications *(Use this section as needed for aggregation and weighting rules, or calculation of individual performance measures if not individually endorsed.)*
N/A

2a. Reliability – See attached Measure Testing Submission Form
2b. Validity – See attached Measure Testing Submission Form
FINAL_Testing_Form_0071_PBH.docx

NATIONAL QUALITY FORUM—Measure Testing (subcriteria 2a2, 2b2-2b7)

Measure Number (*if previously endorsed*)**:** 0071
Measure Title: Persistence of Beta-Blocker Treatment After a Heart Attack
Date of Submission: 6/30/2015
Type of Measure:

☐ Composite – ***STOP – use composite testing form***	☐ Outcome (*including PRO-PM*)
☐ Cost/resource	☒ Process
☐ Efficiency	☐ Structure

Instructions

- Measures must be tested for all the data sources and levels of analyses that are specified. ***If there is more than one set of data specifications or more than one level of analysis, contact NQF staff*** about how to present all the testing information in one form.
- **For all measures, sections 1, 2a2, 2b2, 2b3, and 2b5 must be completed.**
- **For outcome and resource use measures**, section **2b4** also must be completed.
- If specified for **multiple data sources/sets of specificaitons** (e.g., claims and EHRs), section **2b6** also must be completed.
- Respond to all questions as instructed with answers immediately following the question. All information on testing to

demonstrate meeting the subcriteria for reliability (2a2) and validity (2b2-2b6) must be in this form. An appendix for *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 20 pages (*incuding questions/instructions;* minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.
- For information on the most updated guidance on how to address sociodemographic variables and testing in this form refer to the release notes for version 6.6 of the Measure Testing Attachment.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the testing results for this measure meet NQF's evaluation criteria for testing.

2a2. Reliability testing [10] demonstrates the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise. For **PRO-PMs and composite performance measures**, reliability should be demonstrated for the computed performance score.

2b2. Validity testing [11] demonstrates that the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality. For **PRO-PMs and composite performance measures**, validity should be demonstrated for the computed performance score.

2b3. Exclusions are supported by the clinical evidence; otherwise, they are supported by evidence of sufficient frequency of occurrence so that results are distorted without the exclusion; [12]

AND

If patient preference (e.g., informed decisionmaking) is a basis for exclusion, there must be evidence that the exclusion impacts performance on the measure; in such cases, the measure must be specified so that the information about patient preference and the effect on the measure is transparent (e.g., numerator category computed separately, denominator exclusion category computed separately). [13]

2b4. For outcome measures and other measures when indicated (e.g., resource use):

- **an evidence-based risk-adjustment strategy** (e.g., risk models, risk stratification) is specified; is based on patient factors (including clinical and sociodemographic factors) that influence the measured outcome and are present at start of care; [14,15] and has demonstrated adequate discrimination and calibration

OR

- rationale/data support no risk adjustment/ stratification.

2b5. Data analysis of computed measure scores demonstrates that methods for scoring and analysis of the specified measure allow for **identification of statistically significant and practically/clinically meaningful** [16] **differences in performance**;

OR

there is evidence of overall less-than-optimal performance.

2b6. If multiple data sources/methods are specified, there is demonstration they produce comparable results.

2b7. For **eMeasures, composites, and PRO-PMs** (or other measures susceptible to missing data), analyses identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias.

Notes

10. Reliability testing applies to both the data elements and computed measure score. Examples of reliability testing for data elements include, but are not limited to: inter-rater/abstractor or intra-rater/abstractor studies; internal consistency for multi-item scales; test-retest for survey items. Reliability testing of the measure score addresses precision of measurement (e.g., signal-to-noise).

11. Validity testing applies to both the data elements and computed measure score. Validity testing of data elements typically analyzes agreement with another authoritative source of the same information. Examples of validity testing of the measure score include, but are not limited to: testing hypotheses that the measures scores indicate quality of care, e.g., measure scores are different for groups known to have differences in quality assessed by another valid quality measure or method; correlation of measure scores with another valid indicator of quality for the specific topic; or relationship to conceptually related measures (e.g., scores on process measures to scores on outcome measures). Face validity of the measure score as a quality indicator may be adequate if accomplished through a systematic and transparent process, by identified experts, and explicitly addresses whether performance scores resulting from the measure as specified can be used to distinguish good from poor quality.

12. Examples of evidence that an exclusion distorts measure results include, but are not limited to: frequency of occurrence, variability of exclusions across providers, and sensitivity analyses with and without the exclusion.
13. Patient preference is not a clinical exception to eligibility and can be influenced by provider interventions.

14. Risk factors that influence outcomes should not be specified as exclusions
15. With large enough sample sizes, small differences that are statistically significant may or may not be practically or clinically meaningful. The substantive question may be, for example, whether a statistically significant difference of one percentage point in the percentage of patients who received smoking cessation counseling (e.g., 74 percent v. 75 percent) is clinically meaningful; or whether a statistically significant difference of $25 in cost for an episode of care (e.g., $5,000 v. $5,025) is practically meaningful. Measures with overall less-than-optimal performance may not demonstrate much variability across providers.

1. DATA/SAMPLE USED FOR ALL TESTING OF THIS MEASURE

Often the same data are used for all aspects of measure testing. In an effort to eliminate duplication, the first five questions apply to all measure testing. If there are differences by aspect of testing,(e.g., reliability vs. validity) be sure to indicate the specific differences in question 1.7.

1.1. What type of data was used for testing? (*Check all the sources of data identified in the measure specifications and data used for testing the measure. Testing must be provided for all the sources of data specified and intended for measure implementation.* ***If different data sources are used for the numerator and denominator, indicate N [numerator] or D [denominator] after the checkbox.***)

Measure Specified to Use Data From: (***must be consistent with data sources entered in S.23***)	**Measure Tested with Data From:**
☐ abstracted from paper record	☐ abstracted from paper record
☒ administrative claims	☒ administrative claims
☒ clinical database/registry	☒ clinical database/registry
☐ abstracted from electronic health record	☐ abstracted from electronic health record
☐ eMeasure (HQMF) implemented in EHRs	☐ eMeasure (HQMF) implemented in EHRs

☒ other: Electronic Clinical Data: Pharmacy	☒ other: Electronic Clinical Data: Pharmacy

1.2. If an existing dataset was used, identify the specific dataset (*the dataset used for testing must be consistent with the measure specifications for target population and healthcare entities being measured; e.g., Medicare Part A claims, Medicaid claims, other commercial insurance, nursing home MDS, home health OASIS, clinical registry*).
N/A
1.3. What are the dates of the data used in testing? Click here to enter date range

Health Plan Level (2014) HEDIS
Testing of performance measure score with beta binomial reliability was performed with data from measurement year 2013.

Testing of construct validity with Pearson's Correlation was performed using data from measurement year 2013.

1.4. What levels of analysis were tested? (*testing must be provided for all the levels specified and intended for measure implementation, e.g., individual clinician, hospital, health plan*)

Measure Specified to Measure Performance of: (***must be consistent with levels entered in item S.26***)	**Measure Tested at Level of:**
☐ individual clinician	☐ individual clinician
☐ group/practice	☐ group/practice
☐ hospital/facility/agency	☐ hospital/facility/agency
☒ health plan	☒ health plan
☒ other: Integrated Delivery System	☒ other: Integrated Delivery System

1.5. How many and which measured entities were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of measured entities included in the analysis (e.g., size, location, type); if a sample was used, describe how entities were selected for inclusion in the sample*)
Measure Score Reliability Testing and Construct Validity Testing
Measure score reliability and construct validity were calculated from U.S. HEDIS data that included all health plans submitting data to NCQA for HEDIS: 253 Commercial plans, 75 Medicaid plans and 269 Medicare plans. The plans were geographically diverse and varied in size.

Systematic Assessment for Face Validity
This measure was tested for face validity with three expert panels. See additional information: Ad.1. Workgroup/Expert Panel in Measure Development for names and affiliations of expert panels:

1. Cardiovascular Measurement Advisory Panel includes eight physicians and one nurse with expertise in cardiovascular health and quality measurement.
2. The Technical Measurement Advisory Panel includes 12 members, including representation by health plans, methodologists, clinician and auditors.
3. NCQA's Committee on Performance Measurement (CPM) oversees the evolution of the measurement set and includes representation by purchasers, consumers, health plans, health care providers and policy makers. This panel is made up of 16 members. The CPM is organized and managed by NCQA and reports to the NCQA Board of Directors and is responsible for advising NCQA staff on the development and maintenance of performance measures. CPM members reflect the diversity of constituencies that

performance measurement serves; some bring other perspectives and additional expertise in quality management and the science of measurement.

1.6. How many and which patients were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of patients included in the analysis (e.g., age, sex, race, diagnosis); if a sample was used, describe how patients were selected for inclusion in the sample*)

Patient Samples for Measure Score Reliability and Construct Validity Testing

Health Plan Level

In measurement year 2013, HEDIS measures covered more than 171 million people from 814 HMOs and 353 PPOs. Data are summarized at the health plan level and stratified by product line (i.e. commercial, Medicaid, Medicare). Below is a description of the sample. It includes the number of health plans included in HEDIS data collection and the average eligible population for the measure across health plans.

Product Line	Number of Plans	Average Denominator Size per Plan
Commercial (HMO/PPO combined)	253	157
Medicaid	75	83
Medicare	269	171

1.7. If there are differences in the data or sample used for different aspects of testing (e.g., reliability, validity, exclusions, risk adjustment), identify how the data or sample are different for each aspect of testing reported below.

Reliability testing of the measure score and construct validity of this measure were tested using the same sample. Validity was also demonstrated through a systematic assessment of face validity. The composition of each panel is described in question 1.5 above.

1.8 What were the patient-level sociodemographic (SDS) variables that were available and analyzed in the data or sample used? For example, patient-reported data (e.g., income, education, language), proxy variables when SDS data are not collected from each patient (e.g. census tract), or patient community characteristics (e.g. percent vacant housing, crime rate).

Data are stratified by commercial, Medicaid and Medicare product lines.

2a2. RELIABILITY TESTING

***Note**: If accuracy/correctness (validity) of data elements was empirically tested, separate reliability testing of data elements is not required – in 2a2.1 check critical data elements; in 2a2.2 enter "see section 2b2 for validity testing of data elements"; and skip 2a2.3 and 2a2.4.*

2a2.1. What level of reliability testing was conducted? (*may be one or both levels*)

☐ **Critical data elements used in the measure** (*e.g., inter-abstractor reliability; data element reliability must address ALL critical data elements*)

☒ **Performance measure score** (e.g., *signal-to-noise analysis*)

2a2.2. For each level checked above, describe the method of reliability testing and what it tests (*describe the steps—do not just name a method; what type of error does it test; what statistical analysis was used*)

Performance Measure Score (Beta Binomial)

In order to assess measure precision in the context of the observed variability across accountable entities, we utilized the reliability estimate proposed by Adams (2009). The following is quoted from the tutorial which focused on provider-level assessment: "Reliability is a key metric of the suitability of a measure for [provider] profiling because it describes how well one can confidently distinguish the performance of one physician from another. Conceptually, it is the ratio of signal to noise. The signal in this case is the proportion of the variability in measured performance that can be explained by real differences in performance. There are three main drivers of reliability: sample size, differences between physicians, and measurement error. At the physician level, sample size can be increased by increasing the number of patients in the physician's data as well as increasing the number of measures per patient." This approach is also relevant to health plans and other accountable entities.

Adams' approach uses a Beta-binomial model to estimate reliability; this model provides a better fit when estimating the reliability of simple pass/fail rate measures as is the case with most HEDIS® measures. The beta-binomial approach accounts for the non-normal distribution of performance within and across accountable entities. Reliability scores vary from 0.0 to 1.0. A score of zero implies that all variation is attributed to measurement error (noise or the individual accountable entity variance) whereas a reliability of 1.0 implies that all variation is caused by a real difference in performance (across accountable entities).

Adams, J. L. The Reliability of Provider Profiling: A Tutorial. Santa Monica, California: RAND Corporation. TR-653-NCQA, 2009

2a2.3. For each level of testing checked above, what were the statistical results from reliability testing? (e.g., *percent agreement and kappa for the critical data elements; distribution of reliability statistics from a signal-to-noise analysis*)

Results of Reliability Testing of Performance Measure Score (Beta Binomial):

Health Plan Level (Measurement Year 2013)

Below, we present health plan level data, which includes data submitted from 253 commercial plans, 75 Medicaid plans, and 269 Medicare plans.

Commercial		Medicaid		Medicare	
Overall	10th-90th	Overall	10th-90th	Overall	10th-90th
0.78	0.42-0.89	0.81	0.66-0.92	0.78	0.42-0.91

2a2.4 What is your interpretation of the results in terms of demonstrating reliability? (i.e., *what do the results mean and what are the norms for the test conducted?*)

Performance Measure Score (Beta Binomial):

Reliability scores can vary from 0.0 to 1.0. A score of zero implies that all variation is attributed to measurement error (noise) whereas a reliability of 1.0 implies that all variation is caused by a real difference in performance (signal). Generally, a minimum reliability score of 0.7 is used to indicate sufficient signal strength to discriminate performance between accountable entities.

Health Plan Level

Testing suggests that this measure has good reliability at the health plan level between 0.78 and 0.81. The 10th-90th percentile distribution of health plan level reliability on this measure shows there is large variation. This large variation is due to a lower number of plans reporting the rate overall because of small denominators for the plans. It is important to note that overall health plans have met or exceeded the minimally accepted threshold of 0.7 and many of the plans exceeded 0.8. Good reliability is demonstrated since variations in these large populations are due to signal and not to noise.

2b2. VALIDITY TESTING

2b2.1. What level of validity testing was conducted? (*may be one or both levels*)

☐ **Critical data elements** (*data element validity must address ALL critical data elements*)

☒ **Performance measure score**

☒ **Empirical validity testing**

☒ **Systematic assessment of face validity of performance measure score as an indicator** of quality or resource use (*i.e., is an accurate reflection of performance on quality or resource use and can distinguish good from poor performance*)

2b2.2. For each level of testing checked above, describe the method of validity testing and what it tests (*describe the steps—do not just name a method; what was tested, e.g., accuracy of data elements compared to authoritative source, relationship to another measure as expected; what statistical analysis was used)*

Empirical Validity:

Method of testing construct validity: At the health plan level, we tested for construct validity by exploring whether Persistence of Beta-Blocker Treatment after a Heart Attack (#0071) correlated with the following measures:

- Comprehensive Diabetes Care (CDC) LDL-C: The percentage of adults 18-75 years of age with diabetes who had LDL-C control <100 mg/dL during the measurement year.
- Cholesterol Management for Patients with Cardiovascular Conditions (CMC): The percentage of adults 18-75 years of age discharged with an AMI, coronary artery bypass graft (CABG) or percutaneous coronary interventions (PCI) in the year prior to measurement year, or who had a diagnosis of ischemic vascular disease (IVD) during the measurement year and the year prior to the measurement year, and who had LDL-C control (<100 mg/dL).
- Pharmacotherapy Management of COPD Exacerbation (PCE): The percentage of COPD exacerbations for adults 40 years of age and older who had an acute inpatient discharge or ED visit on or between January 1-November 30 of the measure year and who were dispensed appropriate medications.

To test these correlations we used a Person correlation test. This test estimates the strength of the linear association between two continuous variables; the magnitude of correlation ranges from -1 and +1. A value of 1 indicates a perfect linear dependence in which increasing values on one variable is associated with increasing values of the second variable. A value of 0 indicates no linear association. A value of -1 indicates a perfect linear relationship in which increasing values of the first variable is associated with decreasing values of the second variable.

Systematic Assessment of Face Validity:

Health Plan Level

Method of Assessing Face Validity: NCQA has identified and refined measure management into a standardized process called the HEDIS measure life cycle.

STEP 1: NCQA staff identifies areas of interest or gaps in care. Clinical expert panels (MAPs—whose members are authorities on clinical priorities for measurement) participate in this process. Once topics are identified, a literature review is conducted to find supporting documentation on their importance, scientific soundness and feasibility. This information is gathered into a work-up format. Refer to What Makes a Measure "Desirable"? The work-up is vetted by NCQA's Measurement Advisory Panels (MAPs), the Technical Measurement Advisory Panel (TMAP) and the Committee on Performance Measurement (CPM) as well as other panels as necessary.

STEP 2: Development ensures that measures are fully defined and tested before the organization collects them. MAPs participate in this process by helping identify the best measures for assessing health care performance in clinical areas identified in the topic selection phase. Development includes the following tasks: (1) Prepare a detailed conceptual and operational work-up that includes a testing proposal and (2) Collaborate with health plans to conduct field-tests that assess the feasibility and validity of potential measures. The CPM uses testing results and proposed final specifications to determine if the measure will move forward to Public Comment.

STEP 3: Public Comment is a 30-day period of review that allows interested parties to offer feedback to NCQA and the CPM about new measures or about changes to existing measures.
NCQA MAPs and technical panels consider all comments and advise NCQA staff on appropriate recommendations brought to the CPM. The CPM reviews all comments before making a final decision about Public Comment measures. New measures and changes to existing measures approved by the CPM and NCQAs Board of Directors will be included in the next HEDIS year and reported as first-year measures.

STEP 4: First-year data collection requires organizations to collect, be audited on and report these measures, but results are not publicly reported in the first year and are not included in NCQA's State of Health Care Quality, Quality Compass or in accreditation scoring. The first-year distinction guarantees that a measure can be effectively collected, reported and audited before it is used for public accountability or accreditation. This is not testing—the measure was already tested as part of its development—rather, it ensures that there are no unforeseen problems when the measure is implemented in the real world. NCQA's experience is that the first year of large-scale data collection often reveals unanticipated issues. After collection, reporting and auditing on a one-year introductory basis, NCQA conducts a detailed evaluation of first-year data. The CPM uses evaluation results to decide whether the measure should become publicly reportable or whether it needs further modifications.

STEP 5: Public reporting is based on the first-year measure evaluation results. If the measure is approved, it will be publicly reported and may be used for scoring in accreditation.

Step 6: Evaluation is the ongoing review of a measure's performance and recommendations for its modification or retirement. Every measure is reviewed for reevaluation at least every three years. NCQA staff continually monitors the performance of publicly reported measures. Statistical analysis, audit result review and user comments through NCQA's Policy Clarification Support portal contribute to measure refinement during re-evaluation. Information derived from analyzing the performance of existing measures is used to improve development of the next generation of measures.

Each year, NCQA prioritizes measures for re-evaluation and selected measures are researched for changes in clinical guidelines or in the health care delivery systems, and the results from previous years are analyzed. Measure work-ups are updated with new information gathered from the literature review, and the appropriate MAPs review the work-ups and the previous year's data. If necessary, the measure specification may be updated or the measure may be recommended for retirement. The CPM reviews recommendations from the evaluation process and approves or rejects the recommendation. If approved, the change is included in the next year's HEDIS Volume 2.

Expert Participation
This measure was tested for face validity with input from two expert panels. Updated guidelines from the American Heart Association and American College of Cardiology in 2013 and 2014 were also a strong authoritative source in applying the evidence for our persistence of beta-blocker treatment after a heart attack measure

We list an overview of each panel here. Please refer to Ad.1 in the submission form for the names and affiliation of experts in each panel.

1.) Cardiovascular Measurement Advisory Panel includes eight physicians and one nurse with expertise in cardiovascular health and quality measurement.
2.) The Technical Measurement Advisory Panel includes 12 members, including representation by health plans, methodologists, clinician and auditors.
3.) NCQA's Committee on Performance Measurement (CPM) oversees the evolution of the measurement set and includes representation by purchasers, consumers, health plans, health care providers and policy makers. This panel is made up of 16 members. The CPM is organized and managed by NCQA and reports to the NCQA Board of Directors and is responsible for advising NCQA staff on the development and maintenance of performance measures. CPM members reflect the diversity of constituencies that performance measurement serves; some bring other perspectives and additional expertise in quality management and the science of measurement.

ICD-10 CONVERSION:

Goal was to convert this measure to a new code set, fully consistent with the intent of the original measure.

Steps in ICD-9 to ICD-10 Conversion Process

1. NCQA staff identify ICD-10 codes to be considered based on ICD-9 codes currently in measure. Use GEM to identify ICD-10 codes that map to ICD-9 codes. Review GEM mapping in both directions (ICD-9 to ICD-10 and ICD-10 to ICD-9) to identify potential trending issues.
2. NCQA staff identify additional codes (not identified by GEM mapping step) that should be considered. Using ICD-10 tabular list and ICD-10 Index, search by diagnosis or procedure name for appropriate codes.
3. NCQA HEDIS Expert Coding Panel review NCQA staff recommendations and provide feedback.
4. As needed, NCQA Measurement Advisory Panels perform clinical review. Due to increased specificity in ICD-10, new codes and definitions require review to confirm the diagnosis or procedure is intended to be included in the scope of the measure. Not all ICD-10 recommendations are reviewed by NCQA MAP; MAP review items are identified during staff conversion or by HEDIS Expert Coding Panel.
5. Post ICD-10 code recommendations for public review and comment.
6. Reconcile public comments. Obtain additional feedback from HEDIS Expert Coding Panel and MAPs as needed.
7. NCQA staff finalize ICD-10 code recommendations.

Tools Used to Identify/Map to ICD-10

All tools used for mapping/code identification from CMS ICD-10 website (http://www.cms.gov/Medicare/Coding/ICD10/2012-ICD-10-CM-and-GEMs.html).
GEM, ICD-10 Guidelines, ICD-10-CM Tabular List of Diseases and Injuries, ICD-10-PCS Tabular List.

2b2.3. What were the statistical results from validity testing? (*e.g., correlation; t-test*)

Empirical Validity

Health Plan Level

Correlations between Persistence of Beta-Blocker Treatment after a Heart Attack (PBH) and Comprehensive Diabetes Control (CDC) LDL-C, Cholesterol Management for Patients With Cardiovascular Conditions (CMC), and Pharmacotherapy Management of COPD Exacerbation (PCE) measures (2013)

	Person Correlation Coefficients

Quality Measure	CDC-LDL-C	CMC	PCE-Systemic	PCE-Bronchodi	PBH
PBH (Commercial)	0.38094	0.30215	0.25865	0.33448	1
PBH (Medicaid)	0.4031	0.32383	0.47421	0.51638	1
PBH (Medicare)	0.41992	0.36396	0.47394	0.42068	1

Note: All correlations are significant at p<.05

Systematic Assessment of Face Validity

Expert Panels

Our expert panels unanimously supported the necessity of persistent beta-blocker treatment after a heart attack to measure quality of care in patients with cardiovascular disease.

2b2.4. What is your interpretation of the results in terms of demonstrating validity? (i.*e., what do the results mean and what are the norms for the test conducted?*)

Empirical Validity

Health Plan

Correlations testing suggests that the PBH measure has a moderate correlation with the diabetes and cardiovascular disease cholesterol control measures and COPD medication measure, as hypothesized. This positive correlation indicates that plans that are performing well on measures of evidence-based care, are doing so across their members with cardiovascular (PBH, CMC), diabetic (CDC LDL-C), and COPD (PCE) conditions. In other words, plans that perform well on the PBH measure also perform well on the cardiovascular disease (CMC) and diabetes (CDC LDL-C) cholesterol control measures, which focus on cholesterol management for patients with cardiovascular disease and diabetes. Similarly, those same plans perform well on COPD medication measure (PCE) which assesses the provision of appropriate medications for COPD patients who have an exacerbation. The p value of all correlation analyses are <.05 which indicates that the correlations are statistically significant.

Systematic Assessment of Face Validity

Expert Panels

Multiple NCQA panels concluded with good agreement that the measure as specified accurately assesses persistence of beta blocker use for at-risk patients in health plans. Our interpretation of these results is that this measure has sufficient face validity.

2b3. EXCLUSIONS ANALYSIS

NA ☒ no exclusions — *skip to section 2b4*

2b3.1. Describe the method of testing exclusions and what it tests (*describe the steps—do not just name a method; what was tested, e.g., whether exclusions affect overall performance scores; what statistical analysis was used*)

2b3.2. What were the statistical results from testing exclusions? (*include overall number and percentage of individuals excluded, frequency distribution of exclusions across measured entities, and impact on performance*

measure scores)

2b3.3. What is your interpretation of the results in terms of demonstrating that exclusions are needed to prevent unfair distortion of performance results? (*i.e., the value outweighs the burden of increased data collection and analysis. Note: **If patient preference is an exclusion**, the measure must be specified so that the effect on the performance score is transparent, e.g., scores with and without exclusion*)

2b4. RISK ADJUSTMENT/STRATIFICATION FOR OUTCOME OR RESOURCE USE MEASURES
If not an intermediate or health outcome, or PRO-PM, or resource use measure, skip to section 2b5.

2b4.1. What method of controlling for differences in case mix is used?
☒ **No risk adjustment or stratification**
☐ **Statistical risk model with** Click here to enter number of factors **risk factors**
☐ **Stratification by** Click here to enter number of categories **risk categories**
☐ **Other,** Click here to enter description

2b4.2. If an outcome or resource use measure is not risk adjusted or stratified, provide rationale and analyses to demonstrate that controlling for differences in patient characteristics (case mix) is not needed to achieve fair comparisons across measured entities.

2b4.3. Describe the conceptual/clinical and statistical methods and criteria used to select patient factors (clinical factors or sociodemographic factors) used in the statistical risk model or for stratification by risk (*e.g., potential factors identified in the literature and/or expert panel; regression analysis; statistical significance of p<0.10; correlation of x or higher; patient factors should be present at the start of care*)

2b4.4a. What were the statistical results of the analyses used to select risk factors?

2b4.4b. Describe the analyses and interpretation resulting in the decision to select SDS factors (e.g. prevalence of the factor across measured entities, empirical association with the outcome, contribution of unique variation in the outcome, assessment of between-unit effects and within-unit effects)

2b4.5. Describe the method of testing/analysis used to develop and validate the adequacy of the statistical model or stratification approach (*describe the steps—do not just name a method; what statistical analysis was used*)

Provide the statistical results from testing the approach to controlling for differences in patient characteristics (case mix) below.
If stratified, skip to 2b4.9

2b4.6. Statistical Risk Model Discrimination Statistics (*e.g., c-statistic, R-squared*)**:**

2b4.7. Statistical Risk Model Calibration Statistics (*e.g., Hosmer-Lemeshow statistic*):

2b4.8. Statistical Risk Model Calibration – Risk decile plots or calibration curves:

2b4.9. Results of Risk Stratification Analysis:

2b4.10. What is your interpretation of the results in terms of demonstrating adequacy of controlling for differences in patient characteristics (case mix)? (i.*e., what do the results mean and what are the norms for the test conducted*)

2b4.11. Optional Additional Testing for Risk Adjustment (*not required, but would provide additional support of adequacy of risk model, e.g., testing of risk model in another data set; sensitivity analysis for missing data; other methods that were assessed*)

2b5. IDENTIFICATION OF STATISTICALLY SIGNIFICANT & MEANINGFUL DIFFERENCES IN PERFORMANCE

2b5.1. Describe the method for determining if statistically significant and clinically/practically meaningful differences in performance measure scores among the measured entities can be identified (*describe the steps—do not just name a method; what statistical analysis was used? Do not just repeat the information provided related to performance gap in 1b)*

To demonstrate meaningful differences in performance, NCQA calculates an inter-quartile range (IQR) for each indicator. The IQR provides a measure of the dispersion of performance. The IQR can be interpreted as the difference between the 25th and 75th percentile on a measure. To determine if this difference is statistically significant, NCQA calculates an independent sample t-test of the performance difference between two randomly selected plans at the 25th and 75th percentile. The t-test method calculates a testing statistic based on the sample size, performance rate, and standardized error of each plan. The test statistic is then compared against a normal distribution. If the p value of the test statistic is less than .05, then the two plans' performance is significantly different from each other. Using this method, we compared the performance rates of two randomly selected plans, one plan in the 25th percentile and another plan in the 75th percentile of performance. We used these two plans as examples of measured entities. However, the method can be used for comparison of any two measured entities.

2b5.2. What were the statistical results from testing the ability to identify statistically significant and/or clinically/practically meaningful differences in performance measure scores across measured entities? (e.g., *number and percentage of entities with scores that were statistically significantly different from mean or some benchmark, different from expected; how was meaningful difference defined*)

Health Plan Level: HEDIS 2014 Variation in Performance Across Health Plans

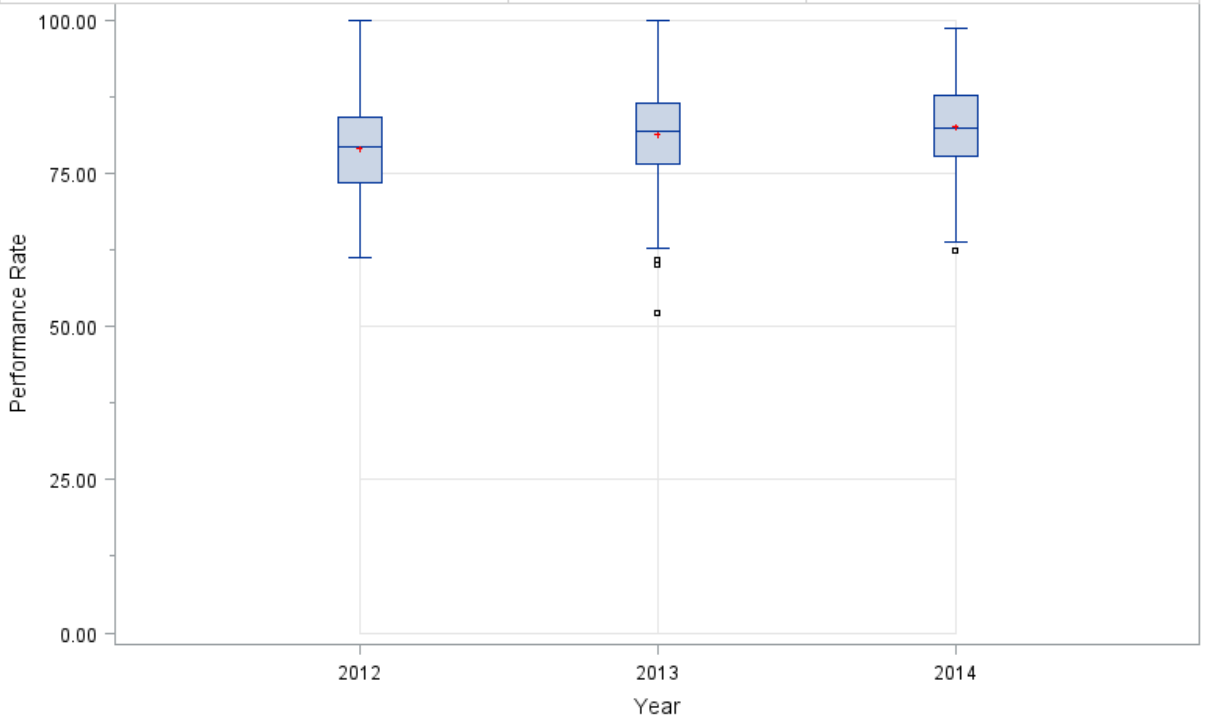
	N	Avg.	SD	10th	25th	50th	75th	90th	IQR	p-value
Commercial	253	83%	7%	73%	78%	82%	88%	91%	10%	<0.05
Medicaid	75	84%	10%	72%	80%	86%	91%	95%	11%	<0.05
Medicare	269	90%	6%	83%	87%	91%	94%	96%	7%	<0.05

N= Number of plans reporting
IQR: Interquartile range
p-value: p-value of independent samples t-test comparing plans at the 25th percentile to plans at the 75th percentile.

Box plots for HEDIS 2014 Variation in Performance Across Health Plans are included below for your reference.

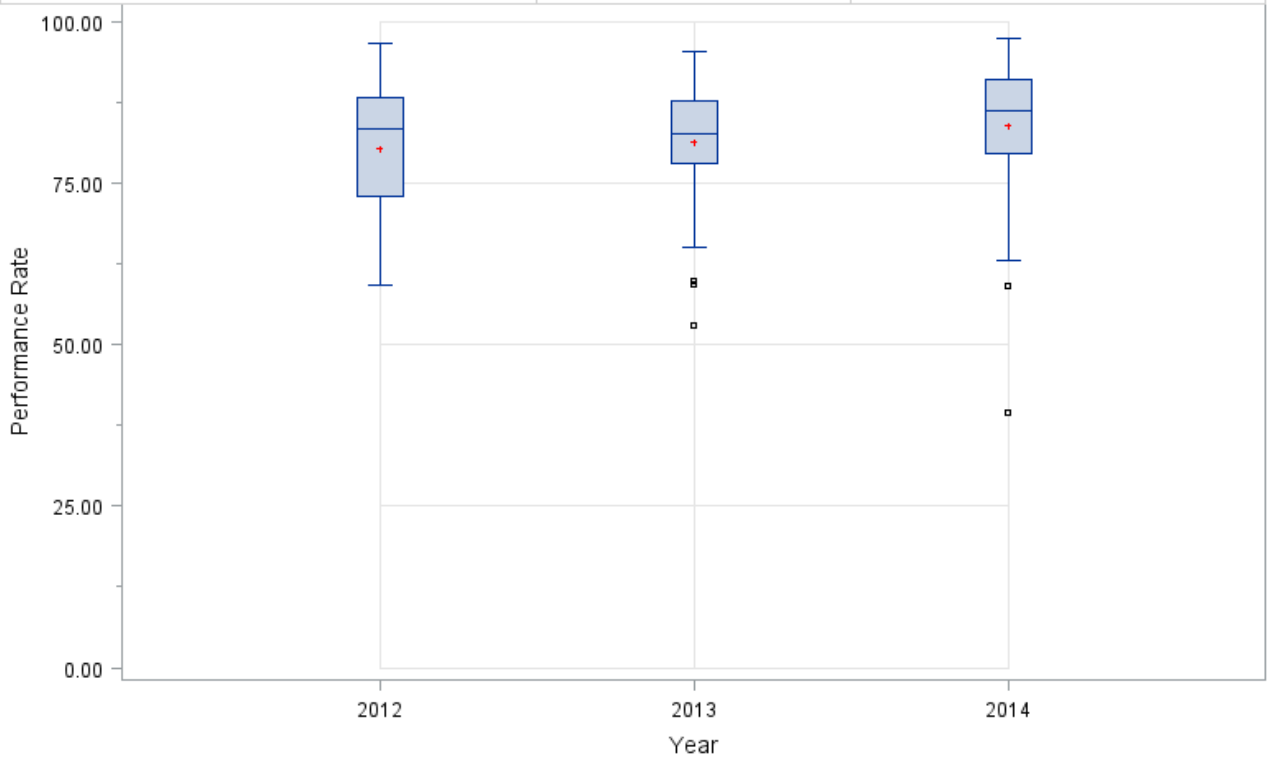
Boxplot Graph for Commercial Persistence of Beta-Blocker Treatment After a Heart Attack from HEDIS 2012-2014

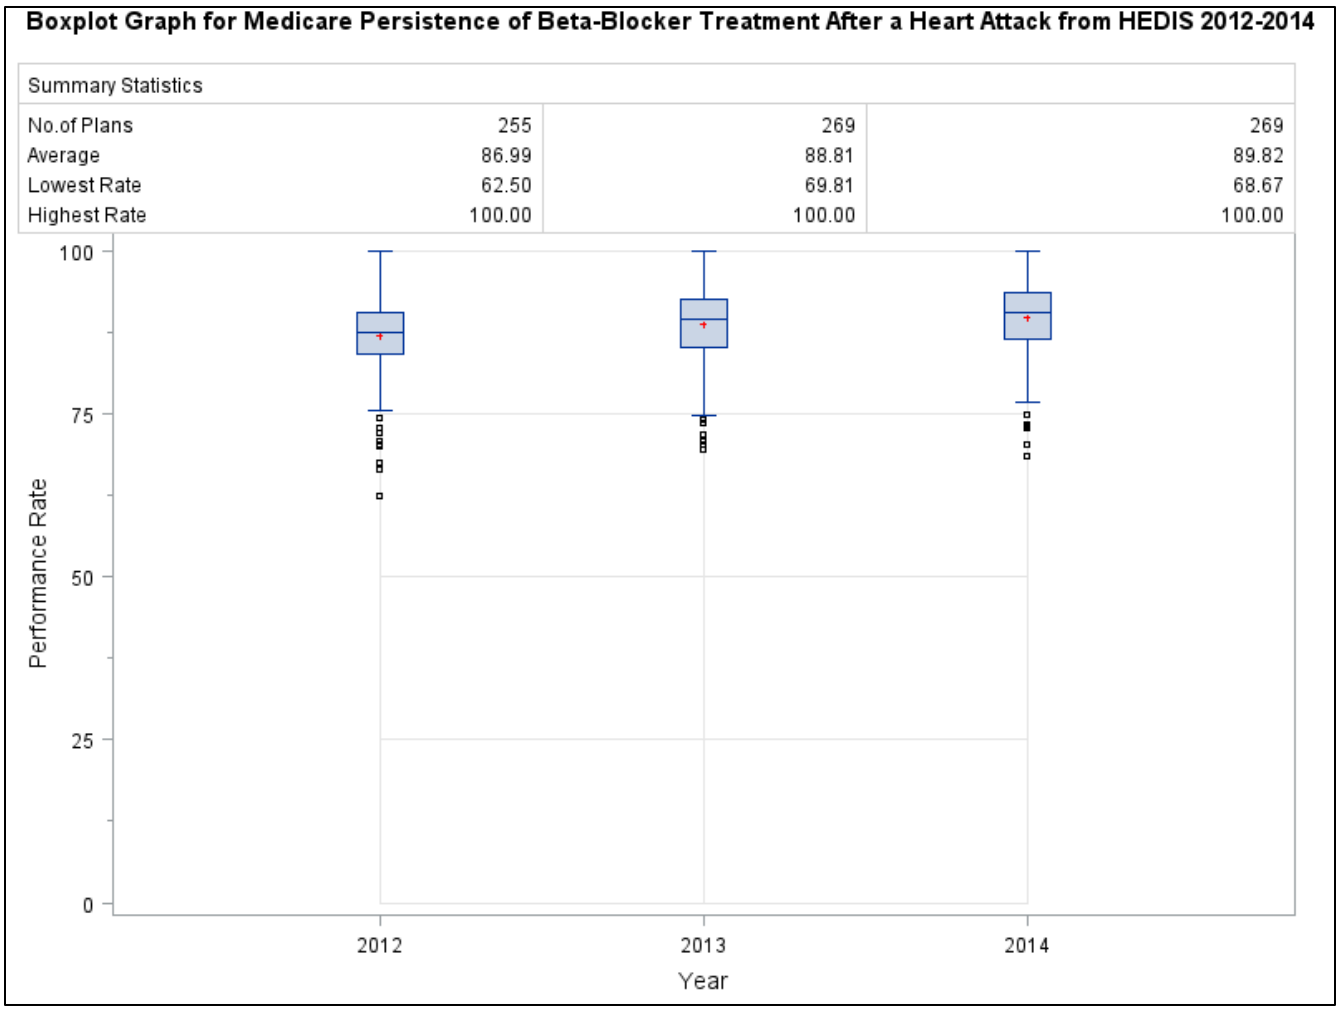
Summary Statistics			
No.of Plans	250	252	253
Average	79.06	81.49	82.62
Lowest Rate	61.29	52.27	62.50
Highest Rate	100.00	100.00	98.68



Boxplot Graph for Medicaid Persistence of Beta-Blocker Treatment After a Heart Attack from HEDIS 2012-2014

Summary Statistics			
No.of Plans	54	64	75
Average	80.49	81.50	83.88
Lowest Rate	59.15	53.14	39.53
Highest Rate	96.74	95.45	97.56





2b5.3. What is your interpretation of the results in terms of demonstrating the ability to identify statistically significant and/or clinically/practically meaningful differences in performance across measured entities? (i.*e., what do the results mean in terms of statistical and meaningful differences?*)

Health Plan Level

The results indicate there is a 7-11% gap in performance between 25th and 75th performing plans. The largest performance gap (11%) is in Medicaid plans. The difference between 25th and 75th percentile is statistically significant for all product lines (Commercial, Medicaid, and Medicare). There is also a 13-23% gap in performance between the 10th and 90th performing plans. Overall, results suggest there are meaningful differences in performance and there is an opportunity for improvement.

2b6. COMPARABILITY OF PERFORMANCE SCORES WHEN MORE THAN ONE SET OF SPECIFICATIONS

If only one set of specifications, this section can be skipped.

Note: *This criterion is directed to measures with more than one set of specifications/instructions (e.g., one set of specifications for how to identify and compute the measure from medical record abstraction and a different set of specifications for claims or eMeasures). It does not apply to measures that use more than one source of data in one set of specifications/instructions (e.g., claims data to identify the denominator and medical record abstraction for the numerator).* ***If comparability is not demonstrated, the different specifications should be submitted as separate measures.***

2b6.1. Describe the method of testing conducted to demonstrate comparability of performance scores for the same entities across the different data sources/specifications (*describe the steps—do not just name a method; what statistical analysis was used*)
N/A

2b6.2. What were the statistical results from testing comparability of performance scores for the same entities when using different data sources/specifications? (*e.g., correlation, rank order*)
N/A

2b6.3. What is your interpretation of the results in terms of demonstrating comparability of performance measure scores for the same entities across the different data sources/specifications? (i.*e., what do the results mean and what are the norms for the test conducted*)
N/A

2b7. MISSING DATA ANALYSIS AND MINIMIZING BIAS

2b7.1. Describe the method of testing conducted to identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias (*describe the steps—do not just name a method; what statistical analysis was used*)
This measure is collected with a complete sample, there is no missing data on this measure.

2b7.2. What is the overall frequency of missing data, the distribution of missing data across providers, and the results from testing related to missing data? (*e.g., results of sensitivity analysis of the effect of various rules for missing data/nonresponse; if no empirical sensitivity analysis, identify the approaches for handling missing data that were considered and pros and cons of each*)
This measure is collected with a complete sample, there is no missing data on this measure.

2b7.3. What is your interpretation of the results in terms of demonstrating that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias**?** (i.*e., what do the results mean in terms of supporting the selected approach for missing data and what are the norms for the test conducted; if no empirical analysis, provide rationale for the selected approach for missing data*)
This measure is collected with a complete sample, there is no missing data on this measure.

3. Feasibility

Extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

3a. Byproduct of Care Processes

For clinical measures, the required data elements are routinely generated and used during care delivery (e.g., blood pressure, lab test, diagnosis, medication order).

3a.1. **Data Elements Generated as Byproduct of Care Processes.**
Generated or collected by and used by healthcare personnel during the provision of care (e.g., blood pressure, lab value, diagnosis, depression score), Coded by someone other than person obtaining original information (e.g., DRG, ICD-9 codes on claims)
If other:

3b. Electronic Sources

The required data elements are available in electronic health records or other electronic sources. If the required data are not in electronic health records or existing electronic sources, a credible, near-term path to electronic collection is specified.

3b.1. **To what extent are the specified data elements available electronically in defined fields?** *(i.e., data elements that are needed to compute the performance measure score are in defined, computer-readable fields)*
ALL data elements are in defined fields in electronic claims

3b.2. **If ALL the data elements needed to compute the performance measure score are not from electronic sources, specify a credible, near-term path to electronic capture, OR provide a rationale for using other than electronic sources.**

3b.3. **If this is an eMeasure, provide a summary of the feasibility assessment in an attached file or make available at a measure-specific URL.**
Attachment:

3c. Data Collection Strategy

Demonstration that the data collection strategy (e.g., source, timing, frequency, sampling, patient confidentiality, costs associated with fees/licensing of proprietary measures) can be implemented (e.g., already in operational use, or testing demonstrates that it is ready to put into operational use). For eMeasures, a feasibility assessment addresses the data elements and measure logic and demonstrates the eMeasure can be implemented or feasibility concerns can be adequately addressed.

3c.1. **Describe what you have learned/modified as a result of testing and/or operational use of the measure regarding data collection, availability of data, missing data, timing and frequency of data collection, sampling, patient confidentiality, time and cost of data collection, other feasibility/implementation issues.**
IF a PRO-PM, consider implications for both individuals providing PROM data (patients, service recipients, respondents) and those whose performance is being measured.
NCQA recognizes that, despite the clear specifications defined for HEDIS measures, data collection and calculation methods may vary, and other errors may taint the results, diminishing the usefulness of HEDIS data for managed care organization (MCO) comparison. In order for HEDIS to reach its full potential, NCQA conducts an independent audit of all HEDIS collection and reporting processes, as well as an audit of the data which are manipulated by those processes, in order to verify that HEDIS specifications are met. NCQA has developed a precise, standardized methodology for verifying the integrity of HEDIS collection and calculation processes through a two-part program consisting of an overall information systems capabilities assessment followed by an evaluation of the MCO´s ability to comply with HEDIS specifications. NCQA-certified auditors using standard audit methodologies will help enable purchasers to make more reliable "apples-to-apples" comparisons between health plans.
The HEDIS Compliance Audit addresses the following functions:
1) Information practices and control procedures
2) Sampling methods and procedures
3) Data integrity
4) Compliance with HEDIS specifications
5) Analytic file production
6) Reporting and documentation
In addition to the HEDIS Audit, NCQA provides a system to allow “real-time” feedback from measure users. Our Policy Clarification Support System receives thousands of inquiries each year on over 100 measures. Through this system NCQA responds immediately to questions and identifies possible errors or inconsistencies in the implementation of the measure. This system is vital to the regular re-evaluation of NCQA measures.
Input from NCQA auditing and the Policy Clarification Support System informs the annual updating of all HEDIS measures including updating value sets and clarifying the specifications. Measures are re-evaluated on a periodic basis and when there is a significant change in evidence. During re-evaluation information from NCQA auditing and Policy Clarification Support System is used to inform evaluation of the scientific soundness and feasibility of the measure.

3c.2. **Describe any fees, licensing, or other requirements to use any aspect of the measure as specified** *(e.g., value/code set, risk model, programming code, algorithm)*.
Broad public use and dissemination of this measure is encouraged. NCQA has agreed with NQF that noncommercial uses do not require the consent of the measure developer. Use by health care providers in connection with their own practices is not commercial use. Commercial use of a measure requires the prior written consent of NCQA. As used herein, “commercial use” refers to any sale, license or distribution of a measure for commercial gain, or incorporation of a measure into any product or service that is sold, licensed or distributed for commercial gain, even if there is no actual charge for inclusion of the measure.

4. Usability and Use

Extent to which potential audiences (e.g., consumers, purchasers, providers, policy makers) are using or could use performance results for both accountability and performance improvement to achieve the goal of high-quality, efficient healthcare for individuals or populations.

4a. Accountability and Transparency

Performance results are used in at least one accountability application within three years after initial endorsement and are publicly reported within six years after initial endorsement (or the data on performance results are available). If not in use at the time of initial endorsement, then a credible plan for implementation within the specified timeframes is provided.

4.1. **Current and Planned Use**

NQF-endorsed measures are expected to be used in at least one accountability application within 3 years and publicly reported within 6 years of initial endorsement in addition to performance improvement.

Planned	Current Use (for current use provide URL)
	Public Reporting Health Plan Ranking; Annual State of Health Care Quality Health Plan Ranking; Annual State of Health Care Quality http://reportcard.ncqa.org/plan/external/plansearch.aspx http://www.ncqa.org/ReportCards/HealthPlans/StateofHealthCareQuality.aspx Regulatory and Accreditation Programs NCQA Accreditation http://www.ncqa.org/tabid/123/Default.aspx Quality Improvement with Benchmarking (external benchmarking to multiple organizations) Quality Compass; Annual State of Health Care Quality http://www.ncqa.org/tabid/177/Default.aspx Quality Compass; Annual State of Health Care Quality http://www.ncqa.org/ReportCards/HealthPlans/StateofHealthCareQuality.aspx

4a.1. **For each CURRENT use, checked above, provide:**

- Name of program and sponsor
- Purpose
- Geographic area and number and percentage of accountable entities and patients included

HEALTH PLAN RANKING: NCQA ranks health plans using the methodology we have used every year since 2005. For the 2014-2015 rankings, NCQA studied almost 1,400 health plans and ranked more than 1,000 of them based on clinical performance, member satisfaction and results from NCQA Accreditation surveys

ANNUAL STATE OF HEALTH CARE QUALITY: NCQA produces the State of Health Care Quality Report yearly to focus on key quality issues facing the United States and to drive improvement in the delivery of evidence-based medicine. The report documents performance trends over time, tracks variations in care and recommends quality improvements. The 2014 report provides data for the 2013 calendar year. Data in the report comes from 814 HMOs and 353 PPOs, representing more than 171 million people or 54 percent of the U.S. population.

HEALTH PLAN ACCREDITATION: This measure is used in scoring for accreditation of Medicare Advantage Health Plans. In 2013, a total of 170 Medicare Advantage health plans were accredited using this measure among others covering 7.1 million Medicare beneficiaries. This measure is also used in scoring for accreditation of 336 commercial health plans covering 87 million lives; 77 Medicaid health plans covering 9.1 million lives. Health plans are scored based on performance compared to benchmarks.

QUALITY COMPASS: This measure is used in Quality Compass which is an indispensable tool used for selecting a health plan, conducting competitor analysis, examining quality improvement and benchmarking plan performance. Provided in this tool is the ability to generate custom reports by selecting plans, measures, and benchmarks (averages and percentiles) for up to three trended years. Results in table and graph formats offer simple comparison of plans' performance against competitors or benchmarks.

4a.2. **If not currently publicly reported OR used in at least one other accountability application (e.g., payment program,**

certification, licensing) what are the reasons? (*e.g., Do policies or actions of the developer/steward or accountable entities restrict access to performance results or impede implementation?*)
N/A

4a.3. **If not currently publicly reported OR used in at least one other accountability application, provide a credible plan for implementation within the expected timeframes -- any accountability application within 3 years and publicly reported within 6 years of initial endorsement.** (*Credible plan includes the specific program, purpose, intended audience, and timeline for implementing the measure within the specified timeframes. A plan for accountability applications addresses mechanisms for data aggregation and reporting.*)
N/A

4b. Improvement

Progress toward achieving the goal of high-quality, efficient healthcare for individuals or populations is demonstrated. If not in use for performance improvement at the time of initial endorsement, then a credible rationale describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.

4b.1. **Progress on Improvement. (Not required for initial endorsement unless available.)**
Performance results on this measure (current and over time) should be provided in 1b.2 and 1b.4. Discuss:

- **Progress (trends in performance results, number and percentage of people receiving high-quality healthcare)**
- **Geographic area and number and percentage of accountable entities and patients included**

Performance across all plan types has steadily improved over the past three years, with Medicare, Medicaid, and commercial plan performance increasing each year by about 2%. Within each percentile (10th, 25th, 50th etc.), there is a steady performance increase over the past three years and it is important to note even the lowest performers have a steady increase in performance. Current average performance (2014) is highest in Medicare plans (90%), followed by Medicaid plans (84%) and then commercial plans (83%).

4b.2. **If no improvement was demonstrated, what are the reasons? If not in use for performance improvement at the time of initial endorsement, provide a credible rationale that describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.**
N/A

4c. Unintended Consequences

The benefits of the performance measure in facilitating progress toward achieving high-quality, efficient healthcare for individuals or populations outweigh evidence of unintended negative consequences to individuals or populations (if such evidence exists).

4c.1. **Were any unintended negative consequences to individuals or populations identified during testing; OR has evidence of unintended negative consequences to individuals or populations been reported since implementation? If so, identify the negative unintended consequences and describe how benefits outweigh them or actions taken to mitigate them.**
There were no unintended negative consequences to individuals identified during the testing and long-standing use of this measure.

5. Comparison to Related or Competing Measures

If a measure meets the above criteria and there are endorsed or new related measures (either the same measure focus or the same target population) or competing measures (both the same measure focus and the same target population), the measures are compared to address harmonization and/or selection of the best measure.

5. Relation to Other NQF-endorsed Measures
Are there related measures (conceptually, either same measure focus or target population) or competing measures (conceptually both the same measure focus and same target population)? If yes, list the NQF # and title of all related and/or competing measures.
Yes

5.1a. **List of related or competing measures (selected from NQF-endorsed measures)**
0070 : Coronary Artery Disease (CAD): Beta-Blocker Therapy-Prior Myocardial Infarction (MI) or Left Ventricular Systolic Dysfunction (LVEF <40%)

5.1b. **If related or competing measures are not NQF endorsed please indicate measure title and steward.**

5a. Harmonization

The measure specifications are harmonized with related measures;
OR
The differences in specifications are justified

5a.1. If this measure conceptually addresses EITHER the same measure focus OR the same target population as NQF-endorsed measure(s):
Are the measure specifications completely harmonized?
No

5a.2. If the measure specifications are not completely harmonized, identify the differences, rationale, and impact on interpretability and data collection burden.
DUE TO THE TEXT LIMIT IN THIS SECTION – WE ARE PROVIDING OUR ANSWER FOR 5a.2 IN SECTION 5b.1

5b. Competing Measures

The measure is superior to competing measures (e.g., is a more valid or efficient way to measure);
OR
Multiple measures are justified.

5b.1. If this measure conceptually addresses both the same measure focus and the same target population as NQF-endorsed measure(s):
Describe why this measure is superior to competing measures (e.g., a more valid or efficient way to measure quality); OR provide a rationale for the additive value of endorsing an additional measure. (Provide analyses when possible.)
ANSWER FOR SECTION 5a.2

NCQA's current Persistence of Beta Blocker Treatment After a Heart Attack measure (NQF measure 0071) uses health plan-reported data to assess the percentage of patients 18 years of age and older during the measurement year who were discharged with a diagnosis of AMI during the 6 months prior to the beginning of the measurement year through the 6 months after the beginning of the measurement year and who received persistent beta-blocker treatment for six months after discharge.

RELATED NQF MEASURE 0070:
This measure assesses the percentage of patients aged 18 years and older with a diagnosis of coronary artery disease seen within a 12 month period who also have a prior MI or a current left ventricular ejection fraction (LVEF) <40% who were prescribed beta-blocker therapy.

HARMONIZED MEASURE ELEMENTS:
Measure 0071 and 0070 focus on patients 18 years and older who are prescribed beta-blocker treatment post-discharge after having a MI or history of MI. The National Quality Strategy Priorities classification for both measures is Prevention and Treatment of Cardiovascular Disease. Both measures exclude patients who are allergic or have an intolerance to beta blockers.

UNHARMONIZED MEASURE ELEMENTS:
Below are the unharmonized measure elements between measure 0071 and measure 0070:

Measure 0071 focuses on beta-blocker treatment post a MI and Measure 0070 focuses on patients who have a prior MI or a current or prior LVEF <40%.

-Data Source: Data for measure 0071 is collected through administrative claims, electronic clinical data, and pharmacy data, while data for measure 0070 is collected through medical record, electronic health record data, electronic clinical data, and paper records

-Level of Accountability: Measure 0071 is a health plan level measure while measure 0070 is a clinician-level measure.

-Population: Measure 0071 focuses on patients who were diagnosed with a MI and discharged and prescribed a beta-blocker therapy treatment. Measure 0070 focuses on patients in a measurement year with a diagnosis of coronary artery diseases who also have a prior MI or current or prior LVEF

-Exclusions: The difference in exclusions is that measure 0071 specifies asthma, COPD, obstructive chronic bronchitis, chronic

respiratory conditions due to fumes and vapors, hypotension, heart block >1 degree, sinus bradycardia, and medication dispensing events indicative of a history of asthma as exclusions. Additionally, measure 0071 excludes hospitalizations in which the patient was transferred directly to a nonacute care facility for any diagnosis. Measure 0070 exclusions include: documentation of patient reason(s) for not prescribing beta-blocker therapy (e.g., patient declined, other patient reasons) and documentation of system reason(s) for not prescribing beta-blocker therapy (e.g., other reasons attributable to the health care system

IMPACT ON INTERPRETABILITY AND DATA COLLECTION BURDEN:
The differences between measures 0071 and 0070 do not have an impact on interpretability of publically reported rates, or the burden of data collection, because all data for both measures are collected from different data sources by different entities.

ANSWER FOR SECTION 5b.1

Our current measure has a long standing history of use by health plans and has been implemented for 10 years.

Appendix

A.1 Supplemental materials may be provided in an appendix. All supplemental materials (such as data collection instrument or methodology reports) should be organized in one file with a table of contents or bookmarks. If material pertains to a specific submission form number, that should be indicated. Requested information should be provided in the submission form and required attachments. There is no guarantee that supplemental materials will be reviewed.

Brief Measure Information

NQF #: 0079
Measure Title: Heart Failure: Left Ventricular Ejection Fraction Assessment (Outpatient Setting)
Measure Steward: American College of Cardiology
Brief Description of Measure: Percentage of patients aged 18 years and older with a diagnosis of heart failure for whom the quantitative or qualitative results of a recent or prior (any time in the past) LVEF assessment is documented within a 12 month period.
Developer Rationale: This measure is aimed at improving the number of patients with heart failure who receive an evaluation of their LVEF.

Measurement of LVEF in heart failure patients is key to the implementation of therapeutic interventions demonstrated to slow disease progression and improve outcomes in patients with left ventricular systolic dysfunction.

Numerator Statement: Patients for whom the quantitative or qualitative results of a recent or prior (any time in the past) LVEF assessment is documented* within a 12 month period.

*Documentation must include documentation in a progress note of the results of an LVEF assessment, regardless of when the evaluation of ejection fraction was performed.

Qualitative results correspond to numeric equivalents as follows:
Hyperdynamic: corresponds to LVEF greater than 70%
Normal: corresponds to LVEF 50% to 70% (midpoint 60%)
Mild dysfunction: corresponds to LVEF 40% to 49% (midpoint 45%)
Moderate dysfunction: corresponds to LVEF 30% to 39% (midpoint 35%)
Severe dysfunction: corresponds to LVEF less than 30%
Denominator Statement: All patients aged 18 years and older with a diagnosis of heart failure.
Denominator Exclusions: None.

Measure Type: Process
Data Source: Electronic Clinical Data : Registry
Level of Analysis: Clinician : Individual
Is this an eMeasure? ☐ **Yes** ☒ **No** **If Yes, was it re-specified from a previously endorsed measure?** ☐ **Yes** ☐ **No**

Is this a MAINTENANCE measure submission? ☒ **Yes** ☐ **No, this is a NEW measure submission.**
For MAINTENANCE, state the Original Endorsement Date: 8/10/09 **Most Recent Endorsement Date:** 1/18/12

Previous Measure Evaluation - Public & Member Comments, Developer Responses & Steering Committee Recommendations from (Cardiology Project 2010):

Public and Member Comment

- Although this measure is intended for an outpatient setting, in the numerator it states that documentation must include documentation in a progress note of the results of an LVEF assessment, regardless of when the evaluation of ejection fraction was performed, which may involve documentation of an LVEF from an in-patient hospital setting. In-patient hospital data may not be readily available.
- It is a waste of resources to collect and report on mere completion of an assessment.
- Request clarification in the specifications about EFs done in prior visits or documented in the Electronic Health Record. A

provider may acknowledge these procedures, but not provide billing codes for a visit done in the office/outpatient setting.

- Functional outcomes such as this are the primary correlate of health-related quality of life (HRQL). HRQL is now recognized as the key patient-centered outcome. Thus, to measure only the indicators of provider care without acknowledging the patients perspective seems ill-advised. I strongly encourage you to reconsider this stance.

Developer response:

- While the measure requires that a patient's LVEF status be documented at least once within a 12 month period, the measure does not specify a time period for the assessment of LVEF - this assessment may have been performed anytime previously or within the last 12 months. Evaluation of LVEF in patients with heart failure provides important information that is required by any clinician managing the patient's outpatient care to appropriately direct treatment.
- This measure is intended to encourage assessment of a patient's LVEF status in order to identify patients who may be candidates for particular therapeutic options. An EHR could be searched for the relevant data to determine results of a previous LVEF assessment. For claims-based reporting, a provider would have to document the results of an LVEF assessment, regardless of when the evaluation of ejection fraction was performed.
- This is an assessment measure, not an outcome measure. The assessment only, without regard to subsequent intervention or follow-up is not proximal to the outcome which is the actual functional status of the patient.

Steering Committee: Reviewed comments and developers responses. No change in recommendations.

Preliminary Analysis

The preliminary analysis was developed in response to recommendations from NQF's Consensus Task Force and measurement stakeholders as a way to enhance and streamline the measures evaluation and voting processes. The preliminary analysis will help to guide the Standing Committee evaluation of each measure by summarizing the measure developer submission, guide measure evaluation discussion, and identify topic areas for additional input. **NQF staff would like to stress that the preliminary analysis is intended to be used as a guide to facilitate the Committee's discussion and evaluation.**

Criteria 1: Importance to Measure and Report

1a. Evidence

1a. Evidence. The evidence requirements for a *process* measure is that it is based on a systematic review (SR) and grading of the body of empirical evidence where the specific focus of the evidence matches what is being measured.

The developer provides the following evidence for this process measure:

- This is a clinician level process measure that calculates the % patients aged 18 years and older with a diagnosis of heart failure for whom the quantitative or qualitative results of a recent or prior (any time in the past) LVEF assessment is documented within a 12 month period in a clinician office/clinic setting.
- The evidence recommends initial evaluation and repeat measurement with a change in patient status.
- The developer provides decision logic from assessment to outcome for the evaluation of LVEF to slowed disease progression and improved health outcomes.
- The developer provides one guideline with two guideline statements for the management of heart failure with the details of the Quantity/Quality/Consistency for the 2013 ACCF/AHA guideline. The guideline statements are both graded **Class I: Level of Evidence: C** or consensus opinion of experts, case studies, or standard of care.
- The developers state that the two articles published after the publication of the 2013 ACCF/AHA guideline both further support the assessment of EF and guideline-directed medical treatment.

Questions for the Committee:

- *For process measures:*
  - *Is the evidence directly applicable to the process of care being measured?*
  - *Is the process of care proximal and closely related to desired outcomes?*
- *For possible exception to the evidence criteria:*
  - *Are there, or could there be, performance measures of a related health outcome, OR evidence-based intermediate clinical outcomes, intervention/treatment?*

- *Is there evidence of a systematic assessment of expert opinion beyond those involved in developing the measure?*
- *Does the SC agree that it is acceptable (or beneficial) to hold providers accountable without empiric evidence?*

1b. Gap in Care/Opportunity for Improvement and 1b. Disparities

1b. Performance Gap. The performance gap requirements include demonstrating quality problems and opportunity for improvement.

- The developer provided 2013 and 2014 performance data from the PINNACLE registry:

	Mean	Std Dev	Min	Max	Interquartile score	# providers	# patients	Male	White	Black	Other
2013	67.8%	32.0%	0.00%	100%	49.6%	2254	409,332	55.8%	89.5%	8.7%	1.9%
2014	72.5%	29.9%	0.00%	100%	41.6%	2219	404,406	55.7%	90.4%	7.2%	2.4%

- A 2003 study of patients within 1 month of treatment initiation indicates 35.2% of patients with CHF received an evaluation of LVEF. Another study cited found that between 2002 and 2003, 84% of inpatients (rather than the outpatient population for this measure) in hospitals had documentation of LVEF assessment.
- Variation in provider performance based on sex, age, race, and insurance is provided. The sample populations also list body mass index (BMI), diabetes, hypertension, Atrial Fibrillation/Flutter, Heart Failure, Peripheral Arterial Disease, Stroke/TIA and Myocardial Infarction co-morbidities apparently for information purpose.
- Data collected by AHRQ from 2001 to 2010, demonstrates disparities among Blacks and lower income residents with CHF despite overall improvement in the quality of care in patients with this diagnosis.

Questions for the Committee:

- *Is there a gap in care that warrants a national performance measure?*
- *If no disparities information is provided, are you aware of evidence that disparities exist in this area of healthcare?*
- *Should this measure be indicated as disparities sensitive?*

1c. Priority

1c. High Priority (previously "High Impact") requires measures to address national health goal/priority or a demonstrated high-impact aspect of care.

- *Beginning in 2015, priority is no longer an NQF measure evaluation criterion.*

Committee pre-evaluation comments

Criteria 1: Importance to Measure and Report (including 1a, 1b, 1c)

1. ***Committee's Overview Comments***:
   - For Measure 0079 (outpatient assessment of LVEF in heart failure patients), there are listed studies and consensus documents indicating the importance of this process measure but there are several important caveats:
     1. This is a process measure intended to support evidence-based clinical decision making. There is not a measure for the decision-making element of heart failure.
     2. The measure data can only reliably come from PINNACLE registry sources, which is limited in its scope so primary care physicians and a large percentage of cardiologists do not use this registry. Those physicians could not have valid data obtained.
     3. The source behind this measure is largely consensus driven with only one cited meta-analysis. As a process measure that is consensus developed it is weaker than an evidence-based outcome measure.
   - On the positive side, the ACC has been using this within the PINNACLE framework. So the greater the adoption of PINNACLE the greater the value of this measure.
   - This is a process measure. The measure is only supported by expert opinion in the heart failure guideline; however it is unlikely that higher level evidence will be available in the future. It is widely accepted that the patient's LVEF in particular is a critical value to consider when determining therapeutic options for patient with HF.
   - The two articles offered as evidence are not direct evidence of the utility of EF determination in HF patients.

One article is about the additional information CMR provides over and above echo. The other deals with predicting mortality of post STEMI patients based on EF -- not specifically HF patients.
- There are more proximal processes (eg. prescription of ACEIs or ARBs) but the EF value is important to determining the appropriateness of prescribing. However reporting the EF and doing something based on the EF are two different things.

1a. ***Committee's Comments on Evidence to Support Measure Focus:***
- The developers cite on meta-analysis and several observational studies for this process measure. The use of left ventricular ejection fraction to guide therapy is included in ACC/AHA guidelines. However I am not aware that the frequency of testing has been defined especially for those with lower grades of heart failure who are clinically stable.
- The body of evidence provided is related to ACEI/ARB use not about performing or recording EF values. No detail is provided other than the types of studies. There was 1 meta-analysis

1b. ***Committee's Comments on Performance Gap:***
- The developers do provide substantial data over two separate time periods involving >4K "clinicians" (presumably only cardiologists) and nearly a half million patients. The developers do clearly show a gap in this performance. What is not clear is whether the appropriate clinical decision making occurred in the absence of documentation of the measurement.
- The cited study from 2003 is irrelevant. Much has changed regarding the management of HF in the past 12 years.
- The Pinnacle Registry information from 2013 and 2014 both show a significant performance gap (67.8% and 72.5%). It should be noted that the Pinnacle Registry patients were 89.5%-90.4% White.
- Data regarding disparities was cited from AHRQ but pertains to hospital admissions for HF, not the indicator being evaluated.
- There were disparities based on insurance provider in the 2013 data with Medicare patients having significantly lower % of EF evaluations recorded (none -69.1%; private-64.4%; Medicaid 60%; Medicare 47.6%)"

1c. ***Committee's Comments on Composite Performance Measure:***
- Not Applicable

Criteria 2: Scientific Acceptability of Measure Properties
2a. Reliability
2a1. Reliability Specifications
2a1. Specifications requires the measure, as specified, to produce consistent (reliable) and credible (valid) results about the quality of care when implemented. • The measure's data source is the PINNACLE Registry with the data dictionary and collection tool provided. HCPCS codes provided for the numerator; ICD-9, ICD-10 and CPT codes provided for the denominator. ICD-10 conversion methodology and calculation algorithm are not provided. • For the numerator, documentation must include documentation in a progress note of the results of an LVEF assessment, regardless of when the evaluation fraction was performed. Theoretically, a provider could continue to successfully report the measure in subsequent measurement periods without additional assessment or interventions, if LVEF was assessed anytime during the patient's history. • LVEF is determined by either quantitative evaluation or narrative findings. The measure includes both concepts. ***Questions for the Committee:*** ○ *Are all the data elements clearly defined? Are all appropriate codes included?* ○ *Is the logic or calculation algorithm clear?* ○ *Is it likely this measure can be consistently implemented?*
2a2. Reliability Testing Testing attachment

2a2. Reliability testing demonstrates if the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise enough to distinguish differences in performance across providers.

- Reliability testing was conducted on the performance score, using PINNACLE data source at the individual clinician level during calendar year 2013 for 2,254 providers and 409,332 patients; & 2014 for 2,219 providers and 404,406 patients.
- A signal-to-noise analysis using the beta-binomial model was conducted. This type of analysis, which is appropriate for the measure, quantifies the amount of variation in performance that is due to differences between providers (as opposed to differences that are due to random measurement error). A reliability of zero implies that all the variability in a measure is attributable to measurement error. A reliability of one implies that all the variability is attributable to real differences in physician performance. The method results in a reliability statistic for each clinician.
- As the minimum number of patient visits required (>10) the average reliability was 0.988 for 2013 & 0.989 for 2014. For providers with the median number of patient encounters, the reliability was even higher, with 0.997 for both years. A reliability of 0.70 is generally considered a minimum threshold for acceptability, and 0.80 is considered very good reliability. Very high quartiles reliability statistics are also provided for both 2013 and 2014.

Questions for the Committee:

- *Is the test sample adequate to generalize for widespread implementation?*
- *Do the results demonstrate sufficient reliability so that differences in performance can be identified?*

2b. Validity

2b1. Validity: Specifications

2b1. Validity Specifications. This section should determine if the measure specifications are consistent with the evidence.

- The clinical practice guidelines supporting this measure recommend measurement of LVEF in patients with CHF during initial evaluation and periodically as symptoms or a change in status warrants.

Question for the Committee:

- *Are the specifications consistent with the evidence?*

2b2. Validity testing

2b2. Validity Testing should demonstrate the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality.

- Content validity was assessed by an expert work group, public comment, concurrent formal peer review process, approval by the ACC Board of Trustee & Science Advisory & Coordination Committees, and PCPI membership.
- The developers state that construct validity (the degree to which the measure is assessing what it claims to be measuring) was difficult to assess as independent auditing has not occurred, though as the data is abstracted from the EHR by direct transfer, errors would occur by mapping or incorrect auditor abstracting.
- Face validity was systematically assessed via survey by 2 committees (one ACC & one AHA) of 42 members with 85.7% agreeing the measure scores as specified provide an accurate reflection of quality and can be used to distinguish good and poor quality. Using a Likert Scale from 1-5, the mean importance rate was 4.24.

Questions for the Committee:

- *Is the test sample adequate to generalize for widespread implementation?*
- *Do the results demonstrate sufficient validity so that conclusions about quality can be made?*
- *Do you agree that the score from this measure as specified is an indicator of quality?*

2b3-2b7. Threats to Validity

2b3. Exclusions:

- There are no exclusions for this measure.

2b4. Risk adjustment:

- This process measure is not risk adjusted.

2b5. Meaningful difference:

- The overall mean performance on this measure is 67.8% (SD = 32.0%) for 2013 and 72.5% (SD = 29.9%) for 2014.
- The developer notes a moderate to large amount of variability across providers for statistically 'identical' patients and suggests that a patient presenting to 1 provider, as opposed to another, would on average, be 2.3 times (2013) and 1.2 times (2014) more likely to have their EF assessed.

Question for the Committee:

- *Does this measure identify meaningful differences about quality?*

2b6. Comparability of data sources/methods:

- As the measure is specified for Registry use, comparability across data sources/methods is not applicable.

2b7. Missing Data

- The developer notes that in the PINNACLE registry, if a data field is not completed, it is assumed the process of care was not done; therefore, missing numerator data is reported as a quality failure.

Committee pre-evaluation comments

Criteria 2: Scientific Acceptability of Measure Properties (including all 2a, 2b, and 2d)

2a1. &2b1.: ***Committee's Comments on Reliability-Specifications:***

- The developers have done a very thoughtful job in developing the specifications so that reliability can be ensured--but that is only for users of PINNACLE. Other cardiologists and primary care physicians would have to manually extract the coding from clinical records with an anticipated reduction in reliability. In other words, it is the structure of the registry that ensures this to be a reliable measure. Outside of that particular registry the reliability may fall secondary to human and charting frailties.
- "Documentation in the progress note"" is somewhat vague. Examples of types of qualitative and quantitative entries are provided for the numerator. I am not sure how Pinnacle is able to extract this information but apparently it can. Possibly this is because the EHR in use is a cardiology application.
- The measure seems to be consistently implemented using Pinnacle and compatible EHRs.

2a2.: ***Committee's Comments on Reliability-Testing:***

- Yes, the reliability for the cardiologists participating with PINNACLE was more than adequate.
- There were over 2,000 providers and 400,000 patients included in each of the reliability testing periods -- adequate. Providers were nationwide. One downside - very low percentage of Black patients included in analyses.
- The signal-to-noise analysis was 0.988 for 2013 and 0.989 for 2014 (very good). A minimum of more than 10 patients was required to establish this level of reliability. Given the incidence of HF, this shouldn't be a problem. Most practices will have more than 10 HF patients.

2b1.: ***Committee's Comments on Validity-Specifications***:

- Since this measure is largely consensus derived process measure, the validity becomes dependent upon the coding associated with the consensus and not that based upon clinical evidence. As such there may be face validity but not statistical validity.
- The HF guidelines recommend determining the EF initially and with any significant change in symptoms or change in condition. Level of evidence is expert opinion.
- The specifications of the measure only require that the EF vlaue be mentioned in the documentation. No timing is specified other than 1 instance of documentation in 12 months. This is sufficiently vague to allow for EF determinations older than 12 months to be credited. However, there are no stipulations about timing in relationship to changes in patient condition. This is a weakness of this measure.

2b2.: ***Committee's Comments on Validity-Testing:***

- As above, the validity was determined through consensus and the testing of the data was performed with that bias included.

- See above. Content validity - expert workgroup; peer review
- Face validity - 1 AHA committee and 1 ACC committee agreed that measure socres reflect quality (85.7%) Importance ranking 4.24/5
- I see the recording of EF as being tangential to actions that could indicate quality (eg. prescription of ACEI/ARBs to patients with EF <40%)"

2b3-7.: ***Committee's Comments on Threats to Validity:***

- This measure was developed within the PINNACLE registry and was thoughtfully developed for that registry. Its appropriate application as a measure of process quality therefore is dependent upon the greater adoption of the registry as a tool. As such the greatest threat to the measure is its symbiotic relationship to PINNACLE.
- This is also critical to the intention of this process measure as a piece of information important to the clinical decision-making of the clinician in appropriately treating the patient with heart failure.
- 2b3 - no exclusions
- 2b4 - might need risk adjustment in populations other than the Pinnacle Registry as socioeconomic factors might impact patients' ability to access the test (echo). No risk adjustment provided with application
- 2b5 - there is enough variability among providers (according to developers) to distinguish differences in quality
- 2b6 - intended to be used with Pinnacle Registry
- 2b7 - missing data is interpreted as not fulfilling the criteria (poorer quality)

2d.: ***Committee's Comments on Composite Performance Measure:***

- Not Applicable

Criterion 3. Feasibility

3. Feasibility is the extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

- The data source is electronic abstraction from the clinical record, MDS, OASIS to the PINNACLE Registry from readily available data occurring during patient care.
- As one of the earliest NQF endorsed measures utilized, the developers state the data collection strategy is implemented, though no information for abstraction time and costs are provided.

Questions for the Committee:

- *Are the required data elements routinely generated and used during care delivery?*
- *Are the required data elements available in electronic form, e.g., EHR or other electronic sources?*
- *Is the data collection strategy ready to be put into operational use?*
- *If an eMeasure, does the eMeasure Feasibility Score Card demonstrate acceptable feasibility in multiple EHR systems and sites?*

Committee pre-evaluation comments

Criteria 3: Feasibility

3.: ***Committee's Comments on Feasibility:***

- This measure is feasible and has been used--but only for those physicians using the PINNACLE registry. It is not feasible for those who do not use PINNACLE. Success of this process measure should be determined by either greater adoption of PINNACLE, incorporation of this into other EHRs, or development of extraction of the data from submitted medical claims.
- No feasibility data is provided.
- EF values are generally determined. Whether they are referenced in the Progress Notes on a routine basis or in a consistent way is unknown.
- May require an abstractor if Pinnacle and compatible EHRs are not used.

Criterion 4: Usability and Use

4. Usability and Use evaluate the extent to which audiences (e.g., consumers, purchasers, providers, policymakers) use or could use performance results for both accountability and performance improvement activities.

- The measure is currently used in the ACC PINNACLE Registry for quality improvement.
- The developers state they continuously seek opportunities for use of this measure in public reporting and accountability programs, and do not have policies that would restrict use.
- NQF policy states that performance results are used in at least 1 accountability application within 3 years after initial endorsement and are publicly reported within 6 years after initial endorsement. This measure was initially endorsed in 2009.
- No unintended consequences have been identified, though the developer continuously monitors.
- In 2012, the Measure Applications Partnership (MAP) Clinician Workgroup supported the measure for the Meaningful Use (EHR Incentive Program) - Eligible Professionals. No comments were provided. In 2014, the Clinician Workgroup did not the measure for Physician Compare and Value-Based Payment Modifier Program stating the measure does not adequately address any current needs of the program.

Questions for the Committee *:*

- *Is the measure publicly reported?*
- *For maintenance measures – is the measure used in at least one accountability application?*
- *How can the performance results be used to further the goal of high-quality, efficient healthcare?*
- *Do the benefits of the measure outweigh any potential unintended consequences?*

Committee pre-evaluation comments

Criteria 4: Usability and Use

4.: ***Committee's Comments on Usability and Use:***

- This measure is not currently being widely used in public reporting. It is used by ACC for feedback and cardiologist self-improvement
- Not publically reported
- Not in an accountability application
- Performance could assist with promoting high quality, efficient care but there are measure that are closer to outcomes of interest (readmissions in 30 days; ACEI/ARBs prescribed, etc.)"

Criterion 5: Related and Competing Measures

- 0135 : Evaluation of Left ventricular systolic function (LVS)
- The developer states that the measure specifications are not completely harmonized because 0135 is inpatient based and focuses on the assessment occurring prior to discharge. 0079 looks at whether the assessment was performed during a 12 month period for a patient with a diagnosis of heart failure.

Pre-meeting public and member comments

-

Measure Number (*if previously endorsed*)**:** 0079

Measure Title: Heart Failure: Left Ventricular Ejection Fraction (LVEF) Assessment (Outpatient Setting)

IF the measure is a component in a composite performance measure, provide the title of the Composite Measure here: Click here to enter composite measure #/ title

Date of Submission: 6/23/2015

Instructions

- *For composite performance measures:*
  - *A separate evidence form is required for each component measure unless several components were studied together.*
  - *If a component measure is submitted as an individual performance measure, attach the evidence form to the individual measure submission.*
- Respond to all questions as instructed with answers immediately following the question. All information needed to demonstrate meeting the evidence subcriterion (1a) must be in this form. An appendix of *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 10 pages (*incudes questions/instructions*; minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the evidence for this measure meets NQF's evaluation criteria.

1a. Evidence to Support the Measure Focus

The measure focus is evidence-based, demonstrated as follows:

- Health outcome: [3] a rationale supports the relationship of the health outcome to processes or structures of care. Applies to patient-reported outcomes (PRO), including health-related quality of life/functional status, symptom/symptom burden, experience with care, health-related behavior.
- Intermediate clinical outcome: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured intermediate clinical outcome leads to a desired health outcome.
- Process: [5] a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured process leads to a desired health outcome.
- Structure: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured structure leads to a desired health outcome.
- Efficiency: [6] evidence not required for the resource use component.

Notes

3. Generally, rare event outcomes do not provide adequate information for improvement or discrimination; however, serious reportable events that are compared to zero are appropriate outcomes for public reporting and quality improvement.

4. The preferred systems for grading the evidence are the U.S. Preventive Services Task Force (USPSTF) grading definitions and methods, or Grading of Recommendations, Assessment, Development and Evaluation (GRADE) guidelines.

5. Clinical care processes typically include multiple steps: assess → identify problem/potential problem → choose/plan intervention (with patient input) → provide intervention → evaluate impact on health status. If the measure focus is one step in such a multistep process, the step with the strongest evidence for the link to the desired outcome should be selected as the focus of measurement. Note: A measure focused only on collecting PROM data is not a PRO-PM.

6. Measures of efficiency combine the concepts of resource use and quality (see NQF's Measurement Framework: Evaluating Efficiency Across

Episodes of Care; AQA Principles of Efficiency Measures).

1a.1.This is a measure of: (*should be consistent with type of measure entered in De.1*)

Outcome

☐ Health outcome: Click here to name the health outcome

☐Patient-reported outcome (PRO): Click here to name the PRO

PROs include HRQoL/functional status, symptom/symptom burden, experience with care, health-related behaviors

☐ Intermediate clinical outcome (*e.g., lab value*): Click here to name the intermediate outcome

☒ Process: Assessment of left ventricular ejection fraction

☐ Structure: Click here to name the structure

☐ Other: Click here to name what is being measured

HEALTH OUTCOME/PRO PERFORMANCE MEASURE *If not a health outcome or PRO, skip to 1a.3*

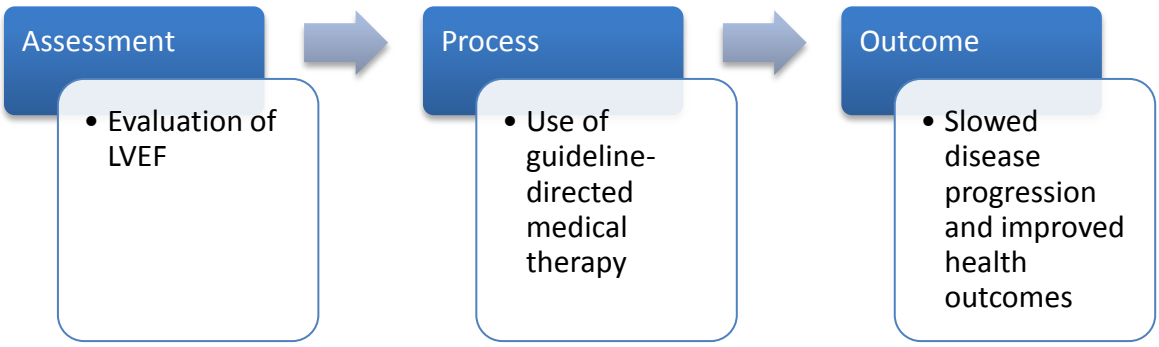
1a.2. Briefly state or diagram the path between the health outcome (or PRO) and the healthcare structures, processes, interventions, or services that influence it.

1a.2.1. State the rationale supporting the relationship between the health outcome (or PRO) to at least one healthcare structure, process, intervention, or service (*i.e., influence on outcome/PRO*).

Note: For health outcome/PRO performance measures, no further information is required; however, you may provide evidence for any of the structures, processes, interventions, or service identified above.

INTERMEDIATE OUTCOME, PROCESS, OR STRUCTURE PERFORMANCE MEASURE

1a.3. Briefly state or diagram the path between structure, process, intermediate outcome, and health outcomes. Include all the steps between the measure focus and the health outcome.



Evaluation of LVEF in patients with heart failure provides important information that is required to appropriately direct treatment. Several pharmacologic therapies have demonstrated efficacy in slowing disease progression and improving outcomes in patients with left ventricular systolic dysfunction. LVEF assessed

during the initial evaluation of patients presenting with heart failure can be considered valid unless the patient has demonstrated a major change in clinical status, experienced or recovered from a clinical event, or received therapy that might have a significant effect on cardiac function.

1a.3.1. What is the source of the systematic review of the body of evidence that supports the performance measure?

☒ Clinical Practice Guideline recommendation – ***complete sections 1a.4, and 1a.7***

☐ US Preventive Services Task Force Recommendation – ***complete sections 1a.5 and 1a.7***

☐ Other systematic review and grading of the body of evidence (*e.g., Cochrane Collaboration, AHRQ Evidence Practice Center*) – ***complete sections 1a.6 and 1a.7***

☐ Other – ***complete section 1a.8***

Please complete the sections indicated above for the source of evidence. You may skip the sections that do not apply.

1a.4. CLINICAL PRACTICE GUIDELINE RECOMMENDATION

1a.4.1. Guideline citation (*including date*) and **URL for guideline** (*if available online*):

Yancy CW, Jessup M, Bozkurt B, Butler J, Casey DE Jr, Drazner MH, Fonarow GC, Geraci SA, Horwich T, Januzzi JL, Johnson MR, Kasper EK, Levy WC, Masoudi FA, McBride PE, McMurray JJV, Mitchell JE, Peterson PN, Riegel B, Sam F, Stevenson LW, Tang WHW, Tsai EJ, Wilkoff BL. 2013 ACCF/AHA guideline for the management of heart failure: a report of the American College of Cardiology Foundation/American Heart Association Task Force on Practice Guidelines. J Am Coll Cardiol 2013;62:e147–239.

http://content.onlinejacc.org/article.aspx?articleid=1695825

1a.4.2. Identify guideline recommendation number and/or page number and **quote verbatim, the specific guideline recommendation**.

2013 ACCF/AHA guideline for the management of heart failure (p. e165-166)

1. A 2-dimensional echocardiogram with Doppler should be performed during initial evaluation of patients presenting with HF to assess ventricular function, size, wall thickness, wall motion, and valve function. **Class I: Level of Evidence: C**
2. Repeat measurement of EF and measurement of the severity of structural remodeling are useful to provide information in patients with HF who have had a significant change in clinical status; who have experienced or recovered from a clinical event; or who have received treatment, including GDMT, that might have had a significant effect on cardiac function; or who may be candidates for device therapy. **Class I: Level of Evidence: C**

1a.4.3. Grade assigned to the quoted recommendation with definition of the grade:

Guideline Statement # (see 1a.4.2 above)	Class of Recommendation/Level of Evidence (for definitions see 1a.4.4 below)
1	Class Ic
2	Class Ic

1a.4.4. Provide all other grades and associated definitions for recommendations in the grading system. (*Note: If separate grades for the strength of the evidence, report them in section 1a.7.*)

Class of Recommendation (COR) is an estimate of the size of the treatment effect considering risks versus benefits in addition to evidence and/or agreement that a given treatment or procedure is or is not useful/effective or in some situations may cause harm.

Class I: Procedure/Treatment should be performed/administered

Class IIa: It is reasonable to perform procedure/administer treatment

Class IIb: Procedure/Treatment may be considered

Class III: No benefit (Not helpful or No proven benefit)

Class III: Harm (Excess cost w/o benefit or Harmful to patients)

Specific COR definitions are included in Table 1 below.

Table 1. Applying Classification of Recommendation and Level of Evidence

SIZE OF TREATMENT EFFECT

ESTIMATE OF CERTAINTY (PRECISION) OF TREATMENT EFFECT	CLASS I *Benefit >>> Risk* Procedure/Treatment **SHOULD** be performed/ administered	CLASS IIa *Benefit >> Risk* *Additional studies with focused objectives needed* **IT IS REASONABLE** to perform procedure/administer treatment	CLASS IIb *Benefit ≥ Risk* *Additional studies with broad objectives needed; additional registry data would be helpful* Procedure/Treatment **MAY BE CONSIDERED**	CLASS III *No Benefit* or CLASS III *Harm* Procedure/ Test / Treatment COR III: No benefit — Not Helpful — No Proven Benefit COR III: Harm — Excess Cost w/o Benefit or Harmful — Harmful to Patients
LEVEL A Multiple populations evaluated* Data derived from multiple randomized clinical trials or meta-analyses	■ Recommendation that procedure or treatment is useful/effective ■ Sufficient evidence from multiple randomized trials or meta-analyses	■ Recommendation in favor of treatment or procedure being useful/effective ■ Some conflicting evidence from multiple randomized trials or meta-analyses	■ Recommendation's usefulness/efficacy less well established ■ Greater conflicting evidence from multiple randomized trials or meta-analyses	■ Recommendation that procedure or treatment is not useful/effective and may be harmful ■ Sufficient evidence from multiple randomized trials or meta-analyses
LEVEL B Limited populations evaluated* Data derived from a single randomized trial or nonrandomized studies	■ Recommendation that procedure or treatment is useful/effective ■ Evidence from single randomized trial or nonrandomized studies	■ Recommendation in favor of treatment or procedure being useful/effective ■ Some conflicting evidence from single randomized trial or nonrandomized studies	■ Recommendation's usefulness/efficacy less well established ■ Greater conflicting evidence from single randomized trial or nonrandomized studies	■ Recommendation that procedure or treatment is not useful/effective and may be harmful ■ Evidence from single randomized trial or nonrandomized studies
LEVEL C Very limited populations evaluated* Only consensus opinion of experts, case studies, or standard of care	■ Recommendation that procedure or treatment is useful/effective ■ Only expert opinion, case studies, or standard of care	■ Recommendation in favor of treatment or procedure being useful/effective ■ Only diverging expert opinion, case studies, or standard of care	■ Recommendation's usefulness/efficacy less well established ■ Only diverging expert opinion, case studies, or standard of care	■ Recommendation that procedure or treatment is not useful/effective and may be harmful ■ Only expert opinion, case studies, or standard of care
Suggested phrases for writing recommendations	should is recommended is indicated is useful/effective/beneficial	is reasonable can be useful/effective/beneficial is probably recommended or indicated	may/might be considered may/might be reasonable usefulness/effectiveness is unknown/unclear/uncertain or not well established	COR III: No Benefit: is not recommended; is not indicated; should not be performed/ administered/ other; is not useful/ beneficial/ effective COR III: Harm: potentially harmful; causes harm; associated with excess morbidity/mortality; should not be performed/ administered/ other
Comparative effectiveness phrases†	treatment/strategy A is recommended/indicated in preference to treatment B treatment A should be chosen over treatment B	treatment/strategy A is probably recommended/indicated in preference to treatment B it is reasonable to choose treatment A over treatment B		

Note: A recommendation with Level of Evidence B or C does not imply that the recommendation is weak. Many important clinical questions addressed in the guidelines do not lend themselves to clinical trials. Although randomized trials are unavailable, there may be a very clear clinical consensus that a particular test or therapy is useful or effective. *Data available from clinical trials or registries about the usefulness/efficacy in different subpopulations, such as sex, age, history of diabetes, history of prior myocardial infarction, history of heart failure, and prior aspirin use. †For comparative effectiveness recommendations (Class I and IIa; Level of Evidence A and B only), studies that support the use of comparator verbs should involve direct comparisons of the treatments or strategies being evaluated.

1a.4.5. Citation and URL for methodology for grading recommendations (*if different from 1a.4.1*)**:**

ACCF/AHA Task Force on Practice Guidelines. Methodology Manual and Policies From the ACCF/AHA Task Force on Practice Guidelines. American College of Cardiology Foundation and American Heart Association, Inc. Cardiosource.com. 2010. 1a.6. OTHER SYSTEMATIC REVIEW OF THE BODY OF EVIDENCE

1a.6.1. Citation (*including date*) and **URL** (*if available online*):

1a.6.2. Citation and URL for methodology for evidence review and grading (*if different from 1a.6.1*)**:**

Complete section 1a.7

1a.7. FINDINGS FROM SYSTEMATIC REVIEW OF BODY OF THE EVIDENCE SUPPORTING THE MEASURE

If more than one systematic review of the evidence is identified above, you may choose to summarize the one (or more) for which the best information is available to provide a summary of the quantity, quality, and consistency of the body of evidence. Be sure to identify which review is the basis of the responses in this section and if more than one, provide a separate response for each review.

1a.7.1. What was the specific structure, treatment, intervention, service, or intermediate outcome addressed in the evidence review?

2013 ACCF/AHA Guideline for the Management of Heart Failure

This guideline covers multiple evaluation and management issues for the adult patient with Heart Failure (HF) including the assessment of left ventricular ejection fraction to enable appropriate treatment.

1a.7.2. Grade assigned for the quality of the quoted evidence with definition of the grade:

An overall grade for the quality of evidence was not assigned. Rather, the quality of a study (or set of studies) supporting a recommendation was graded on an estimate of the certainty or precision of the treatment effect (see 1a.4.3).

Recommendations used to support this measure have a Level of Evidence C: Consensus opinion of experts, case studies, or standard of care.

1a.7.3. Provide all other grades and associated definitions for strength of the evidence in the grading system.

Level of Evidence (LOE) is an estimate of the certainty or precision of the treatment effect.

Level of Evidence A: Data derived from multiple randomized clinical trials or meta- analyses. References used to determine level of evidence must be provided and cited with the recommendation.

Level of Evidence B: Data derived from a single randomized trial, or nonrandomized studies. References used to determine level of evidence must be provided and cited with the recommendation.

Level of Evidence C: Consensus opinion of experts, case studies, or standard of care.

Specific LOE definitions are included in Table 1 in 1a.4.4.

1a.7.4. What is the time period covered by the body of evidence? (*provide the date range, e.g., 1990-2010*).
Date range: An extensive evidence review was conducted through October 2011 and includes selected other references through April 2013.

QUANTITY AND QUALITY OF BODY OF EVIDENCE

1a.7.5. How many and what type of study designs are included in the body of evidence? (*e.g., 3 randomized controlled trials and 1 observational study*)

2013 ACCF/AHA Guideline for the Management of Heart Failure

The body of evidence supporting the recommendations on ACE/ARB therapy includes:

4 observational

1 meta-analysis

1 prospective multicenter cohort

1 retrospective cohort

1 review paper

1a.7.6. What is the overall quality of evidence <u>across studies</u> in the body of evidence? (*discuss the certainty or confidence in the estimates of effect particularly in relation to study factors such as design flaws, imprecision due to small numbers, indirectness of studies to the measure focus or target population*)

2013 ACCF/AHA Guideline for the Management of Heart Failure

The recommendations for this process are rated as Level of Evidence C, meaning consensus opinion of experts, case studies, or standard of care. Additional information on the overall quality of evidence is not provided.

ESTIMATES OF BENEFIT AND CONSISTENCY ACROSS STUDIES IN BODY OF EVIDENCE

1a.7.7. What are the estimates of benefit—magnitude and direction of effect on outcome(s) <u>across studies</u> in the body of evidence? (*e.g., ranges of percentages or odds ratios for improvement/ decline across studies, results of meta-analysis, and statistical significance*)

2013 ACCF/AHA Guideline for the Management of Heart Failure (p. e165)

Although a complete history and physical examination are important first steps, the most useful diagnostic test in the evaluation of patients with or at risk for HF (e.g., postacute MI) is a comprehensive 2-dimensional echocardiogram; coupled with Doppler flow studies, the transthoracic echocardiogram can identify abnormalities of myocardium, heart valves, and pericardium. Echocardiography can reveal subclinical HF and predict risk of subsequent events. Use of echocardiograms in patients with suspected HF improves disease identification and provision of appropriate medical care.

1a.7.8. What harms were studied and how do they affect the net benefit (benefits over harms)?

No harms have been identified related to the evaluation of patients with or at risk for HF. Rather, the 2013 ACCF/AHA Guideline for the Management of Heart Failure discusses whether certain testing modalities are superior to others with echocardiography being preferred "due to its widespread availability and lack of ionizing radiation" (p. e165).

UPDATE TO THE SYSTEMATIC REVIEW(S) OF THE BODY OF EVIDENCE

1a.7.9. If new studies have been conducted since the systematic review of the body of evidence, provide for <u>each</u> new study: 1) citation, 2) description, 3) results, 4) impact on conclusions of systematic review.

One prospective study and one retrospective analysis were published after the publication of the 2013 ACCF/AHA Guideline for the Management of Heart Failure.

Note: Text below for description and results is verbatim from the article abstract.

Abbasi SA, Ertel A, Shah RV, Dandekar V, Chung J, Bhat G, Desai AA, Kwong RY, Farzaneh-Far A. Impact of cardiovascular magnetic resonance on management and clinical decision-making in heart failure patients. J Cardiovasc Magn Reson. 2013;15:89.

Description: We prospectively studied 150 consecutive patients with heart failure and an ejection fraction ≤ 50% referred for CMR [Cardiovascular magnetic resonance]. Definitions for "significant clinical impact" of CMR were pre-defined and collected directly from medical records and/or from patients. Categories of significant clinical impact included: new diagnosis, medication change, hospital admission/discharge, as well as performance or avoidance of invasive procedures (angiography, revascularization, device therapy or biopsy).

Results: Overall, CMR had a significant clinical impact in 65% of patients. This included an entirely new diagnosis in 30% of cases and a change in management in 52%. CMR results directly led to angiography in 9% and to the performance of percutaneous coronary intervention in 7%. In a multivariable model that included clinical and imaging parameters, presence of late gadolinium enhancement (LGE) was the only independent predictor of "significant clinical impact" (OR 6.72, 95% CI 2.56-17.60, p=0.0001).

Conclusion: CMR made a significant additive clinical impact on management, decision-making and diagnosis in 65% of heart failure patients. This additive impact was seen despite universal use of prior echocardiography in this patient group. The presence of LGE was the best independent predictor of significant clinical impact following CMR.

Liosis S, Bauer T, Schiele R, Gohlke H, Gottwik M, Katus H, Sabin G, Zahn R, Schneider S, Rauch B, Senges J, Zeymer U. Predictors of 1-year mortality in patients with contemporary guideline-adherent therapy after acute myocardial infarction: results from the OMEGA study. Clin Res Cardiol. 2013;102:671-7.

Description and Results: We performed a retrospective analysis of 3,782 patients surviving acute ST-elevation and non ST-elevation myocardial infarction who were enrolled in the prospective, randomized, double-blind, controlled OMEGA trial with 104 German centers. The primary objective of the OMEGA study was to determine the effect of highly purified omega-3 fatty acid ethyl esters-90 on the rate of sudden cardiac death in patients surviving AMI and receiving current guideline-adherent treatment within the 1-year of follow-up. 80.8 % of the patients received early revascularization therapy. At discharge, 94.2 % of the patients received beta-blocker, 90.4 % ACE inhibitor/angiotensin receptor blocker, 94.3 % statin, 95.4 % aspirin and 88.4 % clopidogrel. During the 1-year follow-up 139 patients (3.7 %) died. Multivariate logistic regression analysis revealed the following independent predictors of 1-year mortality in decreasing order of importance: ejection fraction <45 % [odds ratio (OR) 2.28, 95 % confidence interval (CI) 1.53-3.41], age ≥70 years (OR 2.17, 95 % CI 1.42-3.32), no acute revascularization (OR 2.02, 95 % CI 1.33-3.08), prior stroke/transient ischemic attack (OR 1.90, 95 % CI 1.09-3.30), peripheral arterial disease (OR 1.86, 95 % CI 1.12-3.10), heart rate >85/min (OR 1.82, 95 % CI 1.23-2.71), chronic obstructive lung disease (OR 1.77, 95 % CI 1.01-3.10) and HDL cholesterol <40 mg/dl (OR 1.75, 95 % CI 1.15-2.67).

Conclusion: In patients surviving AMI and treated with contemporary guideline-adherent therapy, 1-year mortality was low. Nevertheless, traditional risk factors such as ejection fraction <45 %, older age, no acute revascularization and comorbidities were the strongest predictors of long-term mortality supporting the findings from previous studies.

Impact on conclusions of systematic review: Both articles further support the assessment of ejection fraction to enable appropriate guideline-directed medical treatment.

1a.8 OTHER SOURCE OF EVIDENCE

If source of evidence is NOT from a clinical practice guideline, USPSTF, or systematic review, please describe the evidence on which you are basing the performance measure.

1a.8.1 What process was used to identify the evidence?

1a.8.2. Provide the citation and summary for each piece of evidence.

1. Evidence, Performance Gap, Priority – Importance to Measure and Report

Extent to which the specific measure focus is evidence-based, important to making significant gains in healthcare quality, and improving health outcomes for a specific high-priority (high-impact) aspect of healthcare where there is variation in or overall less-than-optimal performance. ***Measures must be judged to meet all subcriteria to pass this criterion and be evaluated against the remaining criteria.***

1a. Evidence to Support the Measure Focus – See attached Evidence Submission Form
HF_LVEF_Assessment_0079_Evidence_Form_5_26_15.pdf

1b. Performance Gap

Demonstration of quality problems and opportunity for improvement, i.e., data demonstrating:

- considerable variation, or overall less-than-optimal performance, in the quality of care across providers; and/or
- disparities in care across population groups.

1b.1. **Briefly explain the rationale for this measure** *(e.g., the benefits or improvements in quality envisioned by use of this measure)*
This measure is aimed at improving the number of patients with heart failure who receive an evaluation of their LVEF.

Measurement of LVEF in heart failure patients is key to the implementation of therapeutic interventions demonstrated to slow disease progression and improve outcomes in patients with left ventricular systolic dysfunction.

1b.2. **Provide performance scores on the measure as specified (current and over time) at the specified level of analysis.** *(This is required for endorsement maintenance. Include mean, std dev, min, max, interquartile range, scores by decile. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities included). This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*
2013 performance data from the Pinnacle registry.

Overall mean performance on this measure is 67.8%, with a standard deviation of 32.0%. The minimum score equals 0.00%, while the maximum score equals 100.00%. The interquartile score is equal to 49.6%.

2,254 providers were measured, and the patient study sample equals 409,332. 55.8% of the sample is male. 89.5% of the sample is white, 8.7% is black, and 1.9% identified as “other.” The sample reached across all US regions, with 14.9% of providers in the

Northeast, 30.7% of providers in the Midwest, 37.4% of providers in the South, and 17.1% of providers in the West.

Mean
Decile 1 4.0%
Decile 2 23.5%
Decile 3 44.5%
Decile 4 62.3%
Decile 5 75.5%
Decile 6 84.9%
Decile 7 90.6%
Decile 8 94.7%
Decile 9 97.7%
Decile 10 99.7%

2014 performance data from the Pinnacle registry.

Overall mean performance on this measure is 72.5%, with a standard deviation of 29.9%. The minimum score equals 0.00%, while the maximum score equals 100.00%. The interquartile score is equal to 41.6%.

2,219 providers were measured, and the patient study sample equals 404,406. 55.7% of the sample is male. 90.4% of the sample is white, 7.2% is black, and 2.4% identified as "other." The sample reached across all US regions, with 15.1% of providers in the Northeast, 24.5% of providers in the Midwest, 42.0% of providers in the South, and 18.5 % of providers in the West.

Mean
Decile 1 7.2%
Decile 2 34.7%
Decile 3 54.4%
Decile 4 69.9%
Decile 5 82.1%
Decile 6 89.4%
Decile 7 93.1%
Decile 8 95.9%
Decile 9 98.0%
Decile 10 99.7%

1b.3. If no or limited performance data on the measure as specified is reported in 1b2, then provide a summary of data from the literature that indicates opportunity for improvement or overall less than optimal performance on the specific focus of measurement.
A 2003 study analyzing the quality of health care in the U.S. found that only 35.25% of participants with congestive heart failure who were beginning medical treatment received an evaluation of their LVEF within 1 month of the start of treatment.(1) For patients hospitalized with heart failure, a study analyzing data from 223 hospitals participating in the Acute Decompensated Heart Failure National Registry (ADHERE) between July 2002 and December 2003 found that left ventricular function assessment was documented in 84% of the 69,069 eligible admissions. Variability among participating hospitals was significant with rates at individual hospitals varying from 14 to 100%.(2)

(1)Appendix to McGlynn EA, Asch SM, Adams J, et al. The quality of health care delivered to adults in the United States. N Engl J Med. 2003;348:2635-2645.

(2)Fonarow GC, Yancy CW, Heywood JT. Adherence to heart failure quality-of-care indicators in US hospitals: analysis of the ADHERE Registry. Arch Intern Med. 2005; 165: 1469–1477.

1b.4. Provide disparities data from the measure as specified (current and over time) by population group, e.g., by race/ethnicity, gender, age, insurance status, socioeconomic status, and/or disability. *(This is required for endorsement maintenance. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities include.) This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*
We examined variation in provider performance on this measure based on sex, age, race and a number of other patient factors to

identify variations. The findings fare represented for 2013 and 2014 respectively.

To view the tables in formatted fashion, see testing form Section 2b5.1 page 14.

The 2013 National Healthcare Disparities Report showed that disparities in care for heart failure exist across populations. [1]

Based on data collected by AHRQ, from 2001 to 2010, the hospitalization rate for congestive heart failure decreased significantly overall and for each racial/ethnic and area income group. Although the quality of care improved overall, the following trends were observed.

•In all years, Blacks had higher rates of admission for congestive heart failure compared with Whites while APIs had lower rates than Whites.

•In all years, residents of the highest area income quartile had lower rates than residents of the two lower area income quartiles.

•The 2008 top 4 State achievable benchmark for congestive heart failure admissions was 195 per 100,000 population. At current rates of improvement, Whites could achieve the benchmark in 6 years. APIs, Hispanics, and Blacks could achieve the benchmark in 1, 4, and 9 years, respectively. Residents of the lowest income quartile would need 13 years while residents of other income quartiles could achieve the benchmark in 7 years.

1b.5. **If no or limited data on disparities from the measure as specified is reported in 1b4, then provide a summary of data from the literature that addresses disparities in care on the specific focus of measurement. Include citations.**

1c. High Priority (previously referred to as High Impact)

The measure addresses:

- a specific national health goal/priority identified by DHHS or the National Priorities Partnership convened by NQF; OR
- a demonstrated high-priority (high-impact) aspect of healthcare (e.g., affects large numbers of patients and/or has a substantial impact for a smaller population; leading cause of morbidity/mortality; high resource use (current and/or future); severity of illness; and severity of patient/societal consequences of poor quality).

1c.1. **Demonstrated high priority aspect of healthcare**

Affects large numbers, A leading cause of morbidity/mortality, Severity of illness

1c.2. **If Other:**

1c.3. **Provide epidemiologic or resource use data that demonstrates the measure addresses a high priority aspect of healthcare. List citations in 1c.4.**

It is estimated 5.1 million Americans >=20 years of age have heart failure. [1] Projections show that the prevalence of HF will increase 46% from 2012 to 2030, resulting in >8 million people >=18 years of age with HF [2]. In 2012, total cost for HF was estimated to be $30.7 million. Of this total, 68% was attributable to direct medical costs. [2] Projections show that by 2030, the total cost of HF will increase almost 127% to $69.7 billion from 2012. This equals about $244 for every US adult.[2]

On the basis of data from the community surveillance component of the ARIC study of the NHLBI, it is estimated that there are 825,000 new HF cases annually and that at ages <75 years, HF incidence is higher in blacks than whites.[1]

The annual rates per 1000 population of new HF events for white men are 15.2 for those 65 to 74 years of age, 31.7 for those 75 to 84 years of age, and 65.2 for those >=85 years of age. For white women in the same age groups, the rates are 8.2, 19.8, and 45.6, respectively. For black men, the rates are 16.9, 25.5, and 50.6 (unreliable estimate), and for black women, the estimated rates are 14.2, 25.5, and 44.0 (unreliable estimate), respectively (CHS, NHLBI). [3]

The death rate for those with heart failure remains high with about 50% of people diagnosed with HF will die within 5 years.13,19 [4,5]

There is data from multiple studies also showing the impact of Heart Failure on American. Some of this data is briefly summarized below.

Data from Olmsted County, MN, indicate the following:
-Among asymptomatic individuals, the prevalence of left ventricular diastolic dysfunction was 21% for mild diastolic dysfunction and 7% for moderate or severe diastolic dysfunction. The prevalence of systolic dysfunction was 6%. The presence of any left ventricular dysfunction (systolic or diastolic) was associated with an increased risk of developing overt HF, and diastolic dysfunction was predictive of all-cause death.[6] After 4 years of follow-up, the prevalence of diastolic dysfunction increased to 39.2%. Diastolic dysfunction was associated with development of HF during 6 years of subsequent follow-up after adjustment for age, hypertension, DM, and CAD (HR, 1 .81; 95% CI, 1.01–3.48). [7]

-Among individuals with symptomatic HF, the prevalence of left ventricular diastolic dysfunction was 6% for mild diastolic dysfunction and 75% for moderate or severe diastolic dysfunction.[8]The proportion of people with HF and preserved EF increased over time. Survival improved over time among individuals with reduced EF but not among those with preserved EF.[9]

In MESA, African Americans had the highest risk of developing HF, followed by Hispanic, white, and Chinese Americans (4.6, 3.5, 2.4, and 1.0 per 1000 person-years, respectively). This higher risk reflected differences in the prevalence of hypertension, DM, and socioeconomic status. African Americans had the highest proportion of incident HF not preceded by clinical MI (75%).[10]

In the NHLBI's ARIC study, the age-adjusted incidence rate per 1000 person-years was 3.4 for white women, less than for all other groups, that is, white men (6.0), black women (8.1), and black men (9.1). The 30-day, 1-year, and 5-year case fatality rates after

hospitalization for HF were 10.4%, 22%, and 42.3%, respectively. Blacks had a greater 5-year case fatality rate than whites (P<0.05). HF incidence rates in black women were more similar to those of men than of white women. The greater HF incidence in blacks than in whites is explained largely by blacks' greater levels of atherosclerotic risk factors.[11]

Data from Kaiser Permanente indicated an increase in the incidence of HF among the elderly, with the effect being greater in men. [12]

1c.5. If a PRO-PM (e.g. HRQoL/functional status, symptom/burden, experience with care, health-related behaviors), provide evidence that the target population values the measured PRO and finds it meaningful. *(Describe how and from whom their input was obtained.)*

Not Applicable.

2. Reliability and Validity—Scientific Acceptability of Measure Properties

Extent to which the measure, as specified, produces consistent (reliable) and credible (valid) results about the quality of care when implemented. ***Measures must be judged to meet the subcriteria for both reliability and validity to pass this criterion and be evaluated against the remaining criteria.***

2a.1. Specifications The measure is well defined and precisely specified so it can be implemented consistently within and across organizations and allows for comparability. eMeasures should be specified in the Health Quality Measures Format (HQMF) and the Quality Data Model (QDM).

De.5. **Subject/Topic Area** *(check all the areas that apply):*
Cardiovascular, Cardiovascular : Congestive Heart Failure

De.6. **Cross Cutting Areas** *(check all the areas that apply):*

S.1. **Measure-specific Web Page** *(Provide a URL link to a web page specific for this measure that contains current detailed specifications including code lists, risk model details, and supplemental materials. Do not enter a URL linking to a home page or to general information.)*
http://www.ama-assn.org/ama1/pub/upload/mm/pcpi/hfset-12-5.pdf

S.2a. **If this is an eMeasure**, HQMF specifications must be attached. Attach the zipped output from the eMeasure authoring tool (MAT) - if the MAT was not used, contact staff. (Use the specification fields in this online form for the plain-language description of the specifications)
This is not an eMeasure **Attachment:**

S.2b. **Data Dictionary, Code Table, or Value Sets** *(and risk model codes and coefficients when applicable) must be attached. (Excel or csv file in the suggested format preferred - if not, contact staff)*
No data dictionary **Attachment:**

S.3. **For endorsement maintenance**, please briefly describe any changes to the measure specifications since last endorsement date and explain the reasons.
For endorsement maintenance, we are not including e-measure specifications as we did in the previous submission cycle. We have updated the measure specifications to include the applicable CPT and ICD-10 codes.

S.4. **Numerator Statement** *(Brief, narrative description of the measure focus or what is being measured about the target population, i.e., cases from the target population with the target process, condition, event, or outcome)*
IF an OUTCOME MEASURE, state the outcome being measured. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
Patients for whom the quantitative or qualitative results of a recent or prior (any time in the past) LVEF assessment is documented* within a 12 month period.

*Documentation must include documentation in a progress note of the results of an LVEF assessment, regardless of when the evaluation of ejection fraction was performed.

Qualitative results correspond to numeric equivalents as follows:
Hyperdynamic: corresponds to LVEF greater than 70%
Normal: corresponds to LVEF 50% to 70% (midpoint 60%)
Mild dysfunction: corresponds to LVEF 40% to 49% (midpoint 45%)
Moderate dysfunction: corresponds to LVEF 30% to 39% (midpoint 35%)
Severe dysfunction: corresponds to LVEF less than 30%

S.5. **Time Period for Data** *(What is the time period in which data will be aggregated for the measure, e.g., 12 mo, 3 years, look back to August for flu vaccination? Note if there are different time periods for the numerator and denominator.)*
Once during the measurement period.

S.6. **Numerator Details** *(All information required to identify and calculate the cases from the target population with the target process, condition, event, or outcome such as definitions, specific data collection items/responses, code/value sets – Note: lists of*

individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)
IF an OUTCOME MEASURE, describe how the observed outcome is identified/counted. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
Left ventricular ejection fraction (LVEF) < 40% or documentation of severely or moderately depressed left ventricular systolic function (G8738)

OR

Left ventricular ejection fraction (LVEF) >=40% or documentation as normal or mildly depressed left ventricular systolic function (G8739)

S.7. **Denominator Statement** *(Brief, narrative description of the target population being measured)*
All patients aged 18 years and older with a diagnosis of heart failure.

S.8. **Target Population Category** *(Check all the populations for which the measure is specified and tested if any):*
Senior Care

S.9. **Denominator Details** *(All information required to identify and calculate the target population/denominator such as definitions, specific data collection items/responses , code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
See 'Registry Supplemental Resources' attached in appendix field A.1 for data dictionary and form.

Codes that are applicable to denominator are:
Diagnosis for heart failure (ICD-9-CM): 402.01, 402.11, 402.91, 404.01, 404.03, 404.11, 404.13, 404.91, 404.93, 428.0, 428.1, 428.20, 428.21, 428.22, 428.23, 428.30, 428.31, 428.32, 428.33, 428.40, 428.41, 428.42, 428.43, 428.9

Diagnosis for heart failure (ICD-10-CM): I11.0, I13.0, I13.2, I50.1, I50.20, I50.21, I50.22, I50.23, I50.30, I50.31, I50.32, I50.33, I50.40, I50.41, I50.42, I50.43, I50.9

Patient encounter during the reporting period (CPT): 99201, 99202, 99203, 99204, 99205, 99212, 99213, 99214, 99215, 99304, 99305, 99306, 99307, 99308, 99309, 99310, 99324, 99325, 99326, 99327, 99328, 99334, 99335, 99336, 99337, 99341, 99342, 99343, 99344, 99345, 99347, 99348, 99349, 99350

S.10. **Denominator Exclusions** *(Brief narrative description of exclusions from the target population)*
None.

S.11. **Denominator Exclusion Details** *(All information required to identify and calculate exclusions from the denominator such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
Not Applicable.

S.12. **Stratification Details/Variables** *(All information required to stratify the measure results including the stratification variables, definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format with at S.2b)*
Not Applicable.

S.13. **Risk Adjustment Type** (Select type. Provide specifications for risk stratification in S.12 and for statistical model in S.14-15)
No risk adjustment or risk stratification
If other:

S.14. **Identify the statistical risk model method and variables** *(Name the statistical method - e.g., logistic regression and list all the risk factor variables. Note - risk model development and testing should be addressed with measure testing under Scientific Acceptability)*
Not applicable.

S.15. **Detailed risk model specifications** *(must be in attached data dictionary/code list Excel or csv file. Also indicate if available at measure-specific URL identified in S.1.)*

Note: Risk model details (including coefficients, equations, codes with descriptors, definitions), should be provided on a separate worksheet in the suggested format in the Excel or csv file with data dictionary/code lists at S.2b.

S.15a. Detailed risk model specifications (*if not provided in excel or csv file at S.2b*)
Not applicable.

S.16. Type of score:
Rate/proportion
If other:

S.17. Interpretation of Score *(Classifies interpretation of score according to whether better quality is associated with a higher score, a lower score, a score falling within a defined interval, or a passing score)*
Better quality = Higher score

S.18. Calculation Algorithm/Measure Logic *(Describe the calculation of the measure score as an ordered sequence of steps including identifying the target population; exclusions; cases meeting the target process, condition, event, or outcome; aggregating data; risk adjustment; etc.)*
To calculate performance rates:

1) Find the patients who meet the initial patient population (i.e., the general group of patients that a set of performance measures is designed to address.

2) From the patients within the initial patient population criteria, find the patients who qualify for the denominator. (i.e., the specific group of patients for inclusion in a specific performance measure based on defined criteria). Note: in some cases the initial patient population and denominator are identical.

4) From the patients within the denominator, find the patients who qualify for the Numerator (i.e., the group of patients in the denominator for whom a process or outcome of care occurs). Validate that the number of patients in the numerator is less than or equal to the number of patients in the denominator.

S.19. Calculation Algorithm/Measure Logic Diagram URL or Attachment *(You also may provide a diagram of the Calculation Algorithm/Measure Logic described above at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
No diagram provided

S.20. Sampling *(If measure is based on a sample, provide instructions for obtaining the sample and guidance on minimum sample size.)*
IF a PRO-PM, identify whether (and how) proxy responses are allowed.
Not Applicable. The measure is not based on a sample.

S.21. Survey/Patient-reported data *(If measure is based on a survey, provide instructions for conducting the survey and guidance on minimum response rate.)*
IF a PRO-PM, specify calculation of response rates to be reported with performance measure results.
Not Applicable. This measure is not based on a survey.

S.22. Missing data (specify how missing data are handled, e.g., imputation, delete case.)
Required for Composites and PRO-PMs.
If data required to determine if an individual patient should be included in a specific performance measure based on defined criteria is missing, those cases would ineligible for inclusion in the denominator and therefore the case would be deleted. If data required to determine if a denominator eligible patient qualifies for the numerator (or has a valid exclusion/exception) is missing, this case would represent a quality failure.

S.23. Data Source *(Check ONLY the sources for which the measure is SPECIFIED AND TESTED).*
If other, please describe in S.24.
Electronic Clinical Data : Registry

S.24. Data Source or Collection Instrument *(Identify the specific data source/data collection instrument e.g. name of database,*

clinical registry, collection instrument, etc.)
IF a PRO-PM, identify the specific PROM(s); and standard methods, modes, and languages of administration.
This measure is currently being used in the ACCF PINNACLE registry for the outpatient office setting. See attached form and data dictionary.

S.25. **Data Source or Collection Instrument** *(available at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
Available in attached appendix at A.1

S.26. **Level of Analysis** *(Check ONLY the levels of analysis for which the measure is SPECIFIED AND TESTED)*
Clinician : Individual

S.27. **Care Setting** *(Check ONLY the settings for which the measure is SPECIFIED AND TESTED)*
Ambulatory Care : Clinician Office/Clinic
If other:

S.28. **COMPOSITE Performance Measure** - Additional Specifications *(Use this section as needed for aggregation and weighting rules, or calculation of individual performance measures if not individually endorsed.)*
Not Applicable.

2b. Validity – See attached Measure Testing Submission Form
HF_LVEF_Assessment_0079_Testing_Form_Version_6.5_6.22.15.pdf

NATIONAL QUALITY FORUM—Measure Testing (subcriteria 2a2, 2b2-2b7)

Measure Number (*if previously endorsed*)**:** 0079
Measure Title: Heart Failure: Left Ventricular Ejection Fraction Assessment (Outpatient Setting)
Date of Submission: 6/23/2015
Type of Measure:

☐ Composite – ***STOP – use composite testing form***	☐ Outcome (*including PRO-PM*)
☐ Cost/resource	☒ Process
☐ Efficiency	☐ Structure

Instructions

- Measures must be tested for all the data sources and levels of analyses that are specified. ***If there is more than one set of data specifications or more than one level of analysis, contact NQF staff*** about how to present all the testing information in one form.
- **For all measures, sections 1, 2a2, 2b2, 2b3, and 2b5 must be completed.**
- **For outcome and resource use measures**, section **2b4** also must be completed.
- If specified for **multiple data sources/sets of specificaitons** (e.g., claims and EHRs), section **2b6** also must be completed.
- Respond to all questions as instructed with answers immediately following the question. All information on testing to demonstrate meeting the subcriteria for reliability (2a2) and validity (2b2-2b6) must be in this form. An appendix for *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 20 pages (*incuding questions/instructions;* minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.
- For information on the most updated guidance on how to address sociodemographic variables and testing in this form

refer to the release notes for version 6.6 of the Measure Testing Attachment.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the testing results for this measure meet NQF's evaluation criteria for testing.

2a2. Reliability testing [10] demonstrates the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise. For **PRO-PMs and composite performance measures**, reliability should be demonstrated for the computed performance score.

2b2. Validity testing [11] demonstrates that the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality. For **PRO-PMs and composite performance measures**, validity should be demonstrated for the computed performance score.

2b3. Exclusions are supported by the clinical evidence; otherwise, they are supported by evidence of sufficient frequency of occurrence so that results are distorted without the exclusion; [12]

AND

If patient preference (e.g., informed decisionmaking) is a basis for exclusion, there must be evidence that the exclusion impacts performance on the measure; in such cases, the measure must be specified so that the information about patient preference and the effect on the measure is transparent (e.g., numerator category computed separately, denominator exclusion category computed separately). [13]

2b4. For outcome measures and other measures when indicated (e.g., resource use):

- **an evidence-based risk-adjustment strategy** (e.g., risk models, risk stratification) is specified; is based on patient factors (including clinical and sociodemographic factors) that influence the measured outcome and are present at start of care; [14,15] and has demonstrated adequate discrimination and calibration

OR

- rationale/data support no risk adjustment/ stratification.

2b5. Data analysis of computed measure scores demonstrates that methods for scoring and analysis of the specified measure allow for **identification of statistically significant and practically/clinically meaningful** [16] **differences in performance**;

OR

there is evidence of overall less-than-optimal performance.

2b6. If multiple data sources/methods are specified, there is demonstration they produce comparable results.

2b7. For **eMeasures, composites, and PRO-PMs** (or other measures susceptible to missing data), analyses identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias.

Notes

10. Reliability testing applies to both the data elements and computed measure score. Examples of reliability testing for data elements include, but are not limited to: inter-rater/abstractor or intra-rater/abstractor studies; internal consistency for multi-item scales; test-retest for survey items. Reliability testing of the measure score addresses precision of measurement (e.g., signal-to-noise).

11. Validity testing applies to both the data elements and computed measure score. Validity testing of data elements typically analyzes agreement with another authoritative source of the same information. Examples of validity testing of the measure score include, but are not limited to: testing hypotheses that the measures scores indicate quality of care, e.g., measure scores are different for groups known to have differences in quality assessed by another valid quality measure or method; correlation of measure scores with another valid indicator of quality for the specific topic; or relationship to conceptually related measures (e.g., scores on process measures to scores on outcome measures). Face validity of the measure score as a quality indicator may be adequate if accomplished through a systematic and transparent process, by identified experts, and explicitly addresses whether performance scores resulting from the measure as specified can be used to distinguish good from poor quality.

12. Examples of evidence that an exclusion distorts measure results include, but are not limited to: frequency of occurrence, variability of exclusions across providers, and sensitivity analyses with and without the exclusion.

13. Patient preference is not a clinical exception to eligibility and can be influenced by provider interventions.

14. Risk factors that influence outcomes should not be specified as exclusions

15. With large enough sample sizes, small differences that are statistically significant may or may not be practically or clinically meaningful. The substantive question may be, for example, whether a statistically significant difference of one percentage point in the percentage of patients who received smoking cessation counseling (e.g., 74 percent v. 75 percent) is clinically meaningful; or whether a statistically significant difference of $25 in cost for an episode of care (e.g., $5,000 v. $5,025) is practically meaningful. Measures with overall less-than-optimal performance may not demonstrate much variability across providers.

1. DATA/SAMPLE USED FOR ALL TESTING OF THIS MEASURE

Often the same data are used for all aspects of measure testing. In an effort to eliminate duplication, the first five questions apply to all measure testing. If there are differences by aspect of testing,(e.g., reliability vs. validity) be sure to indicate the specific differences in question 1.7.

1.1. What type of data was used for testing? (*Check all the sources of data identified in the measure specifications and data used for testing the measure. Testing must be provided for all the sources of data specified and intended for measure implementation.* ***If different data sources are used for the numerator and denominator, indicate N [numerator] or D [denominator] after the checkbox.***)

Measure Specified to Use Data From: (***must be consistent with data sources entered in S.23***)	**Measure Tested with Data From:**
☐ abstracted from paper record	☐ abstracted from paper record
☐ administrative claims	☐ administrative claims
☒ clinical database/registry	☒ clinical database/registry
☐ abstracted from electronic health record	☐ abstracted from electronic health record
☐ eMeasure (HQMF) implemented in EHRs	☐ eMeasure (HQMF) implemented in EHRs
☐ other: Click here to describe	☐ other: Click here to describe

1.2. If an existing dataset was used, identify the specific dataset (*the dataset used for testing must be consistent with the measure specifications for target population and healthcare entities being measured; e.g., Medicare Part A claims, Medicaid claims, other commercial insurance, nursing home MDS, home health OASIS, clinical registry*).

The primary analysis was conducted at the level of the individual provider and included all patients with heart failure (HF) cared for by that provider and captured in the PINNACLE Registry during the one-year study period. The PINNACLE Registry systematically maps each practice's Electronic Health Record to the data elements required for the Registry, with careful validation of the translation process prior to enrollment and reporting the results back to the practice. Using these data, we were able to calculate the number of patients who should have undergone a left ventricular ejection fraction (LVEF) assessment during the 12-month period, or a strong reason why the LVEF assessment was not performed is documented. This means that every patient in that provider's practice is included. For this measure, providers with less than 10 eligible patient encounters during the study period were excluded, since estimates of reliability are unstable with such small numbers. All other cases from all practices and providers were included. We included all visits for each patient in these analyses and meeting the performance measure on any single visit within the year met the criterion for this measure.

1.3. What are the dates of the data used in testing? Click here to enter date range

The primary analysis included encounters between 01/01/2014-12/31/2014. Additionally, we used data from 01/01/2013 thru 12/31/2013 for temporal comparison.

1.4. What levels of analysis were tested? (*testing must be provided for all the levels specified and intended for measure implementation, e.g., individual clinician, hospital, health plan*)

Measure Specified to Measure Performance of: (***must be consistent with levels entered in item S.26***)	**Measure Tested at Level of:**
☒ individual clinician	☒ individual clinician
☐ group/practice	☐ group/practice
☐ hospital/facility/agency	☐ hospital/facility/agency
☐ health plan	☐ health plan
☐ other: Click here to describe	☐ other: Click here to describe

1.5. How many and which measured entities were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of measured entities included in the analysis (e.g., size, location, type); if a sample was used, describe how entities were selected for inclusion in the sample*)

2013

2,254 providers met the minimum number of eligible patients (10) for inclusion in the reliability analysis. The average number of eligible patients for providers included is 181.6 for a total of 409,332 patients. The range of number of patients for providers included is from 10 to 2,730. As noted above, providers with fewer than 10 eligible patient encounters during the study period were excluded.

The unit of analysis for this measure is the provider. A description of the providers studied for the 2013 calendar year is shown below:

	Total **n = 2254**

	Total n = 2254
Provider gender	
(1) Male	1819 (80.8%)
(2) Female	433 (19.2%)
Missing (.)	2
Provider categories	
NP/PA	220 (9.9%)
MD/DO	1951 (88.0%)
RN/nurses	47 (2.1%)
Missing (.)	36
Region	
(1) Northeast	335 (14.9%)
(2) Midwest	691 (30.7%)
(3) South	843 (37.4%)
(4) West	385 (17.1%)

2014

2,219 providers met the minimum number of eligible patients (10) for inclusion in the reliability analysis. The average number of eligible patients for providers included is 182.2 for a total of 404,406 patients. The range of numbers of patients for providers included is from 10 to 2,990. As noted above, providers with fewer than 10 eligible patient encounters during the study period were excluded.

The unit of analysis for this measure is the provider. A description of the providers studied for the 2014 calendar year is shown below:

	Total n = 2219
Provider gender	
(1) Male	1772 (79.9%)
(2) Female	447 (20.1%)
Provider categories	
NP/PA	228 (10.5%)
MD/DO	1907 (87.5%)
RN/nurses	45 (2.1%)
Missing (.)	39
Region	
(1) Northeast	334 (15.1%)
(2) Midwest	543 (24.5%)
(3) South	931 (42.0%)
(4) West	411 (18.5%)

1.6. How many and which patients were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of patients included in the analysis (e.g., age, sex, race, diagnosis); if a sample was used, describe how patients were selected for inclusion in the sample*)

2013

There are a total of 409,332 patients included in the temporal comparison that were treated in 2013. Patients' characteristics are provided below:

	Total
	n = 409332
Race	
(1) White	202768 (89.5%)
(2) Black	19665 (8.7%)
(3) Other	4211 (1.9%)
Missing (.)	90895
Insurance	
(0) No insurance	311 (0.6%)
(1) Private	33938 (70.5%)
(2) Medicare	13596 (28.2%)
(3) Medicaid	107 (0.2%)
(4) Other	204 (0.4%)
Missing (.)	51502
Age	
18 to <60	77884 (19.0%)
60 to <70	96129 (23.5%)
70 to <80	120506 (29.4%)
80 to 114	114813 (28.0%)
Sex	
(1) Male	228280 (55.8%)
(2) Female	180550 (44.2%)
Missing (.)	300
BMI (kg/m2)	30.6 ± 8.4
Missing	86645
Diabetes Mellitus	122242 (32.2%)
Coronary Artery Disease	241431 (66.8%)
Hypertension	312835 (86.5%)
Atrial Fibrillation/Flutter	151755 (40.4%)
Peripheral Arterial Disease	56306 (15.4%)
Stroke/TIA	19269 (7.4%)
Myocardial Infarction	88104 (25.8%)

2014

There are a total of 404,406 patients included in the primary analysis (2014), whose characteristics are described below:

	Total
	n = 404406
Race	
(1) White	186216 (90.4%)
(2) Black	14849 (7.2%)
(3) Other	4932 (2.4%)
Missing (.)	61304
Insurance	
(0) No insurance	236 (0.5%)
(1) Private	39659 (79.2%)
(2) Medicare	9930 (19.8%)
(3) Medicaid	112 (0.2%)
(4) Other	116 (0.2%)
Missing (.)	57545
Age	
18 to <60	76319 (18.9%)
60 to <70	95585 (23.6%)
70 to <80	120341 (29.8%)
80 to 114	112161 (27.7%)
Sex	
(1) Male	224353 (55.7%)
(2) Female	178353 (44.3%)
Missing (.)	12482
BMI (kg/m2)	30.6 ± 8.2
Missing	74286
Diabetes Mellitus	118503 (30.8%)
Coronary Artery Disease	235361 (64.4%)
Hypertension	309664 (86.0%)
Atrial Fibrillation/Flutter	160293 (41.5%)
Peripheral Arterial Disease	54749 (15.4%)
Stroke/TIA	21525 (7.4%)
Myocardial Infarction	84597 (24.2%)

1.7. If there are differences in the data or sample used for different aspects of testing (e.g., reliability, validity, exclusions, risk adjustment), identify how the data or sample are different for each aspect of testing reported below.

The dataset described above was used for all aspects of testing.

1.8 What were the patient-level sociodemographic (SDS) variables that were available and analyzed in the data or sample used? For example, patient-reported data (e.g., income, education, language), proxy variables when SDS data are not collected from each patient (e.g. census tract), or patient community characteristics (e.g. percent vacant housing, crime rate).

We do not currently collect any of the SDS variables examples listed above. As is noted in other sections of this testing form we do collect data or race as well as insurance type.

2a2. RELIABILITY TESTING

***Note**: If accuracy/correctness (validity) of data elements was empirically tested, separate reliability testing of data elements is not required – in 2a2.1 check critical data elements; in 2a2.2 enter "see section 2b2 for validity testing of data elements"; and skip 2a2.3 and 2a2.4.*

2a2.1. What level of reliability testing was conducted? (*may be one or both levels*)
☐ **Critical data elements used in the measure** (*e.g., inter-abstractor reliability; data element reliability must address ALL critical data elements*)
☒ **Performance measure score** (e.g., *signal-to-noise analysis*)

2a2.2. For each level checked above, describe the method of reliability testing and what it tests (*describe the steps—do not just name a method; what type of error does it test; what statistical analysis was used*)

Reliability of the computed measure score was measured as the ratio of signal to noise. The signal in this case is the proportion of the variability in measured performance that can be explained by real differences in physician performance. Reliability at the level of the specific physician is given by:
Reliability = Variance (physician-to-physician) / [Variance (physician-to-physician) + Variance (physician-specific-error], where the latter represents the within-physician estimate of our error in assessing their 'true' performance. Thus, this assessment of reliability is the ratio of the physician-to-physician variance divided by the sum of the physician-to-physician variance plus the error variance specific to a physician. A reliability of zero implies that all the variability in a measure is attributable to measurement error. A reliability of one implies that all the variability is attributable to real differences in physician performance.

Reliability testing was performed by using a beta-binomial model. The beta-binomial model assumes the physician performance score is a binomial random variable conditional on the physician's true value that comes from the beta distribution. The beta distribution is usually defined by two parameters, alpha and beta. Alpha and beta can be thought of as intermediate calculations to get to the needed variance estimates.

Reliability is estimated at five different distributions of provider volumes: at the minimum number of quality reporting events for the measure; at the mean number of quality reporting events per physician; and at the 25th, 50th and 75th percentiles of the number of quality reporting events.

2a2.3. For each level of testing checked above, what were the statistical results from reliability testing? (e.g., *percent agreement and kappa for the critical data elements; distribution of reliability statistics from a signal-to-noise analysis*)

2013 – In 2013, the signal-noise ratios are shown below:

Description	Number of Patients	Signal-to-Noise Ratio
Minimum	10	0.988
25th percentile	61	0.994
50th percentile	128	0.996
75th percentile	227	0.998
Average	182	0.997

2014 – In 2014, the signal-noise ratios are shown below:

Description	Number of Patients	Signal-to-Noise Ratio
Minimum	10	0.989
25th percentile	66	0.994
50th percentile	130	0.996
75th percentile	217	0.997
Average	183	0.997

2a2.4 What is your interpretation of the results in terms of demonstrating reliability? (i.*e., what do the results mean and what are the norms for the test conducted?*)

For this measure the reliability was very high and was similar for 2013 and 2014, supporting the reproducibility of these estimates across years. At the minimum number of patient visits required (>10) the average reliability was 0.988 and 0.989 for 2013 and 2014, respectively. For providers with the median number of patient encounters, the reliability was even higher, 0.997 in both years. Given that a reliability of 0.70 is generally considered a minimum threshold for acceptability, and 0.80 is considered very good reliability, these data suggest that the measure is exceedingly good at describing true differences across physicians.

2b2. VALIDITY TESTING

2b2.1. What level of validity testing was conducted? (*may be one or both levels*)

☐ **Critical data elements** (*data element validity must address ALL critical data elements*)

☒ **Performance measure score**

☐ **Empirical validity testing**

☒ **Systematic assessment of face validity of performance measure score as an indicator** of quality or resource use (*i.e., is an accurate reflection of performance on quality or resource use and can distinguish good from poor performance*)

2b2.2. For each level of testing checked above, describe the method of validity testing and what it tests (*describe the steps—do not just name a method; what was tested, e.g., accuracy of data elements compared to authoritative source, relationship to another measure as expected; what statistical analysis was used)*

Clinical Evidence: Evaluation of LVEF in patients with heart failure provides important information that is required to appropriately direct treatment. Several pharmacologic therapies have demonstrated efficacy in slowing disease progression and improving outcomes in patients with left ventricular systolic dysfunction. LVEF assessed during the initial evaluation of patients presenting with heart failure can be considered valid unless the patient has demonstrated a major change in clinical status, experienced or recovered from a clinical event, or received therapy that might have a significant effect on cardiac function. Both journal articles that are referenced in Section 1a7.9 of the evidence form supports the assessment of ejection fraction to enable appropriate guideline-directed medical treatment.

Construct validity was difficult to establish because there has not been an independent audit of these data. However, it is important to note that an independent audit would merely involve an abstractor reviewing the same medical record from which PINNACLE directly abstracts its data and, given the identical source of the data, any error observed would either be due to the auditor incorrectly abstracting the data from the EHR or

PINNACLE incorrectly mapping the data elements from the EHR. To address the latter, we conduct detailed analyses to insure that this does not happen and quarantine (i.e. not report) data that fails our addition Data Quality Review process. Validity of measure data elements in PINNACLE is routinely evaluated on a quarterly basis as part of the standard data extraction and analytic data set creation process. First, all relevant data elements are reviewed at the record level to ensure that individual data values are valid; any invalid values are set to missing. Next, the *distribution* of each data element is reviewed, aggregating both across practices and across calendar quarters within each practice, to identify outliers, suspicious patterns and/or systematic changes in the prevalence of the data element that may suggest data mapping errors or unanticipated changes in definitions, coding consistency, data completeness, etc. Identification of suspicious data includes both statistical criteria, using quality control charts with rigorous definitions of "out of control" rates, and manual clinical review of each distribution for plausibility. Records that are flagged as suspicious by these criteria are quarantined and excluded from analysis and reporting. In 2013 the rate of records not passing the quality evaluation was 3.1% and in 2014 it was 8.7%. Feedback reports are generated to facilitate investigation of data issues at the practice level to verify accuracy of abstraction and to remap elements whose definitions or recording have changed.

Content validity for this measure was assessed by expert work group members during the development process. Additional input on the content validity of draft measures was established through a 30-day public comment period and concurrent formal peer review process. All comments received were reviewed by the expert work group and the measures were adjusted as needed. Additionally, the measure underwent review and approval by the Board of Trustees of the ACC and the Science Advisory and Coordinating Committee of the AHA, as well as review and voting by the PCPI membership. Members of the expert work group that developed the measure included: Robert O. Bonow, MD, MACC, FAHA, FACP (Co-Chair) (cardiology); Theodore G. Ganiats, MD (Co-Chair) (family medicine; measure methodology); Craig T. Beam, CRE (patient representative); Kathleen Blake, MD (cardiac electrophysiology); Donald E. Casey, Jr., MD, MPH, MBA, FACP (internal medicine); Sarah J. Goodlin, MD (geriatrics, palliative medicine); Kathleen L. Grady, PhD, APN, FAAN, FAHA (cardiac surgery); Randal F. Hundley, MD, FACC (cardiology, health plan representative); Mariell Jessup, MD, FACC, FAHA, FESC (cardiology, heart failure); Thomas E. Lynn, MD (family medicine, measure implementation); Frederick A. Masoudi, MD, MSPH (cardiology); David Nilasena MD, MSPH, MS (general preventive medicine, public health, measure implementation); Paul D. Rockswold, MD, MPH (family medicine); Ileana L. Piña, MD, FACC (cardiology, heart failure); Lawrence B. Sadwin (patient representative); Joanna D. Sikkema, MSN, ANP-BC, FAHA (cardiology); Carrie A. Sincak, PharmD, BCPS (pharmacy); John Spertus, MD, MPH (cardiology); Patrick J. Torcson, MD, FACP, MMM (hospital medicine); Elizabeth Torres, MD (internal medicine); Mark V. Williams, MD, FHM (hospital medicine); John B Wong, MD (internal medicine).

Face validity of the measure score was systematically assessed as follows:

After the measure was fully specified, members of two existing committees, one at the ACC and one at AHA, with expertise in in general cardiology, interventional cardiology, heart failure, electrophysiology and quality improvement, outcomes research, informatics and performance measurement, who were not involved in development of the measure, were asked to review the measure specifications and rate their agreement with the following statement:

"The scores obtained from the measure as specified will provide an accurate reflection of quality and can be used to distinguish good and poor quality."

The respondents recorded their rating on a scale of 1-5, where 1= Strongly Disagree; 3=Neither Agree nor Disagree; 5= Strongly Agree

Forty two (42) committee members completed the survey and provided a mean importance rating of 4.24, with 85.7% agreeing with the use of the measure for quality assessment.

2b2.3. What were the statistical results from validity testing? (*e.g., correlation; t-test*)

Additionally, the results of the expert panel rating of the validity statement were as follows:

N = 42; Mean rating = 4.24 and 85.7% of respondents either agree or strongly agree that this measure can accurately distinguish good and poor quality

Frequency Distribution of Ratings
1 - <2> (Strongly Disagree)
2 - <3>
3 - <1> (Neither Agree nor Disagree)
4 - <13>
5 - <23> (Strongly Agree)

2b2.4. What is your interpretation of the results in terms of demonstrating validity? (i.*e., what do the results mean and what are the norms for the test conducted?*)

The measure was judged to have high face validity by both its clinical importance and by the group of experts asked to rate it. The majority of experts agreed that the measure as specified will provide an accurate reflection of quality and can be used to distinguish good and poor quality.

2b3. EXCLUSIONS ANALYSIS
NA ☒ no exclusions — *skip to section 2b4*

2b3.1. Describe the method of testing exclusions and what it tests (*describe the steps—do not just name a method; what was tested, e.g., whether exclusions affect overall performance scores; what statistical analysis was used*)

Since not all patients with heart failure, in rare circumstances, might not meet the guideline recommendations for EF evaluation, exclusions in this measure are intended to remove patients for whom an EF assessment might not be appropriate (e.g. patient refusal). We divide these into two categories: Exclusions and Exceptions. Exclusions arise when patients who are included in the initial patient or eligible population for the measure set do not meet the denominator criteria specific to the intervention required by the numerator. There are no known exclusions for this assessment, which are usually derived from evidence-based guidelines. Exceptions are not absolute, and are based on clinical judgment and individual patient characteristics, such as refusal to participate in the test.

2b3.2. What were the statistical results from testing exclusions? (*include overall number and percentage of individuals excluded, frequency distribution of exclusions across measured entities, and impact on performance measure scores*)

There are no exclusions and there were no exceptions reported for this measure in any patients.

2b3.3. What is your interpretation of the results in terms of demonstrating that exclusions are needed to prevent unfair distortion of performance results? (*i.e., the value outweighs the burden of increased data collection and analysis. Note: **If patient preference is an exclusion**, the measure must be specified so that the*

effect on the performance score is transparent, e.g., scores with and without exclusion)

All patients are eligible for this measure and all providers caring for HF patients should be able to have a performance rate calculated on their entire population.

_____

2b4. RISK ADJUSTMENT/STRATIFICATION FOR OUTCOME OR RESOURCE USE MEASURES
If not an intermediate or health outcome, or PRO-PM, or resource use measure, skip to section 2b5.

2b4.1. What method of controlling for differences in case mix is used?
☒ **No risk adjustment or stratification**
☐ **Statistical risk model with** Click here to enter number of factors **risk factors**
☐ **Stratification by** Click here to enter number of categories **risk categories**
☐ **Other,** Click here to enter description

2b4.2. If an outcome or resource use measure is not risk adjusted or stratified, provide rationale and analyses to demonstrate that controlling for differences in patient characteristics (case mix) is not needed to achieve fair comparisons across measured entities.

2b4.3. Describe the conceptual/clinical and statistical methods and criteria used to select patient factors (clinical factors or sociodemographic factors) used in the statistical risk model or for stratification by risk (*e.g., potential factors identified in the literature and/or expert panel; regression analysis; statistical significance of p<0.10; correlation of x or higher; patient factors should be present at the start of care*)

2b4.4a. What were the statistical results of the analyses used to select risk factors?

2b4.4b. Describe the analyses and interpretation resulting in the decision to select SDS factors (e.g. prevalence of the factor across measured entities, empirical association with the outcome, contribution of unique variation in the outcome, assessment of between-unit effects and within-unit effects)

2b4.5. Describe the method of testing/analysis used to develop and validate the adequacy of the statistical model or stratification approach (*describe the steps—do not just name a method; what statistical analysis was used*)

Provide the statistical results from testing the approach to controlling for differences in patient characteristics (case mix) below.
If stratified, skip to 2b4.9

2b4.6. Statistical Risk Model Discrimination Statistics (*e.g., c-statistic, R-squared*)**:**

2b4.7. Statistical Risk Model Calibration Statistics (*e.g., Hosmer-Lemeshow statistic*):

2b4.8. Statistical Risk Model Calibration – Risk decile plots or calibration curves:

2b4.9. Results of Risk Stratification Analysis:

2b4.10. What is your interpretation of the results in terms of demonstrating adequacy of controlling for differences in patient characteristics (case mix)? (i.*e., what do the results mean and what are the norms for*

the test conducted)

2b4.11. Optional Additional Testing for Risk Adjustment (*not required, but would provide additional support of adequacy of risk model, e.g., testing of risk model in another data set; sensitivity analysis for missing data; other methods that were assessed*)

2b5. IDENTIFICATION OF STATISTICALLY SIGNIFICANT & MEANINGFUL DIFFERENCES IN PERFORMANCE

2b5.1. Describe the method for determining if statistically significant and clinically/practically meaningful differences in performance measure scores among the measured entities can be identified (*describe the steps—do not just name a method; what statistical analysis was used? Do not just repeat the information provided related to performance gap in 1b)*

We examined variation in provider performance on this measure based on sex, age, race and a number of other patient factors to identify variations. The findings fare represented for 2013 and 2014 respectively.

2013

Label	# of providers	# of patients	Minimum	Lower Quartile	Mean	Upper Quartile	Maximum	Quartile Range	Std Dev

2b5.2. What were the statistical results from testing the ability to identify statistically significant and/or clinically/practically meaningful differences in performance measure scores across measured entities? (e.g., *number and percentage of entities with scores that were statistically significantly different from mean or some benchmark, different from expected; how was meaningful difference defined*)

Provided below is the testing that identified the differences in performance measure scores for 2013 and 2014.

2013

Overall mean performance on this measure is 67.8%, with a standard deviation of 32.0%. The minimum score equals 0.00%, while the maximum score equals 100.00%. The interquartile score is equal to 49.6%.

2,254 providers were measured, and the patient study sample equals 409,332. 55.8% of the sample is male. 89.5% of the sample is white, 8.7% is black, and 1.9% identified as "other." The sample reached across all US regions, with 14.9% of providers in the Northeast, 30.7% of providers in the Midwest, 37.4% of providers in the South, and 17.1% of providers in the West.

# of providers	Minimum	Lower Quartile	Mean	Upper Quartile	Maximum	Quartile Range	Std Dev
2254	0.00%	45.2%	67.8%	94.8%	100%	49.6%	32.0%

	Mean
Decile 1	4.0%
Decile 2	23.5%
Decile 3	44.5%

	Mean
Decile 4	62.3%
Decile 5	75.5%
Decile 6	84.9%
Decile 7	90.6%
Decile 8	94.7%
Decile 9	97.7%
Decile 10	99.7%

2014

Overall mean performance on this measure is 72.5%, with a standard deviation of 29.9%. The minimum score equals 0.00%, while the maximum score equals 100.00%. The interquartile score is equal to 41.6%.

2,219 providers were measured, and the patient study sample equals 404,406. 55.7% of the sample is male. 90.4% of the sample is white, 7.2% is black, and 2.4% identified as "other." The sample reached across all US regions, with 15.1% of providers in the Northeast, 24.5% of providers in the Midwest, 42.0% of providers in the South, and 18.5 % of providers in the West.

# of providers	Minimum	Lower Quartile	Mean	Upper Quartile	Maximum	Quartile Range	Std Dev
2219	0.00%	54.3%	72.5%	95.9%	100%	41.6%	29.9%

	Mean
Decile 1	7.2%
Decile 2	34.7%
Decile 3	54.4%
Decile 4	69.9%
Decile 5	82.1%

	Mean
Decile 6	89.4 %
Decile 7	93.1 %
Decile 8	95.9 %
Decile 9	98.0 %
Decile 10	99.7 %

2b5.3. What is your interpretation of the results in terms of demonstrating the ability to identify statistically significant and/or clinically/practically meaningful differences in performance across measured entities? (i.*e., what do the results mean in terms of statistical and meaningful differences?*)

2013: A moderate to large amount of variability was noted among providers. The performance-met rate range was 0-100% with the inter-quartile range being 45.2% to 94.8%. This yielded a Median Rate Ratio of 2.13 (2.07, 2.18). The Median Rate Ratio measures the variation across providers for statistically 'identical' patients and suggests that a patient presenting to 1 provider, as opposed to another, would, on average, be 2.3-times more likely to have their EF assessed.

2014: A moderate, but slightly lower, amount of variability was noted among providers. The performance-met rate range was 0-100% with the inter-quartile range being 54.3% to 95.9%. This yielded a Median Rate Ratio of 1.92 (1.88, 1.97).

2b6. COMPARABILITY OF PERFORMANCE SCORES WHEN MORE THAN ONE SET OF SPECIFICATIONS

If only one set of specifications, this section can be skipped.

Note: *This item is directed to measures that are risk-adjusted (with or without SDS factors)* ***OR*** *to measures with more than one set of specifications/instructions (e.g., one set of specifications for how to identify and compute the measure from medical record abstraction and a different set of specifications for claims or eMeasures). It does not apply to measures that use more than one source of data in one set of specifications/instructions (e.g., claims data to identify the denominator and medical record abstraction for the numerator).* ***Comparability is not required when comparing performance scores with and without SDS factors in the risk adjustment model. However, if comparability is not demonstrated for measures with more than one set of specifications/instructions, the different specifications (e.g., for medical records vs. claims) should be submitted as separate measures.***

2b6.1. Describe the method of testing conducted to compare performance scores for the same entities across the different data sources/specifications (*describe the steps—do not just name a method; what statistical analysis was used*)

2b6.2. What were the statistical results from testing comparability of performance scores for the same entities when using different data sources/specifications? (*e.g., correlation, rank order*)

2b6.3. What is your interpretation of the results in terms of the differences in performance measure scores for the same entities across the different data sources/specifications? (i.*e., what do the results mean and what are the norms for the test conducted*)

2b7. MISSING DATA ANALYSIS AND MINIMIZING BIAS

2b7.1. Describe the method of testing conducted to identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias (*describe the steps—do not just name a method; what statistical analysis was used*)

In PINNACLE, if a data field is not fulfilled, it is assumed that the process of care was not done. Thus, there are no missing values for this measure, although it is conceivable that the physician did assess the LVEF of the patient, but did not record them in the electronic health record, form which the data in PINNACLE is directly abstracted. If there are missing fields, we believe that these will be rapidly corrected on there is physician level accountability for recording these data occurs.

2b7.2. What is the overall frequency of missing data, the distribution of missing data across providers, and the results from testing related to missing data? (*e.g., results of sensitivity analysis of the effect of various rules for missing data/nonresponse; if no empirical sensitivity analysis, identify the approaches for handling missing data that were considered and pros and cons of each*)

Given our assumptions, noted above, we did not conduct an empirical analysis of frequency or distribution of missing data. For this measure, missing data is reported as a quality failure.

2b7.3. What is your interpretation of the results in terms of demonstrating that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias**?** (i.*e., what do the results mean in terms of supporting the selected approach for missing data and what are the norms for the test conducted; if no empirical analysis, provide rationale for the selected approach for missing data*)

We do not believe any biases are introduced in the assessing of individual physician performance and continued endorsement of this measure would lead to improved care.

3. Feasibility

Extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

3a. Byproduct of Care Processes

For clinical measures, the required data elements are routinely generated and used during care delivery (e.g., blood pressure, lab test, diagnosis, medication order).

3a.1. **Data Elements Generated as Byproduct of Care Processes.**

Generated or collected by and used by healthcare personnel during the provision of care (e.g., blood pressure, lab value, diagnosis, depression score)

If other:

3b. Electronic Sources

The required data elements are available in electronic health records or other electronic sources. If the required data are not in electronic health records or existing electronic sources, a credible, near-term path to electronic collection is specified.

3b.1. **To what extent are the specified data elements available electronically in defined fields?** *(i.e., data elements that are needed to compute the performance measure score are in defined, computer-readable fields)*

ALL data elements are in defined fields in electronic clinical data (e.g., clinical registry, nursing home MDS, home health OASIS)

3b.2. **If ALL the data elements needed to compute the performance measure score are not from electronic sources, specify a credible, near-term path to electronic capture, OR provide a rationale for using other than electronic sources.**

3b.3. **If this is an eMeasure, provide a summary of the feasibility assessment in an attached file or make available at a measure-specific URL.**

Attachment:

3c. Data Collection Strategy

Demonstration that the data collection strategy (e.g., source, timing, frequency, sampling, patient confidentiality, costs associated with fees/licensing of proprietary measures) can be implemented (e.g., already in operational use, or testing demonstrates that it is ready to put into operational use). For eMeasures, a feasibility assessment addresses the data elements and measure logic and demonstrates the eMeasure can be implemented or feasibility concerns can be adequately addressed.

3c.1. **Describe what you have learned/modified as a result of testing and/or operational use of the measure regarding data collection, availability of data, missing data, timing and frequency of data collection, sampling, patient confidentiality, time and cost of data collection, other feasibility/implementation issues.**

IF a PRO-PM, consider implications for both individuals providing PROM data (patients, service recipients, respondents) and those whose performance is being measured.

We have not identified an areas of concern or made any modifications as a result of testing and operational use of the measure in relation to data collection, availability of data, missing data, timing and frequency of data collection, sampling, patient confidentiality, time and cost of data collection, and other feasibility issues unless otherwise noted.

3c.2. **Describe any fees, licensing, or other requirements to use any aspect of the measure as specified** *(e.g., value/code set, risk model, programming code, algorithm)*.

Limited proprietary coding is contained in the measure specifications for convenience. Users of the proprietary code sets should obtain all necessary licenses from the owners of these code sets. The AMA, the ACC, the AHA, the PCPI and its members disclaim all liability for use or accuracy of any Current Procedural Terminology (CPT®) or other coding contained in the specifications.

4. Usability and Use

Extent to which potential audiences (e.g., consumers, purchasers, providers, policy makers) are using or could use performance results for both accountability and performance improvement to achieve the goal of high-quality, efficient healthcare for individuals or populations.

4a. Accountability and Transparency

Performance results are used in at least one accountability application within three years after initial endorsement and are publicly reported within six years after initial endorsement (or the data on performance results are available). If not in use at the time of initial endorsement, then a credible plan for implementation within the specified timeframes is provided.

4.1. **Current and Planned Use**

NQF-endorsed measures are expected to be used in at least one accountability application within 3 years and publicly reported within 6 years of initial endorsement in addition to performance improvement.

Planned	Current Use (for current use provide URL)
Public Reporting Quality Improvement (Internal to the specific organization)	Quality Improvement with Benchmarking (external benchmarking to multiple organizations) ACC Pinnacle Registry URL: http://www.ncdr.com/webncdr/pinnacle/

4a.1. **For each CURRENT use, checked above, provide:**

- Name of program and sponsor
- Purpose
- Geographic area and number and percentage of accountable entities and patients included

PINNACLE Registry (URL: http://www.ncdr.com/webncdr/pinnacle/)
In 2008, the American College of Cardiology Foundation launched the PINNACLE program (Formerly known as the Improving Continuous Cardiac Care or IC3). The PINNACLE Registry® continues to grow rapidly, with more than 3446 providers representing almost 960 unique office locations across the U.S submitting data to the registry. As of March 2015, the registry has more than 19.8 million patient encounter records representing approximately 4.85 million patients. PINNACLE assists practices in understanding and improving care through the production and distribution of quarterly performance reports. These reports, covering all valid patient encounters, detail adherence to 28 cardiovascular clinical measures at the physician, location, and practice levels across coronary artery disease, hypertension, heart failure and atrial fibrillation. All jointly developed ACC/AHA/PCPI performance measures for these topics are reported by the registry.

4a.2. **If not currently publicly reported OR used in at least one other accountability application (e.g., payment program, certification, licensing) what are the reasons?** (*e.g., Do policies or actions of the developer/steward or accountable entities restrict access to performance results or impede implementation?*)
We are continuously seeking opportunities to advocate for expanded use of this measure in government or other programs, including those intended for accountability or public reporting. The ACC, AHA and PCPI do not have any policies that would restrict access to the performance measure specifications or results or that would impede implementation of the measure for any application.

4a.3. **If not currently publicly reported OR used in at least one other accountability application, provide a credible plan for implementation within the expected timeframes -- any accountability application within 3 years and publicly reported within 6 years of initial endorsement.** (*Credible plan includes the specific program, purpose, intended audience, and timeline for implementing the measure within the specified timeframes. A plan for accountability applications addresses mechanisms for data aggregation and reporting.*)
We are continuously seeking opportunities to advocate for expanded use of this measure in government or other programs, including those intended for accountability or public reporting.

4b. Improvement

Progress toward achieving the goal of high-quality, efficient healthcare for individuals or populations is demonstrated. If not in use for performance improvement at the time of initial endorsement, then a credible rationale describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.

4b.1. **Progress on Improvement. (Not required for initial endorsement unless available.)**
Performance results on this measure (current and over time) should be provided in 1b.2 and 1b.4. Discuss:

- **Progress (trends in performance results, number and percentage of people receiving high-quality healthcare)**
- **Geographic area and number and percentage of accountable entities and patients included**

The mean performance rates from the Pinnacle registry increased from 2013 to 2014 from 67.8% to 72.5%. In 2013, 2254 providers were measured, and the patient study sample equals 409,332. In 2014, 2219 providers were measured, and the patient study sample equaled 404,406. The statistical significance of these results was not analyzed.

4b.2. **If no improvement was demonstrated, what are the reasons? If not in use for performance improvement at the time of initial endorsement, provide a credible rationale that describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.**
While the ACCF/AHA and PCPI create measures with an ultimate goal of improving the quality of care, measurement is a mechanism to drive improvement but does not equate with improvement. Measurement can help identify opportunities for improvement with actual improvement requiring making changes to health care processes and structure. In order to promote improvement, quality measurement systems need to provide feedback to front-line clinical staff in as close to real time as possible and at the point of care

whenever possible. (1)

[1]Conway PH, Mostashari F, Clancy C. The future of quality measurement for improvement and accountability. JAMA. 2013 Jun 5;309(21):2215-6.

4c. Unintended Consequences

The benefits of the performance measure in facilitating progress toward achieving high-quality, efficient healthcare for individuals or populations outweigh evidence of unintended negative consequences to individuals or populations (if such evidence exists).

4c.1. **Were any unintended negative consequences to individuals or populations identified during testing; OR has evidence of unintended negative consequences to individuals or populations been reported since implementation? If so, identify the negative unintended consequences and describe how benefits outweigh them or actions taken to mitigate them.**

We are not aware of any unintended consequences at this time, but we continuously monitor for them.

5. Comparison to Related or Competing Measures

If a measure meets the above criteria and there are endorsed or new related measures (either the same measure focus or the same target population) or competing measures (both the same measure focus and the same target population), the measures are compared to address harmonization and/or selection of the best measure.

5. Relation to Other NQF-endorsed Measures

Are there related measures (conceptually, either same measure focus or target population) or competing measures (conceptually both the same measure focus and same target population)? If yes, list the NQF # and title of all related and/or competing measures.

Yes

5.1a. **List of related or competing measures (selected from NQF-endorsed measures)**

0135 : Evaluation of Left ventricular systolic function (LVS)

5.1b. **If related or competing measures are not NQF endorsed please indicate measure title and steward.**

5a. Harmonization

The measure specifications are harmonized with related measures;

OR

The differences in specifications are justified

5a.1. **If this measure conceptually addresses EITHER the same measure focus OR the same target population as NQF-endorsed measure(s):**

Are the measure specifications completely harmonized?

No

5a.2. **If the measure specifications are not completely harmonized, identify the differences, rationale, and impact on interpretability and data collection burden.**

This measure is inpatient based and focuses on the assessment occurring prior to discharge. Our measure looks at whether the assessment was performed during a 12 month period for a patient with a diagnosis of heart failure.

5b. Competing Measures

The measure is superior to competing measures (e.g., is a more valid or efficient way to measure);

OR

Multiple measures are justified.

5b.1. **If this measure conceptually addresses both the same measure focus and the same target population as NQF-endorsed measure(s):**

Describe why this measure is superior to competing measures (e.g., a more valid or efficient way to measure quality); OR provide a rationale for the additive value of endorsing an additional measure. (Provide analyses when possible.)

Related Measures: NQF # 0135: Evaluation of Left ventricular systolic function (LVS). This measure is inpatient based and focuses on

the assessment occurring prior to discharge. Our measure looks at whether the assessment was performed during a 12 month period for a patient with a diagnosis of heart failure.

Appendix

A.1 Supplemental materials may be provided in an appendix. All supplemental materials (such as data collection instrument or methodology reports) should be organized in one file with a table of contents or bookmarks. If material pertains to a specific submission form number, that should be indicated. Requested information should be provided in the submission form and required attachments. There is no guarantee that supplemental materials will be reviewed.

John B Wong, MD (internal medicine)

These measures were developed through cross-specialty, multi-disciplinary work groups. All medical specialties and other health care professional disciplines participating in patient care for the clinical condition or topic under study must be equal contributors to the measure development process. In addition, the we strived to include on its work groups individuals representing the perspectives of patients, consumers, private health plans, and employers. This broad-based approach to measure development ensures buy-in on the measures from all stakeholders and minimizes bias toward any individual specialty or stakeholder group.

Measure Developer/Steward Updates and Ongoing Maintenance
Ad.2 **Year the measure was first released:** 2003
Ad.3 **Month and Year of most recent revision:** 12, 2010
Ad.4 **What is your frequency for review/update of this measure?** Every 3 years or as new evidence becomes available that materially affects the measures
Ad.5 **When is the next scheduled review/update for this measure?** 12, 2016

Ad.6 **Copyright statement:** This Physician Performance Measurement Set (PPMS) and related data specifications were developed by the Physician Consortium for Performance Improvement® (the Consortium) including the American College of Cardiology (ACC), the American Heart Association (AHA) and the American Medical Association (AMA) to facilitate quality improvement activities by physicians. The performance measures contained in this PPMS are not clinical guidelines and do not establish a standard of medical care, and have not been tested for all potential applications. While copyrighted, they can be reproduced and distributed, without modification, for noncommercial purposes, e.g., use by health care providers in connection with their practices. Commercial use is defined as the sale, license, or distribution of the performance measures for commercial gain, or incorporation of the performance measures into a product or service that is sold, licensed or distributed for commercial gain. Commercial uses of the PPMS require a license agreement between the user and the AMA, (on behalf of the Consortium) or the ACC or the AHA. Neither the AMA, ACC, AHA, the Consortium nor its members shall be responsible for any use of this PPMS.

THE MEASURES AND SPECIFICATIONS ARE PROVIDED "AS IS" WITHOUT WARRANTY OF ANY KIND.

Limited proprietary coding is contained in the measure specifications for convenience. Users of the proprietary code sets should obtain all necessary licenses from the owners of these code sets. The AMA, the ACC, the AHA, the Consortium and its members disclaim all liability for use or accuracy of any Current Procedural Terminology (CPT®) or other coding contained in the specifications.

Ad.7 **Disclaimers:** See copyright statement above.

Ad.8 **Additional Information/Comments:** The ACCF, AHA, and PCPI have a formal measurement review process that stipulates regular (usually on a three-year cycle, when feasible) review of the measures. The process can also be activated if there is a major change in scientific evidence, results from testing or other implementation issues are noted that materially affect the integrity of the measure.

MEASURE WORKSHEET

This document summarizes the evaluation of the measure as it progresses through NQF's Consensus Development Process (CDP). The information submitted by measure developers/stewards is included after the Brief Measure Information, Preliminary Analysis, and Pre-meeting Public and Member Comments sections.

Brief Measure Information

NQF #: 0083
De.2. **Measure Title:** Heart Failure (HF): Beta-Blocker Therapy for Left Ventricular Systolic Dysfunction (LVSD)
Co.1.1. **Measure Steward:** AMA-PCPI
De.3. **Brief Description of Measure:** Percentage of patients aged 18 years and older with a diagnosis of heart failure with a current or prior LVEF < 40% who were prescribed beta-blocker therapy either within a 12 month period when seen in the outpatient setting or at hospital discharge
1b.1. **Developer Rationale:** Beta-blockers are recommended for all patients with stable heart failure and left ventricular systolic dysfunction, unless contraindicated. Treatment should be initiated as soon as a patient is diagnosed with left ventricular systolic dysfunction and does not have low blood pressure, fluid overload, or recent treatment with an intravenous positive inotropic agent. Beta-blockers have been shown to lessen the symptoms of heart failure, improve the clinical status of patients, reduce future clinical deterioration, and decrease the risk of mortality and the combined risk of mortality and hospitalization.
Also, a 2011 analysis of IMPROVE HF data by Fonarow and colleagues revealed that all 4 current ACC/AHA HF outpatient performance measures were associated with decreased risk of 24-month mortality. For the 2 summary measures of HF care processes, there was also a strong positive association between greater conformity to the summary measures and improved risk-adjusted survival. These findings may have significant clinical and public health implications, providing evidence to suggest that current, and some emerging, outpatient process measures may effectively reflect the quality of care provided to patients with HF who are treated in outpatient practice settings.

S.4. **Numerator Statement:** Patients who were prescribed* beta-blocker therapy** either within a 12 month period when seen in the outpatient setting or at hospital discharge

*Prescribed may include:
Outpatient setting: prescription given to the patient for beta-blocker therapy at one or more visits in the measurement period OR patient already taking beta-blocker therapy as documented in current medication list
Inpatient setting: prescription given to the patient for beta-blocker therapy at discharge OR beta-blocker therapy to be continued after discharge as documented in the discharge medication list

**Beta-blocker therapy should include bisoprolol, carvedilol, or sustained release metoprolol succinate. (see technical specifications for additional information on medications)
S.7. **Denominator Statement:** All patients aged 18 years and older with a diagnosis of heart failure with a current or prior LVEF < 40%

LVEF < 40% corresponds to qualitative documentation of moderate dysfunction or severe dysfunction
S.10. **Denominator Exclusions:** Documentation of medical reason(s) for not prescribing beta-blocker therapy (eg, low blood pressure, fluid overload, asthma, patients recently treated with an intravenous positive inotropic agent)
Documentation of patient reason(s) for not prescribing beta-blocker therapy
Documentation of system reason(s) for not prescribing beta-blocker therapy

De.1. **Measure Type:**
S.23. **Data Source:** Electronic Clinical Data, Electronic Clinical Data : Electronic Health Record, Electronic Clinical Data : Registry
S.26. **Level of Analysis:** Clinician : Group/Practice, Clinician : Individual
Is this an eMeasure? ☒ **Yes** ☐ **No** **If Yes, was it re-specified from a previously endorsed measure?** ☒ **Yes** ☐ **No**

Is this a MAINTENANCE measure submission? ☒ **Yes** ☐ **No, this is a NEW measure submission.**
For MAINTENANCE, state the Original Endorsement Date: 8/10/09 **Most Recent Endorsement Date:** 1/18/12

Previous Measure Evaluation - Public & Member Comments, Developer Responses & Steering Committee Recommendations from (Cardiology Project 2010):

Public and Member Comments

- Concerns about broad exclusions.
- Clarification requested regarding the setting and data collection for this measure.

Developer response:

- This is a clinician-level measure for the outpatient setting.
- These measures have been tested and found to be generally feasible in EHR, paper, and claims data sources.

Steering Committee: Reviewed comments and developer's responses. No change to recommendations.

IF this measure is paired/grouped, NQF#/title: 0081: eart Failure (HF): Angiotensin-Converting Enzyme (ACE) Inhibitor or Angiotensin Receptor Blocker (ARB) Therapy for Left Ventricular Systolic Dysfunction (LVSD)

IF PAIRED/GROUPED, what is the reason this measure must be reported with other measures to appropriately interpret results? Measures #0083 and #0081 (Angiotensin-Converting Enzyme (ACE) Inhibitor or Angiotensin Receptor Blocker (ARB) Therapy for Left Ventricular Systolic Dysfunction) address related aspects of care for effective treatment for patients with heart failure and should be measured concurrently. Both ACE inhibitors and beta-blockers have been shown to reduce mortality and hospitalizations and improve a patient's clinical status. ARBs can be considered a reasonable alternative for ACE inhibitors. Combined treatment with these agents produces additive benefits and is required for optimal management of heart failure. It is not recommended that either of these measures be used independently. The pairing of these measures is not intended to suggest the use of any particular scoring methodology (ie, a composite score), nor does it imply either equality of or difference in the relative "weights" of the two measures. A performance score for each measure should be reported individually to provide actionable information upon which to focus quality improvement efforts.

Preliminary Analysis

The preliminary analysis was developed in response to recommendations from NQF's Consensus Task Force and measurement stakeholders as a way to enhance and streamline the measures evaluation and voting processes. The preliminary analysis will help to guide the Standing Committee evaluation of each measure by summarizing the measure developer submission, guide measure evaluation discussion, and identify topic areas for additional input. **NQF staff would like to stress that the preliminary analysis is intended to be used as a guide to facilitate the Committee's discussion and evaluation.**

Criteria 1: Importance to Measure and Report

1a. Evidence

1a. Evidence. The evidence requirements for a *process* measure is that it is based on a systematic review (SR) and grading of the body of empirical evidence where the specific focus of the evidence matches what is being measured.

The developer provides the following evidence for this process measure:

- This clinician-level process *registry* and *eMeasure* calculates the percentage of patients aged 18 years and older with a diagnosis of heart failure with a current or prior LVEF < 40% who were prescribed beta-blocker therapy either within a 12 month period when seen in the outpatient setting or at hospital discharge.
- The developer provides the 2013 ACCF/AHA guideline for the management of heart failure (Class I, Level A) that recommends the use of 1 of the 3 beta blockers proven to reduce mortality (eg, bisoprolol, carvedilol, and sustained release metoprolol succinate) for all patients with current or prior symptoms of heart failure, unless contraindicated.
- The articles supporting the beta-blocker recommendation were from 1989-2009 but the developers report that the overall literature search was through October 2011 with select articles included through April 2013.
- QQC: 17 Randomized Controlled Trials, 3 comparative studies.
- The developers provide 4 studies from 2014-2015. The additional studies recommended including nebivolol; compared cardevilol to metoprolol and bisoprolol; and looked at the use of beta-blockers in patients with heart failure and atrial fibrillation – the developers state that they will wait for revised guideline recommendations before considering changes to the measure.

- The developer provides a diagram of how the initiation of beta-blocker therapy for patients with heart failure or LVEF < 40% is linked to patient outcomes.

Questions for the Committee:

- *For process measures:*
  - *Is the evidence directly applicable to the process of care being measured?*
  - *Is the process of care proximal and closely related to desired outcomes?*
- *For possible exception to the evidence criteria:*
  - *Are there, or could there be, performance measures of a related health outcome, OR evidence-based intermediate clinical outcomes, intervention/treatment?*
  - *Is there evidence of a systematic assessment of expert opinion beyond those involved in developing the measure?*
  - *Does the SC agree that it is acceptable (or beneficial) to hold providers accountable without empiric evidence?*

1b. Gap in Care/Opportunity for Improvement and 1b. Disparities

1b. Performance Gap. The performance gap requirements include demonstrating quality problems and opportunity for improvement.

- The developers provided the average performance rates from the PQRS Experience Report from 2010-2013 and data from the literature that shows a beta-blocker was prescribed for 11,868 (86.2%) of 13,772 eligible patients Additional data (std dev, min, max, interquartile range, scores by decile, number of measured entities) that is required per NQF policy for maintenance is not provided.
- The developers report that disparities data from the federal reporting programs using this measure have not yet been made available for them to analyze and report.
- The developers provide data from a 2011 study that suggests that there are some racial and ethnic disparities in the receipt of pharmacological therapy for CHF among TRICARE beneficiaries.

Questions for the Committee:

- *Is there a gap in care that warrants a national performance measure?*
- *If no disparities information is provided, are you aware of evidence that disparities exist in this area of healthcare?*
- *Should this measure be indicated as disparities sensitive?*

1c. Priority

1c. High Priority (previously "High Impact") requires measures to address national health goal/priority or a demonstrated high-impact aspect of care.

- *Beginning in 2015, priority is no longer an NQF measure evaluation criterion.*

Committee pre-evaluation comments

Criteria 1: Importance to Measure and Report (including 1a, 1b, 1c)

1. ***Committee's Overview Comments***:
   - The evidence to support the measure focus was established through several clinical trials. This measure was established as a non-EHR measure in the past. The evidence source is the 2013 ACCF/ACA practice guidelines.
   - The developer provided ample evidence supporting the measure focus for this clinician-level process registry and eMeasure around beta blocker therapy for left ventricular systolic dysfunction (LVSD). The developer cited using the most current ACC/AHA guidelines that recommend as a Class IA the use of 1 of the 3 beta blockers proven to reduce mortality (eg bisoprolol, carvedilol, and sustained release metoprolol succinate) for all patients with current or prior symptoms of heart failure. The source also served as the systematic review of the body of the evidence.
   - As it relates to the quality, quantity and consistency of the evidence supporting this measure, it is quite high with 17 RCTs, and 3 comparative studies, representing literature from 1989 through 2009. However the developer also cited 4 additional recent studies conducted since the systematic review that included nebivolol; a comparison of metoptolol and bisoprolol; evaluated beta blockers in patients with AF and HF that was not included to support any measure changes. The developer will await updated guideline recommendations to refine the measure in any way based upon this new evidence.
   - Based upon the evidence provided, the evidence is directly applicable to the process of care being measured.

1a. ***Committee's Comments on Evidence to Support Measure Focus:***

- This is a process measure that is a paired measure with 0081.
- The evidence for this measure shows that the measure is directly related to an improvement of clinical status, mortality and risk of hospitalization. The evidence is long-standing. The clinical practice guideline is the 2013 ACCF/AHA 2013 Practice Guidelines. Evidence is Level A – multiple RCTs in multiple populations, evidence from 1989-2009, with updates through 2013. Evidence included 17 randomized controlled trials and 3 comparative studies. Benefits were seen in those with and without diabetes, men and women, and in blacks.
- Harms were noted in the evidence review and those potential harms were included as medical exclusions from the measure. (bradycardia, heart block, hypotension, asthma).
- QQC provided

1b. ***Committee's Comments on Performance Gap:***

- Performance gap evidence is provided from 2010-2013 PQRS which shows a performance around 75-85% adherence without sustained improvement over the 4 years presented. This was consistent with results from the IMPROVE-HF registry.
- Disparities data have not been reported and aren't available at this time. A single study from 2011 using TRICARE data found the AA were less likely to receive treatment.
- Heart Failure affects nearly 6 million Americans... it continues to have huge epidemiologic and economic implications, thus remaining a high priority area within healthcare. Based upon the developers submission, there is still a gap in care that warrants a national performance measures. Average performance rates from the PQRS Experience Report from 2010-2013, combined with data from the literature suggests that BBlocker was prescribed 86.2% of eligible patients.
- As it relates to disparities, the developer noted that disparities data from the CMS has not been made available for analysis. That said, the developer provided reference to a study that suggest that there are some racial and ethnic disparities in the receipt of pharmacologic therapy for HF patients among TRICARE beneficiaries."

1c. ***Committee's Comments on Composite Performance Measure:***

- Not Applicable

Criteria 2: Scientific Acceptability of Measure Properties
2a. Reliability
2a1. Reliability Specifications

2a1. Specifications requires the measure, as specified, to produce consistent (reliable) and credible (valid) results about the quality of care when implemented.

- The measure's data source is an EHR and/or registry. ICD 9, ICD 10 and CPT codes provided for the numerator and denominator for registry and inpatient setting. ICD-10 conversion methodology is not discussed. In both sets of specifications (registry and eMeasure), the logic is unambiguous. Higher scores equal better quality.
- In the outpatient setting, "prescribed" may include a beta-blocker prescription given to the patient at one or more visits in the measurement period or beta-blocker listed as current medication. In the inpatient setting, "prescribed" may include prescription given at discharge or beta-blocker listed in discharge medication list.
- The measure is intended for use in an office visit, outpatient consultation, nursing facility, long-term care residential facility, home health and provider interaction during the measurement period.
- Both specifications state, "Beta-blocker therapy should include bisoprolol, carvedilol, and sustained release metoprolol succinate", though an extensive list of beta blockaders are provided for the eMeasure.
- The denominator details state "In the outpatient setting, 2 or more encounters are required to establish the eligible professional has an existing relationship with the patient". Two visits could be added to the measure description or denominator to provide accuracy in measure calculation.
- For the registry specification, the denominator patient, medical & system exclusions/exceptions are reported using a single HCPCS code G8541, though in the paired measure 0081 they are reported using separate CPT-II codes for each of the 3 type of exclusions/exceptions.

- Denominator exclusions/exceptions include broad definitions for medical reason, patient reason and system reason for not prescribing beta-blocker therapy; examples of exceptions provided using CPT-II codes. The developer states that exceptions should only be considered when the numerator activity was not performed, that they are not uniformly relevant across measures, and that there must be a clear rationale to permit an exception for a medical, patient, or system reason. In the provided value sets, broadly defined and inappropriate patient, medical and system reason denominator exclusions include but are not limited to: medical reason: 216952002 failure in dosage (event), patient reason: 224187001 variable income (finding) & 266966009 family illness (situation), system reason:266756008 medical care unavailable (situation).
- Missing numerator data represents a quality failure.
- The calculation algorithm is included.
- The measure is not risk adjusted and SDS variables were not captured for the measure. The developer encourages users to provide collect data and stratify results by race, ethnicity, administrative sex, and payer consistent with CMS' Measures Management System Blueprint and recent national recommendations put forth by the IOM and NQF.
- For the eMeasure, the developer should clarify the following:
    - Atrioventricular Block and Cardiac Pacer in Situ are listed as exceptions in the eMeasure specification, though they are not included in the registry specifications. Should these be exclusions?
    - "Provider interactions" are listed as encounters in the value set spreadsheet and in the eMeasure specifications that include both face-to-face visits and non-face-to-face communications. The developer is encouraged to provide reasoning for inclusion, and clarify if all provider interactions are included in the denominator definition for a patient encounter.
    - "Communication: From Patient to Provider: Patient Reason for ACE Inhibitor or ARB Decline" is listed as an exception and is not included in the Registry specification. Please describe intent of this exception.
    - In the Initial Patient Population (IPP), "Encounter, Performed: Patient Provider Interaction" is listed, though it is not in the Data Criteria (QDM Variables).
    - "Encounter, Performed: Face-to-Face Interaction" is listed in the Data Criteria (QDM Variables), though not in the IPP.
- All eMeasure specifications and values sets meet current NQF eMeasure technical requirements and are provided on Sharepoint for SC review

Questions for the Committee:

- *Are all the data elements clearly defined? Are all appropriate codes included?*
- *Is the logic or calculation algorithm clear?*
- *Is it likely this measure can be consistently implemented?*

2a2. Reliability Testing Testing attachment

2a2. Reliability testing demonstrates if the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise enough to distinguish differences in performance across providers.

The developers present 3 types of reliability testing:

- GPRO EHR Web-Interface – Performance measure score was performed using the CMS PQRS EHR Web Interface data base from January 2013-December 2013: The total number of physicians reporting on this measure is 142. Of those, 129 physicians had all the required data elements and met the minimum number of quality reporting events (10) for inclusion in the reliability analysis. For this measure, 90.8 percent of physicians are included in the analysis, and the average number of quality reporting events is 90.1 for a total of 11,628 events.
    - For this measure, the reliability at the minimum level of quality reporting events (10) was 0.44. The average number of quality reporting events for physicians included is 90.1. The reliability at the average number of quality reporting events was 0.87. The developers conclude "This measure has moderate reliability when evaluated at the minimum level of quality reporting events and high reliability at the average number of quality events."

- GPRO Registry – Performance measure score was performed using the CMS PQRS GPRO database from January 2013-December 2013. The total number of physicians reporting on this measure is 1,748. Of those, 684 physicians had all the required data elements and met the minimum number of quality reporting events (10) for inclusion in the reliability analysis. For this measure, 39.1 percent of physicians are included in the analysis, and the average number of quality reporting events is 33.9 for a total of 23,175 events.
    - For this measure, the reliability at the minimum level of quality reporting events (10) was 0.86. The average number of quality reporting events for physicians included is 33.9. The reliability at the average number of quality reporting events was 0.96. The developers conclude "This measure has high reliability when evaluated at the minimum level of quality reporting events and high reliability at the average number of quality events."
- eMeasure – Critical data element (Validity against the Gold Standard) was conducted. Per NQF criteria, if empirical validity testing was performed of patient-level data, the rating from validity testing of patient-level data elements should be used.
    - The developer provides simple agreement results for critical data element validity. Comparison of the values for several data elements (electronic extracted vs. data abstracted) using EHR data was conducted and could satisfy the data element reliability criterion (Algorithm box 3; validity testing results described in 2b.2 below). Results were provided for most, but not all, critical data elements. Percent agreement statistics were presented; however, percent agreement does not adjust for agreement due to chance, and should not be used alone to demonstrate reliability.
    - Ideally, implementation of an eMeasure can be considered an automated process, and therefore the calculations will be consistent. The submitted eMeasure specification follows industry standards to represent the measure electronically which should enable automated data extraction and measure score calculation.
    - In addition to critical data element testing, the developer submitted pre-testing from the Measure Authoring Tool within the Bonnie Output that tests eMeasure logic. The measure logic successfully validated through the Bonnie Output.
- For both specifications, a missing data assessment was not performed. The developer states data missing from denominator excludes the patient from the measure, while missing numerator data counts as a measure "fail".
- Patient-level socio-demographic (SDS) variables were not captured as part of the testing.

Questions for the Committee:

- *Is the test sample adequate to generalize for widespread implementation?*
- *Do the results demonstrate sufficient reliability so that differences in performance can be identified?*

2b. Validity

2b1. Validity: Specifications

2b1. Validity Specifications. This section should determine if the measure specifications are consistent with the evidence.

- The evidence states 3 beta-blockers should be used for this population, though a lengthy list of beta-blockades are provided for the eMeasure.
- The clinical practice guideline supporting this measure recommends the use of beta-blockers in patients with heart failure, which the specifications reflect.

Question for the Committee:

- *Are the specifications consistent with the evidence?*

2b2. Validity testing

2b2. Validity Testing should demonstrate the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality.

GPRO Registry Testing

- Validity of the measure score was assessed by systematic assessment of face validity by an expert panel of 12

members who either agreed or strongly agreed that this measure can accurately distinguish good and poor quality.

eMeasure Testing

- Data element validity testing against the gold standard was conducted to calculate parallel forms reliability for the measure. Test site was an academic general internal medical clinic; 254 charts were analyzed from 2007. The automated quality assessment results found:
  - a sensitivity of 100.0% for identifying patients with heart failure taking a beta-blocker,
  - 12 of 18 patients with valid exclusion criteria (sensitivity, 66.7%), and
  - 1 of 13 patients who met exclusion criteria were judged not to have a true exclusion.
- Data element validity testing was conducting by comparing, for several data elements, the values obtained from electronic extraction from 1 EHR to those obtained from those abstracted from the EHR by an abstractor. Simple agreement was provided for most, but not all, critical data elements. However, simple agreement does not adjust for agreement due to chance and thus should not be used alone to demonstrate validity; sensitivity/specificity statistics are preferred for demonstrating data element validity. Percentage agreement values were relatively high for most data elements considered. It appears that only one abstractor was utilized, which is acceptable for testing validity against the gold standard in an EHR.
- In addition to critical data element testing, the developer submitted pre-testing from the Measure Authoring Tool within the Bonnie Output that also tests eMeasure performance calculation. This testing does use "live" EHR patients, though NQF currently accepts Bonnie Output pre-testing when EHR testing was not provided. Results in the 56 "pre-test" patients demonstrated 100% agreement for identifying both expected and actual initial patient population, denominator, denominator exclusions, numerator, and denominator exceptions. Testing characteristics are provided for the 56 "pre-test" patients, with 95% of the of data elements concepts included in the Initial Patient Population (IPP), Denominator, Numerator and Denominator Exceptions, with 95% of all possible data elements covered in the pre-test sample.

Questions for the Committee:

- *Is the test sample adequate to generalize for widespread implementation?*
- *Do the results demonstrate sufficient validity so that conclusions about quality can be made?*
- *Do you agree that the score from this measure as specified is an indicator of quality?*
- *Other specific question of the validity testing?*

2b3-2b7. Threats to Validity

2b3. Exclusions:

- GPRO Registry: Of the 129 physicians with the minimum (10) number of quality reporting events, there were a total of 601 exceptions reported. The average number of exceptions per physician in this sample is 4.7. The overall exception rate is 4.9%. The types of exceptions reported are not available from the GRPO Registry.
  - EHR: Measure exceptions were validated 95.32% of the time. Review of the 118 exceptions revealed 98.0% of exceptions were medical reasons for not prescribing beta blocker therapy. Medical reason exceptions consisted of clinical contraindications, drug allergy and drug intolerance. Atrioventricular Block and Cardiac Pacer in Situ are listed as exceptions in the eMeasure specification, though they are not included in the registry specifications.
- Broad exceptions (medical, patient & system) reasons are included within the provided data sets, and include non-relevant codes. For the Registry specification, one code encompasses all 3 types of exceptions.

Questions for the Committee:

- *Are the exclusions consistent with the evidence?*
- *Are any patients or patient groups inappropriately excluded from the measure?*
- *Are the exclusions/exceptions of sufficient frequency and variation across providers to be needed (and outweigh the data collection burden)?*

2b4. Risk adjustment:

- This process measure is not risk adjusted.

2b5. Meaningful difference:

- GPRO EHR Web-Interface: Based on the sample of 129 included physicians, the mean performance rate is 0.90, the median performance rate is 0.92 and the mode is 1.00. The standard deviation is 0.09. The range of the performance rate is 0.37, with a minimum rate of 0.63 and a maximum rate of 1. The interquartile range is 0.12 (0.85 - 0.97).
- GPRO Registry: Based on the sample of 684 included physicians, the mean performance rate is 0.70, the median performance rate is 0.93 and the mode is 1.00. The standard deviation is 0.37. The range of the performance rate is 1.00, with a minimum rate of 0.00 and a maximum rate of 1.00. The interquartile range is 0.58 (0.42 - 1.00).

Question for the Committee:

- *Does this measure identify meaningful differences about quality?*

2b6. Comparability of data sources/methods:

- NQF criteria require a comparability assessment of data sources/methods, such as with multiple specifications for the same measure. This was not provided by the developer, as the eMeasure testing data used fictitious "pre-test" patients.
- For validity testing of the eMeasure, developers did find higher performance & detection rates for the records abstracted with EHR & manual reviews, than EHR-only reviews, and GPRO EHR Web-Interface also demonstrated higher performance than the GPRO Registry.

2b7. Missing Data

- Missing numerator data represent a quality failure.
- The developer reports "Data are not available to complete this testing."

Committee pre-evaluation comments

Criteria 2: Scientific Acceptability of Measure Properties (including all 2a, 2b, and 2d)

2a1. &2b1.: ***Committee's Comments on Reliability-Specifications:***

- Specifications – The denominator is patients 18 and older with a diagnosis of HF and an ejection fraction < 40%. The numerator is for patients prescribed beta blocker therapy within the past 12 months in either the outpatient or inpatient setting. BB therapy is limited to bisoprolol, carvedilol, or sustained release metoprolol succinate. It does not include nebivolol. It requires that the patient has at least 2 encounters with the provider in the measurement period to establish a patient-provider relationship.
- Exclusions – include standard AMA-PCPI exclusions for medical reasons, patient reasons, and system reasons. The patient reasons include a broad range of reasons including patient income, family situations and others. These reasons were problematic with CSAC in Phase 2 as CSAC these reasons should not be included, while the developer commented that these are standard across all of their measure sets, and the developer was not willing to adjust these standard exclusions for individual measures.
- As for the electronic specifications, all elements are specified with VSAC specifications. And are specified in the accepted standard of HQMF format, using the Quality Data Model (QDM) as required. It seemed as if heart block was included in the eMeasure specification as an exclusion but excluded from the registry specifications as an exclusion.
- It appears that if there is any missing data the case is excluded from measurement. The developer states this is a quality failure, but it is unclear exactly what this means.
- "This measure can be calculated using several data sources including registry and EHR. Measure specifications were provided for eMeasures, including the value sets. The developer noted that on an annual basis they review the supporting guidance to keep the measure adherent to current eCQM industry standards and still preserve the original intent of the measure.
- The numerator statement has been clearly defined, noting differences that may arise between the inpatient and outpatient settings. Moreover, the numerator specifications are explicit to just the three pharmacologic agents referenced in the guidelines and supported by the evidence. The time period for data collection was clear, again making note of any difference anticipated depending upon setting of care. In both cases, for EHR and for Registry, the definitions used were provided and/or included in the submission.
- I think that it is worthwhile to note that the measure truly seeks to compare apples to apples by requiring in the outpatient setting that the eligible provider must have had two or more encounters with the patient to

establish an existing relationship with the patient.

- The developer included the calculation algorithm in this submission. The measure is not risk adjusted nor were SDS variables captured.
- As noted, all eMeasure specifications and value sets meet current NQF requirements.
- As the NQF staff noted, there are some inconsistencies between the registry specifications and the eMeasure specifications. Perhaps some clarify regarding those differences would be helpful during the upcoming discussion."

2a2.: ***Committee's Comments on Reliability-Testing:***

- 3 types of reliability testing were provided: for web-interface, for registry use, and for EHRs, against a gold standard – presumably chart abstracted data from an academic setting. Emeasure testing was done using 5 different EHR systems. They looked at the exception analysis, signal to noise ratio.
- Signal to noise ratio showed a reliability of 87-96 depending on the data source. Overall they report moderate to high reliability depending on the data source.
- There are three different approaches used for reliability testing- GPRO EHR Web-interface, GPRO Registry, and eMeasure.
- The developer concluded based upon the GPRO EHR web-interface reliability testing from Jan 2013 through Dec 2013 that ""the measure has average reliability when evaluated at the minimum level of quality reporting events and high reliability at the average number of quality events."
- As for the GPRO Registry reliability testing, also conducted during the same time frame, the measure developer reported that ""the measure had high reliability when evaluated at the minimum level of quality reporting events and high reliability at the average number of quality events."
- Finally for the eMeasure reliability testing

2b1.: ***Committee's Comments on Validity-Specifications***:

- Consistent with the evidence.
- Specifications as outlined are not inconsistent with the evidence. There may be an opportunity to cross check the list of BBlockers included in the eMeasures specifications to ensure that included BBlockers are the Brand name associated with the three BBlockers included in the measure.

2b2.: ***Committee's Comments on Validity-Testing:***

- Face validity was done using an expert panel. HER testing against the gold standard detected 86% of patients on a BB and of the remaining patients, 1 in 3 had an exclusion criteria for an overall performance of 91%. Expert review identified 6additional patients for exclusion and only 1 exclusion that was identified to be false. This was an overall 12 of 18 patients with valid exclusion criteria (sensitivity 67%m and 1 of 13 patients with net exclusion criteria that did not have a valid exclusion out of a total of 254 patients.
- Face validity testing showed that with an N of 12 responses, there were 8 responses of Agree and 4 responses of strongly agreeing that the measure could distinguish between good and poor quality.
- Measure testing with the eMeasure found that measure exceptions were validated 95% of the time. Of 118 exceptions analyzed, 98% were medical reasons for not prescribing. Overall exception rate was 5%.
- Data elements were testing using the Bonnie Output, using 56 test patients. This demonstrated 100% performance with 95% coverage of data elements. Mean performance from the EHR data was 0.9 with a STD Dev 0.09 (IQR 0.85-0.97) and in the registry the mean was 0.7 with an STD Dev 0.37 (IQR 0.42-1)
- The measure is not risk adjusted.
- For GPRO Testing, face validity was assessed by an expert panel of 12 members. For Emeaure Testing, critical data element testing was conducted for several data elements utilizing one abstractor against the gold standard of the EHR. In addition, the measure developer submitted pre-testing form the Measure Authoring Tool to test eMeasure performance calculation.

2b3-7.: ***Committee's Comments on Threats to Validity:***

- Missing data could be a threat to validity although the developers do not discuss this. Missing data assessment was not done that I could tell.
- The measure is not risk adjusted.
- IN my review of the documentation, any threats to validity would arise due to the level of exception reporting. With EHR, measure exceptions were validated 95.3% of the time, 98% of those exceptions due to medical reasons that were consistent with clinical contraindications of allergy and drug intolerance. With GPRO Registry, an assessment of the average number of exceptions were calculated, but the types reported were not available.

2d.: ***Committee's Comments on Composite Performance Measure:***

- Not Applicable

Criterion 3. Feasibility

3. Feasibility is the extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

- The measure is specified for EHR and registry.
- All data elements are in defined fields in EHRs.
- For the eMeasure specifications:
  - An eMeasure Feasibility Scorecard was provided. All coding is available in current uses, though ICD-10 & SNOMED-CT codes are not implemented across all EHRs currently. It is not clear how many and what type of EHRs were used for the assessment.
  - Atrioventricular Block and Cardiac Pacer in Situ are listed as exceptions in the eMeasure specification, though they are not included in the registry specifications.

Questions for the Committee:

- *Are the required data elements routinely generated and used during care delivery?*
- *Are the required data elements available in electronic form, e.g., EHR or other electronic sources?*
- *Is the data collection strategy ready to be put into operational use?*
- *If an eMeasure, does the eMeasure Feasibility Score Card demonstrate acceptable feasibility in multiple EHR systems and sites?*

Committee pre-evaluation comments

Criteria 3: Feasibility

3.: ***Committee's Comments on Feasibility:***

- All data elements are specified using VSAC codes. The Bonnie feasibility scorecard shows this to be feasible.
- At this time the measure is fully specified for EHR and registry, with all the fields being fully defined. Per the requirement, an eMeasure Feasibility Score Card was provided, thus demonstrating acceptable feasibility across multiple EHR systems and sites.

Criterion 4: Usability and Use

4. Usability and Use evaluate the extent to which audiences (e.g., consumers, purchasers, providers, policymakers) use or could use performance results for both accountability and performance improvement activities.

- The measure is currently used in PQRS, Meaningful Use Stage II and the PINNACLE Registry for quality improvement.
- The developer states not unintended consequences have been identified with measure use, and they continuously monitor for applicable mitigation.
- In 2012, the Measure Applications Partnership (MAP) Hospital Workgroup supported the measure stating the measure is strongly tied to outcomes. In 2014, the Clinician Workgroup supported the measure for the Physician Compare and Value-Based Payment Modifier Program stating the measure promotes person- and family-centered care. Promotes alignment across programs, settings, and public- and private-sector efforts. Included in a MAP family of measures. Addresses program goals/requirements. The measure was previously supported by Workgroup for inclusion in Physician Compare and VBPM for clinician group reporting.

Questions for the Committee*:*

- *Is the measure publicly reported?*

- *For maintenance measures – is the measure used in at least one accountability application?*
- *How can the performance results be used to further the goal of high-quality, efficient healthcare?*
- *Do the benefits of the measure outweigh any potential unintended consequences?*

Committee pre-evaluation comments

Criteria 4: Usability and Use

4.: ***Committee's Comments on Usability and Use:***

- It is currently used in PQRS, MU Stage 2, and the PINNACLE Registry. They mention that CMS may adopt this for Physician Compare public reporting. The developers do not report any known unintended consequences.
- This measure is currently used in PQRS and Meaningful Use Stage II. The measure is also captured and reported via the PINNACLE Registry as a part of QI initiatives as well. TO date, there are been no unintended consequences associated with this measure. The MAP in 2014 reviewed the measure and made recommendations for inclusion in Physician Compare and VBPM

Criterion 5: Related and Competing Measures

- 0070: Coronary Artery Disease (CAD): Beta-Blocker Therapy-Prior Myocardial Infarction (MI) or Left Ventricular Systolic Dysfunction (LVEF <40%)
- 0071 : Persistence of Beta-Blocker Treatment After a Heart Attack
- The developer states, "The specifications are harmonized to the extent possible. However, measure 0083 is focused on a patient population with heart failure and therefore the denominator specifications for the measures differ."

Pre-meeting public and member comments

-

NATIONAL QUALITY FORUM—Evidence (subcriterion 1a)

Measure Number (*if previously endorsed*)**:** 0083

Measure Title: **Beta-Blocker Therapy for Left Ventricular Systolic Dysfunction**

IF the measure is a component in a composite performance measure, provide the title of the Composite Measure here: Click here to enter composite measure #/ title

Date of Submission: 6/30/2015

Instructions

- *For composite performance measures:*
  - *A separate evidence form is required for each component measure unless several components were studied together.*
  - *If a component measure is submitted as an individual performance measure, attach the evidence form to the individual measure submission.*
- Respond to all questions as instructed with answers immediately following the question. All information needed to

demonstrate meeting the evidence subcriterion (1a) must be in this form. An appendix of *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 10 pages (*incudes questions/instructions*; minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the evidence for this measure meets NQF's evaluation criteria.

1a. Evidence to Support the Measure Focus

The measure focus is evidence-based, demonstrated as follows:

- Health outcome: [3] a rationale supports the relationship of the health outcome to processes or structures of care. Applies to patient-reported outcomes (PRO), including health-related quality of life/functional status, symptom/symptom burden, experience with care, health-related behavior.
- Intermediate clinical outcome: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured intermediate clinical outcome leads to a desired health outcome.
- Process: [5] a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured process leads to a desired health outcome.
- Structure: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured structure leads to a desired health outcome.
- Efficiency: [6] evidence not required for the resource use component.

Notes

3. Generally, rare event outcomes do not provide adequate information for improvement or discrimination; however, serious reportable events that are compared to zero are appropriate outcomes for public reporting and quality improvement.

4. The preferred systems for grading the evidence are the U.S. Preventive Services Task Force (USPSTF) grading definitions and methods, or Grading of Recommendations, Assessment, Development and Evaluation (GRADE) guidelines.

5. Clinical care processes typically include multiple steps: assess → identify problem/potential problem → choose/plan intervention (with patient input) → provide intervention → evaluate impact on health status. If the measure focus is one step in such a multistep process, the step with the strongest evidence for the link to the desired outcome should be selected as the focus of measurement. Note: A measure focused only on collecting PROM data is not a PRO-PM.

6. Measures of efficiency combine the concepts of resource use and quality (see NQF's Measurement Framework: Evaluating Efficiency Across Episodes of Care; AQA Principles of Efficiency Measures).

1a.1.This is a measure of: (*should be consistent with type of measure entered in De.1*)

Outcome

☐ Health outcome: Click here to name the health outcome

☐ Patient-reported outcome (PRO): Click here to name the PRO

PROs include HRQoL/functional status, symptom/symptom burden, experience with care, health-related behaviors

☐ Intermediate clinical outcome (*e.g., lab value*): Click here to name the intermediate outcome

☒ Process: Click here to name the process

☐ Structure: Click here to name the structure

☐ Other: Click here to name what is being measured

HEALTH OUTCOME/PRO PERFORMANCE MEASURE *If not a health outcome or PRO, skip to 1a.3*

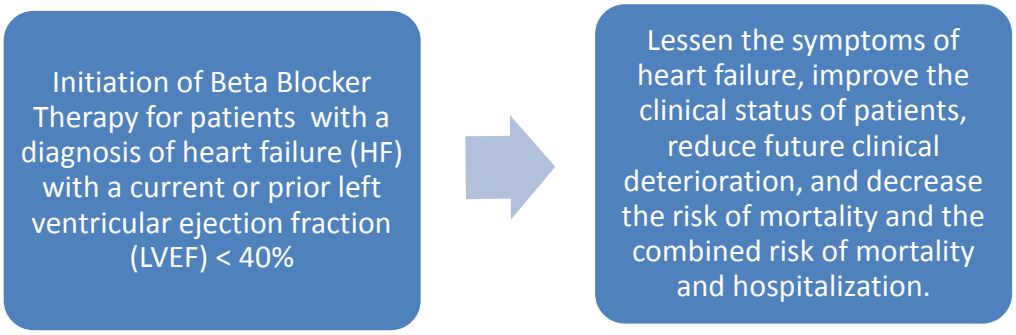
1a.2. Briefly state or diagram the path between the health outcome (or PRO) and the healthcare structures, processes, interventions, or services that influence it.

1a.2.1. State the rationale supporting the relationship between the health outcome (or PRO) to at least one healthcare structure, process, intervention, or service (*i.e., influence on outcome/PRO*).

Note: For health outcome/PRO performance measures, no further information is required; however, you may provide evidence for any of the structures, processes, interventions, or service identified above.

INTERMEDIATE OUTCOME, PROCESS, OR STRUCTURE PERFORMANCE MEASURE

1a.3. Briefly state or diagram the path between structure, process, intermediate outcome, and health outcomes. Include all the steps between the measure focus and the health outcome.



1a.3.1. What is the source of the systematic review of the body of evidence that supports the performance measure?

☒ Clinical Practice Guideline recommendation – ***complete sections 1a.4, and 1a.7***

☐ US Preventive Services Task Force Recommendation – ***complete sections 1a.5 and 1a.7***

☐ Other systematic review and grading of the body of evidence (*e.g., Cochrane Collaboration, AHRQ Evidence Practice Center*) – ***complete sections 1a.6 and 1a.7***

☐ Other – ***complete section 1a.8***

Please complete the sections indicated above for the source of evidence. You may skip the sections that do not apply.

1a.4. CLINICAL PRACTICE GUIDELINE RECOMMENDATION

1a.4.1. Guideline citation (*including date*) and **URL for guideline** (*if available online*):

http://circ.ahajournals.org/content/128/16/e240

Yancy CW, Jessup M, Bozkurt B, Butler J, Casey DE Jr, Drazner MH, Fonarow GC, Geraci SA, Horwich T, Januzzi JL, Johnson MR, Kasper EK, Levy WC, Masoudi FA, McBride PE, McMurray JJV, Mitchell JE,

Peterson PN, Riegel B, Sam F, Stevenson LW, Tang WHW, Tsai EJ, Wilkoff BL. 2013 ACCF/AHA guideline for the management of heart failure: a report of the American College of Cardiology Foundation/American Heart Association Task Force on Practice Guidelines. J Am Coll Cardiol 2013;62:e147-239.

1a.4.2. Identify guideline recommendation number and/or page number and **quote verbatim, the specific guideline recommendation**.

7.3.2.4. Beta Blockers: Recommendation

Class I

1. Use of 1 of the 3 beta blockers proven to reduce mortality (eg, bisoprolol, carvedilol, and sustainedrelease

metoprolol succinate) is recommended for all patients with current or prior symptoms of HF*r*EF, unless contraindicated, to reduce morbidity and mortality.[346,416–419,448] ***(Level of Evidence: A)***

1a.4.3. Grade assigned to the quoted recommendation <u>with definition</u> of the grade:

Class I, Level A =

1a.4.4. Provide all other grades and associated definitions for recommendations in the grading system.
(*Note: If separate grades for the strength of the evidence, report them in section 1a.7.*)

Table 1. Applying Classification of Recommendation and Level of Evidence

ESTIMATE OF CERTAINTY (PRECISION) OF TREATMENT EFFECT	SIZE OF TREATMENT EFFECT: CLASS I *Benefit >>> Risk* Procedure/Treatment **SHOULD** be performed/ administered	CLASS IIa *Benefit >> Risk* *Additional studies with focused objectives needed* **IT IS REASONABLE** to perform procedure/administer treatment	CLASS IIb *Benefit ≥ Risk* *Additional studies with broad objectives needed; additional registry data would be helpful* Procedure/Treatment **MAY BE CONSIDERED**	CLASS III *No Benefit* or CLASS III *Harm* Procedure/Test / Treatment COR III: No benefit — Not Helpful / No Proven Benefit COR III: Harm — Excess Cost w/o Benefit or Harmful / Harmful to Patients
LEVEL A Multiple populations evaluated* Data derived from multiple randomized clinical trials or meta-analyses	■ Recommendation that procedure or treatment is useful/effective ■ Sufficient evidence from multiple randomized trials or meta-analyses	■ Recommendation in favor of treatment or procedure being useful/effective ■ Some conflicting evidence from multiple randomized trials or meta-analyses	■ Recommendation's usefulness/efficacy less well established ■ Greater conflicting evidence from multiple randomized trials or meta-analyses	■ Recommendation that procedure or treatment is not useful/effective and may be harmful ■ Sufficient evidence from multiple randomized trials or meta-analyses
LEVEL B Limited populations evaluated* Data derived from a single randomized trial or nonrandomized studies	■ Recommendation that procedure or treatment is useful/effective ■ Evidence from single randomized trial or nonrandomized studies	■ Recommendation in favor of treatment or procedure being useful/effective ■ Some conflicting evidence from single randomized trial or nonrandomized studies	■ Recommendation's usefulness/efficacy less well established ■ Greater conflicting evidence from single randomized trial or nonrandomized studies	■ Recommendation that procedure or treatment is not useful/effective and may be harmful ■ Evidence from single randomized trial or nonrandomized studies
LEVEL C Very limited populations evaluated* Only consensus opinion of experts, case studies, or standard of care	■ Recommendation that procedure or treatment is useful/effective ■ Only expert opinion, case studies, or standard of care	■ Recommendation in favor of treatment or procedure being useful/effective ■ Only diverging expert opinion, case studies, or standard of care	■ Recommendation's usefulness/efficacy less well established ■ Only diverging expert opinion, case studies, or standard of care	■ Recommendation that procedure or treatment is not useful/effective and may be harmful ■ Only expert opinion, case studies, or standard of care
Suggested phrases for writing recommendations	should is recommended is indicated is useful/effective/beneficial	is reasonable can be useful/effective/beneficial is probably recommended or indicated	may/might be considered may/might be reasonable usefulness/effectiveness is unknown/unclear/uncertain or not well established	COR III: No Benefit: is not recommended; is not indicated; should not be performed/ administered/ other; is not useful/ beneficial/ effective COR III: Harm: potentially harmful; causes harm; associated with excess morbidity/mortality; should not be performed/ administered/ other
Comparative effectiveness phrases†	treatment/strategy A is recommended/indicated in preference to treatment B treatment A should be chosen over treatment B	treatment/strategy A is probably recommended/indicated in preference to treatment B it is reasonable to choose treatment A over treatment B		

A recommendation with Level of Evidence B or C does not imply that the recommendation is weak. Many important clinical questions addressed in the guidelines do not lend themselves to clinical trials. Although randomized trials are unavailable, there may be a very clear clinical consensus that a particular test or therapy is useful or effective.

*Data available from clinical trials or registries about the usefulness/efficacy in different subpopulations, such as sex, age, history of diabetes, history of prior myocardial infarction, history of heart failure, and prior aspirin use.

†For comparative effectiveness recommendations (Class I and IIa; Level of Evidence A and B only), studies that support the use of comparator verbs should involve direct comparisons of the treatments or strategies being evaluated.

1a.4.5. Citation and URL for methodology for grading recommendations (*if different from 1a.4.1*)**:**

1a.6.2. Citation and URL for methodology for evidence review and grading (*if different from 1a.6.1*)**:**

Complete section 1a.7

1a.7. FINDINGS FROM SYSTEMATIC REVIEW OF BODY OF THE EVIDENCE SUPPORTING THE MEASURE

If more than one systematic review of the evidence is identified above, you may choose to summarize the one (or more) for which the best information is available to provide a summary of the quantity, quality, and consistency of the body of evidence. Be sure to identify which review is the basis of the responses in this section and if more than one, provide a separate response for each review.

1a.7.1. What was the specific structure, treatment, intervention, service, or intermediate outcome addressed in the evidence review?

Effectiveness of beta blockers at improving quality of life and clinical status in patients with heart failure; which patients should receive beta blocker therapy; initiation and maintenance of therapy; and risks of treatment with beta blocker therapy.

1a.7.2. Grade assigned for the quality of the quoted evidence <u>with definition</u> of the grade:

Level A-

1a.7.3. Provide all other grades and associated definitions for strength of the evidence in the grading system.

See table in 1a.4.4

1a.7.4. What is the time period covered by the body of evidence? (*provide the date range, e.g., 1990-2010*).
Date range: 1989-2009

QUANTITY AND QUALITY OF BODY OF EVIDENCE

1a.7.5. How many and what type of study designs are included in the body of evidence? (*e.g., 3 randomized controlled trials and 1 observational study*)

17 Randomized Controlled Trials, 3 comparative studies

1a.7.6. What is the overall quality of evidence <u>across studies</u> in the body of evidence? (*discuss the certainty or confidence in the estimates of effect particularly in relation to study factors such as design flaws, imprecision due to small numbers, indirectness of studies to the measure focus or target population*)

There are many solid randomized controlled trials that show that the benefits of using beta blockers greatly outweigh the harms. They are very effective and relatively safe. The benefits of beta blockers were seen in patients with or without CAD and in patients with or without diabetes mellitus, as well as in women and blacks. The favorable effects of beta blockers were also observed in patients already taking ACE inhibitors.

ESTIMATES OF BENEFIT AND CONSISTENCY ACROSS STUDIES IN BODY OF EVIDENCE

1a.7.7. What are the estimates of benefit—magnitude and direction of effect on outcome(s) <u>across studies</u> in the body of evidence? (*e.g., ranges of percentages or odds ratios for improvement/ decline across studies, results of meta-analysis, and statistical significance*)

Long-term treatment with beta blockers can lessen the symptoms of HF, improve the patient's clinical status, and enhance the patient's overall sense of well-being. In addition, like ACE inhibitors, beta blockers can reduce the risk of death and the combined risk of death or hospitalization

1a.7.8. What harms were studied and how do they affect the net benefit (benefits over harms)?

Initiation of treatment with a beta blocker may produce 4 types of adverse reactions that require attention and management: fluid retention and worsening HF; fatigue; bradycardia or heart block; and hypotension. The occurrence of fluid retention or worsening HF is not generally a reason for the permanent withdrawal of treatment. Such patients generally respond favorably to intensification of conventional therapy, and once treated, they remain excellent candidates for long-term treatment with a beta blocker. The slowing of heart rate and cardiac conduction produced by beta blockers is generally asymptomatic and thus requires no treatment; however, if the bradycardia is accompanied by dizziness or lightheadedness or if second- or third-degree heart block occurs, clinicians should decrease the dose of the beta blocker. Clinicians may minimize the risk of hypotension by administering the beta blocker and ACE inhibitor at different times during the day. Hypotensive symptoms may also resolve after a decrease in the dose of diuretics in patients who are volume depleted. If hypotension is accompanied by other clinical evidence of hypoperfusion, beta-blocker therapy should be decreased or discontinued pending further patient evaluation. The symptom of fatigue is multifactorial and is perhaps the hardest symptom to address with confidence. Although fatigue may be related to beta blockers, other causes of fatigue should be considered, including sleep apnea, overdiuresis, or depression.

See Online Data Supplement 20 for additional data on beta blockers.
http://circ.ahajournals.org/content/suppl/2013/06/04/CIR.0b013e31829e8776.DC1/Online_Data_Supplement.pdf

UPDATE TO THE SYSTEMATIC REVIEW(S) OF THE BODY OF EVIDENCE

1a.7.9. If new studies have been conducted since the systematic review of the body of evidence, provide for <u>each</u> new study: 1) citation, 2) description, 3) results, 4) impact on conclusions of systematic review.

The articles supporting the Beta Blocker recommendation were from 1989-2009. However, the overall literature search was through Oct, 2011, with select articles included through April, 2013.

We ran a search for Heart Failure and Beta Blockers for 2014 and 2015. There are several studies related to Beta Blockers and their use in Heart Failure.

Nebivolol is not currently recommended for treatment of Heart Failure and is not included in the measure. The 2013 guideline cites one study from 2009 and says "Beta-1 selective blocker nebivolol demonstrated a modest reduction in the primary endpoint of all-cause mortality or cardiovascular hospitalization but did not affect mortality alone in an elderly population that included patients with HFpEF." Montero et al (2014) does show some benefit, at least in the elderly. We await the next revision of the guideline before considering changes to the measure.

1) Montero-Perez-Barquero M, Flather M, Roughton M, Coats A, Böhm M, Van Veldhuisen DJ, Babalis D, Solal AC, Manzano L. Influence of systolic blood pressure on clinical outcomes in elderly heart failure patients treated with nebivolol: data from the SENIORS trial.
Eur J Heart Fail. 2014 Sep;16(9):1009-15. doi: 10.1002/ejhf.136. Epub 2014 Jul 17.

Montero et al (2014) looked at the influence of systolic blood pressure on clinical outcomes in elderly patients with heart failure treated with nebivolol. Patients were divided into three baseline pre-treatment SBP categories (<110, 110-

130, and >130 mmHg). They also evaluated the influence of SBP (≤ 130 and > 130 mmHg) on patients with LVEF <40% vs. ≥ 40%. Low baseline SBP was associated with worse clinical outcomes irrespective of treatment group, both in patients with reduced EF and in those with preserved EF. Nebivolol had similar benefits irrespective of baseline

SBP: the hazard ratio (HR) for primary outcome of all-cause mortality or cardiovascular hospitalization in the three SBP categories for nebivolol vs. placebo was 0.85 [95% confidence interval (CI) 0.50-1.45], 0.79 (95% CI 0.61-1.01), and 0.88 (95% CI 0.72-1.07), respectively (P for interaction = 0.61). Similar results were obtained for the secondary endpoint of all-cause mortality. There was no significant interaction for the effects of nebivolol by baseline SBP stratified by LVEF.

They conclude that elderly HF patients with lower SBP have a worse outcome than those with higher SBP, but nebivolol appears to be safe and well tolerated, with similar benefits on the composite outcome of death or cardiovascular hospital admission irrespective of baseline SBP and LVEF.

Some studies compared cardevilol to metoprolol and bisoprolol- all 3 are currently recommended by the guideline and are included as part of the measure. One study concluded that heart failure patients receiving high-dose carvedilol (≥50 mg daily) showed significantly lower all-cause mortality risk and hospitalization risk, compared with other beta-blockers. This is clearly still an area of interest in the research community. As such, we will wait for the new research to be examined as part of the guideline update process before considering changes to the measure.

2) Bølling R, Scheller NM, Køber L, Poulsen HE, Gislason GH, Torp-Pedersen C. Comparison of the clinical outcome of different beta-blockers in heart failure patients: a retrospective nationwide cohort study. Eur J Heart Fail. 2014 Jun;16(6):678-84. doi: 10.1002/ejhf.81. Epub 2014 Apr 4.

Bolling et al (2014) looked at all Danish patients ≥35 years of age who were hospitalized with a first admission for heart failure and who initiated treatment with a beta-blocker within 60 days of dischargefrom 1995-2011. The main outcome was all-cause mortality and all-cause hospitalization. Cox proportional hazard models were used to compare survival. The study included 58 634 patients of whom 30.121 (51.4%) died and 46.990 (80.1%) were hospitalized during follow-up. The mean follow-up time was 4.1 years. In an unadjusted model carvedilol was associated with a lower mortality [hazard ratio (HR) 0.737, 0.714-0.761] compared with metoprolol (reference) while bisoprolol was not associated with an increased mortality (HR 1.020, 0.973-1.069). In a model adjusted for possible confounders and stratified according to beta-blocker dosages, patients that received high-dose carvedilol (≥50 mg daily) had a lower all-cause mortality risk (HR 0.873, 0.789-0.966) than patients receiving high-dose (≥200 mg daily) metoprolol (reference). High-dose bisoprolol (≥10 mg daily) was associated with a greater risk of death (HR 1.125, 1.004-1.261). High-dose carvedilol was associated with significantly lower all-cause hospitalization risk (HR 0.842, 0.774-0.915) than high-dose metoprolol (reference), while high-dose bisoprolol had insignificantly lower risk than high-dose metoprolol (HR 0.948, 0.850-1.057).

They concluded that heart failure patients receiving high-dose carvedilol (≥50 mg daily) showed significantly lower all-cause mortality risk and hospitalization risk, compared with other beta-blockers.

3) Molenaar P, Christ T, Berk E, Engel A, Gillette KT, Galindo-Tovar A, Ravens U, Kaumann AJ. Carvedilol induces greater control of β2- than β 1-adrenoceptor-mediated inotropic and lusitropic effects by PDE3, while PDE4 has no effect in human failing myocardium. Naunyn Schmiedebergs Arch Pharmacol. 2014 Jul;387(7):629-40. doi: 10.1007/s00210-014-0974-4. Epub 2014 Mar 26.

The β-blockers carvedilol and metoprolol provide important therapeutic strategies for heart failure treatment. Therapy with metoprolol facilitates the control by phosphodiesterase PDE3, but not PDE4, of inotropic effects of catecholamines in human failing ventricle. However, it is not known whether carvedilol has the same effect. The authors investigated whether the PDE3-selective inhibitor cilostamide (0.3 μM) or PDE4-selective inhibitor rolipram (1 μM) modified the positive inotropic and lusitropic effects of catecholamines in ventricular myocardium of heart failure patients treated with carvedilol. Right ventricular trabeculae from explanted hearts of nine carvedilol-treated patients with terminal heart failure were paced to contract at 1 Hz. The effects of (-)-noradrenaline, mediated through β1-adrenoceptors (β2-adrenoceptors blocked with ICI118551), and (-)-adrenaline, mediated through β2-adrenoceptors (β1-adrenoceptors blocked with CGP20712A), were assessed in the absence and presence of the PDE inhibitors. The inotropic potency, estimated from -logEC50s, was unchanged for (-)-noradrenaline but decreased 16-fold for (-)-adrenaline in carvedilol-treated compared to non-β-blocker-treated patients, consistent with the previously reported β2-adrenoceptor-selectivity of carvedilol. Cilostamide caused 2- to 3-fold and 10- to 35-fold potentiations of the inotropic and lusitropic effects of (-)-noradrenaline and (-)-adrenaline, respectively, in trabeculae from carvedilol-treated patients. Rolipram did not affect the inotropic and lusitropic potencies of (-)-noradrenaline or (-)-adrenaline. Treatment of heart failure patients with carvedilol induces PDE3 to selectively control the positive inotropic and lusitropic effects mediated through ventricular β2-adrenoceptors compared to β1-adrenoceptors. The β2-adrenoceptor-selectivity of carvedilol may provide protection against β2-adrenoceptor-mediated ventricular overstimulation in PDE3 inhibitor-treated patients. PDE4 does not control β1- and β2-adrenoceptor-mediated inotropic and lusitropic effects in carvedilol-treated patients.

And finally, a meta-analysis analyzed patient data to look at the use of beta blockers in the subgroup of patients with heart failure and atrial fibrillation. They concluded that Beta Blockers should not be used preferentially over other rate-control medications and not regarded as standard therapy to improve prognosis in patients with concomitant heart failure and atrial fibrillation. Again, we will wait for revised guideline recommendations before considering changes to the measure.

4) Kotecha D, Holmes J, Krum H, Altman DG, Manzano L, Cleland JG, Lip GY, Coats AJ, Andersson B, Kirchhof P, von Lueder TG, Wedel H, Rosano G, Shibata MC, Rigby A, Flather MD; Beta-Blockers in Heart Failure Collaborative Group. Efficacy of β blockers in patients with heart failure plus atrial fibrillation: an individual-patient data meta-analysis.Lancet. 2014 Dec 20;384(9961):2235-43. doi: 10.1016/S0140-6736(14)61373-8. Epub 2014 Sep 2.

Kotecha et al (2014) noted that the efficacy of these drugs in heart failure patients with concomitant atrial fibrillation is uncertain. They meta-analysed individual-patient data to assess the efficacy of β blockers in patients with heart failure and sinus rhythm compared with atrial fibrillation.

They extracted individual-patient data from ten randomised controlled trials of the comparison of β blockers versus placebo in heart failure. The presence of sinus rhythm or atrial fibrillation was ascertained from the baseline electrocardiograph. The primary outcome was all-cause mortality. Analysis was by intention to treat. Outcome data were meta-analysed with an adjusted Cox proportional hazards regression. The study is registered with Clinicaltrials.gov, number NCT0083244, and PROSPERO, number CRD42014010012.

18,254 patients were assessed, and of these 13,946 (76%) had sinus rhythm and 3066 (17%) had atrial fibrillation at baseline. Crude death rates over a mean follow-up of 1·5 years (SD 1·1) were 16% (2237 of 13,945) in patients with sinus rhythm and 21% (633 of 3064) in patients with atrial fibrillation. β-blocker therapy led to a significant reduction in all-cause mortality in patients with sinus rhythm (hazard ratio 0·73, 0·67-0·80; p<0·001), but not in patients with atrial fibrillation (0·97, 0·83-1·14; p=0·73), with a significant p value for interaction of baseline rhythm (p=0·002). The lack of efficacy for the primary outcome was noted in all subgroups of atrial fibrillation, including age, sex, left ventricular ejection fraction, New York Heart Association class, heart rate, and baseline medical therapy.

Based on their findings, they conclude that β blockers should not be used preferentially over other rate-control medications and not regarded as standard therapy to improve prognosis in patients with concomitant heart failure and atrial fibrillation.

1a.8 OTHER SOURCE OF EVIDENCE

If source of evidence is NOT from a clinical practice guideline, USPSTF, or systematic review, please describe the evidence on which you are basing the performance measure.

1a.8.1 What process was used to identify the evidence?

1a.8.2. Provide the citation and summary for each piece of evidence.

1. Evidence, Performance Gap, Priority – Importance to Measure and Report
Extent to which the specific measure focus is evidence-based, important to making significant gains in healthcare quality, and improving health outcomes for a specific high-priority (high-impact) aspect of healthcare where there is variation in or overall less-than-optimal performance. ***Measures must be judged to meet all subcriteria to pass this criterion and be evaluated against the remaining criteria.***
1a. Evidence to Support the Measure Focus – See attached Evidence Submission Form NQF_measure_submission_evidence_HF_BB.docx
1b. Performance Gap Demonstration of quality problems and opportunity for improvement, i.e., data demonstrating: • considerable variation, or overall less-than-optimal performance, in the quality of care across providers; and/or • disparities in care across population groups. 1b.1. **Briefly explain the rationale for this measure** *(e.g., the benefits or improvements in quality envisioned by use of this measure)* Beta-blockers are recommended for all patients with stable heart failure and left ventricular systolic dysfunction, unless contraindicated. Treatment should be initiated as soon as a patient is diagnosed with left ventricular systolic dysfunction and does not have low blood pressure, fluid overload, or recent treatment with an intravenous positive inotropic agent. Beta-blockers have been shown to lessen the symptoms of heart failure, improve the clinical status of patients, reduce future clinical deterioration, and decrease the risk of mortality and the combined risk of mortality and hospitalization. Also, a 2011 analysis of IMPROVE HF data by Fonarow and colleagues revealed that all 4 current ACC/AHA HF outpatient performance measures were associated with decreased risk of 24-month mortality. For the 2 summary measures of HF care processes, there was also a strong positive association between greater conformity to the summary measures and improved risk-adjusted survival. These findings may have significant clinical and public health implications, providing evidence to suggest that current, and some emerging, outpatient process measures may effectively reflect the quality of care provided to patients with HF who are treated in outpatient practice settings. 1b.2. **Provide performance scores on the measure as specified (current and over time) at the specified level of analysis.** *(This is required for endorsement maintenance. Include mean, std dev, min, max, interquartile range, scores by decile. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities included). This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.* 2013 PQRS Experience Report*: Data Source: 2013 is the most recent year for which PQRS Experience Report measure data is available. The average performance rates on Heart Failure (HF) – Beta Blocker Therapy for Left Ventricular Systolic Dysfunction (LVSD) over the last several years are as follows: 2010: 82.7%

2011: 75.8%
2012: 86.8%
2013: 77.6%
2013 Small Group Practice Exception Rate: 1.04%
Reference: Center for Medicare and Medicaid Services. 2013 Reporting Experience Including Trends. Available: http://www.cms.gov/Medicare/Quality-Initiatives-Patient-Assessment-Instruments/PQRS/index.html?redirect=/PQRS/
*It is important to note that PQRS was a voluntary reporting program, with approximately 51% of eligible professionals participating using any reporting option in 2013, and performance rates may not be nationally representative.

1b.3. **If no or limited performance data on the measure as specified is reported in 1b2, then provide a summary of data from the literature that indicates opportunity for improvement or overall less than optimal performance on the specific focus of measurement.**
According to Fonarow and colleagues (2010), for aggregate practices at baseline, a ß-blocker was prescribed for 11 868 (86.2%) of 13 772 eligible patients.

Improving Evidence-Based Care for Heart Failure in Outpatient Cardiology Practices: Primary Results of the Registry to Improve the Use of Evidence-Based Heart Failure Therapies in the Outpatient Setting (IMPROVE HF). Circulation 2010; 122: 585-596. Published online before print July 26, 2010, doi: 10.1161/CIRCULATIONAHA.109.934471.

1b.4. **Provide disparities data from the measure as specified (current and over time) by population group, e.g., by race/ethnicity, gender, age, insurance status, socioeconomic status, and/or disability.** *(This is required for endorsement maintenance. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities include.) This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*
While this measure is included in several federal reporting programs, those programs have not yet made disparities data available for us to analyze and report.

1b.5. **If no or limited data on disparities from the measure as specified is reported in 1b4, then provide a summary of data from the literature that addresses disparities in care on the specific focus of measurement. Include citations.**
A 2011 study by Bagchi et al of the TRICARE program found that African Americans were less likely than whites to have received beta blockers and angiotensin-converting enzyme inhibitors or angiotensin receptor blockers following a CHF diagnosis (P<0.0001). Hispanics were, in some cases, equally likely as whites to receive pharmacological treatments for CHF. In multivariate models, there were no significant racial/ethnic differences in the odds of a potentially avoidable hospitalization (PAH); age greater than 65 was the most significant predictor of a PAH. This study suggests that although there are some racial and ethnic disparities in the receipt of pharmacological therapy for CHF among TRICARE beneficiaries, these differences do not translate into disparities in the likelihood of a PAH. The findings support previous research suggesting that equal access to care may mitigate racial/ethnic health disparities.

Bagchi AD, Stewart K, McLaughlin C, Higgins P, Croghan T. Treatment and outcomes for congestive heart failure by race/ethnicity in TRICARE. Med Care. 2011 May;49(5):489-95. doi: 10.1097/MLR.0b013e318207ef87.

1c. High Priority (previously referred to as High Impact)
The measure addresses:

- a specific national health goal/priority identified by DHHS or the National Priorities Partnership convened by NQF; OR
- a demonstrated high-priority (high-impact) aspect of healthcare (e.g., affects large numbers of patients and/or has a substantial impact for a smaller population; leading cause of morbidity/mortality; high resource use (current and/or future); severity of illness; and severity of patient/societal consequences of poor quality).

1c.1. **Demonstrated high priority aspect of healthcare**
Affects large numbers, A leading cause of morbidity/mortality, High resource use, Severity of illness, Patient/societal consequences of poor quality
1c.2. **If Other:**

1c.3. **Provide epidemiologic or resource use data that demonstrates the measure addresses a high priority aspect of healthcare.**

List citations in 1c.4.

Heart Failure affects over 5.7 million Americans (2.4% in 2008; 2.7% in 2010) and that number is expected to rise consistently over the next 15 years (Heidenreich et al 2011, Mozaffarian 2015), The AHA forecasting study predicts that total costs for heart failure in the 18-44 age group will increase from $1.51 billion to $2.48 billion, while the costs for the 65-79 age group will increase from $11.50 billion to $29.9 billion (Heidenreich et al 2011).

In a 2014 article, Storrow et al writes that heart failure results in nearly 1 million annual hospital stays (Go 2013, Chen 2011), and is the top reason for Medicare hospital readmissions (Jencks 2009, Dharmarajan 2013). The vast majority of patients hospitalized for acute heart failure (AHF) are originally evaluated and managed in the emergency department (ED). Prior data suggest more than 80% of ED patients with AHF are admitted to the hospital and have a median inpatient length of stay (LOS) of approximately 3.4 days. Of the $39.2 billion dollars spent on heart failure care in the United States in 2010, hospital stay was the single largest proportion of this expenditure (AHA 2010, Heidenreich 2011). Among Medicare beneficiaries, hospital stay accounts for more than 50% of all heart failure costs in the last 6 months of life (Blecker 2012). Despite a small decline in the AHF hospital stay rate among Medicare beneficiaries over the last decade (Go 2013, Chen 2011), mortality remains high (Chen 2011, Richardson 2002, Roger 2004) and uneven across

Storrow et al (2014) utilized Nationwide Emergency Department Sample AHF data from 2006 to 2010 to describe admission proportion, hospital length of stay (LOS), and ED charges as a surrogate for resource utilization. Results were compared across U.S. regions, patient insurance status, and hospital characteristics. They concluded that a very high proportion of ED patients with AHF are admitted nationally, with significant variation in disposition and procedural decisions based on region of the country and type of insurance, even after adjusting for potential confounding.

1c.5. **If a PRO-PM (e.g. HRQoL/functional status, symptom/burden, experience with care, health-related behaviors), provide evidence that the target population values the measured PRO and finds it meaningful.** *(Describe how and from whom their input was obtained.)*

Not applicable. Not a PRO-PM.

2. Reliability and Validity—Scientific Acceptability of Measure Properties

Extent to which the measure, as specified, produces consistent (reliable) and credible (valid) results about the quality of care when implemented. ***Measures must be judged to meet the subcriteria for both reliability and validity to pass this criterion and be evaluated against the remaining criteria.***

2a.1. Specifications The measure is well defined and precisely specified so it can be implemented consistently within and across organizations and allows for comparability. eMeasures should be specified in the Health Quality Measures Format (HQMF) and the Quality Data Model (QDM).

De.5. **Subject/Topic Area** *(check all the areas that apply):*
Cardiovascular, Cardiovascular : Congestive Heart Failure

De.6. **Cross Cutting Areas** *(check all the areas that apply):*

S.1. **Measure-specific Web Page** *(Provide a URL link to a web page specific for this measure that contains current detailed specifications including code lists, risk model details, and supplemental materials. Do not enter a URL linking to a home page or to general information.)*
eCQM Library webpage at: http://www.cms.gov/Regulations-and-Guidance/Legislation/EHRIncentivePrograms/eCQM_Library.html
Value set details at VSAC webpage: https://vsac.nlm.nih.gov

S.2a. **If this is an eMeasure**, HQMF specifications must be attached. Attach the zipped output from the eMeasure authoring tool (MAT) - if the MAT was not used, contact staff. (Use the specification fields in this online form for the plain-language description of the specifications)
This is an eMeasure **Attachment:** EP_CMS144v4_NQF0083_HF_BB-635712712817825444.zip

S.2b. **Data Dictionary, Code Table, or Value Sets** *(and risk model codes and coefficients when applicable) must be attached. (Excel or csv file in the suggested format preferred - if not, contact staff)*
Attachment **Attachment:** 0083_AMAPCPI_HF-BB_ValueSets_June2015-635712735683880063.xlsx

S.3. **For endorsement maintenance**, please briefly describe any changes to the measure specifications since last endorsement date and explain the reasons.
Supporting guidelines and coding value sets included in the measure are reviewed on an annual basis. This annual review resulted in very limited changes to adhere to current eCQM industry standards and preserve the original measure intent.

S.4. **Numerator Statement** *(Brief, narrative description of the measure focus or what is being measured about the target population, i.e., cases from the target population with the target process, condition, event, or outcome)*
IF an OUTCOME MEASURE, state the outcome being measured. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
Patients who were prescribed* beta-blocker therapy** either within a 12 month period when seen in the outpatient setting or at hospital discharge

*Prescribed may include:
Outpatient setting: prescription given to the patient for beta-blocker therapy at one or more visits in the measurement period OR patient already taking beta-blocker therapy as documented in current medication list
Inpatient setting: prescription given to the patient for beta-blocker therapy at discharge OR beta-blocker therapy to be continued after discharge as documented in the discharge medication list

**Beta-blocker therapy should include bisoprolol, carvedilol, or sustained release metoprolol succinate. (see technical specifications for additional information on medications)

S.5. **Time Period for Data** *(What is the time period in which data will be aggregated for the measure, e.g., 12 mo, 3 years, look back to August for flu vaccination? Note if there are different time periods for the numerator and denominator.)*
At least once during the 12 consecutive month measurement period when seen in the outpatient setting OR at each hospital discharge during the 12 consecutive month measurement period if seen in the inpatient setting

S.6. **Numerator Details** *(All information required to identify and calculate the cases from the target population with the target process, condition, event, or outcome such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
IF an OUTCOME MEASURE, describe how the observed outcome is identified/counted. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
For EHR:
HQMF eMeasure developed and is included in this submission.

For Registry:
Definitions:
Prescribed – Outpatient Setting - May include prescription given to the patient for beta-blocker therapy at one or more visits in the measurement period OR patient already taking beta-blocker therapy as documented in current medication list.
Prescribed – Inpatient Setting: May include prescription given to the patient for beta-blocker therapy at discharge OR beta-blocker therapy to be continued after discharge as documented in the discharge medication list.
Beta-blocker Therapy - For patients with prior LVEF < 40%, beta-blocker therapy should include bisoprolol, carvedilol, or sustained release metoprolol succinate.

Report Quality Data Code, G8450: Beta-blocker therapy prescribed

S.7. **Denominator Statement** *(Brief, narrative description of the target population being measured)*
All patients aged 18 years and older with a diagnosis of heart failure with a current or prior LVEF < 40%

LVEF < 40% corresponds to qualitative documentation of moderate dysfunction or severe dysfunction

S.8. **Target Population Category** *(Check all the populations for which the measure is specified and tested if any):*

S.9. **Denominator Details** *(All information required to identify and calculate the target population/denominator such as definitions, specific data collection items/responses , code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
For EHR:
HQMF eMeasure developed and is included in this submission.

DENOMINATOR DEFINITION:
LVEF < 40% corresponds to qualitative documentation of moderate dysfunction or severe dysfunction.

DENOMINATOR NOTES:
To meet this measure, it must be reported for all heart failure patients a minimum of once during the measurement period when seen in the outpatient setting AND reported at each hospital discharge during the measurement period.

The requirement of "Count >=2 of Encounter, Performed" is to establish that the eligible professional has an existing relationship with the patient.

For Registry:
Option 1, Outpatient Setting:
Patients aged >=18 years
AND
Diagnosis for heart failure (ICD-9-CM) [for use 1/1/2015-9/30/2015]: 402.01, 402.11, 402.91, 404.01, 404.03, 404.11, 404.13,

404.91, 404.93, 428.0, 428.1, 428.20, 428.21, 428.22, 428.23, 428.30, 428.31, 428.32, 428.33, 428.40, 428.41, 428.42, 428.43, 428.9
Diagnosis for heart failure (ICD-10-CM) [for use 10/01/2015-12/31/2015]: I11.0, I13.0, I13.2, I50.1, I50.20, I50.21, I50.22, I50.23, I50.30, I50.31, I50.32, I50.33, I50.40, I50.41, I50.42, I50.43, I50.9
AND
Patient encounter(s) during the reporting period (CPT): 99201, 99202, 99203, 99204, 99205, 99212, 99213, 99214, 99215, 99304, 99305, 99306, 99307, 99308, 99309, 99310, 99324, 99325, 99326, 99327, 99328, 99334, 99335, 99336, 99337, 99341, 99342, 99343, 99344, 99345, 99347, 99348, 99349, 99350
AND
Two Denominator Eligible Visits
AND
Left ventricular ejection fraction (LVEF) < 40% or documentation of moderately or severely depressed left ventricular systolic function: G8923

Option 2, Inpatient Setting:
Patients aged >= 18 years
AND
Diagnosis for heart failure (ICD-9-CM) [for use 1/1/2015-9/30/2015]: 402.01, 402.11, 402.91, 404.01, 404.03, 404.11, 404.13, 404.91, 404.93, 428.0, 428.1, 428.20, 428.21, 428.22, 428.23, 428.30, 428.31, 428.32, 428.33, 428.40, 428.41, 428.42, 428.43, 428.9
Diagnosis for heart failure (ICD-10-CM) [for use 10/01/2015-12/31/2015]: I11.0, I13.0, I13.2, I50.1, I50.20, I50.21, I50.22, I50.23, I50.30, I50.31, I50.32, I50.33, I50.40, I50.41, I50.42, I50.43, I50.9
AND
Patient encounter during reporting period (CPT): 99238, 99239
AND
Left ventricular ejection fraction (LVEF) < 40% or documentation of moderately or severely depressed left ventricular systolic function: 3021F

S.10. **Denominator Exclusions** *(Brief narrative description of exclusions from the target population)*
Documentation of medical reason(s) for not prescribing beta-blocker therapy (eg, low blood pressure, fluid overload, asthma, patients recently treated with an intravenous positive inotropic agent)
Documentation of patient reason(s) for not prescribing beta-blocker therapy
Documentation of system reason(s) for not prescribing beta-blocker therapy

S.11. **Denominator Exclusion Details** *(All information required to identify and calculate exclusions from the denominator such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
Exceptions are used to remove a patient from the denominator of a performance measure when the patient does not receive a therapy or service AND that therapy or service would not be appropriate due to patient-specific reasons. The patient would otherwise meet the denominator criteria. Exceptions are not absolute, and are based on clinical judgment, individual patient characteristics, or patient preferences. This measure was developed using the PCPI exception methodology which uses three categories of reasons for which a patient may be removed from the denominator of an individual measure. These measure exception categories are not uniformly relevant across all measures; for each measure, there must be a clear rationale to permit an exception for a medical, patient, or system reason. Examples are provided in the measure exception language of instances that may constitute an exception and are intended to serve as a guide to clinicians. For measure Beta-Blocker Therapy for Left Ventricular Systolic Dysfunction, exceptions may include Documentation of medical reason(s) for not prescribing beta-blocker therapy (eg, low blood pressure, fluid overload, asthma, patients recently treated with an intravenous positive inotropic agent), Documentation of patient reason(s) for not prescribing beta-blocker therapy, or Documentation of system reason(s) for not prescribing beta-blocker therapy. Where examples of exceptions are included in the measure language, value sets for these examples are developed and included in the eSpecifications. Although this methodology does not require the external reporting of more detailed exception data, the PCPI recommends that physicians document the specific reasons for exception in patients' medical records for purposes of optimal patient management and audit-readiness. The PCPI also advocates the systematic review and analysis of each physician's exceptions data to identify practice patterns and opportunities for quality improvement.

Additional details by data source are as follows:

For EHR:
HQMF eMeasure developed and is included in this submission.

For Registry:
Report Quality Data Code G8451: Beta-Blocker Therapy for LVEF < 40% not prescribed for reasons documented by the clinician (eg, low blood pressure, fluid overload, asthma, patients recently treated with an intravenous positive inotropic agent, allergy, intolerance, other medical reasons, patient declined, other patient reasons, other reasons attributable to the healthcare system)

S.12. Stratification Details/Variables *(All information required to stratify the measure results including the stratification variables, definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format with at S.2b)*
Consistent with CMS' Measures Management System Blueprint and recent national recommendations put forth by the IOM and NQF to standardize the collection of race and ethnicity data, we encourage the results of this measure to be stratified by race, ethnicity, administrative sex, and payer and have included these variables as recommended data elements to be collected.

S.13. Risk Adjustment Type (Select type. Provide specifications for risk stratification in S.12 and for statistical model in S.14-15)
No risk adjustment or risk stratification
If other:

S.14. Identify the statistical risk model method and variables *(Name the statistical method - e.g., logistic regression and list all the risk factor variables. Note - risk model development and testing should be addressed with measure testing under Scientific Acceptability)*
n/a

S.15. Detailed risk model specifications *(must be in attached data dictionary/code list Excel or csv file. Also indicate if available at measure-specific URL identified in S.1.)*
Note: Risk model details (including coefficients, equations, codes with descriptors, definitions), should be provided on a separate worksheet in the suggested format in the Excel or csv file with data dictionary/code lists at S.2b.

S.15a. Detailed risk model specifications (*if not provided in excel or csv file at S.2b*)

S.16. Type of score:
Rate/proportion
If other:

S.17. Interpretation of Score *(Classifies interpretation of score according to whether better quality is associated with a higher score, a lower score, a score falling within a defined interval, or a passing score)*
Better quality = Higher score

S.18. Calculation Algorithm/Measure Logic *(Describe the calculation of the measure score as an ordered sequence of steps including identifying the target population; exclusions; cases meeting the target process, condition, event, or outcome; aggregating data; risk adjustment; etc.)*
To calculate performance rates:
1. Find the patients who meet the initial population (ie, the general group of patients that a set of performance measures is designed to address).
2. From the patients within the initial population criteria, find the patients who qualify for the denominator (ie, the specific group of patients for inclusion in a specific performance measure based on defined criteria). Note: in some cases the initial population and denominator are identical.
3. From the patients within the denominator, find the patients who meet the numerator criteria (ie, the group of patients in the denominator for whom a process or outcome of care occurs). Validate that the number of patients in the numerator is less than or equal to the number of patients in the denominator
4. From the patients who did not meet the numerator criteria, determine if the provider has documented that the patient meets any criteria for exception when denominator exceptions have been specified [for this measure: Documentation of medical reason(s) for not prescribing beta-blocker therapy (eg, low blood pressure, fluid overload, asthma, patients recently treated with an intravenous positive inotropic agent); Documentation of patient reason(s) for not prescribing beta-blocker therapy; Documentation of system reason(s) for not prescribing beta-blocker therapy]. If the patient meets any exception criteria, they should be removed from the denominator for performance calculation. --Although the exception cases are removed from the denominator population

for the performance calculation, the exception rate (ie, percentage with valid exceptions) should be calculated and reported along with performance rates to track variations in care and highlight possible areas of focus for QI.

If the patient does not meet the numerator and a valid exception is not present, this case represents a quality failure.

S.19. **Calculation Algorithm/Measure Logic Diagram URL or Attachment** *(You also may provide a diagram of the Calculation Algorithm/Measure Logic described above at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
No diagram provided

S.20. **Sampling** *(If measure is based on a sample, provide instructions for obtaining the sample and guidance on minimum sample size.)*
IF a PRO-PM, identify whether (and how) proxy responses are allowed.
Not applicable. The measure is not based on a sample.

S.21. **Survey/Patient-reported data** *(If measure is based on a survey, provide instructions for conducting the survey and guidance on minimum response rate.)*
IF a PRO-PM, specify calculation of response rates to be reported with performance measure results.
Not applicable. The measure is not based on a survey.

S.22. **Missing data** (specify how missing data are handled, e.g., imputation, delete case.)
Required for Composites and PRO-PMs.
Patient eligibility is determined by a set of defined criteria relevant to a particular measure. If data required to determine patient eligibility are missing, those patients/cases would be ineligible for inclusion in the denominator and therefore the patient/case would be deleted.

If data required to determine if a denominator eligible patient qualifies for the numerator (or has a valid exclusion/exception) are missing, this case would represent a quality failure.

S.23. **Data Source** *(Check ONLY the sources for which the measure is SPECIFIED AND TESTED).*
If other, please describe in S.24.
Electronic Clinical Data, Electronic Clinical Data : Electronic Health Record, Electronic Clinical Data : Registry

S.24. **Data Source or Collection Instrument** *(Identify the specific data source/data collection instrument e.g. name of database, clinical registry, collection instrument, etc.)*
IF a PRO-PM, identify the specific PROM(s); and standard methods, modes, and languages of administration.

S.25. **Data Source or Collection Instrument** *(available at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
No data collection instrument provided

S.26. **Level of Analysis** *(Check ONLY the levels of analysis for which the measure is SPECIFIED AND TESTED)*
Clinician : Group/Practice, Clinician : Individual

S.27. **Care Setting** *(Check ONLY the settings for which the measure is SPECIFIED AND TESTED)*
Ambulatory Care : Clinician Office/Clinic, Home Health, Hospital/Acute Care Facility, Other, Post Acute/Long Term Care Facility : Long Term Acute Care Hospital, Post Acute/Long Term Care Facility : Nursing Home/Skilled Nursing Facility
If other: Domiciliary

S.28. **COMPOSITE Performance Measure** - Additional Specifications *(Use this section as needed for aggregation and weighting rules, or calculation of individual performance measures if not individually endorsed.)*
Not applicable. The measure is not a composite.

2a. Reliability – See attached Measure Testing Submission Form
2b. Validity – See attached Measure Testing Submission Form
NQF_0083_Heart_Failure_-HF-_-_Beta_Blocker_Therapy_for_LVSD_Testing_Attachment.docx

NATIONAL QUALITY FORUM—Measure Testing (subcriteria 2a2, 2b2-2b6)

Measure Title: Heart Failure – Beta Blocker Therapy for Left Ventricular Systolic Dysfunction
Date of Submission: Click here to enter a date

Type of Measure:

☐ Composite – ***STOP – use composite testing form***	☐ Outcome (*including PRO-PM*)
☐ Cost/resource	☒ Process
☐ Efficiency	☐ Structure

Instructions

- Measures must be tested for all the data sources and levels of analyses that are specified. ***If there is more than one set of data specifications or more than one level of analysis, contact NQF staff*** about how to present all the testing information in one form.
- **For all measures, sections 1, 2a2, 2b2, 2b3, and 2b5 must be completed.**
- **For outcome and resource use measures**, section **2b4** also must be completed.
- If specified for **multiple data sources/sets of specificaitons** (e.g., claims and EHRs), section **2b6** also must be completed.
- Respond to all questions as instructed with answers immediately following the question. All information on testing to demonstrate meeting the subcriteria for reliability (2a2) and validity (2b2-2b6) must be in this form. An appendix for *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 20 pages (*incuding questions/instructions;* minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the testing results for this measure meet NQF's evaluation criteria for testing.

2a2. Reliability testing [10] demonstrates the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise.

2b2. Validity testing [11] demonstrates that the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality.

2b3. Exclusions are supported by the clinical evidence; otherwise, they are supported by evidence of sufficient frequency of occurrence so that results are distorted without the exclusion; [12]

AND

If patient preference (e.g., informed decision making) is a basis for exclusion, there must be evidence that the exclusion impacts performance on the measure; in such cases, the measure must be specified so that the information about patient preference and the effect on the measure is transparent (e.g., numerator category computed separately, denominator exclusion category computed separately). [13]

2b4. For outcome measures and other measures when indicated (e.g., resource use):

- **an evidence-based risk-adjustment strategy** (e.g., risk models, risk stratification) is specified; is based on patient factors that influence the measured outcome (but not factors related to disparities in care or the quality of care) and are present at start of care; [14,15] and has demonstrated adequate discrimination and calibration

OR

- rationale/data support no risk adjustment/ stratification.

2b5. Data analysis of computed measure scores demonstrates that methods for scoring and analysis of the specified measure allow for **identification of statistically significant and practically/clinically meaningful** [16] **differences in performance**;

OR

there is evidence of overall less-than-optimal performance.

2b6. If multiple data sources/methods are specified, there is demonstration they produce comparable results.

Notes

10. Reliability testing applies to both the data elements and computed measure score. Examples of reliability testing for data elements include, but are not limited to: inter-rater/abstractor or intra-rater/abstractor

studies; internal consistency for multi-item scales; test-retest for survey items. Reliability testing of the measure score addresses precision of measurement (e.g., signal-to-noise).

11. Validity testing applies to both the data elements and computed measure score. Validity testing of data elements typically analyzes agreement with another authoritative source of the same information. Examples of validity testing of the measure score include, but are not limited to: testing hypotheses that the measures scores indicate quality of care, e.g., measure scores are different for groups known to have differences in quality assessed by another valid quality measure or method; correlation of measure scores with another valid indicator of quality for the specific topic; or relationship to conceptually related measures (e.g., scores on process measures to scores on outcome measures). Face validity of the measure score as a quality indicator may be adequate if accomplished through a systematic and transparent process, by identified experts, and explicitly addresses whether performance scores resulting from the measure as specified can be used to distinguish good from poor quality.

12. Examples of evidence that an exclusion distorts measure results include, but are not limited to: frequency of occurrence, variability of exclusions across providers, and sensitivity analyses with and without the exclusion.

13. Patient preference is not a clinical exception to eligibility and can be influenced by provider interventions.

14. Risk factors that influence outcomes should not be specified as exclusions.

15. Risk models should not obscure disparities in care for populations by including factors that are associated with differences/inequalities in care, such as race, socioeconomic status, or gender (e.g., poorer treatment outcomes of African American men with prostate cancer or inequalities in treatment for CVD risk factors between men and women). It is preferable to stratify measures by race and socioeconomic status rather than to adjust out the differences.

16. With large enough sample sizes, small differences that are statistically significant may or may not be practically or clinically meaningful. The substantive question may be, for example, whether a statistically significant difference of one percentage point in the percentage of patients who received smoking cessation counseling (e.g., 74 percent v. 75 percent) is clinically meaningful; or whether a statistically significant difference of $25 in cost for an episode of care (e.g., $5,000 v. $5,025) is practically meaningful. Measures with overall less-than-optimal performance may not demonstrate much variability across providers.

1. DATA/SAMPLE USED FOR ALL TESTING OF THIS MEASURE

Often the same data are used for all aspects of measure testing. In an effort to eliminate duplication, the first five questions apply to all measure testing. If there are differences by aspect of testing,(e.g., reliability vs. validity) be sure to indicate the specific differences in question 1.7.

1.1. What type of data was used for testing? (*Check all the sources of data identified in the measure specifications and data used for testing the measure. Testing must be provided for all the sources of data specified and intended for measure implementation.* ***If different data sources are used for the numerator and denominator, indicate N [numerator] or D [denominator] after the checkbox.***)

Measure Specified to Use Data From: **(*must be consistent with data sources entered in S.23*)**	**Measure Tested with Data From:**
☐ abstracted from paper record	☐ abstracted from paper record
☐ administrative claims	☐ administrative claims
☒ clinical database/registry	☒ clinical database/registry
☒ abstracted from electronic health record	☒ abstracted from electronic health record
☒ eMeasure (HQMF) implemented in EHRs	☒ eMeasure (HQMF) implemented in EHRs
☐ other: Click here to describe	☐ other: Click here to describe

1.2. If an existing dataset was used, identify the specific dataset (*the dataset used for testing must be consistent with the measure specifications for target population and healthcare entities being measured; e.g., Medicare Part A claims, Medicaid claims, other commercial insurance, nursing home MDS, home health OASIS, clinical registry*).

Data 1 (EHR - Validity Against the Gold Standard)

The data source is EHR data.

Data 2 (GPRO EHR Web-Interface)

The data source is the Centers for Medicare & Medicaid Service PQRS GPRO EHR Web Interface data base.

Bonnie Patient Test Deck

As a supplement to the EHR reliability testing performed on this measure, a deck of patient test cases have been developed and a summary of the details has been included as part of the feasibility attachment in section 3b.3 of the measure submission form.

Data 3 (GPRO Registry)

The data source is the Centers for Medicare & Medicaid Services (CMS) PQRS GPRO database.

Data 4 (EHR – Exceptions Analysis)

The data source is EHR data.

1.3. What are the dates of the data used in testing?

Data 1 (EHR - Validity Against the Gold Standard)

The data are collected from patients sampled from 2007.

Data 2 (GPRO EHR Web-Interface)

The data are for the time period January 2013 – December 2013, and cover the entire United States.

Data 3 (GPRO Registry)

The data are for the time period January 2013 – December 2013, and cover the entire United States.

Data 4 (EHR – Exceptions Analysis)

The data are collected from patients sampled from 2009.

1.4. What levels of analysis were tested? (*testing must be provided for all the levels specified and intended for measure implementation, e.g., individual clinician, hospital, health plan*)

Measure Specified to Measure Performance of: (***must be consistent with levels entered in item S.26***)	**Measure Tested at Level of:**
☒ individual clinician	☒ individual clinician
☒ group/practice	☒ group/practice
☐ hospital/facility/agency	☐ hospital/facility/agency
☐ health plan	☐ health plan
☐ other: Click here to describe	☐ other: Click here to describe

1.5. How many and which measured entities were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of measured entities included in the analysis (e.g., size, location, type); if a sample was used, describe how entities were selected for inclusion in the sample*)

Data 1 (EHR - Validity Against the Gold Standard)

The data sample came from an academic general internal medicine clinic with several years of experience using a commercial EHR.

Data 2 (GPRO EHR Web-Interface)

The total number of physicians reporting on this measure is 142. Of those, 129 physicians had all the required data elements and met the minimum number of quality reporting events (10) for inclusion in the reliability analysis. For this measure, 90.8 percent of physicians are included in the analysis, and the average number of quality reporting events is 90.1 for a total of 11,628 events. The range of quality reporting events for 129 physicians included is from 553 to 10. The average number of quality reporting events for the remaining 9.2 percent of physicians who aren't included is 4.4.

For this measure, the minimum number of observations for inclusion in signal-to-noise reliability testing was 10 events. Given the structure of the PQRS program, a physician may choose to submit or not submit to PQRS. Since these data contain results on a large number of physicians, limiting the reliability analysis to only those physicians who are participating in the program will eliminate the bias introduced by the inclusion of from physicians who are in the data, but are not submitting to PQRS.

Data 3 (GPRO Registry)

The total number of physicians reporting on this measure is 1,748. Of those, 684 physicians had all the required data elements and met the minimum number of quality reporting events (10) for inclusion in the reliability analysis. For this measure, 39.1 percent of physicians are included in the analysis, and the average number of quality reporting events is 33.9 for a total of 23,175 events. The range of quality reporting events for 684 physicians included is from 326 to 10. The average number of quality reporting events for the remaining 60.9 percent of physicians who aren't included is 3.2.

For this measure, the minimum number of observations for inclusion in signal-to-noise reliability testing was 10 events. Given the structure of the PQRS program, a physician may choose to submit or not submit to PQRS. Since these data contain results on a large number of physicians, limiting the reliability analysis to only those physicians who are participating in the program will eliminate the bias introduced by the inclusion of from physicians who are in the data, but are not submitting to PQRS.

Data 4 (EHR – Exceptions Analysis)

The data sample came from five physician offices using five different EHR systems.

1.6. How many and which patients were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of patients included in the analysis (e.g., age, sex, race, diagnosis); if a sample was used, describe how patients were selected for inclusion in the sample*)

Data 1 (EHR - Validity Against the Gold Standard)

The sample consisted of approximately 254 charts for a total of 254 eligible patients. One trained investigator reviewed the 254 charts. The patients were selected using random sampling.

Data 2 (GPRO EHR Web-Interface)

There were 11,628 patients included in this testing and analysis. These were the patients that were associated with physicians who had 10 or more patients eligible for this measure.

Data 3 (GPRO Registry)

There were 23,175 patients included in this testing and analysis. These were the patients that were associated with physicians who had 10 or more patients eligible for this measure.

Data 4 (EHR – Exceptions Analysis)

The sample consisted of approximately 118 eligible patients.

1.7. If there are differences in the data or sample used for different aspects of testing (e.g., reliability, validity, exclusions, risk adjustment), identify how the data or sample are different for each aspect of testing reported below.

Data 1 (EHR - Validity Against the Gold Standard)

The data sample was used for the purposes of reliability and validity testing.

Data 2 (GPRO EHR Web-Interface)

The same data sample from each data source was used for reliability testing and exceptions analysis.

Data 3 (GPRO Registry)

The same data sample from each data source was used for reliability testing and exceptions analysis.

Face Validity (Data 2 & Data 3)

After the measure was fully specified, an expert panel of 12 members was asked to rate their agreement with the following statement:

The scores obtained from the measure as specified will provide an accurate reflection of quality and can be used to distinguish good and poor quality.

Data 4 (EHR – Exceptions Analysis)

The data sample was used for the exception analysis only.

1.8. What were the patient-level sociodemographic (SDS) variables that were available and analyzed in the data or sample used? For example, patient-reported data (e.g., income, education, language), proxy variables when SDS data are not collected from each patient (e.g. census tract), or patient community characteristics (e.g. percent vacant housing, crime rate).

Data 1 (EHR - Validity Against the Gold Standard)

This was not captured as part of the testing.

Data 2 (GPRO EHR Web-Interface)

This was not captured as part of the testing.

Data 3 (GPRO Registry)

This was not captured as part of the testing.

2a2. RELIABILITY TESTING

***Note**: If accuracy/correctness (validity) of data elements was empirically tested, separate reliability testing of data elements is not required – in 2a2.1 check critical data elements; in 2a2.2 enter "see section 2b2 for validity testing of data elements"; and skip 2a2.3 and 2a2.4.*

2a2.1. What level of reliability testing was conducted? (*may be one or both levels*)
☒ **Critical data elements used in the measure** (*e.g., inter-abstractor reliability; data element reliability must address ALL critical data elements*)
☒ **Performance measure score** (e.g., *signal-to-noise analysis*)

2a2.2. For each level checked above, describe the method of reliability testing and what it tests (*describe the steps—do not just name a method; what type of error does it test; what statistical analysis was used*)

Data 1 (EHR - Validity Against the Gold Standard)

See 2b2.2 for Validity Against the Gold Standard Results

Data 2 & Data 3 (Signal-to-Noise Reliability)

Reliability of the computed measure score was measured as the ratio of signal to noise. The signal in this case is the proportion of the variability in measured performance that can be explained by real differences in physician performance. Reliability at the level of the specific physician is given by:

Reliability = Variance (physician-to-physician) / [Variance (physician-to-physician) + Variance (physician-specific-error]

Reliability is the ratio of the physician-to-physician variance divided by the sum of the physician-to-physician variance plus the error variance specific to a physician. A reliability of zero implies that all the variability in a measure is attributable to measurement error. A reliability of one implies that all the variability is attributable to real differences in physician performance.

Reliability testing was performed by using a beta-binomial model. The beta-binomial model assumes the physician performance score is a binomial random variable conditional on the physician's true value that comes from the beta distribution. The beta distribution is usually defined by two parameters, alpha and beta. Alpha and beta can be thought of as intermediate calculations to get to the needed variance estimates.

Reliability is estimated at two different points, at the minimum number of quality reporting events for the measure and at the mean number of quality reporting events per physician.

2a2.3. For each level checked above, what were the statistical results from reliability testing? (e.*g., percent agreement and kappa for the critical data elements; distribution of reliability statistics from a signal-to-noise analysis*)

Data 1 (EHR - Validity Against the Gold Standard)

See 2b2.3 for Validity Against the Gold Standard Results

Data 2 (GPRO EHR Web-Interface)

For this measure, the reliability at the minimum level of quality reporting events (10) was 0.44. The average number of quality reporting events for physicians included is 90.1. The reliability at the average number of quality reporting events was 0.87.

Data 3 (GPRO Registry)

For this measure, the reliability at the minimum level of quality reporting events (10) was 0.86. The average number of quality reporting events for physicians included is 33.9. The reliability at the average number of quality reporting events was 0.96.

2a2.4 What is your interpretation of the results in terms of demonstrating reliability? (i.*e., what do the results mean and what are the norms for the test conducted?*)

Data 1 (EHR - Validity Against the Gold Standard)

See 2b2.4 for Validity Against the Gold Standard Results

Data 2 (GPRO EHR Web-Interface)

This measure has moderate reliability when evaluated at the minimum level of quality reporting events and high reliability at the average number of quality events.

Data 3 (GPRO Registry)

This measure has high reliability when evaluated at the minimum level of quality reporting events and high reliability at the average number of quality events.

2b2. VALIDITY TESTING

2b2.1. What level of validity testing was conducted? (*may be one or both levels*)

☒ **Critical data elements** (*data element validity must address ALL critical data elements*)

☒ **Performance measure score**

☐ **Empirical validity testing**

☒ **Systematic assessment of face validity of performance measure score as an indicator** of quality or resource use (*i.e., is an accurate reflection of performance on quality or resource use and can distinguish good from poor performance*)

2b2.2. For each level checked above, describe the method of validity testing and what it tests (*describe the steps—do not just name a method; what was tested, e.g., accuracy of data elements compared to authoritative source, relationship to another measure as expected; what statistical analysis was used)*

Data 1 (EHR - Validity Against the Gold Standard)

Data abstracted from randomly sampled patient records were used to evaluate parallel forms reliability for the measure. Charts for abstraction were selected for patients aged 18 years and older with heart failure.

Face Validity (Data 2 & Data 3)

Face validity of the measure score as an indicator of quality was systematically assessed as follows.

After the measure was fully specified, the expert panel was asked to rate their agreement with the following statement:

The scores obtained from the measure as specified will provide an accurate reflection of quality and can be used to distinguish good and poor quality.

Scale 1-5, where 1= Strongly Disagree; 3= Neither Agree nor Disagree; 5= Strongly Agree

2b2.3. What were the statistical results from validity testing? (*e.g., correlation; t-test*)

Data 1 (EHR - Validity Against the Gold Standard)

Of the 254 patients sampled, automated EHR review detected 219 (86.2%) with an active electronic prescription for a Beta Blocker. Of the remaining 35 patients, 13(37.1%) met one or more of the exclusion criteria. Performance on the Beta Blocker quality measure was 90.9% by using automated EHR review.

Manual review of clinicians' notes in the EHR did not reveal any additional patients who were being treated with a Beta Blocker. However, 6 additional patients who met the exclusion criteria were identified. One patient had met the exclusion criteria through automated review, but upon manual review, was identified to be false.

Performance on the measure was calculated to be 92.8% through comparison of automated and manual EHR review.

Face Validity (Data 2 & Data 3)

Our expert panel included 12 members. Panel members were comprised of experts from the AMA-PCPI Measure Advisory Committee. The list of expert panel members is as follows:

Amy Sanders, MD, MS

David Seidenwurm, MD

Dianne V. Jewell, PT, DPT, PhD, CCS, FAACVPR

Janet Sullivan, MD
John Easa, MD, FIPP

Joseph P. Drozda, Jr., MD, FACC

Mark Metersky, MD

Martha J. Radford, MD, FACC, FAHA

Michael O'Dell, MD, MS, MSHA, FAAFP

Richard Bankowitz, MD, MBA, FACP

Scott T. MacDonald, MD

Shannon Sims, MD, PhD

2b2.4. What is your interpretation of the results in terms of demonstrating validity? (i.*e., what do the results mean and what are the norms for the test conducted?*)

Data 1 (EHR - Validity Against the Gold Standard)

The automated quality assessment had a sensitivity of 100.0% for identifying patients with heart failure taking a Beta Blocker. The automated quality assessment captured 12 of 18 patients with valid exclusion criteria (sensitivity, 66.7%), and 1 of 13 patients who met exclusion criteria were judged not to have a true exclusion.

Data 2 and Data 3 (GPRO EHR Web-Interface and GPRO Registry-Face Validity)

The results of the expert panel rating of the validity statement were as follows: N = 12; Mean rating = 4.33 and 100.0% of respondents either agree or strongly agree that this measure can accurately distinguish good and poor quality.

Frequency Distribution of Ratings

1 – 0 responses (Strongly Disagree)

2 – 0 responses

3 – 0 responses (Neither Agree nor Disagree)

4 – 8 responses

5 – 4 responses (Strongly Agree)

2b3. EXCLUSIONS ANALYSIS

NA ☐ no exclusions — *skip to section 2b4*

2b3.1. Describe the method of testing exclusions and what it tests (*describe the steps—do not just name a method; what was tested, e.g., whether exclusions affect overall performance scores; what statistical analysis was used*)

Data 1 (EHR - Validity Against the Gold Standard)

This data sample was not used to test exclusions.

Data 2 and Data 3 (GPRO EHR Web-Interface and GPRO Registry)

With the information available from the GPRO Registry and GPRO EHR Web-Interface, we are unable to determine the type of exception reported. However, the exceptions data captured were analyzed to determine frequency and variability across providers.

Data 4 (EHR-Exceptions Analysis)

Exceptions included documentation of medical reason(s), patient reason(s) and system reason(s) for not prescribing beta-blocker therapy. Exceptions were analyzed for frequency and variability across providers.

2b3.2. What were the statistical results from testing exclusions? (*include overall number and percentage of individuals excluded, frequency distribution of exclusions across measured entities, and impact on performance measure scores*)

Data 1 (EHR - Validity Against the Gold Standard)

This data sample was not used to test exclusions.

Data 2 (GPRO EHR Web-Interface)

Amongst the 129 physicians with the minimum (10) number of quality reporting events, there were a total of 601 exceptions reported. The average number of exceptions per physician in this sample is 4.7. The overall exception rate is 4.9%.

Data 3 (GPRO Registry)

Amongst the 684 physicians with the minimum (10) number of quality reporting events, there were a total of 1,203 exceptions reported. The average number of exceptions per physician in this sample is 1.8. The overall exception rate is 4.9%.

Data 4 (EHR-Exceptions Analysis)

Reported exceptions were validated upon manual review of the medical record, against an a priori list generated by expert opinion. Measure exceptions were validated 95.32% of the time. Review of the 118 exceptions revealed 98.0% of exceptions were medical reasons for not prescribing beta blocker therapy. Medical reason exceptions consisted of clinical contraindications, drug allergy and drug intolerance.

2b3.3. What is your interpretation of the results in terms of demonstrating that exclusions are needed to prevent unfair distortion of performance results? (*i.e., the value outweighs the burden of increased data collection and analysis. Note: **If patient preference is an exclusion**, the measure must be specified so that the effect on the performance score is transparent, e.g., scores with and without exclusion*)

Exceptions are necessary to account for those situations when it is not medically appropriate to prescribe beta

blocker therapy. Exceptions are discretionary and the methodology used for measure exception categories are not uniformly relevant across all measures; for this measure, there is a clear rationale to permit an exception for medical, patient or system reasons. Rather than specifying an exhaustive list of explicit medical, patient or system reasons for exception for each measure, the measure developer relies on clinicians to link the exception with a specific reason for the decision not to prescribe beta blocker therapy required by the measure.

Some have indicated concerns with exception reporting including the potential for physicians to inappropriately exclude patients to enhance their performance statistics. Research has indicated that levels of exception reporting occur infrequently and are generally valid (Doran et al., 2008), (Kmetik et al., 2011). Furthermore, exception reporting has been found to have substantial benefits: "it is precise, it increases acceptance of [pay for performance] programs by physicians, and it ameliorates perverse incentives to refuse care to "difficult" patients." (Doran et al., 2008).

Although this methodology does not require the external reporting of more detailed exception data, the measure developer recommends that physicians document the specific reasons for exception in patients' medical records for purposes of optimal patient management and audit-readiness. We also advocate for the systematic review and analysis of each physician's exceptions data to identify practice patterns and opportunities for quality improvement.

Without exceptions, the performance rate would not accurately reflect the true performance of that physician. This would result in an increase in performance failures and false negatives. The additional value of increased data collection of capturing an exception greatly outweighs the reporting burden.

2b4. RISK ADJUSTMENT/STRATIFICATION FOR OUTCOME OR RESOURCE USE MEASURES
If not an intermediate or health outcome, or PRO-PM, or resource use measure, skip to section 2b5.

2b4.1. What method of controlling for differences in case mix is used?

☒ **No risk adjustment or stratification**

☐ **Statistical risk model with** Click here to enter number of factors **risk factors**

☐ **Stratification by** Click here to enter number of categories **risk categories**

☐ **Other,** Click here to enter description

2b4.2. If an outcome or resource use measure is not risk adjusted or stratified, provide rationale and analyses to demonstrate that controlling for differences in patient characteristics (case mix) is not needed to achieve fair comparisons across measured entities.

Not applicable

2b4.3. Describe the conceptual/clinical and statistical methods and criteria used to select patient factors used in the statistical risk model or for stratification by risk (*e.g., potential factors identified in the literature*

and/or expert panel; regression analysis; statistical significance of p<0.10; correlation of x or higher; patient factors should be present at the start of care and not related to disparities)

Not applicable

2b4.4a. What were the statistical results of the analyses used to select risk factors?

Not applicable

2b4.4b. Describe the method of testing/analysis used to develop and validate the adequacy of the statistical model or stratification approach *(describe the steps – do not just name a method; what statistical analysis was used)*

Not applicable

2b4.5. Describe the method of testing/analysis used to develop and validate the adequacy of the statistical model or stratification approach (*describe the steps—do not just name a method; what statistical analysis was used*)

Provide the statistical results from testing the approach to controlling for differences in patient characteristics (case mix) below.
if stratified, skip to 2b4.9

Not applicable

2b4.6. Statistical Risk Model Discrimination Statistics (*e.g., c-statistic, R-squared*)**:**

Not applicable

2b4.7. Statistical Risk Model Calibration Statistics (*e.g., Hosmer-Lemeshow statistic*):

Not applicable

2b4.8. Statistical Risk Model Calibration – Risk decile plots or calibration curves:

Not applicable

2b4.9. Results of Risk Stratification Analysis:

Not applicable

2b4.10. What is your interpretation of the results in terms of demonstrating adequacy of controlling for differences in patient characteristics (case mix)? (i.*e., what do the results mean and what are the norms for the test conducted*)

Not applicable

***2b4.11. Optional Additional Testing for Risk Adjustment** (*not required, but would provide additional support of adequacy of risk model, e.g., testing of risk model in another data set; sensitivity analysis for missing data; other methods*)

Not applicable

2b5. IDENTIFICATION OF STATISTICALLY SIGNIFICANT & MEANINGFUL DIFFERENCES IN PERFORMANCE

2b5.1. Describe the method for determining if statistically significant and clinically/practically meaningful differences in performance measure scores among the measured entities can be identified (*describe the steps—do not just name a method; what statistical analysis was used? Do not just repeat the information provided related to performance gap in 1b)*

Data 1 (EHR - Validity Against the Gold Standard)

This data sample was not used to test for meaningful differences in performance across providers or practice sites.

Data 2 (GPRO EHR Web-Interface)

Measures of central tendency, variability, and dispersion were calculated.

Data 3 (GPRO Registry)

Measures of central tendency, variability, and dispersion were calculated.

2b5.2. What were the statistical results from testing the ability to identify statistically significant and/or clinically/practically meaningful differences in performance measure scores across measured entities? (e.g., *number and percentage of entities with scores that were statistically significantly different from mean or some benchmark, different from expected; how was meaningful difference defined*)

Data 1 (EHR - Validity Against the Gold Standard)

This data sample was not used to test for meaningful differences in performance across providers or practice sites.

Data 2 (GPRO EHR Web-Interface)

Based on the sample of 129 included physicians, the mean performance rate is 0.90, the median performance rate is 0.92 and the mode is 1.00. The standard deviation is 0.09. The range of the performance rate is 0.37, with a minimum rate of 0.63 and a maximum rate of 1. The interquartile range is 0.12 (0.85 - 0.97).

Data 3 (GPRO Registry)

Based on the sample of 684 included physicians, the mean performance rate is 0.70, the median performance rate is 0.93 and the mode is 1.00. The standard deviation is 0.37. The range of the performance rate is 1.00, with a minimum rate of 0.00 and a maximum rate of 1.00. The interquartile range is 0.58 (0.42 - 1.00).

2b5.3. What is your interpretation of the results in terms of demonstrating the ability to identify statistically significant and/or clinically/practically meaningful differences in performance across measured entities? (i.*e., what do the results mean in terms of statistical and meaningful differences?*)

Data 1 (EHR - Validity Against the Gold Standard)

This data sample was not used to test for meaningful differences in performance across providers or practice sites.

Data 2 (GPRO EHR Web-Interface)

The range of performance from 0.63 to 1.00 suggests there's clinically meaningful variation across physicians' performance.

Data 3 (GPRO Registry)

The range of performance from 0.00 to 1.00 suggests there's clinically meaningful variation across physicians' performance.

2b6. COMPARABILITY OF PERFORMANCE SCORES WHEN MORE THAN ONE SET OF SPECIFICATIONS

If only one set of specifications, this section can be skipped.

Note: *This criterion is directed to measures with more than one set of specifications/instructions (e.g., one set of specifications for how to identify and compute the measure from medical record abstraction and a different set of specifications for claims or eMeasures). It does not apply to measures that use more than one source of data in one set of specifications/instructions (e.g., claims data to identify the denominator and medical record abstraction for the numerator).* ***If comparability is not demonstrated, the different specifications should be submitted as separate measures.***

2b6.1. Describe the method of testing conducted to demonstrate comparability of performance scores for the same entities across the different data sources/specifications (*describe the steps—do not just name a method; what statistical analysis was used*)

This test was not performed for this measure.

2b6.2. What were the statistical results from testing comparability of performance scores for the same entities when using different data sources/specifications? (*e.g., correlation, rank order*)

This test was not performed for this measure.

2b6.3. What is your interpretation of the results in terms of demonstrating comparability of performance measure scores for the same entities across the different data sources/specifications? (i.*e., what do the results mean and what are the norms for the test conducted*)

This test was not performed for this measure.

2b7. MISSING DATA ANALYSIS AND MINIMIZING BIAS

2b7.1. Describe the method of testing conducted to identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias (describe the steps – do not just name a method; what statistical analysis was used)

Data are not available to complete this testing.

2b7.2. What is the overall frequency of missing data, the distribution of missing data across providers, and the results from testing related to missing data? (e.g., results of sensitivity analysis of the effect of various rules for missing data/nonresponse; if no empirical sensitivity analysis, identify the approaches for handling missing data that were considered and pros and cons of each)

Data are not available to complete this testing.

2b7.3. What is your interpretation of the results in terms of demonstrating that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias? (i.e., what do the results mean in terms of supporting the selected approach for missing data and what are the norms for the test conducted; if no empirical analysis, provide rationale for the selected approach for missing data)

Data are not available to complete this testing.

3. Feasibility

Extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.
3a. Byproduct of Care Processes

For clinical measures, the required data elements are routinely generated and used during care delivery (e.g., blood pressure, lab test, diagnosis, medication order).

3a.1. **Data Elements Generated as Byproduct of Care Processes.**
Generated or collected by and used by healthcare personnel during the provision of care (e.g., blood pressure, lab value, diagnosis, depression score), Coded by someone other than person obtaining original information (e.g., DRG, ICD-9 codes on claims), Abstracted from a record by someone other than person obtaining original information (e.g., chart abstraction for quality measure or registry)
If other:

3b. Electronic Sources

The required data elements are available in electronic health records or other electronic sources. If the required data are not in electronic health records or existing electronic sources, a credible, near-term path to electronic collection is specified.

3b.1. **To what extent are the specified data elements available electronically in defined fields?** *(i.e., data elements that are needed to compute the performance measure score are in defined, computer-readable fields)*
ALL data elements are in defined fields in electronic health records (EHRs)

3b.2. **If ALL the data elements needed to compute the performance measure score are not from electronic sources, specify a credible, near-term path to electronic capture, OR provide a rationale for using other than electronic sources.**

3b.3. **If this is an eMeasure, provide a summary of the feasibility assessment in an attached file or make available at a measure-specific URL.**
Attachment **Attachment:** NQF_0083_Feasibility_Scorecard_Bonnie_Output_Screen_Shots_Revised.pdf

3c. Data Collection Strategy

Demonstration that the data collection strategy (e.g., source, timing, frequency, sampling, patient confidentiality, costs associated with fees/licensing of proprietary measures) can be implemented (e.g., already in operational use, or testing demonstrates that it is ready to put into operational use). For eMeasures, a feasibility assessment addresses the data elements and measure logic and demonstrates the eMeasure can be implemented or feasibility concerns can be adequately addressed.

3c.1. **Describe what you have learned/modified as a result of testing and/or operational use of the measure regarding data collection, availability of data, missing data, timing and frequency of data collection, sampling, patient confidentiality, time and cost of data collection, other feasibility/implementation issues.**
IF a PRO-PM, consider implications for both individuals providing PROM data (patients, service recipients, respondents) and those whose performance is being measured.
We have not identified an areas of concern or made any modifications as a result of testing and operational use of the measure in relation to data collection, availability of data, missing data, timing and frequency of data collection, sampling, patient confidentiality, time and cost of data collection, and other feasibility issues unless otherwise noted.

3c.2. **Describe any fees, licensing, or other requirements to use any aspect of the measure as specified** *(e.g., value/code set, risk model, programming code, algorithm)*.
The Measures, while copyrighted, can be reproduced and distributed, without modification, for noncommercial purposes, eg, use by health care providers in connection with their practices. Commercial uses of the Measures require a license agreement between the user and the AMA, (on behalf of the PCPI), ACC or AHA.
Limited proprietary coding is contained in the Measure specifications for convenience. Users of the proprietary code sets should obtain all necessary licenses from the owners of these code sets.

4. Usability and Use

Extent to which potential audiences (e.g., consumers, purchasers, providers, policy makers) are using or could use performance results for both accountability and performance improvement to achieve the goal of high-quality, efficient healthcare for individuals or populations.

4a. Accountability and Transparency

Performance results are used in at least one accountability application within three years after initial endorsement and are

publicly reported within six years after initial endorsement (or the data on performance results are available). If not in use at the time of initial endorsement, then a credible plan for implementation within the specified timeframes is provided.

4.1. Current and Planned Use

NQF-endorsed measures are expected to be used in at least one accountability application within 3 years and publicly reported within 6 years of initial endorsement in addition to performance improvement.

Planned	Current Use (for current use provide URL)
	Public Reporting Physician Quality Rating System http://www.cms.gov/Medicare/Quality-Initiatives-Patient-Assessment-Instruments/pqrs/index.html Payment Program Meaningful Use Stage II http://www.cms.gov/Regulations-and-Guidance/Legislation/EHRIncentivePrograms/Stage_2.html Quality Improvement with Benchmarking (external benchmarking to multiple organizations) PINNACLE Registry http://cvquality.acc.org/en/NCDR-Home/Registries/Outpatient-Registries.aspx

4a.1. For each CURRENT use, checked above, provide:

- Name of program and sponsor
- Purpose
- Geographic area and number and percentage of accountable entities and patients included

1) Physician Quality Reporting System (PQRS)-Sponsored by the Centers for Medicare and Medicaid Services (CMS)
Purpose: PQRS is a national reporting program that uses a combination of incentive payments and payment adjustments to promote reporting of quality information by eligible professionals (EPs). The program provides an incentive payment to practices with EPs (identified on claims by their individual National Provider Identifier [NPI] and Tax Identification Number [TIN]). Eps satisfactorily report data on quality measures for covered Physician Fee Schedule (PFS) services furnished to Medicare Part B Fee-for-Service (FFS) beneficiaries (including Railroad Retirement Board and Medicare Secondary Payer). Beginning in 2015, the program also applies a payment adjustment to EPs who do not satisfactorily report data on quality measures for covered professional services. Source: http://www.cms.gov/Medicare/Quality-Initiatives-Patient-Assessment-Instruments/PQRS/index.html It is our understanding that CMS is also planning to move towards publicly
reporting physician data via Physician Compare.

2) Meaningful Use Stage 2 (EHR Incentive Program) – Sponsored by the Centers for Medicare and Medicaid Services (CMS)
The Medicare and Medicaid EHR Incentive Programs provide incentive payments to eligible professionals, eligible hospitals, and critical access hospitals (CAHs) as they adopt, implement, upgrade or demonstrate meaningful use of certified EHR technology.

These professionals are eligible for incentive payments for the "meaningful use" of certified EHR technology, if all program requirements are met, including successful implementation and reporting of program measures, which include this measure, to demonstrate meaningful use of EHR technology.

3) PINNACLE Registry (URL: http://cvquality.acc.org/en/NCDR-Home/Registries/Outpatient-Registries.aspx)
The PINNACLE Registry® is cardiology´s largest outpatient quality improvement registry, capturing data on coronary artery disease, hypertension, heart failure and atrial fibrillation. The PINNACLE Registry® continues to grow rapidly, with more than 2400 providers representing almost 800 unique office locations across the U.S submitting data to the registry as of the fourth quarter of 2013. As of the fourth quarter of 2013, the registry has more than 13 million patient encounter records. PINNACLE assists practices in understanding and improving care through the production and distribution of quarterly performance reports. These reports, covering all valid patient encounters, detail adherence to 28 cardiovascular clinical measures at the physician, location, and practice levels across coronary artery disease, hypertension, heart failure and atrial fibrillation. All jointly developed ACC/AHA/PCPI performance measures for these topics are reported by the registry.

4a.2. **If not currently publicly reported OR used in at least one other accountability application (e.g., payment program, certification, licensing) what are the reasons?** (*e.g., Do policies or actions of the developer/steward or accountable entities restrict access to performance results or impede implementation?*)
We support the expanded use of this measure in government or other programs, including those intended for accountability or public reporting. The ACC, AHA and PCPI do not have any policies that would restrict access to the performance measure specifications or results or that would impede implementation of the measure for any application. We would welcome its implementation in emerging applications such as accountable care organizations (ACO), Medicare Advantage insurance plans or health plans selling on the new insurance marketplace.

4a.3. **If not currently publicly reported OR used in at least one other accountability application, provide a credible plan for implementation within the expected timeframes -- any accountability application within 3 years and publicly reported within 6 years of initial endorsement.** (*Credible plan includes the specific program, purpose, intended audience, and timeline for implementing the measure within the specified timeframes. A plan for accountability applications addresses mechanisms for data aggregation and reporting.*)
As described above, it is our understanding that CMS is also planning to move towards publicly reporting physician data via Physician Compare. Also, although the measure is currently in use, we support expanded use of this measure in government or other programs, including those intended for accountability or public reporting.

4b. Improvement

Progress toward achieving the goal of high-quality, efficient healthcare for individuals or populations is demonstrated. If not in use for performance improvement at the time of initial endorsement, then a credible rationale describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.

4b.1. **Progress on Improvement. (Not required for initial endorsement unless available.)**
Performance results on this measure (current and over time) should be provided in 1b.2 and 1b.4. Discuss:

- **Progress (trends in performance results, number and percentage of people receiving high-quality healthcare)**
- **Geographic area and number and percentage of accountable entities and patients included**

2013 PQRS Experience Report*:
Data Source: 2013 is the most recent year for which PQRS Experience Report measure data is available. The average performance rates on Heart Failure (HF) – Beta Blocker Therapy for Left Ventricular Systolic Dysfunction (LVSD) over the last several years are as follows:

2010: 82.7%
2011: 75.8%
2012: 86.8%
2013: 77.6%

2013 Small Group Practice Exception Rate: 1.04%
Reference: Center for Medicare and Medicaid Services. 2013 Reporting Experience Including Trends. Available: http://www.cms.gov/Medicare/Quality-Initiatives-Patient-Assessment-Instruments/PQRS/index.html?redirect=/PQRS/
*It is important to note that PQRS was a voluntary reporting program, with approximately 51% of eligible professionals participating using any reporting option in 2013, and performance rates may not be nationally representative.

4b.2. **If no improvement was demonstrated, what are the reasons? If not in use for performance improvement at the time of initial endorsement, provide a credible rationale that describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.**
While the PCPI creates measures with an ultimate goal of improving the quality of care, measurement is a mechanism to drive improvement but does not equate with improvement. Measurement can help identify opportunities for improvement with actual improvement requiring making changes to health care processes and structure. In order to promote improvement, quality measurement systems need to provide feedback to front-line clinical staff in as close to real time as possible and at the point of care whenever possible. (1)

1. Conway PH, Mostashari F, Clancy C. The future of quality measurement for improvement and accountability. JAMA. 2013 Jun 5;309(21):2215-6.

4c. Unintended Consequences

The benefits of the performance measure in facilitating progress toward achieving high-quality, efficient healthcare for individuals or populations outweigh evidence of unintended negative consequences to individuals or populations (if such

evidence exists).

4c.1. **Were any unintended negative consequences to individuals or populations identified during testing; OR has evidence of unintended negative consequences to individuals or populations been reported since implementation? If so, identify the negative unintended consequences and describe how benefits outweigh them or actions taken to mitigate them.**
We are not aware of any unintended consequences at this time, but we take unintended consequences very seriously and therefore continuously monitor to identify actions that can be taken to mitigate them.

5. Comparison to Related or Competing Measures

If a measure meets the above criteria and there are endorsed or new related measures (either the same measure focus or the same target population) or competing measures (both the same measure focus and the same target population), the measures are compared to address harmonization and/or selection of the best measure.

5. Relation to Other NQF-endorsed Measures
Are there related measures (conceptually, either same measure focus or target population) or competing measures (conceptually both the same measure focus and same target population)? If yes, list the NQF # and title of all related and/or competing measures.
Yes

5.1a. **List of related or competing measures (selected from NQF-endorsed measures)**
0070 : Coronary Artery Disease (CAD): Beta-Blocker Therapy-Prior Myocardial Infarction (MI) or Left Ventricular Systolic Dysfunction (LVEF <40%)
0071 : Persistence of Beta-Blocker Treatment After a Heart Attack

5.1b. **If related or competing measures are not NQF endorsed please indicate measure title and steward.**

5a. Harmonization

The measure specifications are harmonized with related measures;
OR
The differences in specifications are justified

5a.1. **If this measure conceptually addresses EITHER the same measure focus OR the same target population as NQF-endorsed measure(s):**
Are the measure specifications completely harmonized?
No

5a.2. **If the measure specifications are not completely harmonized, identify the differences, rationale, and impact on interpretability and data collection burden.**
Measure 0083 addresses a therapy which is also covered in part by the following NQF-endorsed measures: NQF 0071: Persistence of Beta-Blocker Treatment After a Heart Attack and NQF 0070: Coronary Artery Disease (CAD): Beta-Blocker Therapy—Prior Myocardial Infarction (MI) or Left Ventricular Systolic Dysfunction (LVEF <40%). The specifications are harmonized to the extent possible. However, measure 0083 is focused on a patient population with heart failure and therefore the denominator specifications for the measures differ.

5b. Competing Measures

The measure is superior to competing measures (e.g., is a more valid or efficient way to measure);
OR
Multiple measures are justified.

5b.1. **If this measure conceptually addresses both the same measure focus and the same target population as NQF-endorsed measure(s):**
Describe why this measure is superior to competing measures (e.g., a more valid or efficient way to measure quality); OR provide a rationale for the additive value of endorsing an additional measure. (Provide analyses when possible.)

Appendix

A.1 Supplemental materials may be provided in an appendix. All supplemental materials (such as data collection instrument or methodology reports) should be organized in one file with a table of contents or bookmarks. If material pertains to a specific submission form number, that should be indicated. Requested information should be provided in the submission form and required attachments. There is no guarantee that supplemental materials will be reviewed.

Additional Information

Ad.1 **Workgroup/Expert Panel involved in measure development**
Provide a list of sponsoring organizations and workgroup/panel members' names and organizations. Describe the members' role in measure development.
PCPI and ACC/AHA measures are developed through cross-specialty, multi-disciplinary work groups. All medical specialties and other health care professional disciplines participating in patient care for the clinical condition or topic under study are invited to participate as equal contributors to the measure development process. In addition, the PCPI and ACC/AHA strive to include on its work groups individuals representing the perspectives of patients, consumers, private health plans, and employers. This broad-based approach to measure development ensures buy-in on the measures from all stakeholders and minimizes bias toward any individual specialty or stakeholder group. All work groups have at least two co-chairs who have relevant clinical and/or measure development expertise and who are responsible for ensuring that consensus is achieved and that all perspectives are voiced.

Work Group members:
Craig T. Beam, CRE (patient representative)
Ileana L. Piña, MD, FACC (cardiology, heart failure)
Kathleen Blake, MD (cardiac electrophysiology)
Paul D. Rockswold, MD, MPH (family medicine)
Donald E. Casey, Jr., MD, MPH, MBA, FACP, FAHA (internal medicine)
Lawrence B. Sadwin (patient representative)
Sarah J. Goodlin, MD (geriatrics, palliative medicine)
Joanna D. Sikkema, MSN, ANP-BC, FAHA (cardiology)
Kathleen L. Grady, PhD, APN, FAAN, FAHA (cardiac surgery)
Carrie A. Sincak, PharmD, BCPS (pharmacy)
Randal F. Hundley, MD, FACC (cardiology, health plan representative)
John Spertus, MD, MPH (cardiology)
Mariell Jessup, MD, FACC, FAHA, FESC (cardiology, heart failure)
Patrick J. Torcson, MD, FACP, MMM (hospital medicine)
Thomas E. Lynn, MD (family medicine, measure implementation)
Elizabeth Torres, MD (internal medicine)
Frederick A. Masoudi, MD, MSPH (cardiology)
Mark V. Williams, MD, FHM (hospital medicine)
David Nilasena MD, MSPH, MS (general preventive medicine, public health, measure implementation)

Measure Developer/Steward Updates and Ongoing Maintenance

Ad.2 **Year the measure was first released:** 2003

Ad.3 **Month and Year of most recent revision:** 12, 2014

Ad.4 **What is your frequency for review/update of this measure?** Coding/Specifications updates occur annually.

Ad.5 **When is the next scheduled review/update for this measure?** 12, 2015

Ad.7 **Disclaimers:** Physician Performance Measures (Measures) and related data specifications have been developed by the American Medical Association (AMA) - convened Physician Consortium for Performance Improvement(R) (PCPI[R]), American College of Cardiology (ACC) and American Heart Association (AHA). These Measures are not clinical guidelines and do not establish a standard of medical care, and have not been tested for all potential applications. The Measures, while copyrighted, can be reproduced and distributed, without modification, for noncommercial purposes, eg, use by health care providers in connection with their practices. Commercial use is defined as the sale, license, or distribution of the Measures for commercial gain, or incorporation of the Measures into a product or service that is sold, licensed or distributed for commercial gain. Commercial uses of the Measures require a license agreement between the user and the AMA, (on behalf of the PCPI), ACC or AHA. Neither the AMA, ACC, AHA, PCPI nor its members shall be responsible for any use of the Measures.

THE MEASURES AND SPECIFICATIONS ARE PROVIDED "AS IS" WITHOUT WARRANTY OF ANY KIND.

Limited proprietary coding is contained in the Measure specifications for convenience. Users of the proprietary code sets should obtain all necessary licenses from the owners of these code sets. The AMA, ACC, AHA, the PCPI and its members disclaim all liability for use or accuracy of any Current Procedural Terminology (CPT[R]) or other coding contained in the specifications.

Ad.8 **Additional Information/Comments:**

MEASURE WORKSHEET

This document summarizes the evaluation of the measure as it progresses through NQF's Consensus Development Process (CDP). The information submitted by measure developers/stewards is included after the Brief Measure Information, Preliminary Analysis, and Pre-meeting Public and Member Comments sections.

To navigate the links in the worksheet: Ctrl + click link to go to the link; ALT + LEFT ARROW to return

Brief Measure Information

NQF #: 0081
Measure Title: Heart Failure (HF): Angiotensin-Converting Enzyme (ACE) Inhibitor or Angiotensin Receptor Blocker (ARB) Therapy for Left Ventricular Systolic Dysfunction (LVSD)
Measure Steward: AMA-PCPI
Brief Description of Measure: Patients who were prescribed* ACE inhibitor or ARB therapy either within a 12 month period when seen in the outpatient setting or at hospital discharge
Developer Rationale: In the absence of contraindications, ACE inhibitors or ARBs are recommended for all patients with symptoms of heart failure and reduced left ventricular systolic function. ACE inhibitors remain the first choice for inhibition of the renin-angiotensin system in chronic heart failure, but ARBs can now be considered a reasonable alternative. Both pharmacologic agents have been shown to decrease the risk of death and hospitalization. Additional benefits of ACE inhibitors include the alleviation of symptoms and the improvement of clinical status and overall sense of well-being of patients with heart failure.

Also, a 2011 analysis of IMPROVE HF data by Fonarow and colleagues revealed that all 4 current ACC/AHA HF outpatient performance measures were associated with decreased risk of 24-month mortality. For the 2 summary measures of HF care processes, there was also a strong positive association between greater conformity to the summary measures and improved risk-adjusted survival. These findings may have significant clinical and public health implications, providing evidence to suggest that current, and some emerging, outpatient process measures may effectively reflect the quality of care provided to patients with HF who are treated in outpatient practice settings.

Numerator Statement: Patients who were prescribed* ACE inhibitor or ARB therapy either within a 12 month period when seen in the outpatient setting or at hospital discharge

*Prescribed may include:
Outpatient setting: prescription given to the patient for ACE inhibitor or ARB therapy at one or more visits in the measurement period OR patient already taking ACE inhibitor or ARB therapy as documented in current medication list
Inpatient setting: prescription given to the patient for ACE inhibitor or ARB therapy at discharge OR ACE inhibitor or ARB therapy to be continued after discharge as documented in the discharge medication list
Denominator Statement: All patients aged 18 years and older with a diagnosis of heart failure with a current or prior LVEF < 40%
Denominator Exclusions: Documentation of medical reason(s) for not prescribing ACE inhibitor or ARB therapy (eg, hypotensive patients who are at immediate risk of cardiogenic shock, hospitalized patients who have experienced marked azotemia, allergy, intolerance, other medical reasons)
Documentation of patient reason(s) for not prescribing ACE inhibitor or ARB therapy (eg, patient declined, other patient reasons)
Documentation of system reason(s) for not prescribing ACE inhibitor or ARB therapy (eg, other system reasons)

Measure Type:
Data Source: Electronic Clinical Data, Electronic Clinical Data : Electronic Health Record, Electronic Clinical Data : Registry
Level of Analysis: Clinician : Group/Practice, Clinician : Individual
Is this an eMeasure? ☒ **Yes** ☐ **No** **If Yes, was it re-specified from a previously endorsed measure?** ☒ **Yes** ☐ **No**

Is this a MAINTENANCE measure submission? ☒ **Yes** ☐ **No, this is a NEW measure submission.**
For MAINTENANCE, state the Original Endorsement Date: 8/10/09 **Most Recent Endorsement Date:** 1/18/12

Previous Measure Evaluation - Public & Member Comments, Developer Responses & Steering Committee Recommendations from (Cardiology Project 2010):

Public and Member Comments

- The excessive patient, system, and medical exclusions in this measure should be revisited so that they all meet the following criteria: evidence-based, highly specific, and explicitly defined.
- Obtaining data to calculate these measures could be challenging for certain end users. Prescription of ACE inhibitor or ARB therapy is occurring at the time of hospital discharge, however to collect the data for individual clinicians would be very labor intensive. Measuring this at both levels may lead to duplication of medications and increase medication errors.
- Suggest limiting to specific drugs that are FDA approved for use in HF/LVSD: ARBs: candesartan (has a mortality claim) and valsartan.
- An ARB should be used when available for black patients as ACEI in black patients cause more angioedema.

Developer response:

- These measures have been tested and found to be generally feasible in EHR, paper, and claims data sources. This is a clinician-level measure for the outpatient setting.
- As specified, this measure applies to patients with CAD and LVSD OR patients with CAD and diabetes. The list of medications/drug names included in the measure specifications is based on clinical guidelines and other evidence. The specified drugs were selected based on the strength of evidence for their clinical effectiveness. Available data suggests that there are no differences among available ACEIs and ARBs in their effects on symptoms or survival.
- This measure is intended to encourage ACEI or ARB therapy in the treatment of patients with HF and LVSD. The specific type of ACEI or ARB prescribed is at the discretion of the clinician and should be specific type of ACEI or ARB prescribed is at the discretion of the clinician and should be specific to the needs of the individual patient.

Steering Committee: Reviewed comments and developer's responses. No change in recommendations.

IF this measure is paired/grouped, list the paired measure NQF#/title: 0083: Beta-Blocker Therapy for Left Ventricular Systolic Dysfunction

IF PAIRED/GROUPED, what is the reason this measure must be reported with other measures to appropriately interpret results? Measures #0083 (Beta-Blocker Therapy for Left Ventricular Systolic Dysfunction) and #0081 address related aspects of care for effective treatment for patients with heart failure and should be measured concurrently. Both ACE inhibitors and beta-blockers have been shown to reduce mortality and hospitalizations and improve a patient's clinical status. ARBs can be considered a reasonable alternative for ACE inhibitors. Combined treatment with these agents produces additive benefits and is required for optimal management of heart failure.14 It is not recommended that either of these measures be used independently. The pairing of these measures is not intended to suggest the use of any particular scoring methodology (ie, a composite score), nor does it imply either equality of or difference in the relative "weights" of the two measures. A performance score for each measure should be reported individually to provide actionable information upon which to focus quality improvement efforts.

Preliminary Analysis

The preliminary analysis was developed in response to recommendations from NQF's Consensus Task Force and measurement stakeholders as a way to enhance and streamline the measures evaluation and voting processes. The preliminary analysis will help to guide the Standing Committee evaluation of each measure by summarizing the measure developer submission, guide measure evaluation discussion, and identify topic areas for additional input. **NQF staff would like to stress that the preliminary analysis is intended to be used as a guide to facilitate the Committee's discussion and evaluation.**

Criteria 1: Importance to Measure and Report

1a. Evidence

1a. Evidence. The evidence requirements for a *process* measure is that it is based on a systematic review (SR) and grading of the body of empirical evidence where the specific focus of the evidence matches what is being measured.

The developer provides the following evidence for this process measure:

- This clinician-level process *registry measure* and *eMeasure* calculates the percentage of patients aged 18 years and older with a diagnosis of heart failure with a current or prior LVEF < 40% who were prescribed an ACE Inhibitor or ARB therapy either within a 12 month period when seen in the outpatient setting or at hospital discharge.
- The developer provides the 2013 ACCF/AHA Guideline for the management of heart failure (Class I, Level A) with one recommendation for ACE Inhibitors (Class I) and four recommendations for ARBs in patients who are: ACE intolerant (Class I), already taking ARBs for other indications (Class IIa), addition of an ARB (Class IIb) and

recommendation to avoid the combined use of ACE, ARB, and aldosterone antagonist (Class III).

- The articles supporting the ACE/ARB recommendations were from 1993-2012 but the developers report that the overall literature search was through October 2011 with select articles included through April 2013. The developer states that additional articles found from 2014 and 2015 would not change the ACE/ARB recommendations.
- QQC - 2 meta-analyses, 10 randomized controlled trials, 3 comparative studies, and 1 review paper supporting the ACE/ARB recommendations.
- The developer provides a diagram of how the initiation of ACE Inhibitor therapy for patients with heart failure or LVEF < 40% is linked to patient outcomes.

Questions for the Committee:

- *For process measures:*
  - *Is the evidence directly applicable to the process of care being measured?*
  - *Is the process of care proximal and closely related to desired outcomes?*
- *For possible exception to the evidence criteria:*
  - *Are there, or could there be, performance measures of a related health outcome, OR evidence-based intermediate clinical outcomes, intervention/treatment?*
  - *Is there evidence of a systematic assessment of expert opinion beyond those involved in developing the measure?*
  - *Does the SC agree that it is acceptable (or beneficial) to hold providers accountable without empiric evidence?*

1b. Gap in Care/Opportunity for Improvement and 1b. Disparities

1b. Performance Gap. The performance gap requirements include demonstrating quality problems and opportunity for improvement.

- The developers provide the average performance rates from the PQRS Experience Report from 2010-2013 and data from the literature that shows an ACEI/ARB was prescribed for 11,165 (79.8%) of 13,987 eligible patients. Additional data (std dev, min, max, interquartile range, scores by decile, number of measured entities) that is required per NQF policy for maintenance is not provided. The developer should clarify if the PINNACLE data collection tool includes race, and other SES factors, such as insurance status.
- The developers report that disparities data from the federal reporting programs using this measure have not yet been made available for them to analyze and report, though they encourage the results of this measure to be stratified by race, ethnicity, sex, and payer.
- The developers provide data from a 2011 study that suggests that there are some racial and ethnic disparities in the receipt of pharmacological therapy for CHF among TRICARE beneficiaries.

Questions for the Committee:

- *Is there a gap in care that warrants a national performance measure?*
- *If no disparities information is provided, are you aware of evidence that disparities exist in this area of healthcare?*
- *Should this measure be indicated as disparities sensitive?*

1c. Priority

1c. High Priority (previously "High Impact") requires measures to address national health goal/priority or a demonstrated high-impact aspect of care.

- *Beginning in 2015, priority is no longer an NQF measure evaluation criterion.*

Committee pre-evaluation comments

Criteria 1: Importance to Measure and Report (including 1a, 1b, 1c)

1. ***Committee's Overview Comments***:
   - Broad and convincing
   - Yes the evidence supports the use of ACE-I or ARB in LVSD based on clinical trial evidence and ACC/AHA guideline recommendations
   - Yes, the process of care is related to the desired outcome, but actual filling of medication would be a better marker than just an rx for the ACE-I or ARB
   - No, there are not exceptions

- The measure is supported by the most recent ACC/AHA HF guidelines from 2013.

1a. ***Committee's Comments on Evidence to Support Measure Focus:***
- Solid consistent evidence
- The guideline supporting evidence directly supports the process being evaluated as it relates to ACE-I or ARB prescribed in individuals with LVSD.

1b. ***Committee's Comments on Performance Gap:***
- Disparities are well demonstrated
- Yes, there is a performance gap as the reported Rx rate of 79.8% is low when looking at the context that it's a Class IA recommendation in guidelines and has been for many years,
- Ethnicity data would be useful to evaluate if black patients are less likely to get prescribed and ACEI/ARB secondary to a higher adverse event rate compared to other races
- Disparity data not available but would be useful

1c. ***Committee's Comments on Composite Performance Measure:***
- The overall, quality construct is logical and aligns with the measure.

Criteria 2: Scientific Acceptability of Measure Properties

2a. Reliability

2a1. Reliability Specifications

2a1. Specifications requires the measure, as specified, to produce consistent (reliable) and credible (valid) results about the quality of care when implemented.

- The measure's data source is an EHR and/or registry. ICD 9, ICD 10 and CPT codes provided for the numerator and denominator for registry and inpatient setting. ICD-10 conversion methodology is not discussed. In both sets of specifications (registry and eMeasure), the logic is unambiguous. Higher scores equal better quality.
- In the outpatient setting, "prescribed" may include an ACEI/ARB prescription given to the patient at one or more visits in the measurement period or ACEI/ARB listed as current medication. In the inpatient setting, "prescribed" may include prescription given at discharge or ACEI/ARB listed in discharge medication list.
- In the outpatient setting, 2 or more encounters are required to establish the eligible professional has an existing relationship with the patient.
- The measure is intended for use in an office visit, outpatient consultation, nursing facility, long-term care residential facility, home health and provider interaction during the measurement period.
- For the registry specification, the denominator patient, medical & system exclusions/exceptions are reported using separate CPT-II codes for each of the 3 type of exclusions/exceptions, though the paired measure 0083 uses a single HCPCS code G8541 to report all 3 types of exclusions/exceptions.
- Denominator exclusions/exceptions include broad definitions for medical reason, patient reason and system reason for not prescribing ACEI/ARB; examples of exceptions provided using CPT-II codes. The developer states that exceptions should only be considered when the numerator activity was not performed, that they are not uniformly relevant across measures, and that there must be a clear rationale to permit an exception for a medical, patient, or system reason. In the provided value sets, broadly defined and inappropriate patient, medical and system reason denominator exclusions include but are not limited to: medical reason: 216952002 failure in dosage (event), patient reason: 224187001 variable income (finding) & 266966009 family illness (situation), system reason:266756008 medical care unavailable (situation).
- Missing numerator data represent a quality failure.
- The calculation algorithm is included.
- The measure is not risk adjusted and SDS variables were not captured for the measure. The developer encourages users to provide collect data and stratify results by race, ethnicity, administrative sex, and payer consistent with CMS' Measures Management System Blueprint and recent national recommendations put forth by the IOM and NQF.

- For the eMeasure, the developer should clarify the following:
    - Pregnancy & Renal Failure due to ACE Inhibitor are included in value sets as exceptions, and not listed in the eMeasure specification, and they are not included in the Registry specification. Should these be exclusions?
    - Atrioventricular Block and Cardiac Pacer in Situ are listed as exceptions in the eMeasure specification, though they are not included in the registry specifications. Should these be exclusions?
    - "Provider interactions" are listed as encounters in the value set spreadsheet and in the eMeasure specifications that include both face-to-face visits and non-face-to-face communications. The developer is encouraged to provide reasoning for inclusion, and clarify if all provider interactions are included in the denominator definition for a patient encounter.
    - "Communication: From Patient to Provider: Patient Reason for ACE Inhibitor or ARB Decline" is listed as an exception and is not included in the Registry specification. Please describe intent of this exception.
    - In the Initial Patient Population (IPP), "Encounter, Performed: Patient Provider Interaction" is listed, though it is not in the Data Criteria (QDM Variables).
    - "Encounter, Performed: Face-to-Face Interaction" is listed in the Data Criteria (QDM Variables), though not in the IPP.
    - Medication initial, maximum & mean does are provided in the header information. The developer should clarify if this is for information purposes, or part of the eMeasure.
- All eMeasure specifications and values sets meet current NQF eMeasure technical requirements and are provided on Sharepoint for SC review.

Questions for the Committee:

- *Are all the data elements clearly defined? Are all appropriate codes included?*
- *Is the logic or calculation algorithm clear?*
- *Is it likely this measure can be consistently implemented?*

2a2. Reliability Testing Testing attachment

2a2. Reliability testing demonstrates if the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise enough to distinguish differences in performance across providers.

GPRO Registry Testing

- The developer tested reliability at the performance measure score level, using a beta-binomial model in a signal-to-noise analysis, to differentiate the true differences between measured entities (the signal) from random measurement error (the noise). A value of 0 indicates that all variation is due to measurement error and a value of 1 indicates that all variation is due to real differences in performance (for this measure, between providers). A value of 0.7 is often regarded as a minimum acceptable reliability value.
- A sample 1,244 (33.4%) of 3,728 physicians reported the measure with results showing the average number of quality reporting events for physicians included is 31.5 for 39,242 events with a reliability of 0.94 (high reliability). For the program required minimum of 10 quality reporting events, with a reliability of 0.83 (high reliability).
- A missing data assessment was not performed. The developer states data missing from denominator excludes the patient from the measure, while missing numerator data counts as a measure "fail".

eMeasure Testing

- Critical data element (Validity against the Gold Standard) was conducted. Per NQF criteria, if empirical validity testing was performed of patient-level data, the rating from validity testing of patient-level data elements should be used. The developer provides simple agreement results for critical data element validity. Comparison of the values for several data elements (electronic extracted vs. data abstracted) using EHR data was conducted and could satisfy the data element reliability criterion (Algorithm box 3; validity testing results described in 2b.2 below). Results were provided for most, but not all, critical data elements. Percent agreement statistics were presented; however, percent agreement does not adjust for agreement due to chance, and should not be used alone to demonstrate reliability.

- Ideally, implementation of an eMeasure can be considered an automated process, and therefore the calculations will be consistent. The submitted eMeasure specification follows industry standards to represent the measure electronically which should enable automated data extraction and measure score calculation.
- In addition to critical data element testing, the developer submitted pre-testing from the Measure Authoring Tool within the Bonnie Output that tests eMeasure logic. The measure logic successfully validated through the Bonnie Output.

- For both specifications, a missing data assessment was not performed. The developer states data missing from denominator excludes the patient from the measure, while missing numerator data counts as a measure "fail".
- Patient-level socio-demographic (SDS) variables were not captured as part of the testing.

Questions for the Committee:

- *Is the test sample adequate to generalize for widespread implementation?*
- *Do the results demonstrate sufficient reliability so that differences in performance can be identified?*

2b. Validity

2b1. Validity: Specifications

2b1. Validity Specifications. This section should determine if the measure specifications are consistent with the evidence.

- The clinical practice guidelines supporting this measure recommend the use of ACEI/ARBs in patients with HF.

Question for the Committee:

- *Are the specifications consistent with the evidence?*

2b2. Validity testing

2b2. Validity Testing should demonstrate the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality.

GPRO Registry Testing

- The developer provided face validity results using 12 members of the PCPI Measure Advisory Committee (MAC) with a mean rating of 4.33 and 100% of respondents either agree or strongly agree the measure is able to distinguish good and poor quality using a 1-5 Likert, highest score was 5. The MAC is independent of the measure developer experts.

eMeasure Testing

- The developer provided critical data element (Validity against the Gold Standard) was conducted. Per NQF criteria, if empirical validity testing was performed of patient-level data, this rating will also be used for reliability testing. Data elements included patient age, visit, problem list, or medical history of CAD, those who met the denominator population.
- The developers provide simple agreement for the 254 patients sampled via automated EHR review. Of the sample, 217 patients (85.4%) were detected for numerator criteria, 23 patients detected for exclusion criteria totaling 93.9% calculation detection to the gold standard (the EHR) via automated review 6 patients were further added and 2 were false inclusions, totaling 96.1% agreement. Additional statistical testing was not provided.
- Data element validity testing was conducting by comparing, for several data elements, the values obtained from electronic extraction from 1 EHR to those obtained from those abstracted from the EHR by an abstractor. Simple agreement was provided for most, but not all, critical data elements. However, simple agreement does not adjust for agreement due to chance and thus should not be used alone to demonstrate validity; sensitivity/specificity statistics are preferred for demonstrating data element validity. Percentage agreement values were relatively high for most data elements considered. It appears that only one abstractor was utilized, which is acceptable for testing validity against the gold standard in an EHR.
- In addition to critical data element testing, the developer submitted pre-testing from the Measure Authoring Tool within the Bonnie Output that also tests eMeasure performance calculation. This testing does use "live" EHR

patients, though NQF currently accepts Bonnie Output pre-testing when EHR testing was not provided. Results in the 46 "pre-test" patients demonstrated 100% agreement for identifying both expected and actual initial patient population, denominator, denominator exclusions, numerator, and denominator exceptions. Testing characteristics are provided for the 46 "pre-test" patients, with 100% of the of data elements concepts included in the Initial Patient Population (IPP), Denominator, Numerator and Denominator Exceptions, with 100% of possible data elements covered in the pre-test sample.

Questions for the Committee:

- ○ *Is the test sample adequate to generalize for widespread implementation?*
- ○ *Do the results demonstrate sufficient validity so that conclusions about quality can be made?*
- ○ *Do you agree that the score from this measure as specified is an indicator of quality?*
- ○ *Other specific question of the validity testing?*

2b3-2b7. Threats to Validity

2b3. Exclusions: Analysis of exclusions found:

- GPRO Registry: Of the 1244 physicians with the minimum (10) number of quality reporting events, there were a total of 8,056 exceptions reported. The average number of exceptions per physician in this sample is 6.5. The overall exception rate is 17.03%. The types of exceptions reported are not available from the GRPO Registry.
- EHR: Measure exceptions were validated 95.32% of the time. Review of the 127 exceptions revealed 99.5% of exceptions were medical reasons for not prescribing ACE inhibitor or ARB therapy. Medical reason exceptions consisted of clinical contraindications, drug allergy and drug intolerance.
- Broad exceptions (medical, patient & system) reasons are included within the provided data sets, and include non-relevant codes.
- For the eMeasure specifications:
  - Pregnancy & Renal Failure due to ACE Inhibitor are included in value sets as exceptions, and not listed in the eMeasure specification, and they are not included in the Registry specification.
  - Atrioventricular Block and Cardiac Pacer in Situ are listed as exceptions in the eMeasure specification, though they are not included in the registry specifications.
- Broad exceptions (medical, patient & system) reasons are included within the provided data sets, and include non-relevant codes.

Questions for the Committee:

- ○ *Are the exclusions consistent with the evidence?*
- ○ *Are any patients or patient groups inappropriately excluded from the measure?*
- ○ *Are the exclusions/exceptions of sufficient frequency and variation across providers to be needed (and outweigh the data collection burden)?*

2b4. Risk adjustment:

- This process measure is not risk adjusted.

2b5. Meaningful difference:

- GPRO Registry: Based on the sample of 1,244 included physicians, the mean performance rate is 0.80, the median performance rate is 0.94 and the mode is 1.00. The standard deviation is 0.29. The range of the performance rate is 1.00, with a minimum rate of 0.00 and a maximum rate of 1.00. The interquartile range is 0.29 (0.71 - 1.00).
- Meaningful difference data for the eMeasure was not provided by the developer, as the eMeasure testing data used fictitious "pre-test" patients, though higher performance and detection rates were noted in eMeasure validity testing with EHR & manual reviews, than in EHR-only reviews.

Question for the Committee:

- ○ *Does this measure identify meaningful differences about quality?*

2b6. Comparability of data sources/methods:

- NQF criteria require a comparability assessment of data sources/methods, such as with multiple specifications for the same measure. This was not provided by the developer, as the eMeasure testing data used fictitious "pre-test" patients.
- For validity testing of the eMeasure, developers did find higher performance & detection rates for the records abstracted with EHR & manual reviews, than EHR-only reviews.

2b7. Missing Data

- Missing data represent a quality failure.
- The developer reports "Data are not available to complete this testing."

Committee pre-evaluation comments

Criteria 2: Scientific Acceptability of Measure Properties (including all 2a, 2b, and 2d)

2a1. &2b1.: ***Committee's Comments on Reliability-Specifications:***

- The problem with this measure is that it compares apples and oranges
  - the numerator specifies use of ACEI/ARB in a 12 month period
  - the denominator specifies any EF (ever) of <40%
- I think this should be remedied so that EF is also considered within the same period of time"
- Need to clarify exclusions (pregnancy, renal failure, AV block)
- The logic and calculation algorithm is clear
- It is likely this measure can be implemented in a consistent fashion.

2a2.: ***Committee's Comments on Reliability-Testing:***

- It is reliable
- High reliability score (0.94)

2b1.: ***Committee's Comments on Validity-Specifications***:

- Same answer as 2a1
- Test sample is of great enough size being 1244/3728
- Yes, valid recommendation per ACC/AHA 2013 guidelines

2b2.: ***Committee's Comments on Validity-Testing:***

- It is valid
- Is the test sample adequate to generalize for widespread implementation? Yes, 254 patients
- Do the results demonstrate sufficient validity so that conclusions about quality can be made? Yes, 96.1% agreement.

2b3-7.: ***Committee's Comments on Threats to Validity:***

- See 2a1
- I think the measure needs to be bit refined as numerator and denominator should be from the same period, rather using denominator definition as having at any point in the past LVEF <40%
- Are the exclusions consistent with the evidence? Yes, but need to clarify the eMeasure specifications
- Are any patients or patient groups inappropriately excluded from the measure? NO
- Are the exclusions/exceptions of sufficient frequency and variation across providers to be needed (and outweigh the data collection burden)? 17.3% Rate of exclusion

2d.: ***Committee's Comments on Composite Performance Measure:***

- Not Applicable

Criterion 3. Feasibility

3. Feasibility is the extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

- For both Registry & eMeasures, data elements are collected by and used by healthcare personnel during provisions of care (BP, lab values), codes by someone other than the person obtaining the information (billing), and abstracted by someone other personnel (quality staff). All data elements are in electronic fields.
- The measure is specified for Clinician : Group/Practice, Clinician : Individual use.
- In the eMeasure Feasibility Scorecard, the developer states all data elements score "3" on a scale of 1 – 3 (3 the highest) for current and future use. The developer should clarify if this includes ICD-10, SNOMED-CT & RxNorm codes for the eMeasure for all data elements. The EHR product(s) & number of EHRs used in the eMeasure Feasibility Scorecard is not reported. NQF requires a Feasibility Scorecard from more than one EHR.

Questions for the Committee:

- *Are the required data elements routinely generated and used during care delivery?*
- *Are the required data elements available in electronic form, e.g., EHR or other electronic sources?*
- *Is the data collection strategy ready to be put into operational use?*
- *If an eMeasure, does the eMeasure Feasibility Score Card demonstrate acceptable feasibility in multiple EHR systems and sites?*

Committee pre-evaluation comments

Criteria 3: Feasibility

3.: ***Committee's Comments on Feasibility:***

- It is feasible.
- Are the required data elements routinely generated and used during care delivery? Yes, collected in route practice
- Are the required data elements available in electronic form, e.g., EHR or other electronic sources? Yes, in route practice
- Is the data collection strategy ready to be put into operational use? Yes, based on the description and feasibility assessment
- If an eMeasure, does the eMeasure Feasibility Score Card demonstrate acceptable feasibility in multiple EHR systems and sites? Need a feasibility score from more than one EHR

Criterion 4: Usability and Use

4. Usability and Use evaluate the extent to which audiences (e.g., consumers, purchasers, providers, policymakers) use or could use performance results for both accountability and performance improvement activities.

- The measure is currently used in PQRS, Meaningful Use Stage II and the PINNACLE Registry for quality improvement.
- The developer states not unintended consequences have been identified with measure use, and they continuously monitor for applicable mitigation.
- In 2014, the Measure Applications Partnership (MAP) Clinician Workgroup supported the measure for the Physician Compare and Value-Based Payment Modifier Program stating the measure promotes person- and family-centered care. Promotes alignment across programs, settings, and public- and private-sector efforts. Provides consideration for healthcare disparities and cultural competency. Included in a MAP family of measures. The measure was previously supported by Workgroup for inclusion in Physician Compare and VBPM for clinician group reporting.

Questions for the Committee (as appropriate) *:*

- *Is the measure publicly reported?*
- *For maintenance measures – is the measure used in at least one accountability application?*
- *How can the performance results be used to further the goal of high-quality, efficient healthcare?*
- *Do the benefits of the measure outweigh any potential unintended consequences?*

Committee pre-evaluation comments
Criteria 4: Usability and Use

4.: ***Committee's Comments on Usability and Use:***

- It is being used successfully
- Is the measure publicly reported? Yes, from multiple registries
- How can the performance results be used to further the goal of high-quality, efficient healthcare? Could be used to compare institutions
- Do the benefits of the measure outweigh any potential unintended consequences? Yes, as recommendation is a class 1A recommendation per ACC/AHA 2013 HF guidelines

Criterion 5: Related and Competing Measures

- None listed

NATIONAL QUALITY FORUM—Evidence (subcriterion 1a)

Measure Number (*if previously endorsed*)**:** Click here to enter NQF number

Measure Title: Click here to enter measure title

IF the measure is a component in a composite performance measure, provide the title of the Composite Measure here: Click here to enter composite measure #/ title

Date of Submission: Click here to enter a date

Instructions

- *For composite performance measures:*
  - *A separate evidence form is required for each component measure unless several components were studied together.*
  - *If a component measure is submitted as an individual performance measure, attach the evidence form to the individual measure submission.*
- Respond to all questions as instructed with answers immediately following the question. All information needed to demonstrate meeting the evidence subcriterion (1a) must be in this form. An appendix of *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 10 pages (*incudes questions/instructions*; minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the evidence for this measure meets NQF's evaluation criteria.

1a. Evidence to Support the Measure Focus

The measure focus is evidence-based, demonstrated as follows:

- Health outcome: [3] a rationale supports the relationship of the health outcome to processes or structures of care. Applies to patient-reported outcomes (PRO), including health-related quality of life/functional status, symptom/symptom burden, experience with care, health-related behavior.
- Intermediate clinical outcome: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured intermediate clinical outcome leads to a desired health outcome.
- Process: [5] a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured process leads to a desired health outcome.
- Structure: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured structure leads to a desired health outcome.
- Efficiency: [6] evidence not required for the resource use component.

Notes

3. Generally, rare event outcomes do not provide adequate information for improvement or discrimination; however, serious reportable events that are compared to zero are appropriate outcomes for public reporting and quality improvement.

4. The preferred systems for grading the evidence are the U.S. Preventive Services Task Force (USPSTF) grading definitions and methods, or Grading of Recommendations, Assessment, Development and Evaluation (GRADE) guidelines.

5. Clinical care processes typically include multiple steps: assess → identify problem/potential problem → choose/plan intervention (with patient input) → provide intervention → evaluate impact on health status. If the measure focus is one step in such a multistep process, the step with the strongest evidence for the link to the desired outcome should be selected as the focus of measurement. Note: A measure focused only on collecting PROM data is not a PRO-PM.

6. Measures of efficiency combine the concepts of resource use and quality (see NQF's Measurement Framework: Evaluating Efficiency Across Episodes of Care; AQA Principles of Efficiency Measures).

1a.1.This is a measure of: (*should be consistent with type of measure entered in De.1*)

Outcome

☐ Health outcome: Click here to name the health outcome

☐Patient-reported outcome (PRO): Click here to name the PRO

PROs include HRQoL/functional status, symptom/symptom burden, experience with care, health-related behaviors

☐ Intermediate clinical outcome (*e.g., lab value*): Click here to name the intermediate outcome

☒ Process: Click here to name the process

☐ Structure: Click here to name the structure

☐ Other: Click here to name what is being measured

HEALTH OUTCOME/PRO PERFORMANCE MEASURE *If not a health outcome or PRO, skip to 1a.3*

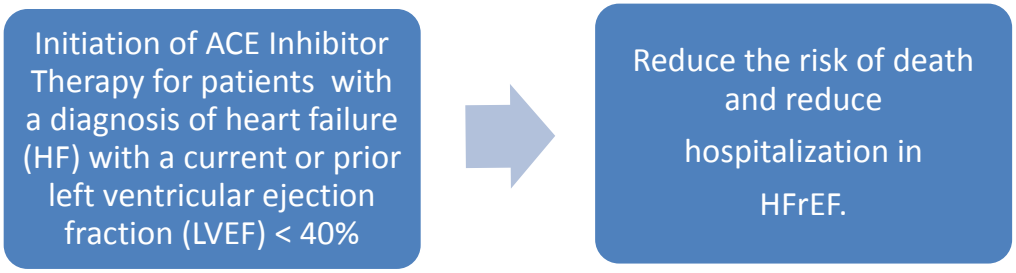
1a.2. Briefly state or diagram the path between the health outcome (or PRO) and the healthcare structures, processes, interventions, or services that influence it.

1a.2.1. State the rationale supporting the relationship between the health outcome (or PRO) to at least one healthcare structure, process, intervention, or service (*i.e., influence on outcome/PRO*).

Note: For health outcome/PRO performance measures, no further information is required; however, you may provide evidence for any of the structures, processes, interventions, or service identified above.

INTERMEDIATE OUTCOME, PROCESS, OR STRUCTURE PERFORMANCE MEASURE

1a.3. Briefly state or diagram the path between structure, process, intermediate outcome, and health outcomes. Include all the steps between the measure focus and the health outcome.



1a.3.1. What is the source of the systematic review of the body of evidence that supports the performance measure?

☒ Clinical Practice Guideline recommendation – ***complete sections 1a.4, and 1a.7***

☐ US Preventive Services Task Force Recommendation – ***complete sections 1a.5 and 1a.7***

☐ Other systematic review and grading of the body of evidence (*e.g., Cochrane Collaboration, AHRQ Evidence Practice Center*) – ***complete sections 1a.6 and 1a.7***

☐ Other – ***complete section 1a.8***

Please complete the sections indicated above for the source of evidence. You may skip the sections that do not apply.

1a.4. CLINICAL PRACTICE GUIDELINE RECOMMENDATION

1a.4.1. Guideline citation (*including date*) and **URL for guideline** (*if available online*):

http://circ.ahajournals.org/content/128/16/e240

Yancy CW, Jessup M, Bozkurt B, Butler J, Casey DE Jr, Drazner MH, Fonarow GC, Geraci SA, Horwich T, Januzzi JL, Johnson MR, Kasper EK, Levy WC, Masoudi FA, McBride PE, McMurray JJV, Mitchell JE, Peterson PN, Riegel B, Sam F, Stevenson LW, Tang WHW, Tsai EJ, Wilkoff BL. 2013 ACCF/AHA guideline for the management of heart failure: a report of the American College of Cardiology Foundation/American Heart Association Task Force on Practice Guidelines. 1a.4.2. Identify guideline recommendation number and/or page number and **quote verbatim, the specific guideline recommendation**.

7.3.2.2. ACE Inhibitors: Recommendation

Class I

1. **ACE inhibitors are recommended in patients with HF*r*EF and current or prior symptoms, unless contraindicated, to reduce morbidity and mortality. 343,412–414 *(Level of Evidence: A)***

7.3.2.3. ARBs: Recommendations

Class I

1. **ARBs are recommended in patients with HFrEF with current or prior symptoms who are ACE inhibitor intolerant, unless contraindicated, to reduce morbidity and mortality.108,345,415,450 (Level of Evidence: A)**

Class IIa

1. **ARBs are reasonable to reduce morbidity and mortality as alternatives to ACE inhibitors as first-line therapy for patients with HFrEF, especially for patients already taking ARBs for other indications, unless contraindicated.451–456 (Level of Evidence: A)**

Class IIb

1. **Addition of an ARB may be considered in persistently symptomatic patients with HFrEF who are already being treated with an ACE inhibitor and a beta blocker in whom an aldosterone antagonist is not indicated or tolerated.420,457 (Level of Evidence: A)**

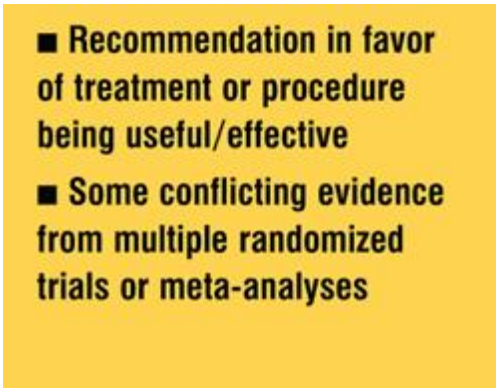
Class III: Harm

1. **Routine combined use of an ACE inhibitor, ARB, and aldosterone antagonist is potentially harmful for patients with HFrEF. (Level of Evidence: C)**

1a.4.3. Grade assigned to the quoted recommendation <u>with definition</u> of the grade:

Class I, Level A =

Class II-A, Level A:



Class II-B, Level A:

Class III, Level C:

1a.4.4. Provide all other grades and associated definitions for recommendations in the grading system.
(*Note: If separate grades for the strength of the evidence, report them in section 1a.7.*)

Table 1. Applying Classification of Recommendation and Level of Evidence

SIZE OF TREATMENT EFFECT

ESTIMATE OF CERTAINTY (PRECISION) OF TREATMENT EFFECT	CLASS I *Benefit >>> Risk* Procedure/Treatment **SHOULD** be performed/ administered	CLASS IIa *Benefit >> Risk* *Additional studies with focused objectives needed* **IT IS REASONABLE** to perform procedure/administer treatment	CLASS IIb *Benefit ≥ Risk* *Additional studies with broad objectives needed; additional registry data would be helpful* Procedure/Treatment **MAY BE CONSIDERED**	CLASS III *No Benefit* or CLASS III *Harm* Procedure/ Test / Treatment COR III: No benefit — Not Helpful — No Proven Benefit COR III: Harm — Excess Cost w/o Benefit or Harmful — Harmful to Patients
LEVEL A Multiple populations evaluated* Data derived from multiple randomized clinical trials or meta-analyses	■ Recommendation that procedure or treatment is useful/effective ■ Sufficient evidence from multiple randomized trials or meta-analyses	■ Recommendation in favor of treatment or procedure being useful/effective ■ Some conflicting evidence from multiple randomized trials or meta-analyses	■ Recommendation's usefulness/efficacy less well established ■ Greater conflicting evidence from multiple randomized trials or meta-analyses	■ Recommendation that procedure or treatment is not useful/effective and may be harmful ■ Sufficient evidence from multiple randomized trials or meta-analyses
LEVEL B Limited populations evaluated* Data derived from a single randomized trial or nonrandomized studies	■ Recommendation that procedure or treatment is useful/effective ■ Evidence from single randomized trial or nonrandomized studies	■ Recommendation in favor of treatment or procedure being useful/effective ■ Some conflicting evidence from single randomized trial or nonrandomized studies	■ Recommendation's usefulness/efficacy less well established ■ Greater conflicting evidence from single randomized trial or nonrandomized studies	■ Recommendation that procedure or treatment is not useful/effective and may be harmful ■ Evidence from single randomized trial or nonrandomized studies
LEVEL C Very limited populations evaluated* Only consensus opinion of experts, case studies, or standard of care	■ Recommendation that procedure or treatment is useful/effective ■ Only expert opinion, case studies, or standard of care	■ Recommendation in favor of treatment or procedure being useful/effective ■ Only diverging expert opinion, case studies, or standard of care	■ Recommendation's usefulness/efficacy less well established ■ Only diverging expert opinion, case studies, or standard of care	■ Recommendation that procedure or treatment is not useful/effective and may be harmful ■ Only expert opinion, case studies, or standard of care
Suggested phrases for writing recommendations	should is recommended is indicated is useful/effective/beneficial	is reasonable can be useful/effective/beneficial is probably recommended or indicated	may/might be considered may/might be reasonable usefulness/effectiveness is unknown/unclear/uncertain or not well established	COR III: No Benefit is not recommended is not indicated should not be performed/ administered/ other is not useful/ beneficial/ effective COR III: Harm potentially harmful causes harm associated with excess morbidity/mortality should not be performed/ administered/ other
Comparative effectiveness phrases†	treatment/strategy A is recommended/indicated in preference to treatment B treatment A should be chosen over treatment B	treatment/strategy A is probably recommended/indicated in preference to treatment B it is reasonable to choose treatment A over treatment B		

A recommendation with Level of Evidence B or C does not imply that the recommendation is weak. Many important clinical questions addressed in the guidelines do not lend themselves to clinical trials. Although randomized trials are unavailable, there may be a very clear clinical consensus that a particular test or therapy is useful or effective.

*Data available from clinical trials or registries about the usefulness/efficacy in different subpopulations, such as sex, age, history of diabetes, history of prior myocardial infarction, history of heart failure, and prior aspirin use.

†For comparative effectiveness recommendations (Class I and IIa; Level of Evidence A and B only), studies that support the use of comparator verbs should involve direct comparisons of the treatments or strategies being evaluated.

1a.4.5. Citation and URL for methodology for grading recommendations (*if different from 1a.4.1*)**:**

1a.5. UNITED STATES PREVENTIVE SERVICES TASK FORCE RECOMMENDATION

1a.5.1. Recommendation citation (*including date*) and **URL for recommendation** (*if available online*):

1a.5.2. Identify recommendation number and/or page number and **quote verbatim, the specific recommendation**.

1a.5.3. Grade assigned to the quoted recommendation with definition of the grade:

1a.5.4. Provide all other grades and associated definitions for recommendations in the grading system. (*Note: the grading system for the evidence should be reported in section 1a.7.*)

1a.5.5. Citation and URL for methodology for grading recommendations (*if different from 1a.5.1*)**:**

Complete section 1a.7

1a.6. OTHER SYSTEMATIC REVIEW OF THE BODY OF EVIDENCE

1a.6.1. Citation (*including date*) and **URL** (*if available online*):

1a.6.2. Citation and URL for methodology for evidence review and grading (*if different from 1a.6.1*)**:**

Complete section 1a.7

1a.7. FINDINGS FROM SYSTEMATIC REVIEW OF BODY OF THE EVIDENCE SUPPORTING THE MEASURE

If more than one systematic review of the evidence is identified above, you may choose to summarize the one (or more) for which the best information is available to provide a summary of the quantity, quality, and consistency of the body of evidence. Be sure to identify which review is the basis of the responses in this section and if more than one, provide a separate response for each review.

1a.7.1. What was the specific structure, treatment, intervention, service, or intermediate outcome addressed in the evidence review?

Effectiveness of ACE/ARBs at reducing the risk of death and reducing hospitalization in patients with heart failure; which patients should receive ACE/ARB therapy; initiation and maintenance of therapy; and risks of treatment with ACE/ARB therapy.

1a.7.2. Grade assigned for the quality of the quoted evidence <u>with definition</u> of the grade:

Level A-

Level C-

1a.7.3. Provide all other grades and associated definitions for strength of the evidence in the grading system.

See table in 1a.4.4

1a.7.4. What is the time period covered by the body of evidence? (*provide the date range, e.g., 1990-2010*).
Date range: 1993-2012

QUANTITY AND QUALITY OF BODY OF EVIDENCE

1a.7.5. How many and what type of study designs are included in the body of evidence? (*e.g., 3 randomized controlled trials and 1 observational study*)

There were 2 meta-analyses, 10 randomized controlled trials, 3 comparative studies, and 1 review paper supporting the ACE/ARB recommendations.

1a.7.6. What is the overall quality of evidence <u>across studies</u> in the body of evidence? (*discuss the certainty or confidence in the estimates of effect particularly in relation to study factors such as design flaws, imprecision due to small numbers, indirectness of studies to the measure focus or target population*)

There are many solid randomized controlled trials that show that the benefits of using any ACE or ARB greatly outweigh the harms.

ESTIMATES OF BENEFIT AND CONSISTENCY ACROSS STUDIES IN BODY OF EVIDENCE

1a.7.7. What are the estimates of benefit—magnitude and direction of effect on outcome(s) <u>across studies</u> in the body of evidence? (*e.g., ranges of percentages or odds ratios for improvement/ decline across studies, results of meta-analysis, and statistical significance*)

ACE inhibitors can reduce the risk of death and reduce hospitalization in HF*r*EF. The benefits of ACE inhibition were seen in patients with mild, moderate, or severe symptoms of HF and in patients with or without CAD.

In several placebo-controlled studies, long-term therapy with ARBs produced hemodynamic, neurohormonal, and clinical effects consistent with those expected after interference with the renin-angiotensin system. Reduced hospitalization and mortality have been demonstrated. ACE inhibitors remain the first choice for inhibition of the renin-angiotensin system in systolic HF, but ARBs can now be considered a reasonable alternative.

1a.7.8. What harms were studied and how do they affect the net benefit (benefits over harms)?

The majority of the adverse reactions of ACE inhibitors can be attributed to the 2 principal pharmacological actions of these drugs: those related to angiotensin suppression and those related to kinin potentiation. Other types of adverse effects may also occur (eg, rash and taste disturbances). Up to 20% of patients will experience an ACE inhibitor–induced cough. With the use of ACE inhibitors, particular care should be given to the patient's volume status, renal function, and concomitant medications (Sections 7.3.2.1 and 7.3.2.9). However, most HF patients (85% to 90%) can tolerate these drugs.

The risks of ARBs are attributed to suppression of angiotensin stimulation. These risks of hypotension, renal dysfunction, and hyperkalemia are greater when combined with another inhibitor of this neurohormonal axis, such as ACE inhibitors or aldosterone antagonists.

UPDATE TO THE SYSTEMATIC REVIEW(S) OF THE BODY OF EVIDENCE

1a.7.9. If new studies have been conducted since the systematic review of the body of evidence, provide for <u>each</u> new study: 1) citation, 2) description, 3) results, 4) impact on conclusions of systematic review.

The articles supporting the ACE and ARB recommendations were from 1993-2012. However, the overall literature search was through Oct, 2011, with select articles included through April, 2013.

We ran a search for Heart Failure and ACE ARB treatment for 2014 and 2015. There are only a few studies that are directly applicable to the target population; none would change the recommendation to use ACE/ARB therapy.

1a.8 OTHER SOURCE OF EVIDENCE

If source of evidence is NOT from a clinical practice guideline, USPSTF, or systematic review, please describe the evidence on which you are basing the performance measure.

1a.8.1 What process was used to identify the evidence?

1a.8.2. Provide the citation and summary for each piece of evidence.

1. Evidence, Performance Gap, Priority – Importance to Measure and Report
Extent to which the specific measure focus is evidence-based, important to making significant gains in healthcare quality, and improving health outcomes for a specific high-priority (high-impact) aspect of healthcare where there is variation in or overall less-than-optimal performance. ***Measures must be judged to meet all subcriteria to pass this criterion and be evaluated against the remaining criteria.***
1a. Evidence to Support the Measure Focus – See attached Evidence Submission Form NQF_measure_submission_evidence_HF_ACE_2.docx
1b. Performance Gap Demonstration of quality problems and opportunity for improvement, i.e., data demonstrating: • considerable variation, or overall less-than-optimal performance, in the quality of care across providers; and/or • disparities in care across population groups. 1b.1. **Briefly explain the rationale for this measure** *(e.g., the benefits or improvements in quality envisioned by use of this measure)* In the absence of contraindications, ACE inhibitors or ARBs are recommended for all patients with symptoms of heart failure and reduced left ventricular systolic function. ACE inhibitors remain the first choice for inhibition of the renin-angiotensin system in chronic heart failure, but ARBs can now be considered a reasonable alternative. Both pharmacologic agents have been shown to decrease the risk of death and hospitalization. Additional benefits of ACE inhibitors include the alleviation of symptoms and the improvement of clinical status and overall sense of well-being of patients with heart failure. Also, a 2011 analysis of IMPROVE HF data by Fonarow and colleagues revealed that all 4 current ACC/AHA HF outpatient performance measures were associated with decreased risk of 24-month mortality. For the 2 summary measures of HF care processes, there was also a strong positive association between greater conformity to the summary measures and improved risk-adjusted survival. These findings may have significant clinical and public health implications, providing evidence to suggest that current, and some emerging, outpatient process measures may effectively reflect the quality of care provided to patients with HF who are treated in outpatient practice settings.

1b.2. **Provide performance scores on the measure as specified (current and over time) at the specified level of analysis.** *(This is required for endorsement maintenance. Include mean, std dev, min, max, interquartile range, scores by decile. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities included). This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*
Data Source: 2013 is the most recent year for which PQRS Experience Report measure data is available. The average performance rates on Heart Failure (HF) – Angiotensin-Converting Enzyme (ACE) Inhibitor or Angiotensin Receptor Blocker (ARB) Therapy for Left Ventricular Systolic Dysfunction (LVSD) over the last several years are as follows:
2010: 85.6%
2011: 79.7%
2012: 82.2%
2013: 83.5%
2013 Small Group Practice Exception Rate: 1.3%
Reference: Center for Medicare and Medicaid Services. 2013 Reporting Experience Including Trends. Available: http://www.cms.gov/Medicare/Quality-Initiatives-Patient-Assessment-Instruments/PQRS/index.html?redirect=/PQRS/
*It is important to note that PQRS was a voluntary reporting program, with approximately 51% of eligible professionals participating using any reporting option in 2013, and performance rates may not be nationally representative.

1b.3. **If no or limited performance data on the measure as specified is reported in 1b2, then provide a summary of data from the literature that indicates opportunity for improvement or overall less than optimal performance on the specific focus of measurement.**
According to Fonarow and colleagues (2010), for aggregate practices at baseline, an ACEI/ARB was prescribed for 11 165 (79.8%) of 13 987 eligible patients.

Improving Evidence-Based Care for Heart Failure in Outpatient Cardiology Practices: Primary Results of the Registry to Improve the Use of Evidence-Based Heart Failure Therapies in the Outpatient Setting (IMPROVE HF). Circulation 2010; 122: 585-596. Published online before print July 26, 2010, doi: 10.1161/CIRCULATIONAHA.109.934471.

1b.4. **Provide disparities data from the measure as specified (current and over time) by population group, e.g., by race/ethnicity, gender, age, insurance status, socioeconomic status, and/or disability.** *(This is required for endorsement maintenance. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities include.) This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*
While this measure is included in several federal reporting programs, those programs have not yet made disparities data available for us to analyze and report.

1b.5. **If no or limited data on disparities from the measure as specified is reported in 1b4, then provide a summary of data from the literature that addresses disparities in care on the specific focus of measurement. Include citations.**
A 2011 study by Bagchi et al of the TRICARE program found that African Americans were less likely than whites to have received beta blockers and angiotensin-converting enzyme inhibitors or angiotensin receptor blockers following a CHF diagnosis (P<0.0001). Hispanics were, in some cases, equally likely as whites to receive pharmacological treatments for CHF. In multivariate models, there were no significant racial/ethnic differences in the odds of a potentially avoidable hospitalization (PAH); age greater than 65 was the most significant predictor of a PAH. This study suggests that although there are some racial and ethnic disparities in the receipt of pharmacological therapy for CHF among TRICARE beneficiaries, these differences do not translate into disparities in the likelihood of a PAH. The findings support previous research suggesting that equal access to care may mitigate racial/ethnic health disparities.

Bagchi AD, Stewart K, McLaughlin C, Higgins P, Croghan T. Treatment and outcomes for congestive heart failure by race/ethnicity in TRICARE. Med Care. 2011 May;49(5):489-95. doi: 10.1097/MLR.0b013e318207ef87.

1c. High Priority (previously referred to as High Impact)
The measure addresses:

- a specific national health goal/priority identified by DHHS or the National Priorities Partnership convened by NQF; OR

- a demonstrated high-priority (high-impact) aspect of healthcare (e.g., affects large numbers of patients and/or has a substantial impact for a smaller population; leading cause of morbidity/mortality; high resource use (current and/or future); severity of illness; and severity of patient/societal consequences of poor quality).

1c.1. Demonstrated high priority aspect of healthcare
Affects large numbers, A leading cause of morbidity/mortality, High resource use, Severity of illness
1c.2. If Other:

1c.3. Provide epidemiologic or resource use data that demonstrates the measure addresses a high priority aspect of healthcare. List citations in 1c.4.
Heart Failure affects over 5.7 million Americans (2.4% in 2008; 2.7% in 2010) and that number is expected to rise consistently over the next 15 years (Heidenreich et al 2011, Mozaffarian 2015), The AHA forecasting study predicts that total costs for heart failure in the 18-44 age group will increase from $1.51 billion to $2.48 billion, while the costs for the 65-79 age group will increase from $11.50 billion to $29.9 billion (Heidenreich et al 2011).

In a 2014 article, Storrow et al writes that heart failure results in nearly 1 million annual hospital stays (Go 2013, Chen 2011), and is the top reason for Medicare hospital readmissions (Jencks 2009, Dharmarajan 2013). The vast majority of patients hospitalized for acute heart failure (AHF) are originally evaluated and managed in the emergency department (ED). Prior data suggest more than 80% of ED patients with AHF are admitted to the hospital and have a median inpatient length of stay (LOS) of approximately 3.4 days. Of the $39.2 billion dollars spent on heart failure care in the United States in 2010, hospital stay was the single largest proportion of this expenditure (AHA 2010, Heidenreich 2011). Among Medicare beneficiaries, hospital stay accounts for more than 50% of all heart failure costs in the last 6 months of life (Blecker 2012). Despite a small decline in the AHF hospital stay rate among Medicare beneficiaries over the last decade (Go 2013, Chen 2011), mortality remains high (Chen 2011, Richardson 2002, Roger 2004) and uneven across

Storrow et al (2014) utilized Nationwide Emergency Department Sample AHF data from 2006 to 2010 to describe admission proportion, hospital length of stay (LOS), and ED charges as a surrogate for resource utilization. Results were compared across U.S. regions, patient insurance status, and hospital characteristics. They concluded that a very high proportion of ED patients with AHF are admitted nationally, with significant variation in disposition and procedural decisions based on region of the country and type of insurance, even after adjusting for potential confounding.

1c.5. IF a PRO-PM (e.g. HRQoL/functional status, symptom/burden, experience with care, health-related behaviors), provide evidence that the target population values the measured PRO and finds it meaningful. (Describe how and from whom their input was obtained.)

1c.5. **If a PRO-PM (e.g. HRQoL/functional status, symptom/burden, experience with care, health-related behaviors), provide evidence that the target population values the measured PRO and finds it meaningful.** *(Describe how and from whom their input was obtained.)*
Not applicable. Not a PRO-PM.

2. Reliability and Validity—Scientific Acceptability of Measure Properties

Extent to which the measure, as specified, produces consistent (reliable) and credible (valid) results about the quality of care when implemented. ***Measures must be judged to meet the subcriteria for both reliability and validity to pass this criterion and be evaluated against the remaining criteria.***

2a.1. Specifications The measure is well defined and precisely specified so it can be implemented consistently within and across organizations and allows for comparability. eMeasures should be specified in the Health Quality Measures Format (HQMF) and the Quality Data Model (QDM).

De.5. **Subject/Topic Area** *(check all the areas that apply):*
Cardiovascular, Cardiovascular : Congestive Heart Failure

De.6. **Cross Cutting Areas** *(check all the areas that apply):*

S.1. **Measure-specific Web Page** *(Provide a URL link to a web page specific for this measure that contains current detailed specifications including code lists, risk model details, and supplemental materials. Do not enter a URL linking to a home page or to general information.)*
Centers for Medicare & Medicaid Services (CMS) eCQM Library webpage at: http://www.cms.gov/Regulations-and-Guidance/Legislation/EHRIncentivePrograms/eCQM_Library.html Value set details at VSAC webpage: https://vsac.nlm.nih.gov

S.2a. **If this is an eMeasure**, HQMF specifications must be attached. Attach the zipped output from the eMeasure authoring tool (MAT) - if the MAT was not used, contact staff. (Use the specification fields in this online form for the plain-language description of the specifications)
This is an eMeasure **Attachment:** EP_CMS135v4_NQF0081_HF_ACEARB.zip

S.2b. **Data Dictionary, Code Table, or Value Sets** *(and risk model codes and coefficients when applicable) must be attached. (Excel or csv file in the suggested format preferred - if not, contact staff)*
Attachment **Attachment:** 0081_AMAPCPI_HF-ACEARB_ValueSets_June2015-635712727320959997.xlsx

S.3. **For endorsement maintenance**, please briefly describe any changes to the measure specifications since last endorsement date and explain the reasons.
Supporting guidelines and coding value sets included in the measure are reviewed on an annual basis. This annual review resulted in very limited changes to adhere to current eCQM industry standards and preserve the original measure intent.

S.4. **Numerator Statement** *(Brief, narrative description of the measure focus or what is being measured about the target population, i.e., cases from the target population with the target process, condition, event, or outcome)*
IF an OUTCOME MEASURE, state the outcome being measured. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
Patients who were prescribed* ACE inhibitor or ARB therapy either within a 12 month period when seen in the outpatient setting or

at hospital discharge

*Prescribed may include:
Outpatient setting: prescription given to the patient for ACE inhibitor or ARB therapy at one or more visits in the measurement period OR patient already taking ACE inhibitor or ARB therapy as documented in current medication list
Inpatient setting: prescription given to the patient for ACE inhibitor or ARB therapy at discharge OR ACE inhibitor or ARB therapy to be continued after discharge as documented in the discharge medication list

S.5. **Time Period for Data** *(What is the time period in which data will be aggregated for the measure, e.g., 12 mo, 3 years, look back to August for flu vaccination? Note if there are different time periods for the numerator and denominator.)*
At least once during the 12 consecutive month measurement period when seen in the outpatient setting OR at each hospital discharge during the 12 consecutive month measurement period if seen in the inpatient setting.

S.6. **Numerator Details** *(All information required to identify and calculate the cases from the target population with the target process, condition, event, or outcome such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
IF an OUTCOME MEASURE, describe how the observed outcome is identified/counted. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
For EHR:
HQMF eMeasure developed and is included in this submission.

For Registry:
Definitions:
Prescribed – Outpatient setting: May include prescription given to the patient for ACE inhibitor or ARB therapy at one or more visits in the measurement period OR patient already taking ACE inhibitor or ARB therapy as documented in current medication list.
Prescribed – Inpatient setting: May include prescription given to the patient for ACE inhibitor or ARB therapy at discharge OR ACE inhibitor or ARB therapy to be continued after discharge as documented in the discharge medication list.

Report CPT Category II Code, 4010F : Angiotensin converting enzyme (ACE) inhibitor or angiotensin receptor blocker (ARB) therapy prescribed or currently being taken

S.7. **Denominator Statement** *(Brief, narrative description of the target population being measured)*
All patients aged 18 years and older with a diagnosis of heart failure with a current or prior LVEF < 40%

S.8. **Target Population Category** *(Check all the populations for which the measure is specified and tested if any):*

S.9. **Denominator Details** *(All information required to identify and calculate the target population/denominator such as definitions, specific data collection items/responses , code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
For EHR:
HQMF eMeasure developed and is included in this submission.

DENOMINATOR DEFINITION:
LVEF < 40% corresponds to qualitative documentation of moderate dysfunction or severe dysfunction.

DENOMINATOR NOTES:
To meet this measure, it must be reported for all heart failure patients a minimum of once during the measurement period when seen in the outpatient setting AND reported at each hospital discharge during the measurement period.

The requirement of “Count >=2 of Encounter, Performed“ is to establish that the eligible professional has an existing relationship with the patient.

For Registry:
Option 1, Outpatient Setting:
Patients aged >= 18 years
AND
Diagnosis for heart failure (ICD-9-CM) [for use 1/1/2015-9/30/2015]: 402.01, 402.11, 402.91, 404.01, 404.03, 404.11, 404.13, 404.91, 404.93, 428.0, 428.1, 428.20, 428.21, 428.22, 428.23, 428.30, 428.31, 428.32, 428.33, 428.40, 428.41, 428.42, 428.43, 428.9
Diagnosis for heart failure (ICD-10-CM) [for use 10/01/2015-12/31/2015]: I11.0, I13.0, I13.2, I50.1, I50.20, I50.21, I50.22, I50.23, I50.30, I50.31, I50.32, I50.33, I50.40, I50.41, I50.42, I50.43, I50.9
AND
Patient encounter(s) during reporting period (CPT): 99201, 99202, 99203, 99204, 99205, 99212, 99213, 99214, 99215, 99304, 99305, 99306, 99307, 99308, 99309, 99310, 99324, 99325, 99326, 99327, 99328, 99334, 99335, 99336, 99337, 99341, 99342, 99343, 99344, 99345, 99347, 99348, 99349, 99350
AND
Two Denominator Eligible Visits
AND
Left ventricular ejection fraction (LVEF) < 40% or documentation of moderately or severely depressed left ventricular systolic function: 3021F

Option 2, Inpatient Setting:
Patients aged >= 18 years
AND
Diagnosis for heart failure (ICD-9-CM) [for use 1/1/2015-9/30/2015]: 402.01, 402.11, 402.91, 404.01, 404.03, 404.11, 404.13, 404.91, 404.93, 428.0, 428.1, 428.20, 428.21, 428.22, 428.23, 428.30, 428.31, 428.32, 428.33, 428.40, 428.41, 428.42, 428.43, 428.9
Diagnosis for heart failure (ICD-10-CM) [for use 10/01/2015-12/31/2015]: I11.0, I13.0, I13.2, I50.1, I50.20, I50.21, I50.22, I50.23, I50.30, I50.31, I50.32, I50.33, I50.40, I50.41, I50.42, I50.43, I50.9
AND
Patient encounter during reporting period (CPT): 99238, 99239
AND
Left ventricular ejection fraction (LVEF) < 40% or documentation of moderately or severely depressed left ventricular systolic function: 3021F

S.10. **Denominator Exclusions** *(Brief narrative description of exclusions from the target population)*
Documentation of medical reason(s) for not prescribing ACE inhibitor or ARB therapy (eg, hypotensive patients who are at immediate risk of cardiogenic shock, hospitalized patients who have experienced marked azotemia, allergy, intolerance, other medical reasons)
Documentation of patient reason(s) for not prescribing ACE inhibitor or ARB therapy (eg, patient declined, other patient reasons)
Documentation of system reason(s) for not prescribing ACE inhibitor or ARB therapy (eg, other system reasons)

S.11. **Denominator Exclusion Details** *(All information required to identify and calculate exclusions from the denominator such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
Exceptions are used to remove a patient from the denominator of a performance measure when the patient does not receive a therapy or service AND that therapy or service would not be appropriate due to patient-specific reasons. The patient would otherwise meet the denominator criteria. Exceptions are not absolute, and are based on clinical judgment, individual patient characteristics, or patient preferences. This measure was developed using PCPI exception methodology which uses three categories of reasons for which a patient may be removed from the denominator of an individual measure. These measure exception categories are not uniformly relevant across all measures; for each measure, there must be a clear rationale to permit an exception for a medical, patient, or system reason. Examples are provided in the measure exception language of instances that may constitute an exception and are intended to serve as a guide to clinicians. For measure : Angiotensin-Converting Enzyme (ACE) Inhibitor or Angiotensin Receptor Blocker (ARB) Therapy for Left Ventricular Systolic Dysfunction, exceptions may include medical reasons (e.g. hypotensive patients who are at immediate risk of cardiogenic shock, hospitalized patients who have experienced marked azotemia), patient, and/or system reasons for not prescribing an ACE/ARB. Where examples of exceptions are included in the measure language, value sets for these examples are developed and included in the eSpecifications. Although this methodology does not require the external reporting of more detailed exception data, the PCPI recommends that physicians document the specific reasons for exception in patients' medical records for purposes of optimal patient management and audit-readiness. The

PCPI also advocates the systematic review and analysis of each physician's exceptions data to identify practice patterns and opportunities for quality improvement.

Additional details by data source are as follows:

For EHR:
HQMF eMeasure developed and is included in this submission.

For Registry:
Append a modifier to CPT Category II Code:
4010F-1P : Documentation of medical reason(s) for not prescribing angiotensin converting enzyme (ACE) inhibitor or angiotensin receptor blocker (ARB) therapy (eg, hypotensive patients who are at immediate risk of cardiogenic shock, hospitalized patients who have experienced marked azotemia, allergy, intolerance, other medical reasons)

4010F-2P : Documentation of patient reason(s) for not prescribing angiotensin converting enzyme (ACE) inhibitor or angiotensin receptor blocker (ARB) therapy (eg, patient declined, other patient reasons)

4010F-3P : Documentation of system reason(s) for not prescribing angiotensin converting enzyme (ACE) inhibitor or angiotensin receptor blocker (ARB) therapy (eg, other system reasons)

S.12. Stratification Details/Variables *(All information required to stratify the measure results including the stratification variables, definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format with at S.2b)*
Consistent with CMS' Measures Management System Blueprint and recent national recommendations put forth by the IOM and NQF to standardize the collection of race and ethnicity data, we encourage the results of this measure to be stratified by race, ethnicity, administrative sex, and payer and have included these variables as recommended data elements to be collected.

S.13. Risk Adjustment Type (Select type. Provide specifications for risk stratification in S.12 and for statistical model in S.14-15)
No risk adjustment or risk stratification
If other:

S.14. Identify the statistical risk model method and variables *(Name the statistical method - e.g., logistic regression and list all the risk factor variables. Note - risk model development and testing should be addressed with measure testing under Scientific Acceptability)*
No risk adjustment or risk stratification

S.15. Detailed risk model specifications *(must be in attached data dictionary/code list Excel or csv file. Also indicate if available at measure-specific URL identified in S.1.)*
Note: Risk model details (including coefficients, equations, codes with descriptors, definitions), should be provided on a separate worksheet in the suggested format in the Excel or csv file with data dictionary/code lists at S.2b.

S.15a. Detailed risk model specifications (*if not provided in excel or csv file at S.2b*)

S.16. Type of score:
Rate/proportion
If other:

S.17. Interpretation of Score *(Classifies interpretation of score according to whether better quality is associated with a higher score, a lower score, a score falling within a defined interval, or a passing score)*
Better quality = Higher score

S.18. Calculation Algorithm/Measure Logic *(Describe the calculation of the measure score as an ordered sequence of steps including identifying the target population; exclusions; cases meeting the target process, condition, event, or outcome; aggregating data; risk adjustment; etc.)*
To calculate performance rates:

1. Find the patients who meet the initial population (ie, the general group of patients that a set of performance measures is designed to address).
2. From the patients within the initial population criteria, find the patients who qualify for the denominator (ie, the specific group of patients for inclusion in a specific performance measure based on defined criteria). Note: in some cases the initial population and denominator are identical.
3. From the patients within the denominator, find the patients who meet the numerator criteria (ie, the group of patients in the denominator for whom a process or outcome of care occurs). Validate that the number of patients in the numerator is less than or equal to the number of patients in the denominator
4. From the patients who did not meet the numerator criteria, determine if the provider has documented that the patient meets any criteria for exception when denominator exceptions have been specified [for this measure: Documentation of medical reason(s) for not prescribing ACE inhibitor or ARB therapy (eg, hypotensive patients who are at immediate risk of cardiogenic shock, hospitalized patients who have experienced marked azotemia); Documentation of patient reason(s) for not prescribing ACE inhibitor or ARB therapy; Documentation of system reason(s) for not prescribing ACE inhibitor or ARB therapy. If the patient meets any exception criteria, they should be removed from the denominator for performance calculation. --Although the exception cases are removed from the denominator population for the performance calculation, the exception rate (ie, percentage with valid exceptions) should be calculated and reported along with performance rates to track variations in care and highlight possible areas of focus for QI.

If the patient does not meet the numerator and a valid exception is not present, this case represents a quality failure.

S.19. **Calculation Algorithm/Measure Logic Diagram URL or Attachment** *(You also may provide a diagram of the Calculation Algorithm/Measure Logic described above at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
No diagram provided

S.20. **Sampling** *(If measure is based on a sample, provide instructions for obtaining the sample and guidance on minimum sample size.)*
IF a PRO-PM, identify whether (and how) proxy responses are allowed.
Not applicable. The measure is not based on a sample.

S.21. **Survey/Patient-reported data** *(If measure is based on a survey, provide instructions for conducting the survey and guidance on minimum response rate.)*
IF a PRO-PM, specify calculation of response rates to be reported with performance measure results.
Not applicable. The measure is not based on a survey.

S.22. **Missing data** (specify how missing data are handled, e.g., imputation, delete case.)
Required for Composites and PRO-PMs.
Patient eligibility is determined by a set of defined criteria relevant to a particular measure. If data required to determine patient eligibility are missing, those patients/cases would be ineligible for inclusion in the denominator and therefore the patient/case would be deleted.

If data required to determine if a denominator eligible patient qualifies for the numerator (or has a valid exclusion/exception) are missing, this case would represent a quality failure.

S.23. **Data Source** *(Check ONLY the sources for which the measure is SPECIFIED AND TESTED).*
If other, please describe in S.24.
Electronic Clinical Data, Electronic Clinical Data : Electronic Health Record, Electronic Clinical Data : Registry

S.24. **Data Source or Collection Instrument** *(Identify the specific data source/data collection instrument e.g. name of database, clinical registry, collection instrument, etc.)*
IF a PRO-PM, identify the specific PROM(s); and standard methods, modes, and languages of administration.
not applicable

S.25. **Data Source or Collection Instrument** *(available at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
No data collection instrument provided

S.26. **Level of Analysis** *(Check ONLY the levels of analysis for which the measure is SPECIFIED AND TESTED)*

Clinician : Group/Practice, Clinician : Individual

S.27. **Care Setting** *(Check ONLY the settings for which the measure is SPECIFIED AND TESTED)*
Ambulatory Care : Clinician Office/Clinic, Home Health, Hospital/Acute Care Facility, Other, Post Acute/Long Term Care Facility : Long Term Acute Care Hospital, Post Acute/Long Term Care Facility : Nursing Home/Skilled Nursing Facility
If other: Domiciliary

S.28. **COMPOSITE Performance Measure** - Additional Specifications *(Use this section as needed for aggregation and weighting rules, or calculation of individual performance measures if not individually endorsed.)*
Not applicable. The measure is not a composite.

2a. Reliability – See attached Measure Testing Submission Form
2b. Validity – See attached Measure Testing Submission Form
NQF_0081_Heart_Failure_-HF-_-_Angiotensin-Converting_Enzyme_Inhibitor_or_ARB_Therapy_for_LVSD_Testing_Attachment.docx

NATIONAL QUALITY FORUM—Measure Testing (subcriteria 2a2, 2b2-2b6)

Measure Title: Heart Failure (HF) – Angiotensin-Converting Enzyme (ACE) Inhibitor or Angiotensin Receptor Blocker (ARB) Therapy for Left Ventricular Systolic Dysfunction (LVSD)
Date of Submission: Click here to enter a date

Type of Measure:

☐ Composite – ***STOP – use composite testing form***	☐ Outcome (*including PRO-PM*)
☐ Cost/resource	☒ Process
☐ Efficiency	☐ Structure

Instructions

- Measures must be tested for all the data sources and levels of analyses that are specified. ***If there is more than one set of data specifications or more than one level of analysis, contact NQF staff*** about how to present all the testing information in one form.
- **For all measures, sections 1, 2a2, 2b2, 2b3, and 2b5 must be completed.**
- **For outcome and resource use measures**, section **2b4** also must be completed.
- If specified for **multiple data sources/sets of specificaitons** (e.g., claims and EHRs), section **2b6** also must be completed.
- Respond to all questions as instructed with answers immediately following the question. All information on testing to demonstrate meeting the subcriteria for reliability (2a2) and validity (2b2-2b6) must be in this form. An appendix for *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 20 pages (*incuding questions/instructions;* minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the testing results for this measure meet NQF's evaluation criteria for testing.

2a2. Reliability testing [10] demonstrates the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is

precise.

2b2. Validity testing [11] demonstrates that the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality.

2b3. Exclusions are supported by the clinical evidence; otherwise, they are supported by evidence of sufficient frequency of occurrence so that results are distorted without the exclusion; [12]

AND

If patient preference (e.g., informed decision making) is a basis for exclusion, there must be evidence that the exclusion impacts performance on the measure; in such cases, the measure must be specified so that the information about patient preference and the effect on the measure is transparent (e.g., numerator category computed separately, denominator exclusion category computed separately). [13]

2b4. For outcome measures and other measures when indicated (e.g., resource use):

- **an evidence-based risk-adjustment strategy** (e.g., risk models, risk stratification) is specified; is based on patient factors that influence the measured outcome (but not factors related to disparities in care or the quality of care) and are present at start of care; [14,15] and has demonstrated adequate discrimination and calibration

OR

- rationale/data support no risk adjustment/ stratification.

2b5. Data analysis of computed measure scores demonstrates that methods for scoring and analysis of the specified measure allow for **identification of statistically significant and practically/clinically meaningful** [16] **differences in performance**;

OR

there is evidence of overall less-than-optimal performance.

2b6. If multiple data sources/methods are specified, there is demonstration they produce comparable results.

Notes

10. Reliability testing applies to both the data elements and computed measure score. Examples of reliability testing for data elements include, but are not limited to: inter-rater/abstractor or intra-rater/abstractor studies; internal consistency for multi-item scales; test-retest for survey items. Reliability testing of the measure score addresses precision of measurement (e.g., signal-to-noise).

11. Validity testing applies to both the data elements and computed measure score. Validity testing of data elements typically analyzes agreement with another authoritative source of the same information. Examples of validity testing of the measure score include, but are not limited to: testing hypotheses that the measures scores indicate quality of care, e.g., measure scores are different for groups known to have differences in quality assessed by another valid quality measure or method; correlation of measure scores with another valid indicator of quality for the specific topic; or relationship to conceptually related measures (e.g., scores on process measures to scores on outcome measures). Face validity of the measure score as a quality indicator may be adequate if accomplished through a systematic and transparent

process, by identified experts, and explicitly addresses whether performance scores resulting from the measure as specified can be used to distinguish good from poor quality.

12. Examples of evidence that an exclusion distorts measure results include, but are not limited to: frequency of occurrence, variability of exclusions across providers, and sensitivity analyses with and without the exclusion.

13. Patient preference is not a clinical exception to eligibility and can be influenced by provider interventions.

14. Risk factors that influence outcomes should not be specified as exclusions.

15. Risk models should not obscure disparities in care for populations by including factors that are associated with differences/inequalities in care, such as race, socioeconomic status, or gender (e.g., poorer treatment outcomes of African American men with prostate cancer or inequalities in treatment for CVD risk factors between men and women). It is preferable to stratify measures by race and socioeconomic status rather than to adjust out the differences.

16. With large enough sample sizes, small differences that are statistically significant may or may not be practically or clinically meaningful. The substantive question may be, for example, whether a statistically significant difference of one percentage point in the percentage of patients who received smoking cessation counseling (e.g., 74 percent v. 75 percent) is clinically meaningful; or whether a statistically significant difference of $25 in cost for an episode of care (e.g., $5,000 v. $5,025) is practically meaningful. Measures with overall less-than-optimal performance may not demonstrate much variability across providers.

1. DATA/SAMPLE USED FOR ALL TESTING OF THIS MEASURE

Often the same data are used for all aspects of measure testing. In an effort to eliminate duplication, the first five questions apply to all measure testing. If there are differences by aspect of testing,(e.g., reliability vs. validity) be sure to indicate the specific differences in question 1.7.

1.1. What type of data was used for testing? (*Check all the sources of data identified in the measure specifications and data used for testing the measure. Testing must be provided for all the sources of data specified and intended for measure implementation.* ***If different data sources are used for the numerator and denominator, indicate N [numerator] or D [denominator] after the checkbox.***)

Measure Specified to Use Data From: (***must be consistent with data sources entered in S.23***)	**Measure Tested with Data From:**
☐ abstracted from paper record	☐ abstracted from paper record
☐ administrative claims	☐ administrative claims
☒ clinical database/registry	☒ clinical database/registry
☒ abstracted from electronic health record	☒ abstracted from electronic health record
☒ eMeasure (HQMF) implemented in EHRs	☒ eMeasure (HQMF) implemented in EHRs
☐ other: Click here to describe	☐ other: Click here to describe

1.2. If an existing dataset was used, identify the specific dataset (*the dataset used for testing must be consistent with the measure specifications for target population and healthcare entities being measured; e.g., Medicare Part A claims, Medicaid claims, other commercial insurance, nursing home MDS, home health OASIS, clinical registry*).

Data 1 (EHR - Validity Against the Gold Standard)

The data source is EHR data.

Bonnie Patient Test Deck

As a supplement to the EHR reliability testing performed on this measure, a deck of patient test cases have been developed and a summary of the details has been included as part of the feasibility attachment in section 3b.3 of the measure submission form.

Data 2 (GPRO Registry)

The data source is the Centers for Medicare & Medicaid Services (CMS) PQRS GPRO database.

Data 3 (EHR – Exceptions Analysis)

The data source is EHR data.

1.3. What are the dates of the data used in testing?

Data 1 (EHR - Validity Against the Gold Standard)

The data are collected from patients sampled from 2007.

Data 2 (GPRO Registry)

The data are for the time period January 2013 – December 2013, and cover the entire United States.

Data 3 (EHR – Exceptions Analysis)

The data are collected from patients sampled from 2009.

1.4. What levels of analysis were tested? (*testing must be provided for all the levels specified and intended for measure implementation, e.g., individual clinician, hospital, health plan*)

Measure Specified to Measure Performance of: (***must be consistent with levels entered in item S.26***)	**Measure Tested at Level of:**
☒ individual clinician	☒ individual clinician
☒ group/practice	☒ group/practice
☐ hospital/facility/agency	☐ hospital/facility/agency
☐ health plan	☐ health plan
☐ other: Click here to describe	☐ other: Click here to describe

1.5. How many and which measured entities were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of measured entities included in the analysis (e.g., size, location, type); if a sample was used, describe how entities were selected for inclusion in the sample*)

Data 1 (EHR - Validity Against the Gold Standard)

The data sample came from an academic general internal medicine clinic with several years of experience using a commercial EHR.

Data 2 (GPRO Registry)

For this measure, the minimum number of observations for inclusion in signal-to-noise reliability testing was 10 events. Given the structure of the PQRS program, a physician may choose to submit or not submit to PQRS. Since these data contain results on a large number of physicians, limiting the reliability analysis to only those physicians who are participating in the program will eliminate the bias introduced by the inclusion of from physicians who are in the data, but are not submitting to PQRS.

Data 2 (GPRO Registry)

The total number of physicians reporting on this measure is 3,728. Of those, 1,244 physicians had all the required data elements and met the minimum number of quality reporting events (10) for inclusion in the reliability analysis. For this measure, 33.4 percent of physicians are included in the analysis, and the average number of quality reporting events is 31.5 for a total of 39,242 events. The range of quality reporting events for 1,244 physicians included is from 319 to 10. The average number of quality reporting events for the remaining 66.6 percent of physicians who aren't included is 3.2.

Data 3 (EHR – Exceptions Analysis)

The data sample came from five physician offices using five different EHR systems.

1.6. How many and which patients were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of patients included in the analysis (e.g., age, sex, race, diagnosis); if a sample was used, describe how patients were selected for inclusion in the sample*)

Data 1 (EHR - Validity Against the Gold Standard)

The sample consisted of approximately 254 charts for a total of 254 eligible patients. One trained investigator reviewed the 254 charts. The patients were selected using random sampling.

Data 2 (GPRO Registry)

There were 39,242 patients included in this testing and analysis. These were the patients that were associated with physicians who had 10 or more patients eligible for this measure.

Data 3 (EHR – Exceptions Analysis)

The sample consisted of approximately 127 eligible patients.

1.7. If there are differences in the data or sample used for different aspects of testing (e.g., reliability, validity, exclusions, risk adjustment), identify how the data or sample are different for each aspect of testing reported below.

Data 1 (EHR - Validity Against the Gold Standard)

The data sample was used for the purposes of reliability and validity testing.

Data 2 (GPRO Registry)

The same data sample was used for reliability testing and exceptions analysis.

Face Validity (Data 2)

After the measure was fully specified, an expert panel of 12 members was asked to rate their agreement with the following statement:

The scores obtained from the measure as specified will provide an accurate reflection of quality and can be used to distinguish good and poor quality.

Data 3 (EHR – Exceptions Analysis)

The data sample was used for the exception analysis only.

1.8. What were the patient-level sociodemographic (SDS) variables that were available and analyzed in the data or sample used? For example, patient-reported data (e.g., income, education, language), proxy variables when SDS data are not collected from each patient (e.g. census tract), or patient community characteristics (e.g. percent vacant housing, crime rate).

Data 1 (EHR - Validity Against the Gold Standard)

Patient-level socio-demographic (SDS) variables were not captured as part of the testing.

Data 2 (GPRO Registry)

Patient-level socio-demographic (SDS) variables were not captured as part of the testing.

2a2. RELIABILITY TESTING

***Note**: If accuracy/correctness (validity) of data elements was empirically tested, separate reliability testing of data elements is not required – in 2a2.1 check critical data elements; in 2a2.2 enter "see section 2b2 for validity testing of data elements"; and skip 2a2.3 and 2a2.4.*

2a2.1. What level of reliability testing was conducted? (*may be one or both levels*)
☒ **Critical data elements used in the measure** (*e.g., inter-abstractor reliability; data element reliability must address ALL critical data elements*)
☒ **Performance measure score** (e.g., *signal-to-noise analysis*)

2a2.2. For each level checked above, describe the method of reliability testing and what it tests (*describe the steps—do not just name a method; what type of error does it test; what statistical analysis was used*)

Data 1 (EHR - Validity Against the Gold Standard)

See 2b2.2 for Validity Against the Gold Standard Results

Data 2 (Signal-to-Noise Reliability)

Reliability of the computed measure score was measured as the ratio of signal to noise. The signal in this case is the proportion of the variability in measured performance that can be explained by real differences in physician performance. Reliability at the level of the specific physician is given by:

Reliability = Variance (physician-to-physician) / [Variance (physician-to-physician) + Variance (physician-specific-error]

Reliability is the ratio of the physician-to-physician variance divided by the sum of the physician-to-physician variance plus the error variance specific to a physician. A reliability of zero implies that all the variability in a measure is attributable to measurement error. A reliability of one implies that all the variability is attributable to real differences in physician performance.

Reliability testing was performed by using a beta-binomial model. The beta-binomial model assumes the physician performance score is a binomial random variable conditional on the physician's true value that comes from the beta distribution. The beta distribution is usually defined by two parameters, alpha and beta. Alpha and beta can be thought of as intermediate calculations to get to the needed variance estimates.

Reliability is estimated at two different points, at the minimum number of quality reporting events for the measure and at the mean number of quality reporting events per physician.

2a2.3. For each level checked above, what were the statistical results from reliability testing? (e.g., *percent agreement and kappa for the critical data elements; distribution of reliability statistics from a signal-to-noise analysis*)

Data 1 (EHR - Validity Against the Gold Standard)

See 2b2.3 for Validity Against the Gold Standard Results

Data 2 (GPRO Registry)

For this measure, the reliability at the minimum level of quality reporting events (10) was 0.83. The average number of quality reporting events for physicians included is 31.5. The reliability at the average number of quality reporting events was 0.94.

2a2.4 What is your interpretation of the results in terms of demonstrating reliability? *(i.e., what do the results mean and what are the norms for the test conducted?)*

Data 1 (EHR - Validity Against the Gold Standard)

See 2b2.4 for Validity Against the Gold Standard Results

Data 2 (GPRO Registry)

This measure has high reliability when evaluated at the minimum level of quality reporting events and high reliability at the average number of quality events.

2b2. VALIDITY TESTING

2b2.1. What level of validity testing was conducted? (*may be one or both levels*)

☒ **Critical data elements** (*data element validity must address ALL critical data elements*)

☒ **Performance measure score**

☐ **Empirical validity testing**

☒ **Systematic assessment of face validity of performance measure score as an indicator** of quality or resource use (*i.e., is an accurate reflection of performance on quality or resource use and can distinguish good from poor performance*)

2b2.2. For each level checked above, describe the method of validity testing and what it tests (*describe the steps—do not just name a method; what was tested, e.g., accuracy of data elements compared to authoritative source, relationship to another measure as expected; what statistical analysis was used)*

Data 1 (EHR - Validity Against the Gold Standard)

Data abstracted from randomly sampled patient records were used to evaluate parallel forms reliability for the measure. Charts for abstraction were selected for patients aged 18 years and older with heart failure.

Face Validity (Data 2)

Face validity of the measure score as an indicator of quality was systematically assessed as follows.

After the measure was fully specified, the expert panel was asked to rate their agreement with the following statement:

The scores obtained from the measure as specified will provide an accurate reflection of quality and can be used to distinguish good and poor quality.

Scale 1-5, where 1= Strongly Disagree; 3= Neither Agree nor Disagree; 5= Strongly Agree

2b2.3. What were the statistical results from validity testing? (*e.g., correlation; t-test*)

Data 1 (EHR - Validity Against the Gold Standard)

Of the 254 patients sampled, automated EHR review detected 217 (85.4%) with an active electronic prescription for an ACE inhibitor or ARB. Of the remaining 37 patients, 23(62.2%) met one or more of the exclusion criteria. Performance on the ACE inhibitor and ARB quality measure was 93.9% by using automated EHR review.

Among the 14 patients without an active prescription for an ACE inhibitor or an ARB in the EHR, manual review of clinicians' notes in the EHR revealed that 5 patients had been prescribed an ACE inhibitor or ARB that was not recorded in the medication list. Six patients were found to have exclusion criteria through manual chart review. In addition, two patients met the exclusion criteria on automated review, but upon manual review, the exceptions were found to be false.

Performance on the measure was calculated to be 98.7% through comparison of automated and manual EHR review.

Face Validity (Data 2)

Our expert panel included 12 members. Panel members were comprised of experts from the AMA-PCPI Measure Advisory Committee. The list of expert panel members is as follows:

Amy Sanders, MD, MS

David Seidenwurm, MD

Dianne V. Jewell, PT, DPT, PhD, CCS, FAACVPR

Janet Sullivan, MD
John Easa, MD, FIPP

Joseph P. Drozda, Jr., MD, FACC

Mark Metersky, MD

Martha J. Radford, MD, FACC, FAHA

Michael O'Dell, MD, MS, MSHA, FAAFP

Richard Bankowitz, MD, MBA, FACP

Scott T. MacDonald, MD

Shannon Sims, MD, PhD

2b2.4. What is your interpretation of the results in terms of demonstrating validity? (i.*e., what do the results mean and what are the norms for the test conducted?*)

Data 1 (EHR - Validity Against the Gold Standard)

The automated quality assessment had a sensitivity of 97.7% for identifying patients with heart failure taking an ACE inhibitor or ARB. The automated quality assessment captured 21 of 29 patients with valid exclusion criteria (sensitivity, 72.4%), and 2 of 23 patients who met exclusion criteria were judged not to have a true exclusion.

Data 2 (GPRO Registry - Face Validity)

The results of the expert panel rating of the validity statement were as follows: N = 12; Mean rating = 4.33 and 100% of respondents either agree or strongly agree that this measure can accurately distinguish good and poor quality.

Frequency Distribution of Ratings

1 – 0 responses (Strongly Disagree)

2 – 0 responses

3 – 0 responses (Neither Agree nor Disagree)

4 – 8 responses

5 – 4 responses (Strongly Agree)

2b3. EXCLUSIONS ANALYSIS

NA ☐ no exclusions — *skip to section 2b4*

2b3.1. Describe the method of testing exclusions and what it tests (*describe the steps—do not just name a method; what was tested, e.g., whether exclusions affect overall performance scores; what statistical analysis was used*)

Data 1 (EHR - Validity Against the Gold Standard)

This data sample was not used to test exclusions.

Data 2 (GPRO Registry)

With the information available from the GPRO Registry, we are unable to determine the type of exception reported. However, the exceptions data captured were analyzed to determine frequency and variability across providers.

Data 3 (EHR-Exceptions Analysis)

Exceptions included documentation of medical reason(s), patient reason(s) and system reason(s) for not prescribing ACE inhibitor or ARB therapy. Exceptions were analyzed for frequency and variability across providers.

2b3.2. What were the statistical results from testing exclusions? (*include overall number and percentage of individuals excluded, frequency distribution of exclusions across measured entities, and impact on performance*

measure scores)

Data 1 (EHR - Validity Against the Gold Standard)

This data sample was not used to test exclusions.

Data 2 (GPRO Registry)

Amongst the 1244 physicians with the minimum (10) number of quality reporting events, there were a total of 8,056 exceptions reported. The average number of exceptions per physician in this sample is 6.5. The overall exception rate is 17.03%.

Data 3 (EHR-Exceptions Analysis)

Reported exceptions were validated upon manual review of the medical record, against an a priori list generated by expert opinion. Measure exceptions were validated 95.32% of the time. Review of the 127 exceptions revealed 99.5% of exceptions were medical reasons for not prescribing ACE inhibitor or ARB therapy. Medical reason exceptions consisted of clinical contraindications, drug allergy and drug intolerance.

2b3.3. What is your interpretation of the results in terms of demonstrating that exclusions are needed to prevent unfair distortion of performance results? (*i.e., the value outweighs the burden of increased data collection and analysis. Note: **If patient preference is an exclusion**, the measure must be specified so that the effect on the performance score is transparent, e.g., scores with and without exclusion*)

Exceptions are necessary to account for those situations when it is not medically appropriate to prescribe ACE inhibitor or ARB therapy. Exceptions are discretionary and the methodology used for measure exception categories are not uniformly relevant across all measures; for this measure, there is a clear rationale to permit an exception for medical, patient or system reasons. Rather than specifying an exhaustive list of explicit medical, patient or system reasons for exception for each measure, the measure developer relies on clinicians to link the exception with a specific reason for the decision not to prescribe ACE inhibitor or ARB therapy required by the measure.

Some have indicated concerns with exception reporting including the potential for physicians to inappropriately exclude patients to enhance their performance statistics. Research has indicated that levels of exception reporting occur infrequently and are generally valid (Doran et al., 2008), (Kmetik et al., 2011). Furthermore, exception reporting has been found to have substantial benefits: "it is precise, it increases acceptance of [pay for performance] programs by physicians, and it ameliorates perverse incentives to refuse care to "difficult" patients." (Doran et al., 2008).

Although this methodology does not require the external reporting of more detailed exception data, the measure developer recommends that physicians document the specific reasons for exception in patients' medical records for purposes of optimal patient management and audit-readiness. We also advocate for the systematic review and analysis of each physician's exceptions data to identify practice patterns and opportunities for quality improvement.

Without exceptions, the performance rate would not accurately reflect the true performance of that physician. This would result in an increase in performance failures and false negatives. The additional value of increased data collection of capturing an exception greatly outweighs the reporting burden.

2b4. RISK ADJUSTMENT/STRATIFICATION FOR OUTCOME OR RESOURCE USE MEASURES
If not an intermediate or health outcome, or PRO-PM, or resource use measure, skip to section 2b5.

2b4.1. What method of controlling for differences in case mix is used?

☒ **No risk adjustment or stratification**

☐ **Statistical risk model with** Click here to enter number of factors **risk factors**

☐ **Stratification by** Click here to enter number of categories **risk categories**

☐ **Other,** Click here to enter description

2b4.2. If an outcome or resource use measure is not risk adjusted or stratified, provide rationale and analyses to demonstrate that controlling for differences in patient characteristics (case mix) is not needed to achieve fair comparisons across measured entities.

Not applicable

2b4.3. Describe the conceptual/clinical and statistical methods and criteria used to select patient factors used in the statistical risk model or for stratification by risk (*e.g., potential factors identified in the literature and/or expert panel; regression analysis; statistical significance of p<0.10; correlation of x or higher; patient factors should be present at the start of care and not related to disparities*)

Not applicable

2b4.4a. What were the statistical results of the analyses used to select risk factors?

Not applicable

2b4.4b. Describe the method of testing/analysis used to develop and validate the adequacy of the statistical model or stratification approach *(describe the steps – do not just name a method; what statistical analysis was used)*

Not applicable

2b4.5. Describe the method of testing/analysis used to develop and validate the adequacy of the statistical model or stratification approach (*describe the steps—do not just name a method; what statistical analysis*

was used)

Provide the statistical results from testing the approach to controlling for differences in patient characteristics (case mix) below.
if stratified, skip to 2b4.9

Not applicable

2b4.6. Statistical Risk Model Discrimination Statistics (*e.g., c-statistic, R-squared*)**:**

Not applicable

2b4.7. Statistical Risk Model Calibration Statistics (*e.g., Hosmer-Lemeshow statistic*):

Not applicable

2b4.8. Statistical Risk Model Calibration – Risk decile plots or calibration curves:

Not applicable

2b4.9. Results of Risk Stratification Analysis:

Not applicable

2b4.10. What is your interpretation of the results in terms of demonstrating adequacy of controlling for differences in patient characteristics (case mix)? (i.*e., what do the results mean and what are the norms for the test conducted*)

Not applicable

***2b4.11. Optional Additional Testing for Risk Adjustment** (*not required, but would provide additional support of adequacy of risk model, e.g., testing of risk model in another data set; sensitivity analysis for missing data; other methods*)

Not applicable

2b5. IDENTIFICATION OF STATISTICALLY SIGNIFICANT & MEANINGFUL DIFFERENCES IN PERFORMANCE

2b5.1. Describe the method for determining if statistically significant and clinically/practically meaningful differences in performance measure scores among the measured entities can be identified (*describe the steps—do not just name a method; what statistical analysis was used? Do not just repeat the information provided related to performance gap in 1b)*

Data 1 (EHR - Validity Against the Gold Standard)

This data sample was not used to test for meaningful differences in performance across providers or practice sites.

Data 2 (GPRO Registry)

Measures of central tendency, variability, and dispersion were calculated.

2b5.2. What were the statistical results from testing the ability to identify statistically significant and/or clinically/practically meaningful differences in performance measure scores across measured entities? (e.g., *number and percentage of entities with scores that were statistically significantly different from mean or some benchmark, different from expected; how was meaningful difference defined*)

Data 1 (EHR - Validity Against the Gold Standard)

This data sample was not used to test for meaningful differences in performance across providers or practice sites.

Data 2 (GPRO Registry)

Based on the sample of 1,244 included physicians, the mean performance rate is 0.80, the median performance rate is 0.94 and the mode is 1.00. The standard deviation is 0.29. The range of the performance rate is 1.00, with a minimum rate of 0.00 and a maximum rate of 1.00. The interquartile range is 0.29 (0.71 - 1.00).

2b5.3. What is your interpretation of the results in terms of demonstrating the ability to identify statistically significant and/or clinically/practically meaningful differences in performance across measured entities? (i.*e., what do the results mean in terms of statistical and meaningful differences?*)

Data 1 (EHR - Validity Against the Gold Standard)

This data sample was not used to test for meaningful differences in performance across providers or practice sites.

Data 2 (GPRO Registry)

The range of performance from 0.00 to 1.00 suggests there's clinically meaningful variation across physicians' performance.

2b6. COMPARABILITY OF PERFORMANCE SCORES WHEN MORE THAN ONE SET OF SPECIFICATIONS

If only one set of specifications, this section can be skipped.

Note: *This criterion is directed to measures with more than one set of specifications/instructions (e.g., one set of specifications for how to identify and compute the measure from medical record abstraction and a different set of specifications for claims or eMeasures). It does not apply to measures that use more than one source of data in one set of specifications/instructions (e.g., claims data to identify the denominator and medical record abstraction for the numerator).* ***If comparability is not demonstrated, the different specifications should be submitted as separate measures.***

2b6.1. Describe the method of testing conducted to demonstrate comparability of performance scores for the same entities across the different data sources/specifications (*describe the steps—do not just name a method; what statistical analysis was used*)

This test was not performed for this measure.

2b6.2. What were the statistical results from testing comparability of performance scores for the same entities when using different data sources/specifications? (*e.g., correlation, rank order*)

This test was not performed for this measure.

2b6.3. What is your interpretation of the results in terms of demonstrating comparability of performance measure scores for the same entities across the different data sources/specifications? (i.*e., what do the results mean and what are the norms for the test conducted*)

This test was not performed for this measure.

2b7. MISSING DATA ANALYSIS AND MINIMIZING BIAS

2b7.1. Describe the method of testing conducted to identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias (describe the steps – do not just name a method; what statistical analysis was used)

Data are not available to complete this testing.

2b7.2. What is the overall frequency of missing data, the distribution of missing data across providers, and the results from testing related to missing data? (e.g., results of sensitivity analysis of the effect of various rules for missing data/nonresponse; if no empirical sensitivity analysis, identify the approaches for handling missing data that were considered and pros and cons of each)

Data are not available to complete this testing.

2b7.3. What is your interpretation of the results in terms of demonstrating that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias? (i.e., what do the results mean in terms of supporting the selected approach for missing data and what are the norms for the test conducted; if no empirical analysis, provide rationale for the selected approach for missing data)

Data are not available to complete this testing.

3. Feasibility

Extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

3a. Byproduct of Care Processes

For clinical measures, the required data elements are routinely generated and used during care delivery (e.g., blood pressure, lab test, diagnosis, medication order).

3a.1. **Data Elements Generated as Byproduct of Care Processes.**

Generated or collected by and used by healthcare personnel during the provision of care (e.g., blood pressure, lab value, diagnosis, depression score), Coded by someone other than person obtaining original information (e.g., DRG, ICD-9 codes on claims), Abstracted from a record by someone other than person obtaining original information (e.g., chart abstraction for quality measure or registry)

If other:

3b. Electronic Sources

The required data elements are available in electronic health records or other electronic sources. If the required data are not in electronic health records or existing electronic sources, a credible, near-term path to electronic collection is specified.

3b.1. **To what extent are the specified data elements available electronically in defined fields?** *(i.e., data elements that are needed to compute the performance measure score are in defined, computer-readable fields)*

ALL data elements are in defined fields in electronic health records (EHRs)

3b.2. **If ALL the data elements needed to compute the performance measure score are not from electronic sources, specify a credible, near-term path to electronic capture, OR provide a rationale for using other than electronic sources.**

3b.3. **If this is an eMeasure, provide a summary of the feasibility assessment in an attached file or make available at a measure-specific URL.**

Attachment **Attachment:** NQF_0081_Feasibility_Scorecard_Bonnie_Output_Screen_Shots_Revised.pdf

3c. Data Collection Strategy

Demonstration that the data collection strategy (e.g., source, timing, frequency, sampling, patient confidentiality, costs associated with fees/licensing of proprietary measures) can be implemented (e.g., already in operational use, or testing demonstrates that it is ready to put into operational use). For eMeasures, a feasibility assessment addresses the data elements and measure logic and demonstrates the eMeasure can be implemented or feasibility concerns can be adequately addressed.

3c.1. **Describe what you have learned/modified as a result of testing and/or operational use of the measure regarding data collection, availability of data, missing data, timing and frequency of data collection, sampling, patient confidentiality, time and cost of data collection, other feasibility/implementation issues.**

IF a PRO-PM, consider implications for both individuals providing PROM data (patients, service recipients, respondents) and those whose performance is being measured.

We have not identified any areas of concern or made any modifications as a result of testing and operational use of the measure in relation to data collection, availability of data, missing data, timing and frequency of data collection, sampling, patient confidentiality, time and cost of data collection, and other feasibility issues unless otherwise noted.

3c.2. **Describe any fees, licensing, or other requirements to use any aspect of the measure as specified** *(e.g., value/code set, risk model, programming code, algorithm)*.

The Measures, while copyrighted, can be reproduced and distributed, without modification, for noncommercial purposes, eg, use by health care providers in connection with their practices. Commercial uses of the Measures require a license agreement between the user and the AMA, (on behalf of the PCPI), ACC or AHA.

Limited proprietary coding is contained in the Measure specifications for convenience. Users of the proprietary code sets should obtain all necessary licenses from the owners of these code sets.

4. Usability and Use

Extent to which potential audiences (e.g., consumers, purchasers, providers, policy makers) are using or could use performance results for both accountability and performance improvement to achieve the goal of high-quality, efficient healthcare for individuals or populations.

4a. Accountability and Transparency

Performance results are used in at least one accountability application within three years after initial endorsement and are publicly reported within six years after initial endorsement (or the data on performance results are available). If not in use at the time of initial endorsement, then a credible plan for implementation within the specified timeframes is provided.

4.1. **Current and Planned Use**

NQF-endorsed measures are expected to be used in at least one accountability application within 3 years and publicly reported within 6 years of initial endorsement in addition to performance improvement.

Planned	Current Use (for current use provide URL)
	Public Reporting Physician Quality Rating System http://www.cms.gov/Medicare/Quality-Initiatives-Patient-Assessment-Instruments/pqrs/index.html Payment Program Meaningful Use Stage II http://www.cms.gov/Regulations-and-Guidance/Legislation/EHRIncentivePrograms/Stage_2.html Quality Improvement with Benchmarking (external benchmarking to multiple organizations) PINNACLE Registry http://cvquality.acc.org/en/NCDR-Home/Registries/Outpatient-Registries.aspx

4a.1. **For each CURRENT use, checked above, provide:**

- Name of program and sponsor
- Purpose
- Geographic area and number and percentage of accountable entities and patients included

1) Physician Quality Reporting System (PQRS)-Sponsored by the Centers for Medicare and Medicaid Services (CMS)

Purpose: PQRS is a national reporting program that uses a combination of incentive payments and payment adjustments to promote reporting of quality information by eligible professionals (EPs). The program provides an incentive payment to practices with EPs (identified on claims by their individual National Provider Identifier [NPI] and Tax Identification Number [TIN]). Eps satisfactorily report data on quality measures for covered Physician Fee Schedule (PFS) services furnished to Medicare Part B Fee-for-Service (FFS) beneficiaries (including Railroad Retirement Board and Medicare Secondary Payer). Beginning in 2015, the program also applies a payment adjustment to EPs who do not satisfactorily report data on quality measures for covered professional services. Source: http://www.cms.gov/Medicare/Quality-Initiatives-Patient-Assessment-Instruments/PQRS/index.html It is our understanding that CMS is also planning to move towards publicly reporting physician data via Physician Compare.

2) Meaningful Use Stage 2 (EHR Incentive Program) – Sponsored by the Centers for Medicare and Medicaid Services (CMS)

The Medicare and Medicaid EHR Incentive Programs provide incentive payments to eligible professionals, eligible hospitals, and

critical access hospitals (CAHs) as they adopt, implement, upgrade or demonstrate meaningful use of certified EHR technology.

These professionals are eligible for incentive payments for the "meaningful use" of certified EHR technology, if all program requirements are met, including successful implementation and reporting of program measures, which include this measure, to demonstrate meaningful use of EHR technology.

3) PINNACLE Registry (URL: http://cvquality.acc.org/en/NCDR-Home/Registries/Outpatient-Registries.aspx)
The PINNACLE Registry® is cardiology´s largest outpatient quality improvement registry, capturing data on coronary artery disease, hypertension, heart failure and atrial fibrillation. The PINNACLE Registry® continues to grow rapidly, with more than 2400 providers representing almost 800 unique office locations across the U.S submitting data to the registry as of the fourth quarter of 2013. As of the fourth quarter of 2013, the registry has more than 13 million patient encounter records. PINNACLE assists practices in understanding and improving care through the production and distribution of quarterly performance reports. These reports, covering all valid patient encounters, detail adherence to 28 cardiovascular clinical measures at the physician, location, and practice levels across coronary artery disease, hypertension, heart failure and atrial fibrillation. All jointly developed ACC/AHA/PCPI performance measures for these topics are reported by the registry.

4a.2. If not currently publicly reported OR used in at least one other accountability application (e.g., payment program, certification, licensing) what are the reasons? (*e.g., Do policies or actions of the developer/steward or accountable entities restrict access to performance results or impede implementation?*)
We support the expanded use of this measure in government or other programs, including those intended for accountability or public reporting. The ACC, AHA and PCPI do not have any policies that would restrict access to the performance measure specifications or results or that would impede implementation of the measure for any application. We would welcome its implementation in emerging applications such as accountable care organizations (ACO), Medicare Advantage insurance plans or health plans selling on the new insurance marketplace.

4a.3. If not currently publicly reported OR used in at least one other accountability application, provide a credible plan for implementation within the expected timeframes -- any accountability application within 3 years and publicly reported within 6 years of initial endorsement. (*Credible plan includes the specific program, purpose, intended audience, and timeline for implementing the measure within the specified timeframes. A plan for accountability applications addresses mechanisms for data aggregation and reporting.*)
As described above, it is our understanding that CMS is also planning to move towards publicly reporting physician data via Physician Compare. Also, although the measure is currently in use, we support expanded use of this measure in government or other programs, including those intended for accountability or public reporting.

4b. Improvement

Progress toward achieving the goal of high-quality, efficient healthcare for individuals or populations is demonstrated. If not in use for performance improvement at the time of initial endorsement, then a credible rationale describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.

4b.1. Progress on Improvement. (Not required for initial endorsement unless available.)
Performance results on this measure (current and over time) should be provided in 1b.2 and 1b.4. Discuss:

- **Progress (trends in performance results, number and percentage of people receiving high-quality healthcare)**
- **Geographic area and number and percentage of accountable entities and patients included**

2013 PQRS Experience Report*:
Data Source: 2013 is the most recent year for which PQRS Experience Report measure data is available. The average performance rates on Heart Failure (HF) – Angiotensin-Converting Enzyme (ACE) Inhibitor or Angiotensin Receptor Blocker (ARB) Therapy for Left Ventricular Systolic Dysfunction (LVSD) over the last several years are as follows:

2010: 85.6%
2011: 79.7%
2012: 82.2%
2013: 83.5%

2013 Small Group Practice Exception Rate: 1.3%
Reference: Center for Medicare and Medicaid Services. 2013 Reporting Experience Including Trends. Available: http://www.cms.gov/Medicare/Quality-Initiatives-Patient-Assessment-Instruments/PQRS/index.html?redirect=/PQRS/

*It is important to note that PQRS was a voluntary reporting program, with approximately 51% of eligible professionals participating using any reporting option in 2013, and performance rates may not be nationally representative.

4b.2. **If no improvement was demonstrated, what are the reasons? If not in use for performance improvement at the time of initial endorsement, provide a credible rationale that describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.**
While the PCPI creates measures with an ultimate goal of improving the quality of care, measurement is a mechanism to drive improvement but does not equate with improvement. Measurement can help identify opportunities for improvement with actual improvement requiring making changes to health care processes and structure. In order to promote improvement, quality measurement systems need to provide feedback to front-line clinical staff in as close to real time as possible and at the point of care whenever possible. (1)

1. Conway PH, Mostashari F, Clancy C. The future of quality measurement for improvement and accountability. JAMA. 2013 Jun 5;309(21):2215-6.

4c. Unintended Consequences

The benefits of the performance measure in facilitating progress toward achieving high-quality, efficient healthcare for individuals or populations outweigh evidence of unintended negative consequences to individuals or populations (if such evidence exists).

4c.1. **Were any unintended negative consequences to individuals or populations identified during testing; OR has evidence of unintended negative consequences to individuals or populations been reported since implementation? If so, identify the negative unintended consequences and describe how benefits outweigh them or actions taken to mitigate them.**
We are not aware of any unintended consequences at this time, but we take unintended consequences very seriously and therefore continuously monitor to identify actions that can be taken to mitigate them.

5. Comparison to Related or Competing Measures

If a measure meets the above criteria and there are endorsed or new related measures (either the same measure focus or the same target population) or competing measures (both the same measure focus and the same target population), the measures are compared to address harmonization and/or selection of the best measure.

5. Relation to Other NQF-endorsed Measures

Are there related measures (conceptually, either same measure focus or target population) or competing measures (conceptually both the same measure focus and same target population)? If yes, list the NQF # and title of all related and/or competing measures.
No

5.1a. **List of related or competing measures (selected from NQF-endorsed measures)**

5.1b. **If related or competing measures are not NQF endorsed please indicate measure title and steward.**

5a. Harmonization

The measure specifications are harmonized with related measures;
OR
The differences in specifications are justified

5a.1. **If this measure conceptually addresses EITHER the same measure focus OR the same target population as NQF-endorsed measure(s):**
Are the measure specifications completely harmonized?

5a.2. **If the measure specifications are not completely harmonized, identify the differences, rationale, and impact on interpretability and data collection burden.**

5b. Competing Measures

The measure is superior to competing measures (e.g., is a more valid or efficient way to measure);
OR
Multiple measures are justified.

5b.1. **If this measure conceptually addresses both the same measure focus and the same target population as NQF-endorsed measure(s):**
Describe why this measure is superior to competing measures (e.g., a more valid or efficient way to measure quality); OR provide a rationale for the additive value of endorsing an additional measure. (Provide analyses when possible.)

Appendix

A.1 Supplemental materials may be provided in an appendix. All supplemental materials (such as data collection instrument or methodology reports) should be organized in one file with a table of contents or bookmarks. If material pertains to a specific submission form number, that should be indicated. Requested information should be provided in the submission form and required attachments. There is no guarantee that supplemental materials will be reviewed.

Additional Information

Ad.1 **Workgroup/Expert Panel involved in measure development**
Provide a list of sponsoring organizations and workgroup/panel members' names and organizations. Describe the members' role in measure development.
PCPI and ACC/AHA measures are developed through cross-specialty, multi-disciplinary work groups. All medical specialties and other health care professional disciplines participating in patient care for the clinical condition or topic under study are invited to participate as equal contributors to the measure development process. In addition, the PCPI and ACC/AHA strive to include on its work groups individuals representing the perspectives of patients, consumers, private health plans, and employers. This broad-based approach to measure development ensures buy-in on the measures from all stakeholders and minimizes bias toward any individual specialty or stakeholder group. All work groups have at least two co-chairs who have relevant clinical and/or measure development expertise and who are responsible for ensuring that consensus is achieved and that all perspectives are voiced.

Work Group members:
Craig T. Beam, CRE (patient representative)
Ileana L. Piña, MD, FACC (cardiology, heart failure)
Kathleen Blake, MD (cardiac electrophysiology)
Paul D. Rockswold, MD, MPH (family medicine)
Donald E. Casey, Jr., MD, MPH, MBA, FACP, FAHA (internal medicine)
Lawrence B. Sadwin (patient representative)
Sarah J. Goodlin, MD (geriatrics, palliative medicine)
Joanna D. Sikkema, MSN, ANP-BC, FAHA (cardiology)
Kathleen L. Grady, PhD, APN, FAAN, FAHA (cardiac surgery)
Carrie A. Sincak, PharmD, BCPS (pharmacy)

Measure Developer/Steward Updates and Ongoing Maintenance

Ad.2 **Year the measure was first released:** 2003

Ad.3 **Month and Year of most recent revision:** 12, 2014

Ad.4 **What is your frequency for review/update of this measure?** Coding/Specifications updates occur annually.

Ad.5 **When is the next scheduled review/update for this measure?** 12, 2015

Ad.7 **Disclaimers:** Physician Performance Measures (Measures) and related data specifications have been developed by the American Medical Association (AMA) - convened Physician Consortium for Performance Improvement(R) (PCPI[R]), American College of Cardiology (ACC) and American Heart Association (AHA). These Measures are not clinical guidelines and do not establish a standard of medical care, and have not been tested for all potential applications. The Measures, while copyrighted, can be reproduced and distributed, without modification, for noncommercial purposes, eg, use by health care providers in connection with their practices. Commercial use is defined as the sale, license, or distribution of the Measures for commercial gain, or incorporation of the Measures into a product or service that is sold, licensed or distributed for commercial gain. Commercial uses of the Measures require a license agreement between the user and the AMA, (on behalf of the PCPI), ACC or AHA. Neither the AMA, ACC, AHA, PCPI nor its members shall be responsible for any use of the Measures.

THE MEASURES AND SPECIFICATIONS ARE PROVIDED "AS IS" WITHOUT WARRANTY OF ANY KIND.

Limited proprietary coding is contained in the Measure specifications for convenience. Users of the proprietary code sets should obtain all necessary licenses from the owners of these code sets. The AMA, ACC, AHA, the PCPI and its members disclaim all liability for use or accuracy of any Current Procedural Terminology (CPT[R]) or other coding contained in the specifications.

Ad.8 **Additional Information/Comments:**

MEASURE WORKSHEET

This document summarizes the evaluation of the measure as it progresses through NQF's Consensus Development Process (CDP). The information submitted by measure developers/stewards is included after the Brief Measure Information, Preliminary Analysis, and Pre-meeting Public and Member Comments sections.

Brief Measure Information

NQF #: 0229
Measure Title: Hospital 30-day, all-cause, risk-standardized mortality rate (RSMR) following heart failure (HF) hospitalization for patients 18 and older
Measure Steward: Centers for Medicare & Medicaid Services (CMS)
Brief Description of Measure: The measure estimates a hospital-level 30-day risk-standardized mortality rate (RSMR). Mortality is defined as death for any cause within 30 days after the date of admission for the index admission, for patients 18 and older discharged from the hospital with a principal diagnosis of heart failure (HF). CMS annually reports the measure for patients who are 65 years or older and are either Medicare fee-for-service (FFS) beneficiaries and hospitalized in non-federal hospitals or patients hospitalized in Veterans Health Administration (VA) facilities.
Developer Rationale: The goal of this measure is to improve patient outcomes by providing patients, physicians, hospitals, and policy makers with information about hospital-level, risk-standardized mortality rates following hospitalization for HF. Measurement of patient outcomes allows for a broad view of quality of care that encompasses more than what can be captured by individual process-of-care measures. Complex and critical aspects of care, such as communication between providers, prevention of and response to complications, patient safety, and coordinated transitions to the outpatient environment, all contribute to patient outcomes but are difficult to measure by individual process measures. The goal of outcomes measurement is to risk-adjust for patients' conditions at the time of hospital admission and then evaluate patient outcomes. This measure was developed to identify institutions' whose performance is better or worse than would be expected based on their patient case mix, and therefore promote hospital quality improvement and better inform consumers about care quality.

Additionally, HF mortality is a priority area for outcomes measure development, as it is a costly and common condition. Hospital mortality is an outcome that is likely attributable to care processes and is an important outcome for patients. Measuring and reporting mortality rates will inform healthcare providers about opportunities to improve care, strengthen incentives for quality improvement, and ultimately improve the quality of care received by Medicare patients. The measure will also provide patients with information that could guide their choices. Furthermore, the measure will increase transparency for consumers and potentially lower the healthcare costs associated with mortality.

Numerator Statement: The outcome for this measure is 30-day all-cause mortality. We define mortality as death from any cause within 30 days of the index admission date for patients 18 and older discharged from the hospital with a principal diagnosis of HF.
Denominator Statement: This claims-based measure can be used in either of two patient cohorts: (1) patients aged 65 years or older or (2) patients aged 18 years or older. We have explicitly tested the measure in both age groups. The cohort includes admissions for patients aged 18 years and older discharged from the hospital with a principal discharge diagnosis of HF and with a complete claims history for the 12 months prior to admission. The measure is currently publicly reported by CMS for those patients 65 years and older who are either Medicare FFS beneficiaries admitted to non-federal hospitals or patients admitted to VA hospitals. Additional details are provided in S.9 Denominator Details.
Denominator Exclusions: The mortality measures exclude index admissions for patients:
1. Discharged alive on the day of admission or the following day who were not transferred to another acute care facility.
2. With inconsistent or unknown vital status or other unreliable demographic (age and gender) data;
3. Enrolled in the Medicare hospice program or used VA hospice services any time in the 12 months prior to the index admission, including the first day of the index admission;
4. Discharged against medical advice (AMA); or
5. Patients undergoing LVAD implantation or heart transplantation during an index admission or who have a history of LVAD or heart transplant in the preceding year.

For patients with more than one admission for a given condition in a given year, only one index admission for that condition is

randomly selected for inclusion in the cohort.

For Medicare FFS patients, the measure additionally excludes admissions for patients without at least 30 days post-discharge enrollment in FFS Medicare (because the 30-day mortality outcome cannot be assessed in this group).

Measure Type: Outcome
Data Source: Administrative claims, Other, Paper Medical Records
Level of Analysis: Facility
Is this an eMeasure? ☐ **Yes** ☒ **No** **If Yes, was it re-specified from a previously endorsed measure?** ☐ **Yes** ☐ **No**

IF this measure is paired/grouped, NQF#/title: 0330: Hospital 30-day, all-cause, risk-standardized readmission rate (RSRR) following heart failure (HF) hospitalization

IF PAIRED/GROUPED, what is the reason this measure must be reported with other measures to appropriately interpret results? This measure is paired with a measure of hospital-level, all-cause, 30-day, risk-standardized readmission (RSRR) following HF hospitalization.

Is this a MAINTENANCE measure submission? ☒ **Yes** ☐ **No, this is a NEW measure submission.**
For MAINTENANCE, state the Original Endorsement Date: 5/9/07 **Most Recent Endorsement Date:** 1/18/12

Previous Measure Evaluation - Public & Member Comments, Developer Responses & Steering Committee Recommendations from (Cardiology Project 2010):

Public and Member Comments on original measure

- Given the advanced age of many HF patients, many in palliative care programs, many deaths cannot be considered a result of substandard care.

Committee response:

- Patients in hospice care are excluded and risk factors account for frailty.

Public and Member Comments on revised measure:

- Clarify the data sources that were used in the all payer data testing.

Developer Response:

- The data source used to complete the all payer testing was the state of California's Patient Discharge Database (PDD) which contains records for all discharges from all non-Federal hospitals located in California. California is a diverse state, and, with more than 37 million residents, California represents 12% of the US population. In 2006, there were approximately 3 million adult discharges from more than 450 hospitals. Records are linked by a unique patient identification number, allowing us to determine patient history from previous hospitalizations and to evaluate rates of both readmission and mortality. Specifically, patients from this database are linked to the California Death Statistical Master File (DSMF) using social security number in order to validate and record deaths.

Steering Committee: Agreed that the developer answered the comment.

Preliminary Analysis

The preliminary analysis was developed in response to recommendations from NQF's Consensus Task Force and measurement stakeholders as a way to enhance and streamline the measures evaluation and voting processes. The preliminary analysis will help to guide the Standing Committee evaluation of each measure by summarizing the measure developer submission, guide measure evaluation discussion, and identify topic areas for additional input. **NQF staff would like to stress that the preliminary analysis is intended to be used as a guide to facilitate the Committee's discussion and evaluation.**

Criteria 1: Importance to Measure and Report

1a. Evidence

1a. Evidence. The evidence requirements for a health outcomes measure include providing a rationale that supports the relationship of the outcome to at least one healthcare structure, process, intervention, or service.

- This measure calculates hospitals' 30-day risk-standardized mortality rate for patients who have been

hospitalized with heart failure (HF).

- As a rationale for measuring this health outcome, the developers suggest that hospitals are able to influence mortality rates through a broad range of clinical activities, including prevention of complications, provision of evidenced-based care, discharge planning, management of care transitions, medication reconciliation, and patient education.
- The developer states that numerous studies show that appropriate and timely treatment for HF patients can reduce the risk of mortality within 30 days of hospital admission; that trials of interventions which improve patient education upon discharge have been shown to improve survival for HF patients; and that evidence that hospitals have been able to reduce mortality rates through these quality-of-care initiatives illustrates the degree to which hospital practices can affect mortality rates.
- The developer states that this measure was developed to identify institutions whose performance is better or worse than would be expected based on their patient case mix, and therefore promote hospital quality improvement and better inform consumers about care quality.

Question for the Committee:

- *Does the Committee agree that hospitals have the ability to influence 30-day mortality rates among heart failure patients?*

1b. Gap in Care/Opportunity for Improvement and 1b. Disparities

1b. Performance Gap. The performance gap requirements include demonstrating quality problems and opportunity for improvement.

- The developer notes that studies suggest quality gaps in hospital care for heart failure patients, particularly in the transition to outpatient care.
- The developer also notes that there is substantial inter-hospital variation in the risk of death among heart failure patients that is not clearly explained by differences in case mix, and suggests that measurement of this patient outcome allows for a broad view of quality of care.
- The developer provides performance data from four measurement periods, covering a total of 991,007 admissions.
- The data show that the average 30-day risk-standardized HF mortality rate was **11.7 percent** during the measurement period of 07/2011–06/2014.
- During this same period, scores ranged from a **minimum of 7.0%** to a **maximum of 19.3%**, with the **10th percentile at 10.1%** and the **90th percentile at 13.4%.**
- To help in assessment of potential disparities, the developers also provide performance scores for hospitals serving a low proportion of Medicaid patients vs. those serving a high proportion of Medicaid patients, and performance scores for hospitals serving a low proportion of African-American patients vs. those serving a high proportion of African-American patients.
- By proportion of **Medicaid** patients:

  // **Low proportion (=7.0%) Medicaid patients** // **High proportion (=29.6%) Medicaid patients**
  Number of Measured Entities (Hospitals)// 373 // 373
  Number of Patients// 84,068 patients in low-proportion hospitals/74,416 in high-proportion hospitals
  Maximum// 15.1 // 16.4
  90th percentile// 13.2 // 13.3
  75th percentile// 12.4 // 12.4
  Median (50th percentile)// 11.6 // 11.3
  25th percentile// 10.9 // 10.5
  10th percentile// 10.1 // 9.5
  Minimum // 7.7 // 7.2

- By proportion of **African-American** patients:

  // **Low Proportion (=0%) Af-Am patients** // **High proportion (=23.3%) Af-Am patients**
  Number of Measures Entities (Hospitals)// 526 // 376

Number of Patients//31,904 patients in low-proportion hospitals/92,579 in high-proportion hospitals
Maximum// 16.4 // 15.9
90th percentile// 13.8 // 12.9
75th percentile// 12.8 // 12.0
Median (50%)// 12.0 // 11.1
25th percentile// 11.3 // 10.2
10th percentile// 10.8 // 9.3
Minimum// 9.1 // 7.2

- The developers do not provide interpretation or analysis of these data; in both cases there are differences in performance between the groups compared, but these differences do not appear to be substantial.

Questions for the Committee:

- *Is there a gap in care that warrants a national performance measure?*
- *Should this measure be indicated as disparities sensitive?*

1c. Priority

1c. High Priority (previously "High Impact") requires measures to address national health goal/priority or a demonstrated high-impact aspect of care.

- *Beginning in 2015, priority is no longer an NQF measure evaluation criterion.*

Committee pre-evaluation comments

Criteria 1: Importance to Measure and Report (including 1a, 1b, 1c)

1. ***Committee's Overview Comments***:
   - Evidence is strong.
   - The measure steward provided a sound rationale to support this risk adjusted outcome measure, one that estimates a hospital-level 30 day risk standardized mortality after discharge from the hospital with a principal diagnosis of HF. More specifically the measure developed provided a very nice diagram showcasing the linkage between the health outcome, in this case decreased risk of mortality and the processes, interventions, or services that influence. Furthermore, they provide numerous studies that demonstrate this link based upon well designed studies.

1a. ***Committee's Comments on Evidence to Support Measure Focus:***

- Strong.

1b. ***Committee's Comments on Performance Gap:***

- Data show that the average 30-day risk-standardized HF mortality rate was 11.7 percent during the measurement period of 07/2011–06/2014. During this same period, scores ranged from a minimum of 7.0% to a maximum of 19.3%, with the 10th percentile at 10.1% and the 90th percentile at 13.4%. So there is a clear gap.

1c. ***Committee's Comments on Composite Performance Measure:***

- Not Applicable

Criteria 2: Scientific Acceptability of Measure Properties

2a. Reliability

2a1. Reliability Specifications

2a1. Specifications requires the measure, as specified, to produce consistent (reliable) and credible (valid) results about the quality of care when implemented.

- This measure calculates 30-day all-cause mortality for patients hospitalized with heart failure (HF) using a risk standardized mortality ratio (RSMR), which is calculated as the ratio of the number of "predicted" to the number of "expected" deaths, multiplied by the national unadjusted mortality rate.

- The denominator includes patients aged 18 years and older discharged from the hospital with a principal discharge diagnosis of HF and with a complete claims history for the 12 months prior to admission. The measure can also be calculated for patients aged 65 and older only.
- The numerator includes patients who died of any cause within 30 days of the date of admission of the index HF hospitalization.
- The denominator population is defined using ICD-9 and ICD-10 codes; a list of applicable codes is included in the submission.
- The numerator population is defined using vital status data, which may be derived from the Medicare Enrollment Database (EDB), State-based data systems, the Social Security Administration's Death Master File (DMF), or the Centers for Disease Control and Prevention's National Death Index (NDI).
- The data sources for this measure may include Medicare Part A and B claims, Veterans Health Administration claims, the Medicare Enrollment Database (EDB), and all-payer data sources such as the California Patient Discharge Database.
- The measure's time window can be specified from one to three years.
- The measure is risk-adjusted using a statistical risk model (see details below).

Questions for the Committee:

- *Are all the data elements clearly defined? Are all appropriate codes included?*
- *Is it likely this measure can be consistently implemented?*

2a2. Reliability Testing Testing attachment

2a2. Reliability testing demonstrates if the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise enough to distinguish differences in performance across providers.

- The developer has assessed reliability at both the data element and the performance score levels.
- **Data element reliability**:
  - With regard to data element reliability, the developer notes that the measure has been developed to avoid the use of claims data elements that are thought to be coded inconsistently across hospitals or providers, instead using fields that are consequential for payment and which are audited by CMS. [*Note: NQF does not typically consider temporal consistency to be a valid method of demonstrating reliability of data elements*.]
  - In addition, the developer compared frequencies and odds ratios of variables from their risk model across three years of data in order to assess the consistency of those variables over time.
  - Summarizing the results of this analysis, the developer notes that the frequency of some model variables increased between 2011 and 2014, which may reflect increased co-morbidity rates, but may also be due to increased coding opportunities on administrative claims.
  - The developer states that examination of the odds ratios for each risk variable in the model shows that, overall, the odds ratios for individual risk variables remained relatively constant across three years.
- **Performance score reliability**:
  - The developer defines performance score reliability as the degree to which repeated measurements of the same entity agree with each other.
  - In line with this thinking, the developer's approach to assessing score-level reliability was to consider the extent to which assessments of a hospital using different but randomly-selected subsets of patients produce similar measures of hospital performance. The developers refer to this as a "test-retest" approach; it may also be called a "split-half" method. [*Note: NQF considers this to be an appropriate method of assessing reliability*.]
  - A total of 991,007 admissions over a 3-year period were examined, with 494,297 in one sample and 496,710 in the other randomly-selected sample; two risk-standardized mortality rates (RSMR) were calculated for each hospital, one from each of the two separate samples.
  - The agreement between the two RSMRs for each hospital (as measured by intra-class correlation coefficient (ICC)) was **0.55**; the developers state that according to the conventional interpretation, this is considered a "moderate" level of agreement.
  - The developer notes that this analysis was limited to hospitals with 12 or more cases in each split sample, and

that splitting the total population into two samples resulted in a sample equivalent of only 1.5 years of data, whereas the measure is reported with the full three years of data. [*Note: It is unclear whether the measure itself is limited to hospitals with 12 or more cases; if it is not, then testing was not conducted with the measure as specified*.]
    - The developer expects that the correlation coefficient would be higher using a full three-year sample since it would include more patients.
- The developer's overall interpretation of reliability testing results is that the stability of the risk factor frequencies and odds ratios over time suggests that the underlying data elements are reliable, and that the ICC score from performance score analysis demonstrates moderate agreement across samples using a conservative approach to assessment.

Questions for the Committee:

- *Do the testing results presented by the developer demonstrate an adequate level of reliability?*
- *In addition to the consistency of measurement results, assessments of performance score reliability often examine the ability of the measure to differentiate between measured entities. Do the reliability testing results reported by the developer demonstrate that meaningful differences in performance can be identified?*

2b. Validity

2b1. Validity: Specifications

2b1. Validity Specifications. This section should determine if the measure specifications are consistent with the evidence.

- This measure calculates 30-day all-cause mortality for patients hospitalized with heart failure (HF).
- As a rationale for measuring this health outcome, the developers suggest that hospitals are able to influence mortality rates through a broad range of clinical activities, including prevention of complications, provision of evidenced-based care, discharge planning, management of care transitions, medication reconciliation, and patient education.

Question for the Committee:

- *Are the specifications consistent with the evidence?*

2b2. Validity testing

2b2. Validity Testing should demonstrate the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality.

- The developer conducted empirical validity testing of the measure score.
- To assess validity, the developer compared scores from the administrative claims-based measure (i.e., the measure as specified) to scores derived from medical record review in the same patient cohort.
- This assessment was conducted on data from 1998-2001, comprising 46,700 heart failure hospitalizations; the unadjusted 30-day mortality rate in this population was 11.9%.
- Hospital-level risk-standardized mortality rates (RSMRs) were estimated using the claims-based model and the medical record-based model; the linear relationship between these two sets of estimates was then examined, using regression techniques and weighting by the total number of cases in each hospital.
- The correlation between the claims-based RSMRs and the record-based RSMRs was estimated at 0.95, which the developer suggests shows that the resulting measure from the administrative claims model is as good as that from the medical record model.

Questions for the Committee:

- *Do the method and results of testing demonstrate sufficient validity so that conclusions about quality can be made?*
- *Do you agree that the score from this measure as specified is an indicator of quality?*

2b3-2b7. Threats to Validity

2b3. Exclusions:

- Patients in the following categories are excluded from the measure:
  1. Discharged alive on the day of admission or the following day who were not transferred to another acute care facility.
  2. With inconsistent or unknown vital status or other unreliable demographic (age and gender) data;
  3. Enrolled in the Medicare hospice program or used VA hospice services any time in the 12 months prior to the index admission, including the first day of the index admission;
  4. Discharged against medical advice (AMA); or
  5. Patients undergoing LVAD implantation or heart transplantation during an index admission or who have a history of LVAD or heart transplant in the preceding year.
- Additional exclusions listed by the developer include:
  - HF admissions within 30 days of discharge from a qualifying index admission, which are identified by comparing the discharge date from the index admission with the readmission date
  - For Medicare FFS patients, the measure additionally excludes admissions for patients without at least 30 days post-discharge enrollment in FFS Medicare (because the 30-day mortality outcome cannot be assessed in this group)
- To determine the impact of exclusions, the developer examined overall frequencies and proportions of the total cohort excluded for each exclusion criterion.
- The number and percentage of patients excluded for each criterion are as follows:
  1. Discharged alive on the day of admission or the following day who were not transferred to another acute care facility: **88,023 (6.45%)**
  2. Inconsistent or unknown vital status or other unreliable demographic (age and gender) data: **55 (<0.01%)**
  3. Enrolled in the Medicare hospice program or used VA hospice services any time in the 12 months prior to the index admission, including the first day of the index admission: **18,753 (1.37%)**
  4. LVAD or Transplant in index admission or prior year: **2,362 (0.17%)**
  5. Discharged against medical advice (AMA): **5,933 (0.43%)**
- The developer also provides the distribution across hospitals for each exclusion criterion.
- The developer notes that the first exclusion criterion accounts for the majority of all exclusions and is meant to ensure a clinically coherent cohort, preventing the inclusion of patients who likely did not have clinically significant HF.

Questions for the Committee:

- *Are the exclusions consistent with the evidence?*
- *Are any patients or patient groups inappropriately excluded from the measure?*
- *Are the exclusions of sufficient frequency and variation across providers to be needed (and outweigh the data collection burden)?*

2b4. Risk adjustment:

- To control for differences in case mix between hospitals, the developers have risk-adjusted this measure using a statistical risk model.
- Specifically, the developer employs a hierarchical logistic regression model to create a hospital-level 30-day risk-standardized mortality ratio (RSMR).
- The developer notes that the risk-adjustment approach simultaneously models data at the patient and hospital levels to account for the variance in patient outcomes both within and between hospitals.
- At the patient level, the odds of mortality are adjusted for age, sex, and selected clinical covariates present at the time of admission.
- For each patient, covariates were obtained from claims records extending 12 months prior to and including the index admission. The covariates are defined using condition categories (CCs), which are clinically-meaningful groupings of more than 15,000 ICD-9-CM diagnosis codes.
- The measure does not adjust for CCs that were possible adverse events of care and that were only recorded in the index admission.
- Variables considered for inclusion in the risk-adjustment model were patient-level risk-adjustors that are expected to be predictive of mortality based on empirical analysis, prior literature, and clinical judgment.
- The final set of 24 clinical risk-adjustment variables, along with odds ratios for each, is available in the testing

attachment.

- The developers also considered a number of variables related to sociodemographic status (SDS) for potential inclusion in the risk-adjustment model. Candidate SDS variables were selected for examination based on a review of literature, conceptual pathways, and feasibility of collection from national data sources.
- **Conceptual analysis of the need for SDS adjustment**:
    - The developers note that there is a large body of literature linking various SDS factors to worse health status and higher mortality over a lifetime, with income, education, and occupational level being the most commonly examined variables, though literature directly related to 30-day mortality after heart failure hospitalization is much more limited.
    - One potential pathway for SDS factors to affect 30-day mortality (independent of the quality of care) is patients' health status at the time of admission.
        - SDS factors can influence admission health status both due to the impact of multiple related stressors over a lifetime contributing to overall worse health, as well as through poorer access to care and potentially delayed presentation.
        - The developers note that this pathway should be largely accounted for by their clinical risk-adjustment model.
    - Another potential pathway for SDS factors to affect 30-day mortality is for lower-income patients to elect not to follow prescribed care (for example, refill a prescription or keep a follow-up visit with a primary care provider) because limited resources create competing priorities for the patient.
    - The developers also argue that there are a number of pathways for SDS to affect 30-day mortality that are *not* independent of the quality of care. These may include:
        - Contextual effects, such as patients of low SDS presenting at lower-quality institutions for care;
        - Patients of low SDS receiving differentiated care as compared to counterparts of higher SDS—which may be appropriate or inappropriate in different instances.
- **Empirical analysis of SDS factors**:
    - The developers state that they found race (black vs non-black) and dual-eligible status—e.g. enrolled in both Medicare and Medicaid (obtained from CMS claims enrollment data)—to be the only two patient-level SDS variables available for direct examination. The conceptual relationship between race and mortality from heart failure was not explained by the developer, although they state that they "felt it was important to understand the association with race as well as more traditional socio-economic variables". Guidance from the NQF panel that examined use of SDS factors in risk-adjustment approaches noted that race should generally not be used as a proxy for socioeconomic status.
    - Also considered were a number of neighborhood-level variables (represented in a validated AHRQ composite index of SDS variables found in census data, including income and education) that could serve as a proxy for patient-level SDS.
        - These variables are linked to patients by zip code; however, the data are only linked at a **5-digit zip code level**—nine-digit zip code data, which may provide a more granular view of patient sociodemographic status, were not available.
        - Patients were identified as low SDS if they lived in a neighborhood in the lowest quartile of the AHRQ SDS index.
    - The developer's method was to first evaluate variation in the prevalence of low-SDS patients among providers; they then assessed the relationship (univariate) between the SDS variables and 30-day HF mortality, and examined the incremental effect of SDS in a multivariable model, evaluating the extent to which the addition of any one of these variables improved model performance or changed hospital results.
    - The developers' analysis found that the prevalence of SDS factors in the HF cohort does vary across measured entities.
        - With regard to the empirical association of each SDS variable with the outcome (univariate), the analysis found that patient-level observed HF mortality rates were lower for dual-eligible patients, black patients, and patients in the lowest AHRQ SDS quartile as compared to, respectively, mortality rates for non-dual-eligible patients, non-black patients, and patients above the lowest QHRQ SDS quartile.

    - With regard to the strength and significance of the SDS variables in the context of a multivariable model, the developers' analysis found that the effect size of each of these variables was small, that the c-statistic (i.e., predictive value) of the model was essentially unchanged with the addition of any of these variables, and that addition of the variables to the model had little to no effect on hospital performance.
- The developers note that, among the SDS variables that could be feasibly incorporated into their model, the relationship between minority status, dual-eligible status, and low SES (AHRQ indicator status) is in the opposite direction than what has been the expressed concern of stakeholders interested in adding such adjustment to the models (although it is unclear what, exactly, this means). The developers state that, given the controversial nature of incorporating such variables into a risk-model, they do not support doing so in a case that is unlikely to affect hospital profiling. As a result, the developers **did not incorporate SDS variables into this measure**.

- **Risk Model Diagnostics**
  - To assess the overall performance of their risk-adjustment model, the developers computed several summary statistics, including:
    - *Area under the receiver operating characteristic (ROC) curve* (also known as a ***c-statistic***, which reflects how well the risk model can distinguish those who have the outcome of interest from those who do not)
    - *Predictive ability* (the model's ability to distinguish high-risk subjects from low-risk subjects)
    - *Over-fitting indices (model calibration)* (to ensure that the model is not only describing the relationship between predictive variables and outcome in the development dataset but also providing valid predictions in new patients)
  - For the current measure cohort, the findings from this analysis are as follows:
    - C-statistic: **0.68**
      - A c-statistic of 0.68 means that for 68% of all possible pairs of patients—one who died and one who lived—the model correctly assigned a higher probability to those who died. Generally, a c-statistic of at least 0.70 is considered acceptable.
      - The developers interpret this as 'fair' model discrimination.
    - Predictive ability (lowest decile %, highest decile %): (**3.7, 27.3**)
      - The developers state that this indicates a wide range between the lowest decile and highest decile, indicating the ability to distinguish high-risk subjects from low-risk subjects.
    - Overfitting indices (model calibration) [presented as (γ0, γ1)]:
      - The developer states that if the γ0 in the validation samples are substantially far from zero and the γ1 is substantially far from one, there is potential evidence of over-fitting. The calibration value of close to 0 at one end and close to 1 to the other end indicates good calibration of the model.
        - 1st half of split sample: Calibration: (**0.0000, 1.0000**)
        - 2nd half of split sample: Calibration: (**-0.0035, 0.9928**)
  - The developer's overall interpretation of the results of their analyses is that the findings demonstrate the risk-adjustment model adequately controls for differences in patient characteristics (case mix).

- The developer also conducted additional analyses to determine whether the measure could be applied to Medicare FFS 65+ patients using only Medicare Part A data and whether it could be applied to a population of patients aged 18+ using all-payer data.
- The developers report that their results indicate their model had good discrimination and predictive ability in both groups.

Questions for the Committee:

- *Are the candidate and final variables included in the risk adjustment model adequately described for the measure to be implemented?*
- *Are all of the risk-adjustment variables present at the start of care?*

- *Does the Standing Committee agree with the developer's rationale that there is no conceptual basis for adjusting this measure for SDS factors?*
- *Do you agree with the developer's decision, based on their empirical analysis, to not include SDS factors in their risk-adjustment model?*

2b5. Meaningful difference:

- For public reporting of this measure, CMS characterizes the uncertainty associated with the RSMR by estimating the 95% interval estimate.
- If the RSMR's interval estimate does not include the national observed mortality rate (is lower or higher than the rate), then CMS is confident that the hospital's RSMR is different from the national rate, and describes the hospital on the Hospital Compare website as "better than the U.S. national rate" or "worse than the U.S. national rate."
- If the interval includes the national rate, then CMS describes the hospital's RSMR as "no different than the U.S. national rate" or "the difference is uncertain."
- The developer reports that for the performance period of July 2011-June 2014, the median hospital RSMR was 11.7%, with a range of 7.0% to 19.3%. The interquartile range was 10.9%-12.4%.
- Out of 4,771 hospitals in the U.S., 145 performed "better than the U.S. national rate," 3,662 performed "no different from the U.S. national rate," and 93 performed "worse than the U.S. national rate." 871 were classified as "number of cases too small" (fewer than 25) to reliably tell how well the hospital is performing.
- The developer's interpretation of this data is that the variation in rates and number of performance outliers suggests there remain differences in the quality of care received across hospitals for heart failure that support measurement to reduce the variation.

Question for the Committee:

- *Does this measure identify meaningful differences about quality?*

2b6. Comparability of data sources/methods:

- While the developer did not decide to include SDS variables in their final model, they did compare measure results with and without SDS adjustment.

2b7. Missing Data

- N/A

Committee pre-evaluation comments

Criteria 2: Scientific Acceptability of Measure Properties (including all 2a, 2b, and 2d)

2a1. &2b1.: ***Committee's Comments on Reliability-Specifications:***

- Why are patients discharged alive on the day of admission or the following day excluded?
- In the Medicare population how can the vital status be unknown?
- Should not patients who are admitted with end stage heart failure and are sent out to Hospice be excluded?
- This 30-day all cause mortality measure for patients hospitalized with HF using a standardized risk standardized mortality ratio (RSMR) is well specified and has been updated to reflect the ICD9 CM CC map to capture all relevant co morbidities coded in patient administrative claims data. The measure developer also described other updates for the 2016 Reporting that notes the future exclusion of patients undergoing LVAD implantation or heart transplant during the index admission or who have had a history of LVAD or heart transplant in the previous year. The measure developer also provided the rationale behind that decision citing that this patient population would have distinctly different mortality risk and risk factors from the primary heart failure cohort.
- Denominator statement includes patients 18 and older discharged from hospital with a principal discharge diagnosis of HF and with a complete claims history for the 12 months prior to admission. The measure can also be calculated for patients 65 and older only as well. The denominator population was defined using ICD 9 and 10 codes, with all codes included in the submission.
- The numerator statement is "any patient who died of any cause within 30 days of the date of admission of the index HF hospitalization." Data used to construct numerator includes Death Master File, state-based data systems, and Medicare Enrollment Database, among others.
- Data sources used to construct this measure include the following: Medicare Part A and B claims, all payer data sources, Veterans Health Administration claims
- The measure can be calculated from 1 to three years.
- Based upon the rigor in defining all elements needed to construct the measures, and the incorporation of all important and relevant codes, I think that it is likely that this measures can be consistently implemented."

2a2.: ***Committee's Comments on Reliability-Testing:***

- I understand what they did and I am fine with it. But is 0.55 adequate?? And I am not sure I agree with the following: The developer expects that the correlation coefficient would be higher using a full three-year sample since it would include more patients. Without data to support this, I do not think such claims can be made.
- In keeping with the requirements for measure endorsement, the measure development assessed reliability at both the individual data element and at the performance score levels. Based upon the data submitted , the testing results demonstrate an adequate level of reliability. More specifically, the presentation of the odds ratios for each risk variable in the model remained relatively constant across the three years, even though some model variables increased during that same time frame. The measure developed cited that there may be an increase in co-morbidity rates or improved coding on administrative claims.
- The measure developer used a test-re-test approach to assess reliability of the hospital performance, a method endorsed by NQF. A total of 991,007 admissions over a 3 year period were examined, and RSMRs were calculated in one sample and in another randomly selected sample. The agreement between the two was .55 which was considered moderate level of agreement. Not nearly as high as I would have expected. Would love to see a re-run of the analysis with a more robust set of data over a longer time frame...

2b1.: ***Committee's Comments on Validity-Specifications***:

- Why are patients discharged alive on the day of admission or the following day excluded?
- In the Medicare population how can the vital status be unknown?
- Should not patients who are admitted with end stage heart failure and are sent out to Hospice be excluded?
- The numerator, denominator were appropriately defined. Specific data elements like 30-day all cause mortality.
- I think that the specifications are consistent with the evidence.

2b2.: ***Committee's Comments on Validity-Testing:***

- Excellent correlation between the claims-based RSMRs and the record-based RSMRs.
- The measure developed conducted empirical validity testing of the sure score. To assess validity, the measure developer compared scores from the administrative claims based measure to those computed from the medical record review from the same cohort of patients. The correlation between the claims based and the medical record review RSMR was estimated at 0.95 which suggests that the measure is as good as that which is derived from the medical record model.
- As such the methods and results of testing truly demonstrate sufficient validity so that accurate conclusions about quality can be made. Moreover, the score that is calculated form this measure is an indicator of quality.

2b3-7.: ***Committee's Comments on Threats to Validity:***

- Model is not great (c statistic is only 0.68).
- One of the variables they include in the model is Hf, but all pts have HF, so it does not make sense to include such a variable.
- The measure developer listed a number of exclusions and determined its impact by examining overall frequencies and proportions of the total cohort excluded for each exclusion criteria. The measure developer then presented the distribution of these exclusions across hospitals. Interesting to note that the majority of the excluded patient population were those who were discharged on the day of admission or the following day who were not transferred to another acute care facility, thus demonstrating that the patients included in the cohort are clinically relevant. Based upon the measure developers submission, a final set of clinical risk-adjustment variables, along with ORs were presented. The measure developers also considered a set of sociodemographic status (SDS) variables, presented a conceptual analysis for the need for SDS adjustment, and then set out to conduct an empirical analysis of the SDS factors. Based upon their findings, the measure developers first stated that the literature was limited in linking various SDS factors to 30 day mortality after HF. Howeer they did note that SDS could be feasibly incorporated into their model, however, noted that given the controversial nature of incorporating such variables into a risk model they've chosen not to do so.
- As for the risk adjustment model, the measure developers computed several summary statistics- C-statistic, predictive ability, and overfitting indices. While with a Cstatistic at .68, the measure developers noted that this is considered fair model discrimination, the predictive ability of distinguishing high risk subjects from low-risk subjects was good. Overall, the measure developer noted that their findings demonstrated that the risk adjustment model adequately controls for difference in case mix. Not being a statistician, I must defer to my colleagues who may have a different interpretation of the results. Stratifying for 65+ using Medicare part A data and for patients 18+ using all payer data, the model still had good discrimination.
- I think that the final variables in the risk model are adequately described. I believe that all of the risk adjustment variables are present at the start of care.

- Based upon the data presented around meaningful differences, there seems to be variability in the quality of care across hospitals. The median hospital RSMR was 11.7% with a range of 7% to 19.3%. The interquartile range was 10.9% -12.4%.

2d.: ***Committee's Comments on Composite Performance Measure:***

- Not Applicable

Criterion 3. Feasibility

3. Feasibility is the extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

- This measure is based on administrative claims data (e.g., DRG, ICD-9/10), which the developers note are routinely generated and collected as part of hospitals' billing processes.
- The developer indicates that all data elements are in defined fields in electronic claims.

Questions for the Committee:

- *Are the required data elements routinely generated and used during care delivery?*
- *Is the data collection strategy ready to be put into operational use?*

Committee pre-evaluation comments

Criteria 3: Feasibility

3.: ***Committee's Comments on Feasibility:***

- Very good
- Currently the data used to construct this measure is routinely captured as a par6t of hospitals' bulling processes.

Criterion 4: Usability and Use

4. Usability and Use evaluate the extent to which audiences (e.g., consumers, purchasers, providers, policymakers) use or could use performance results for both accountability and performance improvement activities.

- Measure results are publicly reported through CMS's Hospital Inpatient Quality Reporting (IQR) Program.
- In addition, measure results are incorporated into the calculation of hospital payment rates through CMS's Hospital Value Based Purchasing (HVBP) Program.
- The developer reports that there has been significant progress in 30-day mortality rates for heart failure, noting that the median 30-day RSMR decreased by 0.7 absolute percentage points from 2011-2012 (median RSMR: 11.7%) to 2013-2014 (median RSMR: 11.0%).
- The developers did not identify any unintended consequences during measure development or model testing, but note that they are committed to monitoring this measure's use and assessing potential unintended consequences over time.

Questions for the Committee*:*

- *Are this measure's performance results being used to further the goal of high-quality, efficient healthcare?*
- *Do the benefits of the measure outweigh any potential unintended consequences?*

Committee pre-evaluation comments

Criteria 4: Usability and Use

4.: ***Committee's Comments on Usability and Use:***

- It is in use. Publically reported.
- The measure results have been and currently are being publicly reported through CMS' IQR Program, as well as

is being incorporated in the Hospital Value Based Purchasing (HVBP) Program. While the unintended consequences were note identified by the developer, there was a note that showcased that there has been progress in 30-day mortality rates for heart failure, noting that the median 30-day RSMR decreased by .7 absolute percentage form 2011-2012 to 2013-2014.

Criterion 5: Related and Competing Measures
• List any related or competing measures based on harmonization protocol. • Summarize any harmonization efforts, i.e., responses from the developers regarding harmonization. • Briefly summarize next steps according to protocol

Pre-meeting public and member comments

•

NATIONAL QUALITY FORUM—Evidence (subcriterion 1a)

Measure Title: Hospital 30-day, all-cause, risk-standardized mortality rate (RSMR) following heart failure (HF) hospitalization for patients 18 and older

IF the measure is a component in a composite performance measure, provide the title of the Composite Measure here: Click here to enter composite measure title

Date of Submission: Click here to enter a date

Instructions

- *For composite performance measures:*
  - *A separate evidence form is required for each component measure unless several components were studied together.*
  - *If a component measure is submitted as an individual performance measure, attach the evidence form to the individual measure submission.*
- Respond to all questions as instructed with answers immediately following the question. All information needed to demonstrate meeting the evidence subcriterion (1a) must be in this form. An appendix of *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 10 pages (*incudes questions/instructions*; minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the evidence for this measure meets NQF's evaluation criteria.

1a. Evidence to Support the Measure Focus

The measure focus is evidence-based, demonstrated as follows:

- Health outcome: [3] a rationale supports the relationship of the health outcome to processes or structures of care. Applies to patient-reported outcomes (PRO), including health-related quality of life/functional status, symptom/symptom burden, experience with care, health-related

behavior.

- Intermediate clinical outcome: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured intermediate clinical outcome leads to a desired health outcome.
- Process: [5] a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured process leads to a desired health outcome.
- Structure: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured structure leads to a desired health outcome.
- Efficiency: [6] evidence not required for the resource use component.

Notes

3. Generally, rare event outcomes do not provide adequate information for improvement or discrimination; however, serious reportable events that are compared to zero are appropriate outcomes for public reporting and quality improvement.

4. The preferred systems for grading the evidence are the U.S. Preventive Services Task Force (USPSTF) grading definitions and methods, or Grading of Recommendations, Assessment, Development and Evaluation (GRADE) guidelines.

5. Clinical care processes typically include multiple steps: assess → identify problem/potential problem → choose/plan intervention (with patient input) → provide intervention → evaluate impact on health status. If the measure focus is one step in such a multistep process, the step with the strongest evidence for the link to the desired outcome should be selected as the focus of measurement. Note: A measure focused only on collecting PROM data is not a PRO-PM.

6. Measures of efficiency combine the concepts of resource use and quality (see NQF's Measurement Framework: Evaluating Efficiency Across Episodes of Care; AQA Principles of Efficiency Measures).

1a.1.This is a measure of:

Outcome

☒ Health outcome: cost/resource use.

☐ Patient-reported outcome (PRO): Click here to name the PRO

PROs include HRQoL/functional status, symptom/symptom burden, experience with care, health-related behaviors

☐ Intermediate clinical outcome (e.g. lab value): Click here to name the intermediate outcome

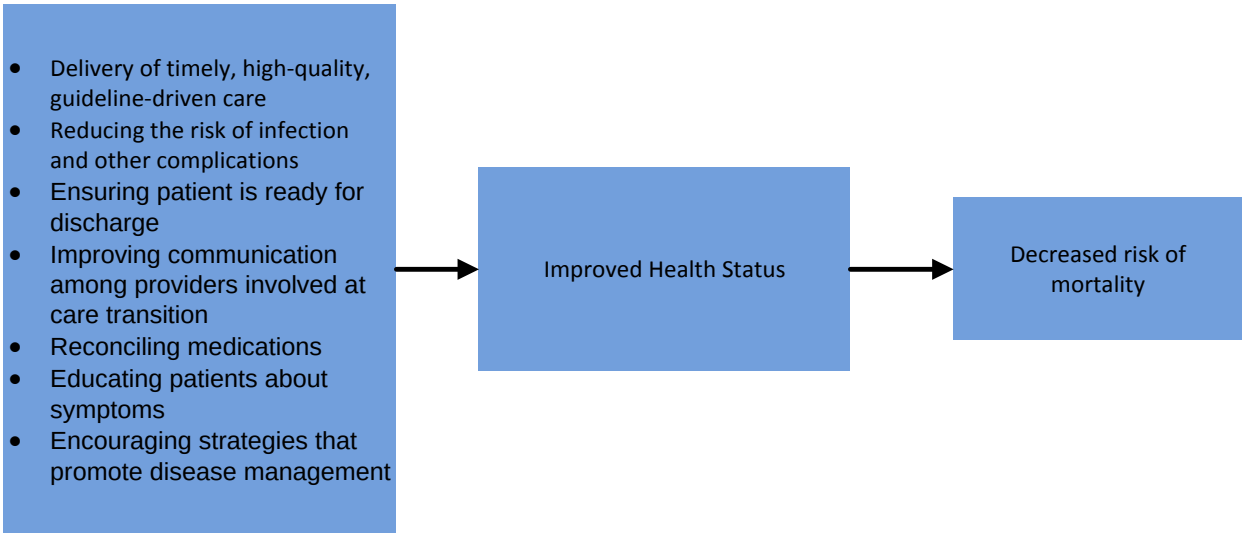
☐ Process: Click here to name the process

☐ Structure: Click here to name the structure

☐ Other: Click here to name what is being measured

HEALTH OUTCOME PERFORMANCE MEASURE *If not a health outcome, skip to 1a.3*

1a.2. Briefly state or diagram the linkage between the health outcome (or PRO) and the healthcare structures, processes, interventions, or services that influence it.



The goal of this measure is to directly affect patient outcomes by measuring risk-standardized rates of mortality. Measurement of patient outcomes, including mortality, allows for a broad view of quality of care that encompasses more than what can be captured by individual process-of-care measures. As described below, mortality is likely to be influenced by a broad range of clinical activities such as the prevention of complications and the provision of evidenced-based care.

1a.2.1. State the rationale supporting the relationship between the health outcome (or PRO) and at least one healthcare structure, process, intervention, or service.

Heart failure (HF) incidence approaches 10 per 1000 of the population after 65 years of age (NHLBI 2007), and is the most common discharge diagnosis among the elderly (Jessup and Brozena 2003); prevalence of HF in the U.S. is estimated at nearly 6 million (Mozaffarian 2015, Lloyd-Jones 2009), and is suspected as the leading cause of death in people over age 65.

According to the 2015 AHA update report, one in 9 deaths has HF mentioned on the death certificate. In 2011, HF any-mention mortality was 284,388. HF was the underlying cause in 58,309 of those deaths in 2011 (Mozaffarian 2015, National Center for Health Statistics 2011). There are 870,000 new HF cases annually (Mozaffarian 2015). Survival after HF diagnosis has improved over time, however, the death rate remains high:

≈50% of people diagnosed with HF will die within 5 years (Mozaffarian 2015, Levy et al. 2002, Roger et al. 2004). Among Medicare beneficiaries, the overall 1-year HF mortality rate declined slightly from 1998 to 2008 but remained high at 29.6% (Chen et al. 2011). Rates of mortality decline were uneven across states.

Clinical experience suggests that the care for these patients is highly variable, and studies suggest quality gaps in hospital care—particularly in the transition to outpatient care (Albert 2009, Jha 2005). Moreover, there is substantial inter-hospital variation in the risk of death that is not clearly explained by differences in case mix. Measurement of patient outcomes allows for a broad view of quality of care that encompasses more than what can be captured by individual process-of-care measures. Complex and critical aspects of care, such as communication between providers, prevention of and response to complications, patient safety, and coordinated transitions to the outpatient environment, all contribute to patient outcomes but are difficult to measure by individual process measures.

The HF RSMR measure is thus intended to inform quality-of-care improvement efforts, as individual process-based performance measures cannot encompass all the complex and critical aspects of care within a hospital that contribute to patient outcomes. Many stakeholders, including patient organizations, are interested in outcomes measures that allow patients and providers to assess relative outcomes performance for hospitals.

The diagram above indicates some of the many care processes that can influence mortality risk. Numerous studies have demonstrated that appropriate and timely treatment for HF patients can reduce the risk of mortality within 30 days of hospital admission (Hunt 2009, Jha 2007). Additionally, trials of interventions which improve patient education upon discharge have been shown to improve survival for HF patients (McAllister 2001). Evidence that hospitals have been able to reduce mortality rates through these quality-of-care initiatives illustrates the degree to which hospital practices can affect mortality rates.

Note: For health outcome performance measures, no further information is required; however, you may provide evidence for any of the structures, processes, interventions, or service identified above.

INTERMEDIATE OUTCOME, PROCESS, OR STRUCTURE PERFORMANCE MEASURE

1a.3. Briefly state or diagram the linkages between structure, process, intermediate outcome, and health outcomes. Include all the steps between the measure focus and the health outcome.

1a.3.1. What is the source of the systematic review of the body of evidence that supports the performance measure?

☐ Clinical Practice Guideline recommendation – ***complete sections 1a.4, and 1a.7***

☐ US Preventive Services Task Force Recommendation – ***complete sections 1a.5 and 1a.7***

☐ Other systematic review and grading of the body of evidence (*e.g., Cochrane Collaboration, AHRQ Evidence Practice Center*) – ***complete sections 1a.6 and 1a.7***

☐ Other – ***complete section 1a.8***

Please complete the sections indicated above for the source of evidence. You may skip the sections that do not apply.

1a.4. CLINICAL PRACTICE GUIDELINE RECOMMENDATION

1a.4.1. Guideline citation (*including date*) and **URL for guideline** (*if available online*):

1a.4.2. Identify guideline recommendation number and/or page number and **quote verbatim, the specific guideline recommendation**.

1a.4.3. Grade assigned to the quoted recommendation with definition of the grade:

1a.4.4. Provide all other grades and associated definitions for recommendations in the grading system. (*Note: If separate grades for the strength of the evidence, report them in section 1a.7.*)

1a.4.5. Citation and URL for methodology for grading recommendations (*if different from 1a.4.1*)**:**

1a.4.6. If guideline is evidence-based (rather than expert opinion), are the details of the quantity, quality, and consistency of the body of evidence available (e.g., evidence tables)?

☐ Yes → ***complete section 1a.7***

☐ No → ***report on another systematic review of the evidence in sections 1a.6 and 1a.7; if another review does not exist, provide what is known from the guideline review of evidence in 1a.7***

1a.5. UNITED STATES PREVENTIVE SERVICES TASK FORCE RECOMMENDATION

1a.5.1. Recommendation citation (*including date*) and **URL for recommendation** (*if available online*):

1a.5.2. Identify recommendation number and/or page number and **quote verbatim, the specific recommendation**.

1a.5.3. Grade assigned to the quoted recommendation with definition of the grade:

1a.5.4. Provide all other grades and associated definitions for recommendations in the grading system.
(*Note: the grading system for the evidence should be reported in section 1a.7.*)

1a.5.5. Citation and URL for methodology for grading recommendations (*if different from 1a.5.1*)**:**

Complete section 1a.7

1a.6. OTHER SYSTEMATIC REVIEW OF THE BODY OF EVIDENCE

1a.6.1. Citation (*including date*) and **URL** (*if available online*):

1a.6.2. Citation and URL for methodology for evidence review and grading (*if different from 1a.6.1*)**:**

Complete section 1a.7

1a.7. FINDINGS FROM SYSTEMATIC REVIEW OF BODY OF THE EVIDENCE SUPPORTING THE MEASURE

If more than one systematic review of the evidence is identified above, you may choose to summarize the one (or more) for which the best information is available to provide a summary of the quantity, quality, and consistency of the body of evidence. Be sure to identify which review is the basis of the responses in this section and if more than one, provide a separate response for each review.

1a.7.1. What was the specific structure, treatment, intervention, service, or intermediate outcome addressed in the evidence review?

1a.7.2. Grade assigned for the quality of the quoted evidence with definition of the grade:

1a.7.3. Provide all other grades and associated definitions for strength of the evidence in the grading system.

1a.7.4. What is the time period covered by the body of evidence? (*provide the date range, e.g., 1990-2010*).
Date range: Click here to enter date range

QUANTITY AND QUALITY OF BODY OF EVIDENCE

1a.7.5. How many and what type of study designs are included in the body of evidence? (*e.g., 3 randomized controlled trials and 1 observational study*)

1a.7.6. What is the overall quality of evidence <u>across studies</u> in the body of evidence? (*discuss the certainty or confidence in the estimates of effect particularly in relation to study factors such as design flaws, imprecision due to small numbers, indirectness of studies to the measure focus or target population*)

ESTIMATES OF BENEFIT AND CONSISTENCY ACROSS STUDIES IN BODY OF EVIDENCE

1a.7.7. What are the estimates of benefit—magnitude and direction of effect on outcome(s) <u>across studies</u> in the body of evidence? (*e.g., ranges of percentages or odds ratios for improvement/ decline across studies, results of meta-analysis, and statistical significance*)

1a.7.8. What harms were studied and how do they affect the net benefit (benefits over harms)?

UPDATE TO THE SYSTEMATIC REVIEW(S) OF THE BODY OF EVIDENCE

1a.7.9. If new studies have been conducted since the systematic review of the body of evidence, provide for <u>each</u> new study: 1) citation, 2) description, 3) results, 4) impact on conclusions of systematic review.

1a.8 OTHER SOURCE OF EVIDENCE

If source of evidence is NOT from a clinical practice guideline, USPSTF, or systematic review, please describe the evidence on which you are basing the performance measure.

1a.8.1 What process was used to identify the evidence?

1a.8.2. Provide the citation and summary for each piece of evidence.

1. Evidence, Performance Gap, Priority – Importance to Measure and Report

Extent to which the specific measure focus is evidence-based, important to making significant gains in healthcare quality, and improving health outcomes for a specific high-priority (high-impact) aspect of healthcare where there is variation in or overall less-than-optimal performance. ***Measures must be judged to meet all subcriteria to pass this criterion and be evaluated against the remaining criteria.***

1a. Evidence to Support the Measure Focus – See attached Evidence Submission Form
HF_Mortality_NQF_Evidence_Attachment_06-29-15.docx

1b. Performance Gap

Demonstration of quality problems and opportunity for improvement, i.e., data demonstrating:

- considerable variation, or overall less-than-optimal performance, in the quality of care across providers; and/or
- disparities in care across population groups.

1b.1. **Briefly explain the rationale for this measure** *(e.g., the benefits or improvements in quality envisioned by use of this measure)*
The goal of this measure is to improve patient outcomes by providing patients, physicians, hospitals, and policy makers with information about hospital-level, risk-standardized mortality rates following hospitalization for HF. Measurement of patient outcomes allows for a broad view of quality of care that encompasses more than what can be captured by individual process-of-care measures. Complex and critical aspects of care, such as communication between providers, prevention of and response to complications, patient safety, and coordinated transitions to the outpatient environment, all contribute to patient outcomes but are difficult to measure by individual process measures. The goal of outcomes measurement is to risk-adjust for patients' conditions at the time of hospital admission and then evaluate patient outcomes. This measure was developed to identify institutions' whose performance is better or worse than would be expected based on their patient case mix, and therefore promote hospital quality improvement and better inform consumers about care quality.

Additionally, HF mortality is a priority area for outcomes measure development, as it is a costly and common condition. Hospital mortality is an outcome that is likely attributable to care processes and is an important outcome for patients. Measuring and reporting mortality rates will inform healthcare providers about opportunities to improve care, strengthen incentives for quality improvement, and ultimately improve the quality of care received by Medicare patients. The measure will also provide patients with information that could guide their choices. Furthermore, the measure will increase transparency for consumers and potentially lower the healthcare costs associated with mortality.

1b.2. **Provide performance scores on the measure as specified (current and over time) at the specified level of analysis.** *(This is required for endorsement maintenance. Include mean, std dev, min, max, interquartile range, scores by decile. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities included). This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*

1b.5. If no or limited data on disparities from the measure as specified is reported in 1b4, then provide a summary of data from the literature that addresses disparities in care on the specific focus of measurement. Include citations.
N/A

1c. High Priority (previously referred to as High Impact)
The measure addresses:

- a specific national health goal/priority identified by DHHS or the National Priorities Partnership convened by NQF; OR
- a demonstrated high-priority (high-impact) aspect of healthcare (e.g., affects large numbers of patients and/or has a substantial impact for a smaller population; leading cause of morbidity/mortality; high resource use (current and/or future); severity of illness; and severity of patient/societal consequences of poor quality).

1c.1. Demonstrated high priority aspect of healthcare
Affects large numbers, A leading cause of morbidity/mortality, High resource use, Severity of illness, Patient/societal consequences of poor quality

1c.2. **If Other:**

1c.3. **Provide epidemiologic or resource use data that demonstrates the measure addresses a high priority aspect of healthcare. List citations in 1c.4.**
HF incidence approaches 10 per 1000 population after 65 years of age (NHLBI 2007), and is the most common discharge diagnosis among the elderly (Jessup and Brozena 2003); prevalence of HF in the U.S. is estimated at nearly 6 million. (Lloyd-Jones 2009), and is suspected to be the leading cause of death in people over age 65.

Many current hospital interventions are known to decrease the risk of death within 30 days of hospital admission (Jha 2007). Current process-based performance measures, however, cannot capture all the ways that care within the hospital might influence outcomes. As a result, many stakeholders, including patient organizations, are interested in outcomes measures that allow patients and providers to assess relative hospital performance on outcomes measures.

Numerous studies have demonstrated that appropriate and timely treatment for HF patients can reduce the risk of mortality within 30 days of hospital admission. (Hunt 2009, Jha 2007) Additionally, trials of interventions which improve patient education upon discharge have been shown to improve survival for HF patients (Mcalister 2001).

1c.5. **If a PRO-PM (e.g. HRQoL/functional status, symptom/burden, experience with care, health-related behaviors), provide evidence that the target population values the measured PRO and finds it meaningful.** *(Describe how and from whom their input was obtained.)*
N/A

2. Reliability and Validity—Scientific Acceptability of Measure Properties

Extent to which the measure, as specified, produces consistent (reliable) and credible (valid) results about the quality of care when implemented. ***Measures must be judged to meet the subcriteria for both reliability and validity to pass this criterion and be evaluated against the remaining criteria.***

2a.1. Specifications The measure is well defined and precisely specified so it can be implemented consistently within and across organizations and allows for comparability. eMeasures should be specified in the Health Quality Measures Format (HQMF) and the Quality Data Model (QDM).

De.5. **Subject/Topic Area** *(check all the areas that apply):*
Cardiovascular, Cardiovascular : Congestive Heart Failure

S.3. **For endorsement maintenance**, please briefly describe any changes to the measure specifications since last endorsement date and explain the reasons.
Annual Updates
1. Updated CC map.
a. Rationale: The ICD-9-CM CC map was updated annually to capture all relevant comorbidities coded in patient administrative claims data.

No other updates made after 2013 Measure Updates except for use of new years of data for public reporting

Planned Update for 2016 public reporting – (changes reflected in this application)
1. Exclude patients undergoing LVAD implantation or heart transplantation during an index admission or who have a history of LVAD or heart transplant in the preceding year.
a. Rationale: Patients undergoing implantation of an LVAD designed to offer intermediate to long-term support (weeks to years) as a bridge to heart transplant or destination therapy represent a clinically distinct, highly-selected group of patients cared for at highly specialized medical centers. This is a subgroup of patients that has grown in recent years and that have distinct mortality risk and risk factors from the primary heart failure cohort.

S.4. **Numerator Statement** *(Brief, narrative description of the measure focus or what is being measured about the target population, i.e., cases from the target population with the target process, condition, event, or outcome)*
IF an OUTCOME MEASURE, state the outcome being measured. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
The outcome for this measure is 30-day all-cause mortality. We define mortality as death from any cause within 30 days of the index admission date for patients 18 and older discharged from the hospital with a principal diagnosis of HF.

S.5. **Time Period for Data** *(What is the time period in which data will be aggregated for the measure, e.g., 12 mo, 3 years, look back to August for flu vaccination? Note if there are different time periods for the numerator and denominator.)*
Numerator time window: We define the time period for death from any cause within 30 days from the date of admission for the index HF hospitalization.

Denominator time window: This measure was developed with 12 months of data. The time window can be specified from one to three years. Currently, the measure is publicly reported with three years of index hospitalizations.

S.6. **Numerator Details** *(All information required to identify and calculate the cases from the target population with the target process, condition, event, or outcome such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
IF an OUTCOME MEASURE, describe how the observed outcome is identified/counted. Calculation of the risk-adjusted outcome

should be described in the calculation algorithm.
The measure counts deaths for any cause within 30 days of the date of admission of the index HF hospitalization.

Identifying deaths in the FFS measure
As currently reported, we identify deaths for FFS Medicare patients 65 years and older in the Medicare Enrollment Database (EDB).

Identifying deaths in the all-payer measure
For the purposes of development of an all-payer measure, deaths were identified using the California vital statistics data file. Nationally, post-discharge deaths can be identified using an external source of vital status, such as the Social Security Administration's Death Master File (DMF) or the Centers for Disease Control and Prevention's National Death Index (NDI).

S.7. **Denominator Statement** *(Brief, narrative description of the target population being measured)*
This claims-based measure can be used in either of two patient cohorts: (1) patients aged 65 years or older or (2) patients aged 18 years or older. We have explicitly tested the measure in both age groups. The cohort includes admissions for patients aged 18 years and older discharged from the hospital with a principal discharge diagnosis of HF and with a complete claims history for the 12 months prior to admission. The measure is currently publicly reported by CMS for those patients 65 years and older who are either Medicare FFS beneficiaries admitted to non-federal hospitals or patients admitted to VA hospitals. Additional details are provided in S.9 Denominator Details.

S.8. **Target Population Category** *(Check all the populations for which the measure is specified and tested if any):*
Populations at Risk, Senior Care

S.9. **Denominator Details** *(All information required to identify and calculate the target population/denominator such as definitions, specific data collection items/responses , code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
To be included in the measure cohort used in public reporting, patients must meet the following additional inclusion criteria:
1. Have a principal discharge diagnosis of heart failure
2. Enrolled in Medicare fee-for-service (FFS)
3. Aged 65 or over
4. Discharged from non-federal acute care hospitals or VA hospitals
5. Enrolled in Part A and Part B Medicare for the 12 months prior to the date of index admission.

VA beneficiaries/hospitalizations are also included in the HF mortality measure. Enrollment in Medicare FFS is not required for these patients.

This measure can also be used for an all-payer population aged 18 years and older. We have explicitly tested the measure in both patients aged 18+ years and those aged 65+ years (see Testing Attachment for details).

International Classification of Diseases, 9th Revision, Clinical Modification (ICD-9-CM) codes used to define the cohort for each measure are:
402.01 Malignant hypertensive heart disease with heart failure
402.11 Benign hypertensive heart disease with heart failure
402.91 Unspecified hypertensive heart disease with heart failure
404.01 Hypertensive heart and chronic kidney disease, malignant, with heart failure and with chronic kidney disease stage I through stage IV, or unspecified
404.03 Hypertensive heart and chronic kidney disease, malignant, with heart failure and with chronic kidney disease stage V or end stage renal disease
404.11 Hypertensive heart and chronic kidney disease, benign, with heart failure and with chronic kidney disease stage I through stage IV, or unspecified
404.13 Hypertensive heart and chronic kidney disease, benign, with heart failure and chronic kidney disease stage V or end stage renal disease
404.91 Hypertensive heart and chronic kidney disease, unspecified, with heart failure and with chronic kidney disease stage I through stage IV, or unspecified
404.93 Hypertensive heart and chronic kidney disease, unspecified, with heart failure and chronic kidney disease stage V or end stage renal disease
428.0 Congestive heart failure, unspecified

428.1 Left heart failure
428.20 Systolic heart failure, unspecified
428.21 Acute systolic heart failure
428.22 Chronic systolic heart failure
428.23 Acute on chronic systolic heart failure
428.30 Diastolic heart failure, unspecified
428.31 Acute diastolic heart failure
428.32 Chronic diastolic heart failure
428.33 Acute on chronic diastolic heart failure
428.40 Combined systolic and diastolic heart failure, unspecified
428.41 Acute combined systolic and diastolic heart failure
428.42 Chronic combined systolic and diastolic heart failure
428.43 Acute on chronic combined systolic and diastolic heart failure
428.9 Heart failure, unspecified

ICD-10 Codes that define the patient cohort:
I110 Hypertensive heart disease with heart failure
I130 Hypertensive heart and chronic kidney disease with heart failure and stage 1 through stage 4 chronic kidney disease, or unspecified chronic kidney disease
I132 Hypertensive heart and chronic kidney disease with heart failure and with stage 5 chronic kidney disease, or end stage renal disease
I509 Heart failure, unspecified
I501 Left ventricular failure
I5020 Unspecified systolic (congestive) heart failure
I5021 Acute systolic (congestive) heart failure
I5022 Chronic systolic (congestive) heart failure
I5023 Acute on chronic systolic (congestive) heart failure
I5030 Unspecified diastolic (congestive) heart failure
I5031 Acute diastolic (congestive) heart failure
I5032 Chronic diastolic (congestive) heart failure
I5033 Acute on chronic diastolic (congestive) heart failure
I5040 Unspecified combined systolic (congestive) and diastolic (congestive) heart failure
I5041 Acute combined systolic (congestive) and diastolic (congestive) heart failure
I5042 Chronic combined systolic (congestive) and diastolic (congestive) heart failure
I5043 Acute on chronic combined systolic (congestive) and diastolic (congestive) heart failure

An ICD-9 to ICD-10 crosswalk is attached in field S.2b. (Data Dictionary or Code Table).

S.10. Denominator Exclusions *(Brief narrative description of exclusions from the target population)*
The mortality measures exclude index admissions for patients:
1. Discharged alive on the day of admission or the following day who were not transferred to another acute care facility.
2. With inconsistent or unknown vital status or other unreliable demographic (age and gender) data;
3. Enrolled in the Medicare hospice program or used VA hospice services any time in the 12 months prior to the index admission, including the first day of the index admission;
4. Discharged against medical advice (AMA); or
5. Patients undergoing LVAD implantation or heart transplantation during an index admission or who have a history of LVAD or heart transplant in the preceding year.

For patients with more than one admission for a given condition in a given year, only one index admission for that condition is randomly selected for inclusion in the cohort.

For Medicare FFS patients, the measure additionally excludes admissions for patients without at least 30 days post-discharge enrollment in FFS Medicare (because the 30-day mortality outcome cannot be assessed in this group).

S.11. Denominator Exclusion Details *(All information required to identify and calculate exclusions from the denominator such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*

1. The discharge disposition indicator is used to identify patients alive at discharge. Transfers are identified in the claims when a patient with a qualifying admission is discharged from an acute care hospital and admitted to another acute care hospital on the same day or next day. Patient length of stay and condition is identified from the admission claim.
2. Inconsistent vital status or unreliable data are identified if any of the following conditions are met 1) the patient's age is greater than 115 years: 2) if the discharge date for a hospitalization is before the admission date; 3) if the patient has a sex other than 'male' or 'female'.
3. Hospice enrollment in the 12 months prior to or on the index admission is identified using hospice data and the Inpatient standard analytic file (SAF). This exclusion applies when the measure is used in Medicare FFS patients only.
4. Discharges against medical advice (AMA) are identified using the discharge disposition indicator.
5. Patients with LVAD implantation or heart transplantation during an index admission or in the previous 12 months are identified by the corresponding codes for these procedures included in claims data.

Additional exclusions:
• HF admissions within 30 days of discharge from a qualifying index admission, which are identified by comparing the discharge date from the index admission with the readmission date.
• Admissions without at least 30 days post-discharge enrollment in FFS Medicare are determined by examining the Medicare Enrollment Database (EDB)

S.12. Stratification Details/Variables *(All information required to stratify the measure results including the stratification variables, definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format with at S.2b)*
N/A

S.13. Risk Adjustment Type (Select type. Provide specifications for risk stratification in S.12 and for statistical model in S.14-15)
Statistical risk model
If other:

S.14. Identify the statistical risk model method and variables *(Name the statistical method - e.g., logistic regression and list all the risk factor variables. Note - risk model development and testing should be addressed with measure testing under Scientific Acceptability)*
Our approach to risk adjustment is tailored to and appropriate for a publicly reported outcome measure, as articulated in the American Heart Association (AHA) Scientific Statement, "Standards for Statistical Models Used for Public Reporting of Health Outcomes" (Krumholz et al., 2006).

The measure employs a hierarchical logistic regression model to create a hospital-level 30-day RSMR. In brief, the approach simultaneously models data at the patient and hospital levels to account for the variance in patient outcomes within and between hospitals (Normand & Shahian, 2007). At the patient level, the model adjusts the log-odds of mortality within 30 days of admission for age, sex, and selected clinical covariates. At the hospital level, the approach models the hospital-specific intercepts as arising from a normal distribution. The hospital intercept represents the underlying risk of a death at the hospital, after accounting for patient risk. If there were no differences among hospitals, then after adjusting for patient risk, the hospital intercepts should be identical across all hospitals.

Candidate and Final Risk-adjustment Variables: Candidate variables were patient-level risk-adjustors that were expected to be predictive of mortality, based on empirical analysis, prior literature, and clinical judgment, including age, sex, and indicators of comorbidity and disease severity. For each patient, covariates are obtained from claims records extending 12 months prior to and including the index admission. For the measure currently implemented by CMS, these risk-adjusters are identified using both inpatient and outpatient Medicare FFS claims data. However, in the all-payer hospital discharge database measure, the risk-adjustment variables can be obtained only from inpatient claims in the prior 12 months and the index admission. (This was tested explicitly in our all-payer testing, as many all-payer datasets do not include outpatient claims.)

The model adjusts for case-mix differences based on the clinical status of patients at the time of admission. We use condition categories (CCs), which are clinically meaningful groupings of more than 15,000 ICD-9-CM diagnosis codes (Pope et al., 2000). A file that contains a list of the ICD-9-CM codes and their groupings into CCs is attached in data field S.2b (Data Dictionary or Code Table). In addition, only comorbidities that convey information about the patient at admission or in the 12 months prior, and not complications that arise during the course of the index hospitalization, are included in the risk adjustment. Hence, we do not risk adjust for CCs that may represent adverse events of care and that are only recorded in the index admission.

The final set of risk adjustment variables is:

Demographics
Male
Age-65 (years above 65, continuous) for 65 and over cohorts; or Age (years, continuous) for 18 and over cohorts.

Comorbidities
Congestive heart failure (CC 80)
Acute myocardial infarction (CC 81)
Other acute/subacute forms of ischemic heart disease (CC 82)
Coronary atherosclerosis or angina (CC 83-84)
Cardio-respiratory failure and shock (CC 79)
Valvular and rheumatic heart disease (CC 86)
Hypertension (CC 89, 91)
Stroke (CC 95-96)
Renal failure (CC 131)
Chronic obstructive pulmonary disease (COPD) (CC 108)
Pneumonia (CC 111-113)
Diabetes mellitus (DM) or DM complications except proliferative retinopathy (CC 15-20, 120)
Protein-calorie malnutrition (CC 21)
Dementia or other specified brain disorders (CC 49-50)
Hemiplegia, paraplegia, paralysis, functional disability (CC 67-69, 100-102, 177-178)
Vascular disease and complications (CC 104-105)
Metastatic cancer, acute leukemia and other severe cancers (CC 7-8)
Trauma in last year (CC 154-156, 158-162)
Major psychiatric disorders (CC 54-56)
Chronic Liver Disease (CC 25-27)
History of CABG (ICD-9-CM V45.81, 36.10-36.16)
History of PTCA (ICD-9-CM V45.82, 00.66, 36.01, 36.02, 36.05, 36.06, 36.07)

S.16. **Type of score:**
Rate/proportion
If other:

S.17. **Interpretation of Score** *(Classifies interpretation of score according to whether better quality is associated with a higher score, a lower score, a score falling within a defined interval, or a passing score)*
Better quality = Lower score

S.18. Calculation Algorithm/Measure Logic *(Describe the calculation of the measure score as an ordered sequence of steps including identifying the target population; exclusions; cases meeting the target process, condition, event, or outcome; aggregating data; risk adjustment; etc.)*

The measure estimates hospital-level 30-day all-cause RSMRs following hospitalization for HF using hierarchical logistic regression models. In brief, the approach simultaneously models data at the patient and hospital levels to account for variance in patient outcomes within and between hospitals [Normand and Shahian, 2007]. At the patient level, it models the log-odds of mortality within 30 days of index admission using age, sex, selected clinical covariates, and a hospital-specific intercept. At the hospital level, it models the hospital-specific intercepts as arising from a normal distribution. The hospital intercept represents the underlying risk of a mortality at the hospital, after accounting for patient risk. The hospital-specific intercepts are given a distribution to account for the clustering (non-independence) of patients within the same hospital. If there were no differences among hospitals, then after adjusting for patient risk, the hospital intercepts should be identical across all hospitals.

The RSMR is calculated as the ratio of the number of "predicted" to the number of "expected" deaths at a given hospital, multiplied by the national observed mortality rate. For each hospital, the numerator of the ratio is the number of deaths within 30 days predicted on the basis of the hospital's performance with its observed case mix, and the denominator is the number of deaths expected based on the nation's performance with that hospital's case mix. This approach is analogous to a ratio of "observed" to "expected" used in other types of statistical analyses. It conceptually allows for a comparison of a particular hospital's performance given its case mix to an average hospital's performance with the same case mix. Thus, a lower ratio indicates lower-than-expected mortality rates or better quality, and a higher ratio indicates higher-than-expected mortality rates or worse quality.

The "predicted" number of deaths (the numerator) is calculated by using the coefficients estimated by regressing the risk factors and the hospital-specific intercept on the risk of mortality. The estimated hospital-specific intercept is added coefficients multiplied by the patient characteristics. The results are transformed and summed over all patients attributed to a hospital to get a predicted value. The "expected" number of deaths (the denominator) is obtained in the same manner, but a common intercept using all hospitals in our sample is added in place of the hospital-specific intercept. The results are transformed and summed over all patients in the hospital to get an expected value. To assess hospital performance for each reporting period, we re-estimate the model coefficients using the years of data in that period.

This calculation transforms the ratio of predicted over expected into a rate that is compared to the national observed readmission rate. The hierarchical logistic regression models are described fully in the original methodology report [Krumholz et al., 20052].

S.19. Calculation Algorithm/Measure Logic Diagram URL or Attachment *(You also may provide a diagram of the Calculation Algorithm/Measure Logic described above at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*

Available at measure-specific web page URL identified in S.1

S.20. Sampling *(If measure is based on a sample, provide instructions for obtaining the sample and guidance on minimum sample size.)*

IF a PRO-PM, identify whether (and how) proxy responses are allowed.

N/A. This measure is not based on a sample or survey.

S.21. Survey/Patient-reported data *(If measure is based on a survey, provide instructions for conducting the survey and guidance on minimum response rate.)*

IF a PRO-PM, specify calculation of response rates to be reported with performance measure results.

N/A. This measure is not based on a sample or survey.

S.22. Missing data (specify how missing data are handled, e.g., imputation, delete case.)

Required for Composites and PRO-PMs.

Missing values are rare among variables used from claims data in this measure.

S.23. Data Source *(Check ONLY the sources for which the measure is SPECIFIED AND TESTED).*
If other, please describe in S.24.

Administrative claims, Other, Paper Medical Records

S.24. **Data Source or Collection Instrument** *(Identify the specific data source/data collection instrument e.g. name of database, clinical registry, collection instrument, etc.)*
IF a PRO-PM, identify the specific PROM(s); and standard methods, modes, and languages of administration.
Data sources for the Medicare FFS measure:
1. Medicare Part A inpatient and Part B outpatient claims: This data source contains claims data for FFS inpatient and outpatient services including: Medicare inpatient hospital care, outpatient hospital services, skilled nursing facility care, some home health agency services, as well as inpatient and outpatient physician claims for the 12 months prior to an index admission.
2. Medicare Enrollment Database (EDB): This database contains Medicare beneficiary demographic, benefit/coverage, and vital status information. This data source was used to obtain information on several inclusion/exclusion indicators such as Medicare status on admission as well as vital status. These data have previously been shown to accurately reflect patient vital status (Fleming et al., 1992).
3. Veterans Health Administration (VA) Data: This data source contains claims data for VA inpatient and outpatient services including: inpatient hospital care, outpatient hospital services, skilled nursing facility care, some home health agency services, as well as inpatient and outpatient physician claims for the 12 months prior to and including each index admission. Unlike Medicare FFS patients, VA patients are not required to have been enrolled in Part A and Part B Medicare for the 12 months prior to the date of admission.

All-payer data sources:
For our analyses to examine use in all-payer data, we used all-payer data from California in addition to CMS data for Medicare FFS 65+ patients in California hospitals. California is a diverse state, and, with more than 37 million residents, California represents 12% of the US population. We used the California Patient Discharge Data, a large, linked database of patient hospital admissions. In 2006, there were approximately 3 million adult discharges from more than 450 non-Federal acute care hospitals. Records are linked by a unique patient identification number, allowing us to determine patient history from previous hospitalizations and to evaluate rates of both readmission and mortality (via linking with California vital statistics records).

Using all-payer data from California as well as CMS Medicare FFS data for California hospitals, we performed analyses to determine whether the HF mortality measure can be applied to all adult patients, including not only FFS Medicare patients aged 65+ but also non-FFS Medicare patients aged 18-64 years at the time of admission.

Measure Title: Hospital 30-day, all-cause, risk-standardized mortality rate (RSMR) following heart failure (HF) hospitalization for patients 18 and older

Date of Submission:[enter submission date]

Type of Measure:

☐ Composite – ***STOP – use composite testing form***	☒ Outcome (*including PRO-PM*)
☐ Cost/resource	☐ Process
☐ Efficiency	☐ Structure

Instructions

- Measures must be tested for all the data sources and levels of analyses that are specified. ***If there is more than one set of data specifications or more than one level of analysis, contact NQF staff*** about how to present all the testing information in one form.
- **For all measures, sections 1, 2a2, 2b2, 2b3, and 2b5 must be completed.**
- **For outcome and resource use measures**, section **2b4** also must be completed.
- If specified for **multiple data sources/sets of specificaitons** (e.g., claims and EHRs), section **2b6** also must be completed.
- Respond to all questions as instructed with answers immediately following the question. All information on testing to demonstrate meeting the subcriteria for reliability (2a2) and validity (2b2-2b6) must be in this form. An appendix for *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 20 pages (*incuding questions/instructions;* minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.
- For information on the most updated guidance on how to address sociodemographic variables and testing in this form refer to the release notes for version 6.6 of the Measure Testing Attachment.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the testing results for this measure meet NQF's evaluation criteria for testing.

2a2. Reliability testing [10] demonstrates the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise. For **PRO-PMs and composite performance measures**, reliability should be demonstrated for the computed performance score.

2b2. Validity testing [11] demonstrates that the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality. For **PRO-PMs and composite performance measures**, validity should be demonstrated for the computed performance score.

2b3. Exclusions are supported by the clinical evidence; otherwise, they are supported by evidence of sufficient frequency of occurrence so that results are distorted without the exclusion; [12]

AND

If patient preference (e.g., informed decisionmaking) is a basis for exclusion, there must be evidence that the exclusion impacts performance on the measure; in such cases, the measure must be specified so that the information about patient preference and the effect on the measure is transparent (e.g., numerator category computed separately, denominator

exclusion category computed separately). [13]

2b4. For outcome measures and other measures when indicated (e.g., resource use):

- **an evidence-based risk-adjustment strategy** (e.g., risk models, risk stratification) is specified; is based on patient factors (including clinical and sociodemographic factors) that influence the measured outcome and are present at start of care; [14,15] and has demonstrated adequate discrimination and calibration

OR

- rationale/data support no risk adjustment/ stratification.

2b5. Data analysis of computed measure scores demonstrates that methods for scoring and analysis of the specified measure allow for **identification of statistically significant and practically/clinically meaningful [16] differences in performance**;

OR

there is evidence of overall less-than-optimal performance.

2b6. If multiple data sources/methods are specified, there is demonstration they produce comparable results.

2b7. For **eMeasures, composites, and PRO-PMs** (or other measures susceptible to missing data), analyses identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias.

Notes

10. Reliability testing applies to both the data elements and computed measure score. Examples of reliability testing for data elements include, but are not limited to: inter-rater/abstractor or intra-rater/abstractor studies; internal consistency for multi-item scales; test-retest for survey items. Reliability testing of the measure score addresses precision of measurement (e.g., signal-to-noise).

11. Validity testing applies to both the data elements and computed measure score. Validity testing of data elements typically analyzes agreement with another authoritative source of the same information. Examples of validity testing of the measure score include, but are not limited to: testing hypotheses that the measures scores indicate quality of care, e.g., measure scores are different for groups known to have differences in quality assessed by another valid quality measure or method; correlation of measure scores with another valid indicator of quality for the specific topic; or relationship to conceptually related measures (e.g., scores on process measures to scores on outcome measures). Face validity of the measure score as a quality indicator may be adequate if accomplished through a systematic and transparent process, by identified experts, and explicitly addresses whether performance scores resulting from the measure as specified can be used to distinguish good from poor quality.

12. Examples of evidence that an exclusion distorts measure results include, but are not limited to: frequency of occurrence, variability of exclusions across providers, and sensitivity analyses with and without the exclusion.

13. Patient preference is not a clinical exception to eligibility and can be influenced by provider interventions.

14. Risk factors that influence outcomes should not be specified as exclusions

15. With large enough sample sizes, small differences that are statistically significant may or may not be practically or clinically meaningful. The substantive question may be, for example, whether a statistically significant difference of one percentage point in the percentage of patients who received smoking cessation counseling (e.g., 74 percent v. 75 percent) is clinically meaningful; or whether a statistically significant difference of $25 in cost for an episode of care (e.g., $5,000 v. $5,025) is practically meaningful. Measures with overall less-than-optimal performance may not demonstrate much variability across providers.

1. DATA/SAMPLE USED FOR ALL TESTING OF THIS MEASURE

Often the same data are used for all aspects of measure testing. In an effort to eliminate duplication, the first five questions apply to all measure testing. If there are differences by aspect of testing,(e.g., reliability vs. validity) be sure to indicate the specific differences in question 1.7.

1.1. What type of data was used for testing? (*Check all the sources of data identified in the measure specifications and data used for testing the measure. Testing must be provided for all the sources of data specified and intended for measure implementation.* ***If different data sources are used for the numerator and denominator, indicate N [numerator] or D [denominator] after the checkbox.***)

Measure Specified to Use Data From: (***must be consistent with data sources entered in S.23***)	**Measure Tested with Data From:**
☐ abstracted from paper record	☒ abstracted from paper record
☒ administrative claims	☒ administrative claims
☐ clinical database/registry	☐ clinical database/registry
☐ abstracted from electronic health record	☐ abstracted from electronic health record
☐ eMeasure (HQMF) implemented in EHRs	☐ eMeasure (HQMF) implemented in EHRs
☐ other: Click here to describe	☒ other: Census Data/American Community Survey

1.2. If an existing dataset was used, identify the specific dataset (*the dataset used for testing must be consistent with the measure specifications for target population and healthcare entities being measured; e.g., Medicare Part A claims, Medicaid claims, other commercial insurance, nursing home MDS, home health OASIS, clinical registry*).

The datasets used for testing included Medicare Parts A and B claims, Veterans' Health Administration claims, as well as the Medicare Enrollment Database (EDB). Additionally, census data were used to assess sociodemographic factors. The dataset used varies by testing type; see Section 1.7 for details.

1.3. What are the dates of the data used in testing? Click here to enter date range

The dates used vary by testing type; see Section 1.7 for details.

1.4. What levels of analysis were tested? (*testing must be provided for all the levels specified and intended for measure implementation, e.g., individual clinician, hospital, health plan*)

Measure Specified to Measure Performance of: (***must be consistent with levels entered in item S.26***)	**Measure Tested at Level of:**
☐ individual clinician	☐ individual clinician
☐ group/practice	☐ group/practice
☒ hospital/facility/agency	☒ hospital/facility/agency
☐ health plan	☐ health plan
☐ other: Click here to describe	☐ other: Click here to describe

1.5. How many and which measured entities were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of measured entities included in the analysis (e.g., size, location, type); if a sample was used, describe how entities were selected for inclusion in the sample*)

For this measure, hospitals are the measured entities. All non-federal, acute inpatient US hospitals (including territories) with Medicare fee-for-service (FFS) beneficiaries aged 65 years and older are included. All Veteran's Health Administration Hospitals are also included in the current publically reported measure. The number of measured entities (hospitals) varies by testing type; see Section 1.7 for details.

1.6. How many and which patients were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of patients included in the analysis (e.g., age, sex, race, diagnosis); if a sample was used, describe how patients were selected for inclusion in the sample*)

The number of admissions/patients varies by testing type: see Section 1.7 for details

1.7. If there are differences in the data or sample used for different aspects of testing (e.g., reliability, validity, exclusions, risk adjustment), identify how the data or sample are different for each aspect of testing reported below.

The datasets, dates, number of measured entities, and number of admissions used in each type of testing are as follows:

For reliability testing (Section 2a2)
The reliability of the model was tested by randomly selecting 50% of the Medicare patients aged 65+ in the most recent 3-year cohort and developing a risk-adjusted model for this group. We then developed a second model for the remaining 50% of patients and compared the two. Thus, for reliability testing, we randomly split Dataset 1 into two samples. In each year of measure maintenance, we also re-fit the model and compare the frequencies and model coefficients of risk variables (condition categories for patient comorbidities) and model fit across 3 years (Dataset 1 below).

Dataset 1 (current public reporting cohort): Medicare Part A Inpatient and Outpatient and Part B Outpatient claims
Dates of Data: July 1, 2011 – June 30, 2014 (current public reporting cohort)
Number of Admissions: 991,007
Patient Descriptive Characteristics: average age=81.1, % male=46.3084
Number of Measured Entities: 4,775

For validity testing (Section 2b2)
Dataset 2 (medical record validation): Chart Validation: National Heart Failure (NHF) Dataset for clinical data from HF hospital admissions, linked with the Medicare Part A Inpatient and Outpatient and Part B Outpatient claims and the Medicare Enrollment Database to assess the mortality outcome.
Dates of Data: 1998-2001
Number of Admissions: N=46,700

For testing of measure exclusions (Section 2b3)
Dataset 1 (current public reporting cohort)

For testing of measure risk adjustment (Section 2b4)
Dataset 1 (current public reporting cohort)

Dataset 3 (development dataset): Medicare Part A Inpatient and Outpatient and Part B Outpatient claims
Dates of Data: 1998
Number of Admissions: N=222,424 (first half of split sample); N=222,157 (second half of split sample)
Number of Measured Entities: 5,087 (first half of split sample); 5,088 (second half of split sample)

Dataset 4 (all payer dataset): California Patient Discharge Data in addition to CMS Medicare FFS data for patients in California hospitals
Dates of Data: January 1, 2006 – December 31, 2006
Number of Discharges: 60,022 (all 18+ total); 27,977 (FFS 65+); 16,447 (non-FFS 65+); 15,598 (all 18-64)
Patient Descriptive Characteristics: mean age=73, %male=49 (all 18+ total); mean age=81, %male=43 (FFS 65+); mean age=80, %male=46 (non-FFS 65+); mean age=53, %male=61 (all 18-64)
Number of Measured Entities: >450 non-Federal acute care hospitals
The measure was applied to California Patient Discharge Data, a large, linked all-payer database of patient hospital admissions. Records are linked by a unique patient identification number, allowing us to determine patient history from previous hospitalizations. In addition, the unique patient ID number is used to link with state vital statistics records to assess 30-day mortality.

For testing to identify meaningful differences in performance (Section 2b5)
Dataset 1 (current public reporting cohort)

For testing of socio-demographic factors in risk models (Section 2b4.3)
Dataset 1 (current public reporting cohort)

1.8 What were the patient-level sociodemographic (SDS) variables that were available and analyzed in the data or sample used? For example, patient-reported data (e.g., income, education, language), proxy variables when SDS data are not collected from each patient (e.g. census tract), or patient community characteristics (e.g. percent vacant housing, crime rate).

We selected sociodemographic status (SDS) variables to analyze after reviewing the literature and examining available national data sources. Few patient-level SDS variables that can be linked to Medicare data are available nationally. We found both race [black vs non-black] and dual-eligible status, e.g. enrolled in both Medicare and Medicaid, [obtained from CMS claims enrollment data] as the only two patient-level SDS variables available to examine directly. While some argue against consideration of race in risk-adjustment, we felt it was important to understand the association with race as well as more traditional socio-economic variables.

We also considered neighborhood-level variables, linked by patient zip code, that could serve in a risk model as a proxy for patient-level SDS. A range of census-collected SDS variables [collected annually as part of American Community Survey and aggregated over 5-years] including income and education, were available. Currently, we are only able to link the data at a 5-digit zip code level. Nine-digit zip code data may provide a more granular view of patient sociodemographic status, but this data is not available to us at this time; we therefore cannot ascertain the incremental, if any, value of greater geographic discrimination for risk adjustment purposes.

Our conceptual model and the literature regarding how SDS may influence post-discharge mortality did not identify a single SDS concept as predominant in the pathway. There is a large body of literature linking various SDS factors to worse health status and higher mortality over a lifetime (Adler and Newman 2002, Mackenbach et al. 2000). Income, education, and occupational level are the most commonly examined variables. However, literature directly examining how different SDS factors might influence the likelihood of older, insured, Medicare patients of dying within 30 days of an admission for cardiovascular disease is much more limited. Assuming that the risk imparted based on zip code may reflect multiple different SDS variables, we chose to analyze a validated AHRQ composite index of SDS which has been used and tested among Medicare beneficiaries (Blum et al. 2014; Bonito et al. 2008). This index is a composite of 7 different variables found in the census data which may capture SDS better than any single variable. The index variables include rates of

unemployment, percent of person living below poverty, education level (percent below 12th grade education and percent with college education), crowding (average of more than one person per room) median household income and median housing value. We identified patients as low SDS if they lived in a neighborhood in lowest quartile of this index.

Other variables can be found at a county or regional level and could represent the hospital's community. We did not directly test any such variables because they are not as closely related to patient's sociodemographic status given the wide scope of a county and seemed unlikely to be ideal for patient-level risk adjustment.

2a2. RELIABILITY TESTING

***Note**: If accuracy/correctness (validity) of data elements was empirically tested, separate reliability testing of data elements is not required – in 2a2.1 check critical data elements; in 2a2.2 enter "see section 2b2 for validity testing of data elements"; and skip 2a2.3 and 2a2.4.*

2a2.1. What level of reliability testing was conducted? (*may be one or both levels*)

☒ **Critical data elements used in the measure** (*e.g., inter-abstractor reliability; data element reliability must address ALL critical data elements*)

☒ **Performance measure score** (e.g., *signal-to-noise analysis*)

2a2.2. For each level checked above, describe the method of reliability testing and what it tests (*describe the steps—do not just name a method; what type of error does it test; what statistical analysis was used*)

Data Element Reliability

In constructing the measure, we aim to utilize only those data elements from the claims that have both face validity and reliability. We avoid the use of fields that are thought to be coded inconsistently across hospitals or providers. Specifically, we use fields that are consequential for payment and which are audited. We identify such variables through empiric analyses and our understanding of CMS auditing and billing policies and seek to avoid variables which do not meet this standard. For example, "discharge disposition" is a variable in Medicare claims data that is not thought to be a reliable variable for identifying a transfer between two acute care facilities. Thus, we derive a variable using admission and discharge dates as a surrogate for "discharge disposition" to identify hospital admissions involving transfers. This allows us to identify these admissions using variables in the claims data which have greater reliability than the "discharge disposition" variable. In addition, CMS has in place several hospital auditing programs used to assess overall claims code accuracy, to ensure appropriate billing, and for overpayment recoupment. CMS routinely conducts data analysis to identify potential problem areas and detect fraud, and audits important data fields used in our measures, including diagnosis and procedure codes and other elements that are consequential to payment.

Finally, we assess the reliability of the data elements by comparing model variable frequencies and odds ratios from logistic regression models across three years of data.

Measure Score reliability

The reliability of a measurement is the degree to which repeated measurements of the same entity agree with each other. For measures of hospital performance, the measured entity is naturally the hospital, and reliability is the extent to which repeated measurements of the same hospital give similar results. In line with this thinking, our approach to assessing reliability is to consider the extent to which assessments of a hospital using different but randomly selected subsets of patients produces similar measures of hospital performance. That is, we take a "test-retest" approach in which hospital performance is measured once using a random subset of patients, then measured again using a second random subset exclusive of the first, and finally comparing the agreement between the two resulting performance measures across hospitals (Rousson et al., 2002). For test-retest reliability, we combined index admissions from successive measurement periods into one dataset, randomly sampled half of patients within each hospital, calculated the measure for each hospital, and repeated the calculation using the second half. Thus, each hospital is measured twice, but each measurement is made using an entirely distinct set of patients. To the extent that the calculated measures of these two subsets agree, we have evidence that the measure is assessing an attribute of the hospital, not of the patients. As a metric of agreement we calculated the intra-class correlation coefficient (ICC) (Shrout and Fleiss, 1979), and assessed the values according to conventional standards (Landis and Koch, 1977). Specifically, we used dataset 1 split sample and calculated the RSRR for each hospital for each sample. The agreement of the two RSRRs was quantified for hospitals using the intra-class correlation as defined by ICC (2,1) by Shrout and Fleiss (1979).

Using two independent samples provides a stringent estimate of the measure's reliability, compared with using two random but potentially overlapping samples which would exaggerate the agreement. Moreover, because our final measure is derived using hierarchical logistic regression, and a known property of hierarchical logistic regression models is that smaller volume hospitals contribute less ´signal´, a split sample using a single measurement period would introduce extra noise. This leads to an underestimate in the actual test-retest reliability that would be achieved if the measure were reported using the full measurement period, as evidenced by the Spearman Brown prophecy formula (Spearman 1910, Brown 1910), which estimates the reliability of the measure if the whole cohort were used, based on an estimate from half the cohort.

2a2.3. For each level of testing checked above, what were the statistical results from reliability testing? (e.*g., percent agreement and kappa for the critical data elements; distribution of reliability statistics from a signal-to-noise analysis*)

Data element reliability results (Dataset 1)

The frequency of some model variables increased between 2011 and 2014, which may reflect an increased rate of comorbidity in the FFS population, but may also be due, in part, to increased coding opportunities on administrative claims. In the 2012 update to the measures, we increased the number of diagnosis and procedure codes to align with the version 5010 format changes DHHS required. Hospitals could begin to submit up to 25 diagnosis and procedure codes starting in 2010. Over time, more hospitals submitted more codes, which translated into increased frequencies for some model variables. Notable decreases occurred in Coronary atherosclerosis or angina (CC 83-84) (73.5% to 72.0%), Congestive heart failure (CC 80) (74.8% to 73.7%), and Acute myocardial infarction (CC 81) (9.7% to 9.5%). Notable increases occurred in Cardio-respiratory

failure or shock (CC 79) (25.6% to 27.9%), History of Percutaneous Transluminal Coronary Angioplasty (PTCA) (ICD-9 codes V45.82, 00.66, 36.06, and 36.07) (12.7% to 13.8%), and Hypertension (CC 89, 91) (93.3% to 93.8%). Examination of the odds ratios for each risk variable in the model shows that, overall, the odds ratios for individual risk variables remained relatively constant across three years.

These frequencies are from the model containing the LVAD exclusion, which will be incorporated into the Annual Updates Reports in 2016. For the model variable frequencies and risk variable odds ratios without the LVAD exclusion, see the 2015 Annual Updates Report (Dorsey et al. 2015).

Measure Score Reliability Results (Dataset 1)
There were 991,007 admissions in the combined 3-year sample, with 494,297 in one sample and 496,710 in the other randomly selected sample. The agreement between the two RSMRs for each hospital was 0.55, which according to the conventional interpretation is "moderate" (Landis & Koch, 1977).
Note that this analysis was limited to hospitals with 12 or more cases in each split sample. The intra-class correlation coefficient is based on a split sample of three years of data, resulting in a volume of patients in each sample equivalent to only 1.5 years of data, whereas the measure is reported with the full three years of data. The correlation coefficient is expected to be higher using the full three-year sample since it would include more patients.

2a2.4 What is your interpretation of the results in terms of demonstrating reliability? (i.*e., what do the results mean and what are the norms for the test conducted?*)

The stability over time of the risk factor frequencies and odds ratios suggests that the underlying data elements are reliable. Additionally, the ICC score demonstrates moderate agreement across samples using a conservative approach to assessment.

2b2. VALIDITY TESTING

2b2.1. What level of validity testing was conducted? (*may be one or both levels*)

☐ **Critical data elements** (*data element validity must address ALL critical data elements*)

☒ **Performance measure score**

☒ **Empirical validity testing**

☐ **Systematic assessment of face validity of performance measure score as an indicator** of quality or resource use (*i.e., is an accurate reflection of performance on quality or resource use and can distinguish good from poor performance*)

2b2.2. For each level of testing checked above, describe the method of validity testing and what it tests (*describe the steps—do not just name a method; what was tested, e.g., accuracy of data elements compared to authoritative source, relationship to another measure as expected; what statistical analysis was used)*

During original measure development we validated the HF mortality administrative model against a medical record model in the same cohort of patients for which hospital-level HF mortality medical record data are available.

We developed a medical record measure to compare with the administrative measure. We developed a measure cohort with the medical record data using the inclusion/exclusion criteria and risk-adjustment strategy that was consistent with the claims-based administrative measure but using chart-based risk adjusters, such as blood pressure, not available in the claims data. We then matched a sample of the same patients in the administrative data for comparison. The matched sample included 46,700 patients. We compared the output of the two measures, the state performance results, in the same group of patients.

For the derivation of the chart-based model, we used cases identified through a Health Care Financing Administration (now CMS) quality initiative, which sampled admissions from FFS Medicare beneficiaries for several clinical conditions, including HF (Jencks et al., 2000). Cases were identified over a 6-month period within each state, plus the District of Columbia and Puerto Rico, during the period April 1, 1998 through October 31, 1999. Based on the principal discharge diagnosis, approximately 800 HF discharges per state were identified, and the corresponding medical records were abstracted by 2 clinical data abstraction centers. In states with fewer than 900 HF discharges, all cases were used. The abstractors first sorted eligible claims by age, race, sex, and hospital. Then, they systematically sampled cases from a random starting point. Patients must have been enrolled in FFS Medicare. CMS subsequently conducted a re-measurement using the same data collection methodology for 2000 and 2001 discharges (Jencks et al., 2003), and the combined 1998-2001 data, including 73,832 patients, served as the NHF dataset for development of the chart-based model.

From the medical chart-abstracted HF cases, we linked these files to the corresponding administrative data and mortality data from the Medicare enrollment database. Because only patients aged 65 years and older were included, and some data were excluded based on linkage and other factors, a total of 46,700 HF hospitalizations were used in the analysis**.**

The same coding and transfer rules described in the HF administrative dataset were used in defining the HF chart dataset.

The chart model was derived in the NHF dataset. The derivation sample contained 46,700 cases with an unadjusted 30-day mortality rate of 11.9%. Twenty-eight covariates were included in the final model, with age having the largest impact on risk. While the administrative mortality models explained about 10-12% of the observed variation and had accuracy of 69-71%, the chart model explained 21-22% of the variation and had accuracy of 75-78%. Moreover, the predictive ability of the model is excellent—observed mortality in the lowest estimated decile is 1.8% for 30-day mortality, compared with 42.4% (30-day mortality) in the highest estimated decile, a range of 40.6%.

<u>Validity Indicated by Established Measure Development Guidelines:</u>
We developed this measure in consultation with national guidelines for publicly reported outcomes measures, with outside experts, and with the public. The measure is consistent with the technical approach to outcomes measurement set forth in NQF guidance for outcomes measures (National Quality Forum, 2010), CMS Measure Management System (MMS) guidance, and the guidance articulated in the American Heart Association scientific statement, “Standards for Statistical Models Used for Public Reporting of Health Outcomes” (Krumholz, Brindis, et al. 2006).

ICD-9 to ICD-10 Conversion

Statement of Intent

[X] Goal was to convert this measure to a new code set, fully consistent with the intent of the original measure.
[ ] Goal was to take advantage of the more specific code set to form a new version of the measure, but fully consistent with the original intent.
[ ] The intent of the measure has changed.

Process of Conversion

ICD-10 codes were initially identified using 2015 GEM mapping software. We then enlisted the help of clinicians with expertise in relevant areas to select and evaluate which ICD-10 codes map to the ICD-9 codes currently in use for this measure. We verify each year that there are no changes. An ICD-9 to ICD-10 crosswalk is attached in field S.2b. (Data Dictionary or Code Table).

2b2.3. What were the statistical results from validity testing? (*e.g., correlation; t-test*)

The performance of the administrative and medical record models is similar (Dataset 2). The areas under the receiver operating characteristic (ROC) curve for the two models are 0.71 and 0.78, respectively.

We estimated hospital-level RSMRs using the corresponding hierarchical logistic regression administrative and medical record models for the linked patient sample. We then examined the linear relationship between the two sets of estimates using regression techniques and weighting by the total number of cases in each hospital. The correlation coefficient of the standardized rates from the administrative and medical record models is 0.95.

2b2.4. What is your interpretation of the results in terms of demonstrating validity? (i.*e., what do the results mean and what are the norms for the test conducted?*)

The results between the administrative and medical record models proved to be similar in each of the model testing that was performed. The ROC results were nearly identical and in line with other mortality models. The correlation between the resulting RSMRs calculated from both models was 0.95, which shows the resulting measure from the administrative claims model is as good as that from the medical record model.

2b3. EXCLUSIONS ANALYSIS

NA ☐ no exclusions — *skip to section 2b4*

2b3.1. Describe the method of testing exclusions and what it tests (*describe the steps—do not just name a method; what was tested, e.g., whether exclusions affect overall performance scores; what statistical analysis was used*)

All exclusions were determined by careful clinical review and have been made based on clinically relevant decisions and to ensure accurate calculation of the measure. To ascertain impact of exclusions on the cohort, we examined overall frequencies and proportions of the total cohort excluded for each exclusion criterion (Dataset 1). These exclusions are consistent with similar NQF-endorsed outcome measures. Rationales for the exclusions are detailed in data field S.10 (Denominator Exclusions).

2b3.2. What were the statistical results from testing exclusions? (*include overall number and percentage of individuals excluded, frequency distribution of exclusions across measured entities, and impact on performance measure scores*)

Among 4,775 hospitals with at least 25 index stays in July 1, 2011 – June 30, 2014:

Exclusion	N	%	Distribution across hospitals: Min, 25th, 50th, 75th percentile, max
1. Discharged alive on the day of admission or the following day who were not transferred to another acute care facility	88,023	6.45%	(0, 3.51, 6.07, 9.33, 100.00*) *due to small size hospital

2. Inconsistent or unknown vital status or other unreliable demographic (age and gender) data	55	<0.01%	(0, 0, 0, 0, 2.86)
3. Enrolled in the Medicare hospice program or used VA hospice services any time in the 12 months prior to the index admission, including the first day of the index admission	18,753	1.37%	(0, 0, 0.88, 1.96, 50.00)
4. LVAD or Transplant in index admission or prior year	2,362	0.17%	(0, 0, 0, 0.49, 50.00)
5. Discharged against medical advice (AMA)	5,933	0.43%	(0, 0, 0, 0, 11.52)

2b3.3. What is your interpretation of the results in terms of demonstrating that exclusions are needed to prevent unfair distortion of performance results? (*i.e., the value outweighs the burden of increased data collection and analysis. Note: **If patient preference is an exclusion**, the measure must be specified so that the effect on the performance score is transparent, e.g., scores with and without exclusion*)

Exclusion 1 (patients who were discharged alive on the day of admission or the following day who were not transferred to another acute care facility) accounts for 6.45% of all index admissions excluded from the initial index cohort, the majority of all exclusions, and is meant to ensure a clinically coherent cohort. This exclusion prevents inclusion of patients who likely did not have clinically significant HF. One of the remaining four exclusions applies to less than 2% of admissions, and the other three apply to less than 1% of admissions. For exclusion 2 (patients with inconsistent or unknown vital status or other unreliable demographic (age and gender) data), we do not include stays for patients where the age is greater than 115, where the gender is neither male nor female, where the admission date is after the date of death in the Medicare Enrollment Database, or where the date of death occurs before the date of discharge but the patient was discharged alive. For exclusion 3 (patients enrolled in the Medicare hospice program or used VA hospice services any time in the 12 months prior to the index admission, including the first day of the index admission), these patients are likely continuing to seek comfort measures only; thus, mortality is not necessarily an adverse outcome or signal of poor quality care. Exclusions 4 (patients with LVAD, history of LVAD, transplant, history of transplant) are meant to ensure a clinically coherent cohort. Patients undergoing implantation of an LVAD designed to offer intermediate to long-term support (weeks to years) as a bridge to heart transplant or destination therapy represent a clinically distinct, highly-selected group of patients cared for at highly specialized medical centers. Exclusion 5 (patients who are discharged AMA) is needed for acceptability of the measure to hospitals, who do not have the opportunity to deliver full care and prepare the patient for discharge.

After all exclusions are applied, the measure randomly selects one index admission per patient per year for inclusion in the cohort so that each episode of care is mutually independent with the same probability of the outcome. For each patient, the probability of death increases with each subsequent admission, and therefore, the episodes of care are not mutually independent. Similarly, for the three year combined data, when index admissions occur during the transition between measure reporting periods (June and July of each year) and both are randomly selected for inclusion in the measure, the measure includes only the June admission. The July admissions are excluded to avoid assigning a single death to two admissions.

2b4. RISK ADJUSTMENT/STRATIFICATION FOR OUTCOME OR RESOURCE USE MEASURES
If not an intermediate or health outcome, or PRO-PM, or resource use measure, skip to section 2b5.

2b4.1. What method of controlling for differences in case mix is used?

☐ **No risk adjustment or stratification**
☒ **Statistical risk model with 24 risk factors**
☐ **Stratification by** Click here to enter number of categories **risk categories**
☐ **Other,** Click here to enter description

2b4.2. If an outcome or resource use measure is not risk adjusted or stratified, provide rationale and analyses to demonstrate that controlling for differences in patient characteristics (case mix) is not needed to achieve fair comparisons across measured entities.

2b4.3. Describe the conceptual/clinical and statistical methods and criteria used to select patient factors (clinical factors or sociodemographic factors) used in the statistical risk model or for stratification by risk (*e.g., potential factors identified in the literature and/or expert panel; regression analysis; statistical significance of p<0.10; correlation of x or higher; patient factors should be present at the start of care*)

Our approach to risk adjustment was tailored to and appropriate for a publicly reported outcome measure, as articulated in the American Heart Association (AHA) Scientific Statement, "Standards for Statistical Models Used for Public Reporting of Health Outcomes" (Krumholz et al. 2006).

The measure employs a hierarchical logistic regression model (a form of hierarchical generalized linear model [HGLM]) to create a hospital-level 30-day RSMR. This approach to modeling appropriately accounts for the structure of the data (patients clustered within hospitals), the underlying risk due to patients' comorbidities, and sample size at a given hospital when estimating hospital mortality rates. In brief, the approach simultaneously models two levels (patient and hospital) to account for the variance in patient outcomes within and between hospitals (Normand and Shahian et al. 2007). At the patient level, each model adjusts the log-odds of mortality within 30-days of admission for age, sex, selected clinical covariates and a hospital-specific intercept. The second level models the hospital-specific intercepts as arising from a normal distribution. The hospital intercept, or hospital-specific effect, represents the hospital contribution to the risk of mortality, after accounting for patient risk and sample size, and can be inferred as a measure of quality. The hospital-specific intercepts are given a distribution in order to account for the clustering (non-independence) of patients within the same hospital. If there were no differences among hospitals, then after adjusting for patient risk, the hospital intercepts should be identical across all hospitals.

Clinical Factors
Candidate and Final Risk-adjustment Variables: The original measure was developed using Medicare FFS claims data. Candidate variables were patient-level risk-adjustors that are expected to be predictive of mortality, based on empirical analysis, prior literature, and clinical judgment, including demographic factors (age, sex) and indicators of comorbidity and disease severity. For each patient, covariates were obtained from Medicare claims extending 12 months prior to and including the index admission. The model adjusted for case differences based on the clinical status of the patient at the time of admission. We used condition categories (CCs), which are clinically meaningful groupings of more than 15,000 ICD-9-CM diagnosis codes. We did not risk-adjust for CCs that were possible adverse events of care and that were only recorded in the index admission. In addition, only comorbidities that conveyed information about the patient at that time or in the 12-months prior, and not complications that arose during the course of the hospitalization were included in the risk-adjustment.

The final set of risk-adjustment variables is:

Demographic
• Age-65 (years above 65, continuous) for 65 and over cohorts; or Age (years, continuous) for 18 and over cohorts
• Male

Cardiovascular
• History of PTCA
• History of CABG
• Congestive heart failure
• Acute myocardial infarction
• Unstable angina
• Chronic atherosclerosis
• Cardio-respiratory failure and shock
• Valvular and rheumatic heart disease

Comorbidity
• Hypertension
• Stroke
• Renal failure
• Pneumonia
• Diabetes and DM complications
• Protein-calorie malnutrition
• Dementia and senility
• Hemiplegia, paraplegia, paralysis, functional disability
• Peripheral vascular disease
• Metastatic cancer, acute leukemia, and other severe cancers
• Trauma in last year
• Major psych disorders
• Chronic liver disease

Sociodemographic Factors

We selected candidate sociodemographic factors for examination based on a review of literature, conceptual pathways and feasibility. In section 1.8, we describe the variables that we considered and analyzed based on this review. Below we describe the pathways by which SDS may influence 30-day mortality.

Our conceptualization of the pathways by which patient SDS affects 30-day mortality is informed by the literature. However, as noted previously, although there is a long list of studies showing a relationship between lower SDS status and mortality rates generally, there is relatively little literature directly examining how SDS might influence the likelihood of older, insured, Medicare patients dying within 30 days of a admission for cardiovascular disease and even less literature to directly illuminate the pathways by which SDS influences this outcome. The ability to distinguish between these pathways is challenging but important for making decisions regarding risk adjustment.

One important pathway by which patients' SDS influences 30-day mortality is through health status at the time of admission. SDS factors can influence admission health status both due to the impact of multiple related stressors over a lifetime contributing to overall worse health as well as through poorer access to care and potentially delayed presentation. This results in low SDS patients, when compared with other patients, often arriving for hospital admission with greater levels of illness or comorbidity burden. This pathway should be largely accounted for in our current clinical risk-adjustment model.

However, there are a number of other pathways by which patient SDS may influence 30-day mortality that are related to hospital quality. The first, sometimes referred to as contextual effects, is the instance of patients of low SDS that may present at lower quality institutions for care. Therefore, some part of the apparent relationship between SDS and mortality may be due to clustering of patients of low SDS at poorer quality institutions (Barnato et al. 2005; Hasnain-Wynia et al. 2010; Jha et al. 2011; Skinner et al. 2005).

Next, within the hospital, patients of low SDS may receive differentiated care as compared to counterparts of higher SDS. This can occur for a variety of reasons, and in some cases, differentiated care could be worse quality and in others better quality. For example, providers may be less likely to offer guideline-concordant care to patients of low SDS – perhaps based on discrimination or misunderstanding of patients' wishes and values (Institute of Medicine, 2009). However, in other cases, differentiated care may be patients of low SDS appropriately needing different types of care or services – such as low literacy information, social worker support, or transportation at discharge. Providing needed differentiated care is patient-centered and appropriate, the equivalent to ensuring a diabetic goes home with insulin. However, low SDS patients may not always receive needed differentiated care. This lack of needed differentiated care may also contribute to relatively worse outcomes.

Finally, there may be pathways by which SDS influences 30-day mortality risk outside of healthcare quality and admission health status. Some SDS factors may affect the likelihood of mortality without directly affecting health status on admission or the quality of care received during the hospital stay. For instance, despite a hospital making appropriate care decisions and providing tailored care and education, a lower-income patient may elect not to follow prescribed care (for example, refill a prescription or keep a follow-up visit with a primary care provider) because limited resources create competing priorities for the patient.

These set of proposed pathways are complex to distinguish analytically. We, therefore, first assessed if there was evidence of a meaningful effect on the risk model to warrant efforts to distinguish among these pathways. First we evaluated the variation in the prevalence of low SDS patients among providers. We then assessed the relationship between the SDS variables and the outcome and examined the incremental effect of SDS in a multivariable model. For these measures, we also examined the extent to which the addition of any one of these variables improved model performance or changed hospital results. Given no meaningful improvement in the risk-model or change in performance scores we did not further seek to distinguish the causal pathways for these measures.

Based on this model and the considerations outlines in 1.8, the following SDS variables were considered:

- Dual eligible status
- African American race
- AHRQ SES index

2b4.4a. What were the statistical results of the analyses used to select risk factors?

Below are tables showing the final variables that made it into the model.

Final Model Variables (variables meeting criteria in field 2b4.3) (Dataset 1)

Variable	07/2011-06/2014 OR (95% CI)
Age minus 65 (years above 65, continuous)	1.05 (1.05 - 1.05)
Male	1.29 (1.28 - 1.31)
History of Percutaneous Transluminal Coronary Angioplasty (PTCA) (ICD-9 codes V45.82, 00.66, 36.06, 36.07)	0.74 (0.73 - 0.76)
History of Coronary Artery Bypass Graft (CABG) surgery (ICD-9 codes V45.81, 36.10-36.16)	0.89 (0.87 - 0.90)
Congestive heart failure (CC 80)	1.22 (1.20 - 1.24)
Acute myocardial infarction (CC 81)	1.25 (1.22 - 1.28)
Other acute/subacute forms of ischemic heart disease (CC 82)	0.97 (0.95 - 0.99)
Coronary atherosclerosis or angina (CC 83-84)	0.97 (0.95 - 0.98)
Cardio-respiratory failure or shock (CC 79)	1.18 (1.16 - 1.20)
Valvular or rheumatic heart disease (CC 86)	1.08 (1.06 - 1.09)
Hypertension (CC 89, 91)	0.66 (0.65 - 0.68)
Stroke (CC 95-96)	0.96 (0.94 - 0.98)
Renal failure (CC 131)	1.22 (1.20 - 1.24)
Chronic obstructive pulmonary disease (COPD) (CC 108)	1.06 (1.05 - 1.08)
Pneumonia (CC 111-113)	1.32 (1.31 - 1.34)
Diabetes mellitus (DM) or DM complications except proliferative retinopathy (CC 15-20, 120)	0.98 (0.96 - 0.99)
Protein-calorie malnutrition (CC 21)	1.95 (1.91 - 1.98)
Dementia or other specified brain disorders (CC 49-50)	1.37 (1.35 - 1.39)
Hemiplegia, paraplegia, paralysis, functional disability (CC 67-69, 100-102, 177-178)	1.12 (1.09 - 1.14)
Vascular disease and complications (CC 104-105)	1.01 (1.00 - 1.03)
Metastatic cancer, acute leukemia and other severe cancers (CC 7-8)	1.79 (1.74 - 1.83)
Trauma in last year (CC 154-156, 158-162)	1.08 (1.07 - 1.10)
Major psychiatric disorders (CC 54-56)	1.12 (1.10 - 1.14)
Chronic liver disease (CC 25-27)	1.55 (1.50 - 1.60)

2b4.4b. Describe the analyses and interpretation resulting in the decision to select SDS factors (e.g. prevalence of the factor across measured entities, empirical association with the outcome, contribution of unique variation in the outcome, assessment of between-unit effects and within-unit effects)

Variation in prevalence of the factor across measured entities

The prevalence of SDS factors in the HF cohort varies across measured entities. The median percentage of dual eligible patients is 13.2% (interquartile range [IQR] 8.2%-20.8%). The median percentage of black patients is 3.3% (IQR 0.0%-12.6%). The median percentage of low SES AHRQ indicator patients is 17.6% (IQR 4.0%-49.7%).

Empirical association with the outcome (univariate)

The patient-level observed HF mortality rate is lower for dual-eligible patients, 10.84%, compared with 11.77% for all other patients. The mortality rate for black patients was also lower at 7.39% compared with 12.19% for patients of all other races. Similarly the mortality rate for patients in the lowest SES quartile by AHRQ Index was 10.85% compared with 11.96% for patients in the highest SES quartile.

Incremental effect of SDS variables in a multivariable model

We then examined the strength and significance of the SDS variables in the context of a multivariable model. Consistent with the above findings, when we include any of these variables in a multivariate model that includes all of the claims-based clinical variables the effect size of each of these variables is small and protective. We also find that the c-statistic is essentially unchanged with the addition of any of these variables into the model. Furthermore we find that the addition of any of these variables into the model has little to no effect on hospital performance. We examined the change in hospitals' RSMRs with the addition of any of these variables. The mean absolute change in hospitals' RSMRs when adding a dual eligibility indicator is -0.00009% with a correlation coefficient between RSMRs for each hospital with and without dual eligibility added of 0.99996. The mean absolute change in hospitals' RSMRs when adding a race indicator is -.01023% with a correlation coefficient between RSMRs for each hospital with and without race added of 0.98496. The mean absolute change in hospitals' RSMRs when adding a low SES AHRQ indicator is 0.00036% with a correlation coefficient between RSMRs for each hospital with and without low SES added of 0.9998.

Overall, we find that among the SDS variables that could be feasibly incorporated into this model the relationship between minority status, dual-eligible status, and low SES (AHRQ indicator status) is in the opposite direction than what has been the expressed concern of stakeholders interested in adding such adjustment to the models. We also find that the impact of any of these indicators is very small to negligible on model performance and hospital profiling. Given the controversial nature of incorporating such variables into a risk-model we do not support doing so in a case that is unlikely to affect hospital profiling. Given these findings and complex pathways could explain any relationship between SDS and mortality, which do not all support risk-adjustment, we did not incorporate SDS variables into the measure.

We do think further investigation or lower mortality among dual eligible and black patients will be valuable and may shed light on proposed future modifications to the measure. For instance, we find that black patients have higher rates of hypertensive heart disease as opposed to other mechanisms for heart failure, which is also consistent with the literature (Echols et al. 2006, Kamath et al. 2008, Thomas et al. 2011). Future reevaluation efforts will explore the relationship between SDS and types of heart failure once ICD-10 data is available.

2b4.5. Describe the method of testing/analysis used to develop and validate the adequacy of the statistical model or stratification approach (*describe the steps—do not just name a method; what statistical analysis was used*)

Approach to assessing model performance (Dataset 3)
During measure development, we computed three summary statistics for assessing model performance (Harrell and Shih, 2001) for the development and validation cohort:

Discrimination Statistics
(1) Area under the receiver operating characteristic (ROC) curve (the c-statistic (also called ROC) is the probability that predicting the outcome is better than chance, which is a measure of how accurately a statistical model is able to distinguish between a patient with and without an outcome)
(2) Predictive ability (discrimination in predictive ability measures the ability to distinguish high-risk subjects from low-risk subjects. Therefore, we would hope to see a wide range between the lowest decile and highest decile)

Calibration Statistics
(3) Over-fitting indices (over-fitting refers to the phenomenon in which a model accurately describes the relationship between predictive variables and outcome in the development dataset but fails to provide valid predictions in new patients)

We tested the performance of the model in all four datasets described in section 1.7.

Provide the statistical results from testing the approach to controlling for differences in patient characteristics (case mix) below.
If stratified, skip to 2b4.9

2b4.6. Statistical Risk Model Discrimination Statistics (*e.g., c-statistic, R-squared*)**:**
For the development cohort (Dataset 3) the results are summarized below:
1st half of randomly split development sample: c-statistic = 0.71; Predictive ability (lowest decile %, highest decile %) = (3.0, 28.5)
2nd half of randomly split development sample: c-statistic = 0.70; Predictive ability (lowest decile %, highest decile %) = (2.8, 29.0)

For the current measure cohort (Dataset 1) the results are summarized below:
c-statistic = 0.68
Predictive ability (lowest decile %, highest decile %) = (3.7, 27.3)

For the medical record validation cohort (Dataset 2) the results are summarized below:
c-statistic = 0.78
Predictive ability (lowest decile %, highest decile %) = (1.8, 42.4)

c-statistic (linked administrative model validation) = 0.70
Predictive ability (lowest decile %, highest decile %) (linked administrative model validation) = (2.9, 28.4)

For comparison of model with and without inclusion of SDS factors, see above section.

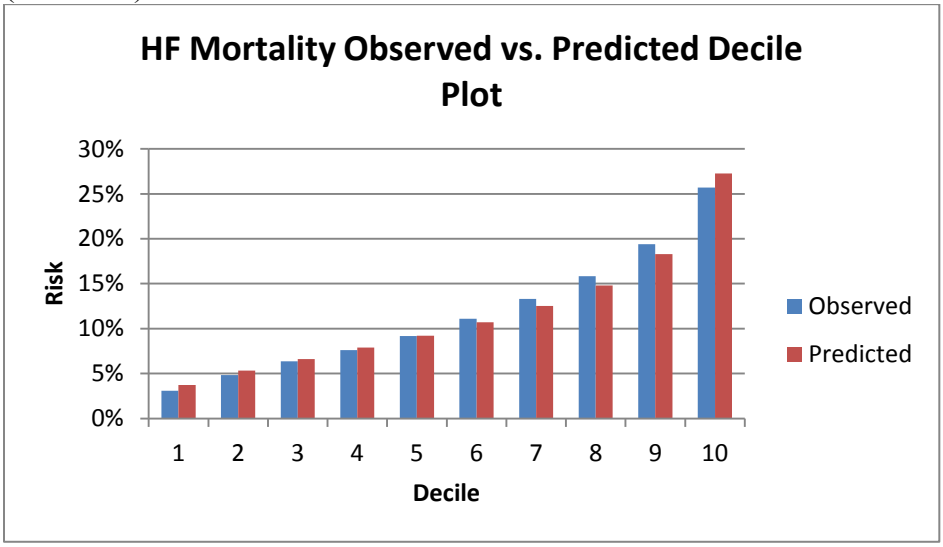
2b4.7. Statistical Risk Model Calibration Statistics (*e.g., Hosmer-Lemeshow statistic*):

For the development cohort (Dataset 3) the results are summarized below:
1st half of split sample: Calibration: (0.0000, 1.0000)
2nd half of split sample: Calibration: (-0.0035, 0.9928)

For the medical record validation cohort (Dataset 2) the results are summarized below:
Calibration: (0.0000, 1.0000)
Calibration (linked administrative model validation): (-0.0045, 1.0021)

2b4.8. Statistical Risk Model Calibration – Risk decile plots or calibration curves:

The risk decile plot is a graphical depiction of the deciles calculated to measure predictive ability. Below, we present the risk decile plot showing the distributions for Medicare FFS data from July 2011 to June 2014 (Dataset 1).



2b4.9. Results of Risk Stratification Analysis:

N/A

2b4.10. What is your interpretation of the results in terms of demonstrating adequacy of controlling for differences in patient characteristics (case mix)? (i.*e., what do the results mean and what are the norms for the test conducted*)

Discrimination Statistics
The c-statistics of 0.68 indicate fair model discrimination (Dataset 1). The model indicated a wide range between the lowest decile and highest decile, indicating the ability to distinguish high-risk subjects from low-risk subjects.

Calibration Statistics
Over-fitting (Calibration γ0, γ1)

If the $\gamma 0$ in the validation samples are substantially far from zero and the $\gamma 1$ is substantially far from one, there is potential evidence of over-fitting. The calibration value of close to 0 at one end and close to 1 to the other end indicates good calibration of the model.

Risk Decile Plots
Higher deciles of the predicted outcomes are associated with higher observed outcomes, which show a good calibration of the model. This plot indicates excellent discrimination of the model and good predictive ability.

Overall Interpretation
Interpreted together, our diagnostic results demonstrate the risk-adjustment model adequately controls for differences in patient characteristics (case mix).

2b4.11. Optional Additional Testing for Risk Adjustment (*not required, but would provide additional support of adequacy of risk model, e.g., testing of risk model in another data set; sensitivity analysis for missing data; other methods that were assessed*)

This measure is fully risk-adjusted using a hierarchical logistic regression model to calculate hospital RSMRs accounting for differences in hospital case-mix.

Approach to assessing model performance:
During measure development, we computed five summary statistics for assessing model performance (Harrell and Shih 2001) for the development and validation cohort:
(1) over-fitting indices (over-fitting refers to the phenomenon in which a model accurately describes the relationship between predictive variables and outcome in the development dataset but fails to provide valid predictions in new patients)
(2) predictive ability
(3) area under the receiver operating characteristic (ROC) curve
(4) distribution of residuals
(5) model chi-square (A test of statistical significance usually employed for categorical data to determine whether there is a good fit between the observed data and expected values; i.e., whether the differences between observed and expected values are attributable to true differences in characteristics or instead the result of chance variation).

Application to Medicare FFS Beneficiaries Using Inpatient Data Only for Risk Adjustment (Dataset 4)
As part of testing the model in all-payer data, we also applied the model to CMS data for Medicare FFS 65+ patients in California hospitals using only inpatient data for risk adjustment. Specifically, we created a 2006 measure cohort with complete one-year history data and 30-day follow-up data (N= 24,035).

To help determine whether the measure could be applied to Medicare FFS 65+ patients using only Medicare Part A data, we performed analyses to assess how the model performs when using only admission claims data for risk adjustment, as all-payer hospital discharge databases do not have outpatient claims. To assess the validity of using only admission claims data for risk adjustment, we fit the model separately using the full data and using only admission claims data and (a) compared the odds ratios (ORs) for the various risk factors; (b) conducted a reclassification analysis to compare risk prediction at the patient level; (c) compared model performance in terms of the c-statistic (discrimination); and (d) compared hospital-level risk-standardized rates (scatterplot, correlation coefficient, and R2) to assess whether the model with only admission claims data is different from the current model in profiling hospital rates.

Adjustment Using CMS data for Medicare FFS 65+ beneficiaries in California hospitals: (a) the magnitude of odds ratios for most risk factors was similar when comparing the model using full data and using only admission claims data; (b) when comparing the model with full data and with only admission claims data, the

reclassification analysis demonstrated good patient-level risk prediction; (c) the c-statistic was similar (0.681 vs. 0.684); and (d) hospital-level risk-standardized rates were highly correlated (r=0.993).

Application to Patients Aged 18 and Older (Dataset 4)
We also applied the model to all-payer data from California. The analytic sample included 60,022 cases aged 18 and older in the 2006 California Patient Discharge Data. When used in all-payer data, only admission claims data are used for risk adjustment, as the hospital discharge databases do not have outpatient claims.

To help determine whether the measure could be applied to an population of patients aged 18+, we examined the interaction terms between age (18-64 vs. 65+) and each of the other risk factors. Specifically, we fit the model in all patients 18+ with and without interaction terms and (a) conducted a reclassification analysis to compare risk prediction at the patient level; (b) compared the c-statistic; and (c) compared hospital-level risk-standardized rates (scatterplot, correlation coefficient, and R2) to assess whether the model with interactions is different from the current model in profiling hospital rates.

When the model was applied to all patients 18 and over (18+), overall discrimination was good (c-statistic=0.718). In addition, there was good discrimination and predictive ability in both those aged 18-64 and those aged 65+. Moreover, the distribution of Pearson residuals was comparable across the patient subgroups. When comparing the model with and without interaction terms, (a) the reclassification analysis demonstrated good patient-level risk prediction (1.9% to 25.4% vs. 2.0% to 25.1%, respectively, from the bottom decile to the top decile of the prediction values); (b) the c-statistic was nearly identical (0.720 vs. 0.718); and (c) hospital-level risk-standardized rates were highly correlated (r=1.000). Thus, the inclusion of the interactions did not substantively affect either patient-level model performance or hospital-level results.

Therefore, the measure can be applied to all-payer data for patients 18 and older.

Yale New Haven Health Services Corporation – Center for Outcomes Research and Evaluation (YNHHSC/CORE) (January 2012). Hospital 30-Day, All-Cause, Risk-Standardized Readmission Rate (RSRR) following Pneumonia Hospitalization. In *Testing Publicly Report 30-Day Acute Myocardial Infarction, Heart Failure, and Pneumonia Risk-Standardized Mortality and Readmission Measures in California All-Payer Data.*

2b5. IDENTIFICATION OF STATISTICALLY SIGNIFICANT & MEANINGFUL DIFFERENCES IN PERFORMANCE

2b5.1. Describe the method for determining if statistically significant and clinically/practically meaningful differences in performance measure scores among the measured entities can be identified (*describe the steps—do not just name a method; what statistical analysis was used? Do not just repeat the information provided related to performance gap in 1b)*

For public reporting of the measure, CMS characterizes the uncertainty associated with the RSMR by estimating the 95% interval estimate. This is similar to a 95% confidence interval but is calculated differently. If the RSMR's interval estimate does not include the national observed mortality rate (is lower or higher than the

rate), then CMS is confident that the hospital's RSMR is different from the national rate, and describes the hospital on the Hospital Compare website as "better than the U.S. national rate" or "worse than the U.S. national rate." If the interval includes the national rate, then CMS describes the hospital's RSMR as "no different than the U.S. national rate" or "the difference is uncertain." CMS does not classify performance for hospitals that have fewer than 25 cases in the three-year period.

2b5.2. What were the statistical results from testing the ability to identify statistically significant and/or clinically/practically meaningful differences in performance measure scores across measured entities? (e.g., *number and percentage of entities with scores that were statistically significantly different from mean or some benchmark, different from expected; how was meaningful difference defined*)

Recent analyses of Medicare FFS data show substantial variation in RSMRs among hospitals. Using data from July 2011-June 2014 (Dataset 1), the median hospital RSMR was 11.7%, with a range of 7.0% to 19.3%. The interquartile range was 10.9%-12.4%.

Out of 4,771 hospitals in the U.S., 145 performed "better than the U.S. national rate," 3,662 performed "no different from the U.S. national rate," and 93 performed "worse than the U.S. national rate." 871 were classified as "number of cases too small" (fewer than 25) to reliably tell how well the hospital is performing. These numbers were reported in the 2015 Condition-Specific Measures Updates and Specifications Report: Hospital-Level 30-Day Risk-Standardized Mortality Measures, prior to exclusion of LVAD, history of LVAD, organ transplantation, and history of organ transplantation.

2b5.3. What is your interpretation of the results in terms of demonstrating the ability to identify statistically significant and/or clinically/practically meaningful differences in performance across measured entities? (i.*e., what do the results mean in terms of statistical and meaningful differences?*)

Despite recent decreases in mortality rates nationally, the mortality rate for HF remains high at 11.7%.

The variation in rates and number of performance outliers suggests there remain differences in the quality of care received across hospitals for heart failure that support measurement to reduce the variation.

2b6. COMPARABILITY OF PERFORMANCE SCORES WHEN MORE THAN ONE SET OF SPECIFICATIONS

If only one set of specifications, this section can be skipped.

Note: *This criterion is directed to measures with more than one set of specifications/instructions (e.g., one set of specifications for how to identify and compute the measure from medical record abstraction and a different set of specifications for claims or eMeasures). It does not apply to measures that use more than one source of data in one set of specifications/instructions (e.g., claims data to identify the denominator and medical record abstraction for the numerator).* ***If comparability is not demonstrated, the different specifications should be submitted as separate measures.***

2b6.1. Describe the method of testing conducted to demonstrate comparability of performance scores for the same entities across the different data sources/specifications (*describe the steps—do not just name a method; what statistical analysis was used*)

N/A

2b6.2. What were the statistical results from testing comparability of performance scores for the same entities when using different data sources/specifications? (*e.g., correlation, rank order*)

N/A

2b6.3. What is your interpretation of the results in terms of demonstrating comparability of performance measure scores for the same entities across the different data sources/specifications? (i.*e., what do the results mean and what are the norms for the test conducted*)

N/A

2b7. MISSING DATA ANALYSIS AND MINIMIZING BIAS

2b7.1. Describe the method of testing conducted to identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias (*describe the steps—do not just name a method; what statistical analysis was used*)

N/A

2b7.2. What is the overall frequency of missing data, the distribution of missing data across providers, and the results from testing related to missing data? (*e.g., results of sensitivity analysis of the effect of various rules for missing data/nonresponse; if no empirical sensitivity analysis, identify the approaches for handling missing data that were considered and pros and cons of each*)

N/A

2b7.3. What is your interpretation of the results in terms of demonstrating that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias**?** (i.*e., what do the results mean in terms of supporting the selected approach for missing data and what are the norms for the test conducted; if no empirical analysis, provide rationale for the selected approach for missing data*)

N/A

3. Feasibility

Extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

3a. Byproduct of Care Processes

For clinical measures, the required data elements are routinely generated and used during care delivery (e.g., blood pressure, lab test, diagnosis, medication order).

3a.1. **Data Elements Generated as Byproduct of Care Processes.**

Coded by someone other than person obtaining original information (e.g., DRG, ICD-9 codes on claims)

If other:

3b. Electronic Sources

The required data elements are available in electronic health records or other electronic sources. If the required data are not in

electronic health records or existing electronic sources, a credible, near-term path to electronic collection is specified.

3b.1. **To what extent are the specified data elements available electronically in defined fields?** *(i.e., data elements that are needed to compute the performance measure score are in defined, computer-readable fields)*
ALL data elements are in defined fields in electronic claims

3b.2. **If ALL the data elements needed to compute the performance measure score are not from electronic sources, specify a credible, near-term path to electronic capture, OR provide a rationale for using other than electronic sources.**

3b.3. **If this is an eMeasure, provide a summary of the feasibility assessment in an attached file or make available at a measure-specific URL.**
Attachment:

3c. Data Collection Strategy

Demonstration that the data collection strategy (e.g., source, timing, frequency, sampling, patient confidentiality, costs associated with fees/licensing of proprietary measures) can be implemented (e.g., already in operational use, or testing demonstrates that it is ready to put into operational use). For eMeasures, a feasibility assessment addresses the data elements and measure logic and demonstrates the eMeasure can be implemented or feasibility concerns can be adequately addressed.

3c.1. **Describe what you have learned/modified as a result of testing and/or operational use of the measure regarding data collection, availability of data, missing data, timing and frequency of data collection, sampling, patient confidentiality, time and cost of data collection, other feasibility/implementation issues.**
IF a PRO-PM, consider implications for both individuals providing PROM data (patients, service recipients, respondents) and those whose performance is being measured.
Administrative data are routinely collected as part of the billing process.

3c.2. **Describe any fees, licensing, or other requirements to use any aspect of the measure as specified** *(e.g., value/code set, risk model, programming code, algorithm)*.
There are no fees associated with the use of this measure.

4. Usability and Use

Extent to which potential audiences (e.g., consumers, purchasers, providers, policy makers) are using or could use performance results for both accountability and performance improvement to achieve the goal of high-quality, efficient healthcare for individuals or populations.

4a. Accountability and Transparency

Performance results are used in at least one accountability application within three years after initial endorsement and are publicly reported within six years after initial endorsement (or the data on performance results are available). If not in use at the time of initial endorsement, then a credible plan for implementation within the specified timeframes is provided.

4.1. **Current and Planned Use**
NQF-endorsed measures are expected to be used in at least one accountability application within 3 years and publicly reported within 6 years of initial endorsement in addition to performance improvement.

Planned	Current Use (for current use provide URL)
	Public Reporting Hospital Inpatient Quality Reporting (IQR) Program http://cms.gov/Medicare/Quality-Initiatives-Patient-Assessment-Instruments/HospitalQualityInits/HospitalRHQDAPU.html Payment Program

	Hospital Value Based Purchasing (HVBP) Program http://www.cms.gov/Medicare/Quality-Initiatives-Patient-Assessment-Instruments/hospital-value-based-purchasing/index.html

4a.1. For each CURRENT use, checked above, provide:

- Name of program and sponsor
- Purpose
- Geographic area and number and percentage of accountable entities and patients included

Public Reporting

1. Program Name, Sponsor: Hospital Inpatient Quality Reporting (IQR) Program, Centers for Medicare and Medicaid Services (CMS)

Purpose: The Hospital Inpatient Quality Reporting (Hospital IQR) program was originally mandated by Section 501(b) of the Medicare Prescription Drug, Improvement, and Modernization Act (MMA) of 2003. This section of the MMA authorized CMS to pay hospitals that successfully report designated quality measures a higher annual update to their payment rates. Initially, the MMA provided for a 0.4 percentage point reduction in the annual market basket (the measure of inflation in costs of goods and services used by hospitals in treating Medicare patients) update for hospitals that did not successfully report. The Deficit Reduction Act of 2005 increased that reduction to 2.0 percentage points.

In addition to giving hospitals a financial incentive to report the quality of their services, the hospital reporting program provides CMS with data to help consumers make more informed decisions about their health care. Some of the hospital quality of care information gathered through the program is available to consumers on the Hospital Compare website at: www.hospitalcompare.hhs.gov.

Geographic area and number and percentage of accountable entities and patients included: The IQR program includes all IPPS non-federal acute care hospitals and VA hospitals in the United States. The number and percentage of accountable entities included in the program, as well as the number of patients included in the measure, varies by reporting year. For 2015 public reporting, the RSMR will be reported for 4,775 hospitals across the US. The final index cohort includes 991,007 admissions.

2. Program Name, Sponsor: Hospital Value-Based Purchasing (HVBP) Program, Centers for Medicare and Medicaid Services (CMS)

Purpose: The Hospital Value-Based Purchasing (VBP) Program is a CMS initiative that rewards acute-care hospitals with incentive payments for the quality of care they provide to people with Medicare. It was established by the Affordable Care Act of 2010 (ACA), which added Section 1886(o) to the Social Security Act. The law requires the Secretary of the Department of Health and Human Services (HHS) to establish a value-based purchasing program for inpatient hospitals. To improve quality, the ACA builds on earlier legislation—the 2003 Medicare Prescription Drug, Improvement, and Modernization Act and the 2005 Deficit Reduction Act. These earlier laws established a way for Medicare to pay hospitals for reporting on quality measures, a necessary step in the process of paying for quality rather than quantity.

Geographic area and number and percentage of accountable entities and patients included: More than 3,000 hospitals across the country are eligible to participate in Hospital VBP. The program applies to subsection (d) hospitals located in the 50 states and the District of Columbia and acute-care hospitals in Maryland. Hospital VBP is based on data collected through the Hospital Inpatient Quality Reporting (IQR) Program. More details about the Hospital IQR program are online at https://www.cms.gov/HospitalQualityInits/08_HospitalRHQDAPU.asp.

The following hospitals are excluded from Hospital VBP:
• Hospitals and hospital units excluded from the Inpatient Prospective Payment System, such as psychiatric, rehabilitation, long-term care, children's, and cancer hospitals;
• Hospitals that do not participate in Hospital IQR during the Hospital VBP performance period;
• Hospitals cited by the Secretary of HHS for deficiencies during the performance period that pose an immediate jeopardy to patients' health or safety; and
• Hospitals that do not meet the minimum number of cases, measures, or surveys required by Hospital VBP.

4a.2. If not currently publicly reported OR used in at least one other accountability application (e.g., payment program, certification, licensing) what are the reasons? (*e.g., Do policies or actions of the developer/steward or accountable entities restrict access to performance results or impede implementation?*)

N/A, this measure is currently publicly reported

4a.3. **If not currently publicly reported OR used in at least one other accountability application, provide a credible plan for implementation within the expected timeframes -- any accountability application within 3 years and publicly reported within 6 years of initial endorsement.** (*Credible plan includes the specific program, purpose, intended audience, and timeline for implementing the measure within the specified timeframes. A plan for accountability applications addresses mechanisms for data aggregation and reporting.*)
N/A, this measure is currently publicly reported

4b. Improvement

Progress toward achieving the goal of high-quality, efficient healthcare for individuals or populations is demonstrated. If not in use for performance improvement at the time of initial endorsement, then a credible rationale describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.

4b.1. **Progress on Improvement. (Not required for initial endorsement unless available.)**
Performance results on this measure (current and over time) should be provided in 1b.2 and 1b.4. Discuss:

- **Progress (trends in performance results, number and percentage of people receiving high-quality healthcare)**
- **Geographic area and number and percentage of accountable entities and patients included**

There has been significant progress in 30-day RSMR for HF. The median 30-day RSMR decreased by 0.7 absolute percentage points from 2011-2012 (median RSMR: 11.7%) to 2013-2014 (median RSMR: 11.0%). The median hospital RSMR from 2011-2014 was 11.7% (IQR 11.0% - 12.5%). In addition, hospitals with a high proportion of Medicaid and African American patients achieve a similar range of performance as compared with hospitals with a low proportion of these patients, indicating that both groups of hospitals can perform well on the measure.

4b.2. **If no improvement was demonstrated, what are the reasons? If not in use for performance improvement at the time of initial endorsement, provide a credible rationale that describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.**
N/A

4c. Unintended Consequences

The benefits of the performance measure in facilitating progress toward achieving high-quality, efficient healthcare for individuals or populations outweigh evidence of unintended negative consequences to individuals or populations (if such evidence exists).

4c.1. **Were any unintended negative consequences to individuals or populations identified during testing; OR has evidence of unintended negative consequences to individuals or populations been reported since implementation? If so, identify the negative unintended consequences and describe how benefits outweigh them or actions taken to mitigate them.**
We did not identify any unintended consequences during measure development or model testing. However, we are committed to monitoring this measure's use and assessing potential unintended consequences over time, such as the inappropriate shifting of care, increased patient morbidity and mortality, and other negative unintended consequences for patients.

5. Comparison to Related or Competing Measures

If a measure meets the above criteria and there are endorsed or new related measures (either the same measure focus or the same target population) or competing measures (both the same measure focus and the same target population), the measures are compared to address harmonization and/or selection of the best measure.

5. Relation to Other NQF-endorsed Measures
Are there related measures (conceptually, either same measure focus or target population) or competing measures (conceptually both the same measure focus and same target population)? If yes, list the NQF # and title of all related and/or competing measures.
Yes

5.1a. **List of related or competing measures (selected from NQF-endorsed measures)**
0230 : Hospital 30-day, all-cause, risk-standardized mortality rate (RSMR) following acute myocardial infarction (AMI) hospitalization for patients 18 and older
0330 : Hospital 30-day, all-cause, risk-standardized readmission rate (RSRR) following heart failure (HF) hospitalization
0358 : Heart Failure Mortality Rate (IQI 16)

0468 : Hospital 30-day, all-cause, risk-standardized mortality rate (RSMR) following pneumonia hospitalization
0505 : Hospital 30-day all-cause risk-standardized readmission rate (RSRR) following acute myocardial infarction (AMI) hospitalization.
0506 : Hospital 30-day, all-cause, risk-standardized readmission rate (RSRR) following pneumonia hospitalization
1551 : Hospital-level 30-day, all-cause risk-standardized readmission rate (RSRR) following elective primary total hip arthroplasty (THA) and/or total knee arthroplasty (TKA)
1789 : Hospital-Wide All-Cause Unplanned Readmission Measure (HWR)
1891 : Hospital 30-Day, All-Cause, Risk-Standardized Readmission Rate (RSRR) following Chronic Obstructive Pulmonary Disease (COPD) Hospitalization
1893 : Hospital 30-Day, All-Cause, Risk-Standardized Mortality Rate (RSMR) following Chronic Obstructive Pulmonary Disease (COPD) Hospitalization

5.1b. **If related or competing measures are not NQF endorsed please indicate measure title and steward.**

5a. Harmonization

The measure specifications are harmonized with related measures;
OR
The differences in specifications are justified

5a.1. **If this measure conceptually addresses EITHER the same measure focus OR the same target population as NQF-endorsed measure(s):**
Are the measure specifications completely harmonized?
Yes

5a.2. **If the measure specifications are not completely harmonized, identify the differences, rationale, and impact on interpretability and data collection burden.**
We did not include in our list of related measures any non-outcome (e.g., process) measures with the same target population as our measure. Our measure cohort was heavily vetted by clinical experts, a technical expert panel, and a public comment period. Additionally, the measure, with the specified cohort, has been publicly reported since 2008. Because this is an outcome measure, clinical coherence of the cohort takes precedence over alignment with related non-outcome measures. Furthermore, non-outcome measures are limited due to broader patient exclusions. This is because they typically only include a specific subset of patients who are eligible for that measure (for example, patients who receive a specific medication or undergo a specific procedure).

5b. Competing Measures

The measure is superior to competing measures (e.g., is a more valid or efficient way to measure);
OR
Multiple measures are justified.

5b.1. **If this measure conceptually addresses both the same measure focus and the same target population as NQF-endorsed measure(s):**
Describe why this measure is superior to competing measures (e.g., a more valid or efficient way to measure quality); OR provide a rationale for the additive value of endorsing an additional measure. (Provide analyses when possible.)
N/A

Appendix

A.1 Supplemental materials may be provided in an appendix. All supplemental materials (such as data collection instrument or methodology reports) should be organized in one file with a table of contents or bookmarks. If material pertains to a specific submission form number, that should be indicated. Requested information should be provided in the submission form and required attachments. There is no guarantee that supplemental materials will be reviewed.

Brief Measure Information

NQF #: 0230
Measure Title: Hospital 30-day, all-cause, risk-standardized mortality rate (RSMR) following acute myocardial infarction (AMI) hospitalization for patients 18 and older
Measure Steward: Centers for Medicare & Medicaid Services (CMS)
Brief Description of Measure: The measure estimates a hospital-level 30-day risk-standardized mortality rate (RSMR). Mortality is defined as death for any cause within 30 days after the date of admission for the index admission, for patients 18 and older discharged from the hospital with a principal diagnosis of acute myocardial infarction (AMI). CMS annually reports the measure for patients who are 65 years or older and are either Medicare fee-for-service (FFS) beneficiaries and hospitalized in non-federal hospitals or are hospitalized in Veterans Health Administration (VA) facilities.
Developer Rationale: The goal of this measure is to improve patient outcomes by providing patients, physicians, and hospitals with information about hospital-level, risk-standardized mortality rates following hospitalization for AMI. Measurement of patient outcomes allows for a broad view of quality of care that encompasses more than what can be captured by individual process-of-care measures. Complex and critical aspects of care, such as communication between providers, prevention of and response to complications, patient safety, and coordinated transitions to the outpatient environment, all contribute to patient outcomes but are difficult to measure by individual process measures. The goal of outcomes measurement is to risk-adjust for patients' conditions at the time of hospital admission and then evaluate patient outcomes. This measure was developed to identify institutions whose performance is better or worse than what would be expected based on their patient case mix, and therefore promote hospital quality improvement and better inform consumers about care quality.

Additionally, AMI mortality is a priority area for outcomes measure development as it is a costly and common condition. Hospital mortality is an outcome that is likely attributable to care processes and is an important outcome for patients. Measuring and reporting mortality rates will inform health care providers about opportunities to improve care, strengthen incentives for quality improvement, and ultimately improve the quality of care received by Medicare patients. The measure will also provide patients with information that could guide their choices. Furthermore, the measure will increase transparency for consumers and has the potential to lower health care costs associated with mortality.

Numerator Statement: The outcome for this measure is 30-day all-cause mortality. We define mortality as death from any cause within 30 days of the index admission date for patients 18 and older discharged from the hospital with a principal diagnosis of AMI.
Denominator Statement: This claims-based measure can be used in either of two patient cohorts: (1) patients aged 65 years or older or (2) patients aged 18 years or older. The cohort includes admissions for patients discharged from the hospital with a principal discharge diagnosis of AMI and with a complete claims history for the 12 months prior to admission. Currently, the measure is publicly reported by CMS for those patients 65 years and older who are either Medicare FFS beneficiaries admitted to non-federal hospitals or patients admitted to VA hospitals. Additional details are provided in S.9 Denominator Details.
Denominator Exclusions: The mortality measures exclude index admissions for patients:
1. Discharged alive on the day of admission or the following day who were not transferred to another acute care facility.
2. With inconsistent or unknown vital status or other unreliable demographic (age and gender) data;
3. Enrolled in the Medicare hospice program or used VA hospice services any time in the 12 months prior to the index admission, including the first day of the index admission; or
4. Discharged against medical advice (AMA).

For patients with more than one admission for a given condition in a given year, only one index admission for that condition is randomly selected for inclusion in the cohort.

For Medicare FFS patients, the measure additionally excludes admissions for patients without at least 30 days post-discharge

enrollment in FFS Medicare (because the 30-day mortality outcome cannot be assessed in this group).

Measure Type: Outcome
Data Source: Administrative claims, Other, Paper Medical Records
Level of Analysis: Facility
Is this an eMeasure? ☐ **Yes** ☒ **No** **If Yes, was it re-specified from a previously endorsed measure?** ☐ **Yes** ☐ **No**

Is this a MAINTENANCE measure submission? ☒ **Yes** ☐ **No, this is a NEW measure submission.**
For MAINTENANCE, state the Original Endorsement Date: 5/9/07 **Most Recent Endorsement Date:** 1/18/12

Previous Measure Evaluation - Public & Member Comments, Developer Responses & Steering Committee Recommendations from (Cardiology Project 2010):

Public and Member Comments on original measure

- All-cause mortality rate does not correlate well with AMI mortality.

Committee response:

- All patient care is inter-related. All-cause mortality reflects the reality of caring for patients. It is not possible to separate "cardiovascular causes" independent of other conditions affecting a patient

Public and Member Comments on revised measure:

- Clarify the data sources that were used in the all payer data testing.

Developer Response:

- The data source used to complete the all payer testing was the state of California's Patient Discharge Database (PDD) which contains records for all discharges from all non-Federal hospitals located in California. California is a diverse state, and, with more than 37 million residents, California represents 12% of the US population. In 2006, there were approximately 3 million adult discharges from more than 450 hospitals. Records are linked by a unique patient identification number, allowing us to determine patient history from previous hospitalizations and to evaluate rates of both readmission and mortality. Specifically, patients from this database are linked to the California Death Statistical Master File (DSMF) using social security number in order to validate and record deaths.

Steering Committee: Agreed that the developer answered the comment.

Preliminary Analysis

The preliminary analysis was developed in response to recommendations from NQF's Consensus Task Force and measurement stakeholders as a way to enhance and streamline the measures evaluation and voting processes. The preliminary analysis will help to guide the Standing Committee evaluation of each measure by summarizing the measure developer submission, guide measure evaluation discussion, and identify topic areas for additional input. **NQF staff would like to stress that the preliminary analysis is intended to be used as a guide to facilitate the Committee's discussion and evaluation.**

Criteria 1: Importance to Measure and Report

1a. Evidence

1a. Evidence. The evidence requirements for a health outcomes measure include providing a rationale that supports the relationship of the outcome to at least one healthcare structure, process, intervention, or service.

- This measure calculates hospitals' 30-day risk-standardized mortality rate (RSMR) for patients who have been hospitalized with acute myocardial infarction (AMI).
- As a rationale for measuring this health outcome, the developer suggests that hospitals are able to influence mortality rates through a broad range of clinical activities, including prevention of complications, use of appropriate medications, timely percutaneous coronary interventions, discharge planning, management of care transitions, medication reconciliation, and patient education.
- The developer states that recent qualitative research funded by AHRQ, Commonwealth Fund, and United Healthcare identified common system-level approaches to care and, specifically, the tailored use of protocols, in those hospitals that have low RSMRs compared with hospitals with high RSMRs.
- The developer has included a number of references to support this rationale.

Question for the Committee:

- *Does the Committee agree that hospitals have the ability to influence 30-day mortality rates among AMI patients?*

1b. Gap in Care/Opportunity for Improvement and 1b. Disparities

1b. Performance Gap. The performance gap requirements include demonstrating quality problems and opportunity for improvement.

- The developer notes that AMI mortality is a priority area for outcomes measure development as it is a costly and common condition.
- The developer provides performance data from four measurement periods, covering a total of 497,550 admissions.
- The data show that during the measurement period of 07/2011–06/2014, AMI mortality rates ranged from a minimum of 9.9% to a maximum of 20.6%, with the 10th percentile at 13.0%, the 50th percentile at 14.2%, and the 90th percentile at 15.4%.
- To help in assessment of potential disparities, the developers also provide performance scores (using 2011-2014 data) for hospitals serving a low proportion of Medicaid patients vs. those serving a high proportion of Medicaid patients, and performance scores for hospitals serving a low proportion of African-American patients vs. those serving a high proportion of African-American patients.
- By proportion of **Medicaid Patients**:

  // **Low proportion (=8.4%) Medicaid patients** // **High proportion (=30.5%) Medicaid patients**
  Number of Measured Entities (Hospitals)// 242 // 243
  Number of Patients// 49,022 in low-proportion hospitals // 37,060 in high-proportion hospitals
  Maximum// 18.9 // 18.1
  90th percentile// 15.3 // 15.7
  75th percentile// 14.6 // 15.1
  Median (50th percentile)// 13.7 // 14.3
  25th percentile// 13.1 // 13.5
  10th percentile// 12.5 // 12.9
  Minimum // 10.0 // 11.0

- By proportion of **African-American patients**:

  // **Low Proportion (=0%) Af-Am patients** // **High proportion (=23.7%) Af-Am patients**
  Number of Measured Entities (Hospitals)// 244 // 245
  Number of Patients// 28,674 patients in low-proportion hospitals//38,275 in high-proportion hospitals
  Maximum// 17.5 // 17.9
  90th percentile// 16.0 // 15.8
  75th percentile// 15.2 // 15.1
  Median (50%)// 14.3 // 14.2
  25th percentile// 13.5 // 13.4
  10th percentile// 12.7 // 12.7
  Minimum// 11.5 // 10.4

- The developers do not provide interpretation or analysis of these data; in both cases there are differences in performance between the groups compared, but these differences do not appear to be substantial.

Questions for the Committee:

- *Is there a gap in care that warrants a national performance measure?*
- *Should this measure be indicated as disparities sensitive?*

1c. Priority

1c. High Priority (previously "High Impact") requires measures to address national health goal/priority or a demonstrated high-impact aspect of care.

- *Beginning in 2015, priority is no longer an NQF measure evaluation criterion.*

Committee pre-evaluation comments

Criteria 1: Importance to Measure and Report (including 1a, 1b, 1c)

1. ***Committee's Overview Comments***:
   - Sufficient evidence was presented - and has previously been presented - to justify monitoring this risk-adjusted outcome

1a. ***Committee's Comments on Evidence to Support Measure Focus:***
   - Strong evidence.

1b. ***Committee's Comments on Performance Gap:***
   - Large gap in performance
   - The variability in this outcome is substantial across hospitals

1c. ***Committee's Comments on Composite performance Measure:***
   - Not Applicable

Criteria 2: Scientific Acceptability of Measure Properties

2a. Reliability

2a1. Reliability Specifications

2a1. Specifications requires the measure, as specified, to produce consistent (reliable) and credible (valid) results about the quality of care when implemented.

- This measure calculates 30-day all-cause mortality for patients hospitalized with acute myocardial infarction (AMI).
- The measure produces a risk-standardized mortality rate (RSMR), which is calculated as the ratio of the number of "predicted" to the number of "expected" deaths, multiplied by the national unadjusted mortality rate.
- The denominator includes patients aged 18 years and older discharged from the hospital with a principal discharge diagnosis of AMI and with a complete claims history for the 12 months prior to admission. The measure can also be calculated for patients aged 65 and older only.
- The numerator includes patients who died of any cause within 30 days of the date of admission of the index AMI hospitalization.
- The denominator population is defined using ICD-9 and ICD-10 codes; a list of applicable codes is included in the submission.
- The numerator population is defined using vital status data, which may be derived from the Medicare Enrollment Database (EDB), State-based data systems, the Social Security Administration's Death Master File (DMF), or the Centers for Disease Control and Prevention's National Death Index (NDI).
- The data sources for this measure may include Medicare Part A and B claims, Veterans Health Administration claims, the Medicare Enrollment Database (EDB), and all-payer data sources such as the California Patient Discharge Database.
- The measure's time window can be specified from one to three years.
- The measure is risk-adjusted using a statistical risk model (see details below).

Questions for the Committee:

- *Are all the data elements clearly defined? Are all appropriate codes included?*
- *Is it likely this measure can be consistently implemented?*

2a2. Reliability Testing Testing attachment

2a2. Reliability testing demonstrates if the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise enough to distinguish differences in performance across providers.

- The developer has assessed reliability at both the data element and the performance score levels.
- Datasets used for testing included Medicare Parts A and B claims, Veterans' Health Administration claims, as well as the Medicare Enrollment Database (EDB). Additionally, census data were used to assess socio-demographic factors.
    - **Data element reliability**:
        - With regard to data element reliability, the developer notes that the measure has been developed to avoid the use of claims data elements that are thought to be coded inconsistently across hospitals or providers, instead using fields that are consequential for payment and which are audited by CMS.
        - In addition, the developer compared frequencies and odds ratios of variables from their risk model across three years of data in order to assess the consistency of those variables over time. [*Note: NQF does not typically consider temporal consistency to be a valid method of demonstrating reliability of data elements*.]
        - Summarizing the results of this analysis, the developer notes that the frequency of some model variables increased between 2011 and 2014, which may reflect increased co-morbidity rates, but may also be due to increased hospital coding of comorbidities.
        - The developer notes that as part of the 2012 update to this measure, the number of diagnosis codes and procedure codes were increased to align with the Version 5010 format changes required by the Department of Health and Human Services (DHHS).
    - **Performance score reliability**:
        - The developer defines performance score reliability as the degree to which repeated measurements of the same entity agree with each other.
        - In line with this thinking, the developer's approach to assessing score-level reliability was to consider the extent to which assessments of a hospital using different but randomly-selected subsets of patients produce similar measures of hospital performance. The developers refer to this as a "test-retest" approach; it may also be called a "split-half" method. [*Note: NQF considers this to be an appropriate method of assessing reliability*.]
        - A total of 497,550 admissions over a 3-year period were examined, with 247,641 in one sample and 249,909 in the other randomly-selected sample. Two risk-standardized mortality rates (RSMR) were calculated for each hospital: one from each of the two separate samples.
        - The agreement between the two RSMRs for each hospital (as measured by an intra-class correlation coefficient (ICC)) was **0.41**; the developer states that according to the conventional interpretation, this is considered a "moderate" level of agreement.
        - The developer notes that this analysis was limited to hospitals with 12 or more cases in each split sample, and that splitting the total population into two samples resulted in a sample equivalent of only 1.5 years of data, whereas the measure is reported with the full three years of data. [*Note: It is unclear whether the measure itself is limited to hospitals with 12 or more cases; if it is not, then testing was not conducted with the measure as specified*.]
        - The developer expects that the correlation coefficient would be higher using a full three-year sample since it would include more patients.
- The developer's overall interpretation of reliability testing results is that the stability of the risk factor frequencies and odds ratios over time suggests that the underlying data elements are reliable, and that the ICC score from performance score analysis demonstrates moderate agreement across samples using a conservative approach to assessment.

Questions for the Committee:

- *Do the testing results presented by the developer demonstrate an adequate level of reliability?*
- *In addition to the consistency of measurement results, assessments of performance score reliability often examine the ability of the measure to differentiate between measured entities. Do the reliability testing results reported by the developer demonstrate that meaningful differences in performance can be identified?*

2b. Validity

2b1. Validity: Specifications

2b1. Validity Specifications. This section should determine if the measure specifications are consistent with the evidence.

- This measure estimates 30-day all-cause mortality for patients hospitalized with acute myocardial infarction (AMI) using a risk standardized mortality ratio (RSMR), which is calculated as the ratio of the number of "predicted" to the number of "expected" deaths, multiplied by the national unadjusted mortality rate.
- As a rationale for measuring this health outcome, the developers suggest that hospitals are able to influence mortality rates through a broad range of clinical activities, including prevention of complications, provision of evidenced-based care, discharge planning, management of care transitions, medication reconciliation, and patient education.

Question for the Committee:

- *Are the specifications consistent with the evidence?*

2b2. Validity testing

2b2. Validity Testing should demonstrate the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality.

- The developer conducted empirical validity testing of the measure score.
- To assess validity, the developer compared scores from the administrative claims-based measure (i.e., the measure as specified) to scores derived from medical record review in the same patient cohort.
- This assessment was conducted on data from 1994 and 1995, comprising 178,188 AMI hospitalizations; the unadjusted 30-day mortality rate in this population was 19.0%.
- Hospital-level risk-standardized mortality rates (RSMRs) were estimated using the claims-based model and the medical record-based model; the linear relationship between these two sets of estimates was then examined, using regression techniques and weighting by the total number of cases in each hospital.
- The correlation between the claims-based RSMRs and the record-based RSMRs was estimated at 0.91, which the developer characterizes as a "strong" level of correlation.

Questions for the Committee:

- *Do the method and results of testing demonstrate sufficient validity so that conclusions about quality can be made?*
- *Do you agree that the score from this measure as specified is an indicator of quality?*

2b3-2b7. Threats to Validity

2b3. Exclusions:

- Patients in the following categories are excluded from the measure:
- Discharged alive on the day of admission or the following day who were not transferred to another acute care facility.
- With inconsistent or unknown vital status or other unreliable demographic (age and gender) data;
- Enrolled in the Medicare hospice program or used VA hospice services any time in the 12 months prior to the index admission, including the first day of the index admission; or
- Discharged against medical advice (AMA).
- In addition, patients without at least 30 days post-discharge enrollment in FFS Medicare are excluded from the measure (because the 30-day mortality outcome cannot be assessed in this group).
- The developer notes that all exclusions were determined by careful clinical review and have been made based on clinically relevant decisions and to ensure accurate calculation of the measure
- To determine the impact of exclusions, the developer examined overall frequencies and proportions of the total cohort excluded for each exclusion criterion.
- The number and percentage of patients excluded for each criterion are as follows:

1. Discharged alive on the day of admission or the following day who were not transferred to another acute care facility: **34,657 (6.17%)**
2. With inconsistent or unknown vital status or other unreliable demographic (age and gender) data: **26 (<0.01%)**
3. Enrolled in the Medicare hospice program or used VA hospice services any time in the 12 months prior to the index admission, including the first day of the index admission: **4,770 (0.85%)**
4. Discharged against medical advice (AMA): **2,630 (0.47%)**

- The developer also provides the distribution across hospitals for each exclusion criterion.
- The developer notes that the first exclusion criterion, which accounts for the majority of all exclusions, is meant to ensure a clinically coherent cohort, preventing the inclusion of patients who likely did not suffer a clinically-significant AMI.
- The developer comments that for most hospitals, this results in very few patients being excluded, and that for those hospitals with greater proportions of excluded patients, the measure is likely excluding less severe patients that may not be considered as AMI at other hospitals. The developer notes that this exclusion was guided by the input of clinical experts at the time of measure development.
- The developer states that exclusion criteria 2 and 3 are necessary for valid calculation of the measure, and that exclusion 4 is needed for acceptability of the measure to hospitals who do not have the opportunity to adequately prepare such patients for discharge, noting that the aforementioned exclusions are unlikely to affect the measure score because they exclude a very small percentage of patients.

Questions for the Committee:

- *Are the exclusions consistent with the evidence?*
- *Are any patients or patient groups inappropriately excluded from the measure?*
- *Are the exclusions of sufficient frequency and variation across providers to be needed (and outweigh the data collection burden)?*

2b4. Risk adjustment:

- This measure employs a hierarchical logistic regression model (a form of hierarchical generalized linear model [HGLM]) to create a hospital level 30-day risk-standardized mortality rate (RSMR).
- The developer suggests that this approach to modeling appropriately accounts for the structure of the data (patients clustered within hospitals), the underlying risk due to patients' comorbidities, and the sample size at a given hospital when estimating hospital mortality rates
- The developer notes that this risk-adjustment approach simultaneously models data at the patient and hospital levels to account for the variance in patient outcomes both within and between hospitals.
- Variables considered for inclusion in the model were patient-level risk-adjustors that are expected to be predictive of mortality based on empirical analysis, prior literature, and clinical judgment, including demographic factors (age, sex) and indicators of comorbidity and disease severity.
- For each patient, covariates were obtained from claims records extending 12 months prior to and including the index admission. The covariates are defined using condition categories (CCs), which are clinically-meaningful groupings of more than 15,000 ICD-9-CM diagnosis codes.
- The measure does not adjust for CCs that were possible adverse events of care and that were only recorded in the index admission.
- The final set of 27 risk-adjustment variables is included in the testing attachment; the odds ratio associated with each variable is also provided.

- The developers also considered a number of variables related to sociodemographic status (SDS) for potential inclusion in the risk-adjustment model. Candidate SDS variables were selected for examination based on a review of literature and national data sources.

- **Conceptual analysis of the need for SDS adjustment:**
  - The developers note that there is a large body of literature linking various SDS factors to worse health status and higher mortality over a lifetime, with income, education, and occupational level being the

most commonly examined variables, though literature directly related to 30-day mortality after admission for cardiovascular disease is much more limited.
    - One potential pathway for SDS factors to affect 30-day mortality (independent of the quality of care) is patients' health status at the time of admission.
        - SDS factors can influence admission health status both due to the impact of multiple related stressors over a lifetime contributing to overall worse health, as well as through poorer access to care and potentially delayed presentation.
        - The developers note that this pathway should be largely accounted for by their clinical risk-adjustment model.
    - Another potential pathway for SDS factors to affect 30-day mortality is for lower-income patients to elect not to follow prescribed care (for example, refill a prescription or keep a follow-up visit with a primary care provider) because limited resources create competing priorities for the patient.
    - The developers also argue that there are a number of pathways for SDS to affect 30-day mortality that are *not* independent of the quality of care. These may include:
        - Contextual effects, such as patients of low SDS presenting at lower-quality institutions for care;
        - Patients of low SDS receiving differentiated care as compared to counterparts of higher SDS—which may be appropriate or inappropriate in different instances.

- **Empirical analysis of SDS factors:**
    - The developers state that they found race (black vs non-black) and dual-eligible status—i.e., enrolled in both Medicare and Medicaid (obtained from CMS claims enrollment data)—to be the only two patient-level SDS variables available for direct examination.
    - Also considered were a number of neighborhood-level variables (represented in a validated AHRQ composite index of SDS variables found in census data, including income and education) that could serve as a proxy for patient-level SDS.
        - These variables are linked to patients by zip code; however, the data are only linked at a 5-digit zip code level—nine-digit zip code data, which may provide a more granular view of patient sociodemographic status, were not available.
        - Patients were identified as low SDS if they lived in a neighborhood in the lowest quartile of the AHRQ SDS index.
    - The developer's method was to first evaluate variation in the prevalence of low-SDS patients among providers; they then assessed the relationship (univariate) between the SDS variables and 30-day HF mortality, and examined the incremental effect of SDS in a multivariable model, evaluating the extent to which the addition of any one of these variables improved model performance or changed hospital results.
    - The developers' analysis found that the prevalence of SDS factors in the HF cohort does vary across measured entities.
    - With regard to the empirical association of each SDS variable with the outcome (univariate), the analysis found that patient-level observed AMI unadjusted mortality rate for dual-eligible patients was somewhat higher, at 16.1% compared with 14.0% for all other patients; the mortality rate for black patients was lower at 12.6% compared with 14.4% for patients of all other races, and the mortality rate for patients in the lowest SES quartile by AHRQ Index was slightly higher at 14.4% compared with 13.9% for patients in the highest SES quartile.
        - With regard to the strength and significance of the SDS variables in the context of a multivariable model, the developers' analysis found that:
            - For dual eligibility and the AHRQ SES indicator, the variable is associated with higher risk of modest strength. Odds ratios are on the order of 1.12 for dual eligibility and 1.09 for AHRQ SES.
            - The developer notes that this is similar to the odds ratio for comorbidities such as COPD and substantially lower than the risk associated with comorbidities such as metastatic cancer.
            - For race, black race is associated with a lower risk of mortality, with an odds ratio of 0.81.
        - However, the developer states that in all cases, the c-statistic (i.e., predictive value) for the AMI patient-level multivariate model with the SDS variable in the model is essentially unchanged from that without.
        - To further understand the relative importance of these risk-factors in the measure, the developers compared hospital performance with and without the addition of each SDS variable.

    - Their analysis found that the addition of any of these variables into the model had little to no effect on hospital performance.
- Regarding their overall findings, the developers state that among the SDS variables that could be feasibly incorporated into this model,
    - The relationship with mortality is small;
    - The relative effect of black race is stronger than the other two SDS variables but is in the opposite direction than what has been the expressed concern of stakeholders interested in adding such adjustment to the models;
    - The impact of adding any of these indicators is very small to negligible on model performance and hospital profiling.
- The developers state that given these findings and complex pathways that could explain any relationship between SDS and mortality, which do not all support risk-adjustment, **they did not incorporate SDS variables into the measure**.

- **Risk Model Diagnostics:**
    - To assess the overall performance of their risk-adjustment model, the developers computed several summary statistics, including:
        - *Area under the receiver operating characteristic (ROC) curve* (also known as a c-statistic, which measures the probability that the model's prediction of the outcome is better than chance)
        - *Predictive ability* (the model's ability to distinguish high-risk subjects from low-risk subjects)
        - *Over-fitting indices (model calibration)* (to ensure that the model is not only describing the relationship between predictive variables and outcome in the development dataset but also providing valid predictions in new patients)
    - For the current measure cohort, the findings from this analysis are as follows:
        - C-statistic: **0.72**
            - A c-statistic of 0.72 means that for 72% of all possible pairs of patients—one who died and one who lived—the model correctly assigned a higher probability to those who died. Generally, a c-statistic of at least 0.70 is considered acceptable.
            - The developers interpret this as 'good' model discrimination
        - Predictive ability (lowest decile %, highest decile %): (**2.8%, 33.3%**)
            - The developers state that this indicates a wide range between the lowest decile and highest decile, indicating the ability to distinguish high-risk subjects from low-risk subjects.
        - Overfitting indices (model calibration) [presented as (γ0, γ1)]:
            - The developer states that if the γ0 in the validation samples are substantially far from zero and the γ1 is substantially far from one, there is potential evidence of over-fitting. The calibration value of close to 0 at one end and close to 1 to the other end indicates good calibration of the model.
                - 1st half of split sample: Calibration: (**0.0000, 1.0000**)
                - 2nd half of split sample: Calibration: (**-0.0035, 0.9928**)
    - The developer's overall interpretation of the results of their analysis is that the findings demonstrate the risk-adjustment model adequately controls for differences in patient characteristics (case mix).

    - The developer also conducted additional analyses to determine whether the measure could be applied to Medicare FFS 65+ patients using only Medicare Part A data and whether it could be applied to a population of patients aged 18+ using all-payer data.
    - The developers report that their results indicate their model had good discrimination and predictive ability in both groups.

Questions for the Committee:

- *Are the candidate and final variables included in the risk adjustment model adequately described for the measure to be implemented?*

- *Does the Standing Committee agree with the developer's rationale that there is no conceptual basis for adjusting this measure for SDS factors?*
- *Do you agree with the developer's decision, based on their empirical analysis, to not include SDS factors in their risk-adjustment model?*

2b5. Meaningful difference:

- For public reporting of this measure, CMS characterizes the uncertainty associated with the RSMR by estimating the 95% interval estimate.
- If the RSMR's interval estimate does not include the national observed mortality rate (is lower or higher than the rate), then CMS is confident that the hospital's RSMR is different from the national rate, and describes the hospital on the Hospital Compare website as "better than the U.S. national rate" or "worse than the U.S. national rate."
- If the interval includes the national rate, then CMS describes the hospital's RSMR as "no different than the U.S. national rate" or "the difference is uncertain."
- The developer reports that for the performance period of July 2011-June 2014, the mean hospital RSMR was 14.3%, with a range of 9.9% to 20.6%. The interquartile range was 13.8%-14.8%.
- Of 4,490 hospitals in the study cohort, 41 performed "better than the U.S. national rate," 2,474 performed "no different from the U.S. national rate," 21 performed "worse than the U.S. national rate," and 1,954 were classified as "number of cases too small" (fewer than 25) to reliably tell how well the hospital is performing.
- The developer's interpretation of this data is that the variation in rates and number of performance outliers suggests there remain differences in the quality of care received across hospitals for AMI that support measurement to reduce the variation.

Question for the Committee:

- *Does this measure identify meaningful differences about quality?*

2b6. Comparability of data sources/methods:

- While the developer did not decide to include SDS variables in their final model, they did compare measure results with and without SDS adjustment.

2b7. Missing Data

- N/A

Committee pre-evaluation comments

Criteria 2: Scientific Acceptability of Measure Properties (including all 2a, 2b, and 2d)

2a1. & 2b1.: ***Committee's Comments on Reliability-Specifications:***

- Clearly defined administrative claims data
- "The developers do not mention a potential lag in the reporting of numerator data. Also - the verbiage below could cause concern in terms of definitions:
  - Summarizing the results of this analysis, the developer notes that the frequency of some model variables increased between 2011 and 2014, which may reflect increased co-morbidity rates, but may also be due to increased hospital coding of comorbidities.
  - The developer notes that as part of the 2012 update to this measure, the number of diagnosis codes and procedure codes were increased to align with the Version 5010 format changes required by the Department of Health and Human Services (DHHS).
  - [Note: It is unclear whether the measure itself is limited to hospitals with 12 or more cases; if it is not, then testing was not conducted with the measure as specified.]

2a2.: ***Committee's Comments on Reliability-Testing:***

- Intra-class correlation coefficient of 0.41 between RSMRs for same hospital in 1.5 year periods back to back (split half method). Just barely acceptable
- The measure appears to be reliably reproducible,

2b1.: ***Committee's Comments on Validity-Specifications*** :

- Clearly defined administrative claims data
- None evident

2b2.: ***Committee's Comments on Validity-Testing:***

- Intraclass coefficient of 0.91 compared to medical record review in large sample
- Reliability testing would have been more meaningful if the developers had demonstrated (as they did for SDS factors) differences in RSMRs between the clinical and the claims model

2b3-7.: ***Committee's Comments on Threats to Validity:***

- They opted not to use SDS, but at least did extensive testing to show that the impact of candidate variables on the model was very little
- "2b3-Some sites appear to have 100% exclusions - that would be worrisome
    - 2b4 - the model was generated on a California population, which may not be representative - it is curious that a model on the entire population was not developed
    - 2b5 - meaningful differences between top and bottom percentiles are apparent
    - 2b6 - the results presented are supportive of not including the SDS factors
    - 2b7 - developers maintain that missing values are rare but do not demonstrate the extent of missing values

2d.: ***Committee's Comments on Composite Performance Measure:***

- Not Applicable

Criterion 3. Feasibility

3. Feasibility is the extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

- This measure is based on administrative claims data (e.g., DRG, ICD-9/10), which the developers note are routinely generated and collected as part of hospitals' billing processes.
- The developer indicates that all data elements are in defined fields in electronic claims.

Questions for the Committee:

- *Are the required data elements routinely generated and used during care delivery?*
- *Is the data collection strategy ready to be put into operational use?*

Committee pre-evaluation comments

Criteria 3: Feasibility

3.: ***Committee's Comments on Feasibility***

- Claims data, very feasible
- The measure should be readily feasible

Criterion 4: Usability and Use

4. Usability and Use evaluate the extent to which audiences (e.g., consumers, purchasers, providers, policymakers) use or could use performance results for both accountability and performance improvement activities.

- Measure results are publicly reported through CMS's Hospital Inpatient Quality Reporting (IQR) Program.
- In addition, measure results are incorporated into the calculation of hospital payment rates through CMS's Hospital Value Based Purchasing (HVBP) Program.
- The developer reports that there has been significant progress in 30-day mortality rates for AMI, noting that the median 30-day RSMR decreased by 1.4% from 2011-2012 (median RSMR: 14.7%) to 2013-2014 (median RSMR:

13.3%).

- The developers did not identify any unintended consequences during measure development or model testing, but note that they are committed to monitoring this measure's use and assessing potential unintended consequences over time.

***Questions for the Committee**:*

- *Are this measure's performance results being used to further the goal of high-quality, efficient healthcare?*
- *Do the benefits of the measure outweigh any potential unintended consequences?*

Committee pre-evaluation comments

Criteria 4: Usability and Use

4.: ***Committee's Comments on Usability and Use:***

- Publicly reported and should be
- The measure is currently being used by several programs.

Criterion 5: Related and Competing Measures

- List any related or competing measures based on harmonization protocol.
- Summarize any harmonization efforts, i.e., responses from the developers regarding harmonization.
- Briefly summarize next steps according to protocol

Pre-meeting public and member comments

-

NATIONAL QUALITY FORUM—Evidence (subcriterion 1a)

Measure Title: Hospital 30-day, all-cause, risk-standardized mortality rate (RSMR) following acute myocardial infarction (AMI) hospitalization for patients 18 and older

IF the measure is a component in a composite performance measure, provide the title of the Composite Measure here: Click here to enter composite measure title

Date of Submission: Click here to enter a date

Instructions

- *For composite performance measures:*
  - *A separate evidence form is required for each component measure unless several components were studied together.*
  - *If a component measure is submitted as an individual performance measure, attach the evidence form to the individual measure submission.*
- Respond to all questions as instructed with answers immediately following the question. All information needed to demonstrate meeting the evidence subcriterion (1a) must be in this form. An appendix of *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.

- Maximum of 10 pages (*incudes questions/instructions*; minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the evidence for this measure meets NQF's evaluation criteria.

1a. Evidence to Support the Measure Focus

The measure focus is evidence-based, demonstrated as follows:

- Health outcome: [3] a rationale supports the relationship of the health outcome to processes or structures of care. Applies to patient-reported outcomes (PRO), including health-related quality of life/functional status, symptom/symptom burden, experience with care, health-related behavior.
- Intermediate clinical outcome: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured intermediate clinical outcome leads to a desired health outcome.
- Process: [5] a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured process leads to a desired health outcome.
- Structure: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured structure leads to a desired health outcome.
- Efficiency: [6] evidence not required for the resource use component.

Notes

3. Generally, rare event outcomes do not provide adequate information for improvement or discrimination; however, serious reportable events that are compared to zero are appropriate outcomes for public reporting and quality improvement.

4. The preferred systems for grading the evidence are the U.S. Preventive Services Task Force (USPSTF) grading definitions and methods, or Grading of Recommendations, Assessment, Development and Evaluation (GRADE) guidelines.

5. Clinical care processes typically include multiple steps: assess → identify problem/potential problem → choose/plan intervention (with patient input) → provide intervention → evaluate impact on health status. If the measure focus is one step in such a multistep process, the step with the strongest evidence for the link to the desired outcome should be selected as the focus of measurement. Note: A measure focused only on collecting PROM data is not a PRO-PM.

6. Measures of efficiency combine the concepts of resource use and quality (see NQF's Measurement Framework: Evaluating Efficiency Across Episodes of Care; AQA Principles of Efficiency Measures).

1a.1.This is a measure of:

Outcome

☒ Health outcome: cost/resource use.

☐ Patient-reported outcome (PRO): Click here to name the PRO

PROs include HRQoL/functional status, symptom/symptom burden, experience with care, health-related behaviors

☐ Intermediate clinical outcome (*e.g., lab value*):

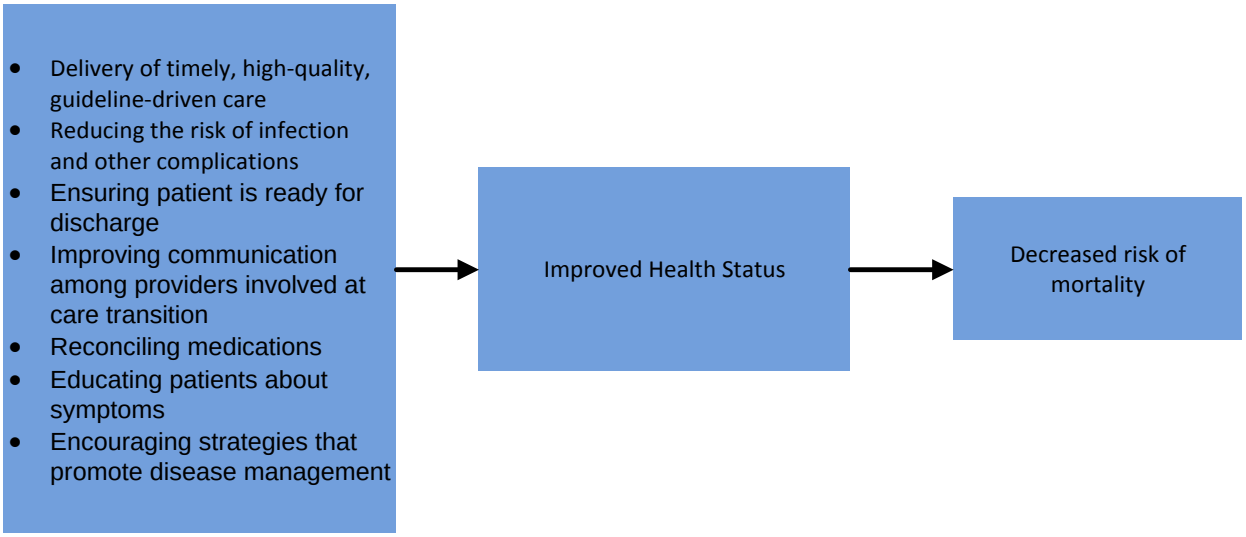
☐ Process: Click here to name the process

☐ Structure: Click here to name the structure

☐ Other: Click here to name what is being measured

HEALTH OUTCOME PERFORMANCE MEASURE *If not a health outcome, skip to 1a.3*

1a.2. Briefly state or diagram the linkage between the health outcome (or PRO) and the healthcare structures, processes, interventions, or services that influence it.



The goal of this measure is to directly affect patient outcomes by measuring risk-standardized rates of mortality. Measurement of patient outcomes, including mortality, allows for a broad view of quality of care that encompasses more than what can be captured by individual process-of-care measures. As described below, mortality is likely to be influenced by a broad range of clinical activities such as the prevention of complications and the provision of evidenced-based care.

1a.2.1. State the rationale supporting the relationship between the health outcome (or PRO) and at least one healthcare structure, process, intervention, or service.

Acute myocardial infarction (AMI) is one of the most common principal hospital discharge diagnoses among older adults and is associated with high mortality. Approximately 635,000 Americans will have AMI and approximately 280,000 will have a recurrent attack (Go et al. 2013). It is estimated that an additional 150,000 AMIs occur each year, estimating a total of 1,065,000 AMI-related events a year (Go et al. 2013). The estimated acute myocardial infarction (AMI) incidence in 2011 was 610,000 new attacks and 325,000 recurrent attacks (National Quality Measures). Additionally, AMI was the tenth most common principal discharge diagnosis among patients with Medicare in 2012 (AHRQ 2010).

The high prevalence and considerable morbidity and mortality associated with AMI create an economic burden on the healthcare system (American Heart Association, 2010). AMI accounts for a large fraction of hospitalization costs, and was the sixth most expensive condition billed to Medicare in 2011 (Torio et al 2013). It is estimated that in 2009 the combination of direct and indirect health care costs of coronary Heart disease reached over $195.2 billion (Go et al. 2013).

Hospital interventions, such as use of appropriate medications, timely percutaneous coronary interventions and prevention of complications, are known to decrease the risk of death within 30 days of hospital admission (Rathore et al. 2009; Antman et al. 2008; Jha et al. 2007).Current process-based performance measures, however, cannot capture all the ways that care within the hospital might influence outcomes. As a result, many stakeholders, including patient organizations, are interested in outcomes measures that allow patients and providers to assess relative outcomes performance for hospitals.

Over the last 10 years, nationally, risk-standardized mortality rates have decreased for AMI (Krumholz et al. 2009). Yet, continued variation in performance suggests continued opportunities for improvements. In addition, recent qualitative research funded by AHRQ, Commonwealth Fund, and United Healthcare identified common system-level approaches to care and, specifically, the tailored use of protocols in those hospitals that have low RSMRs compared with hospitals with high RSMRs (Curry et al. 2011).

Note: For health outcome performance measures, no further information is required; however, you may provide evidence for any of the structures, processes, interventions, or service identified above.

INTERMEDIATE OUTCOME, PROCESS, OR STRUCTURE PERFORMANCE MEASURE

1a.3. Briefly state or diagram the linkages between structure, process, intermediate outcome, and health outcomes. Include all the steps between the measure focus and the health outcome.

1a.3.1. What is the source of the systematic review of the body of evidence that supports the performance measure?

☐ Clinical Practice Guideline recommendation – ***complete sections 1a.4, and 1a.7***

☐ US Preventive Services Task Force Recommendation – ***complete sections 1a.5 and 1a.7***

☐ Other systematic review and grading of the body of evidence (*e.g., Cochrane Collaboration, AHRQ Evidence Practice Center*) – ***complete sections 1a.6 and 1a.7***

☐ Other – ***complete section 1a.8***

Please complete the sections indicated above for the source of evidence. You may skip the sections that do not apply.

1a.4. CLINICAL PRACTICE GUIDELINE RECOMMENDATION

1a.4.1. Guideline citation (*including date*) and **URL for guideline** (*if available online*):

1a.4.2. Identify guideline recommendation number and/or page number and **quote verbatim, the specific guideline recommendation**.

1a.4.3. Grade assigned to the quoted recommendation with definition of the grade:

1a.4.4. Provide all other grades and associated definitions for recommendations in the grading system.
(*Note: If separate grades for the strength of the evidence, report them in section 1a.7.*)

1a.4.5. Citation and URL for methodology for grading recommendations (*if different from 1a.4.1*)**:**

1a.4.6. If guideline is evidence-based (rather than expert opinion), are the details of the quantity, quality, and consistency of the body of evidence available (e.g., evidence tables)?

☐ Yes → ***complete section 1a.7***

☐ No → ***report on another systematic review of the evidence in sections 1a.6 and 1a.7; if another review does not exist, provide what is known from the guideline review of evidence in 1a.7***

1a.5. UNITED STATES PREVENTIVE SERVICES TASK FORCE RECOMMENDATION

1a.5.1. Recommendation citation (*including date*) and **URL for recommendation** (*if available online*):

1a.5.2. Identify recommendation number and/or page number and **quote verbatim, the specific recommendation**.

1a.5.3. Grade assigned to the quoted recommendation with definition of the grade:

1a.5.4. Provide all other grades and associated definitions for recommendations in the grading system.
(*Note: the grading system for the evidence should be reported in section 1a.7.*)

1a.5.5. Citation and URL for methodology for grading recommendations (*if different from 1a.5.1*)**:**

Complete section 1a.7

1a.6. OTHER SYSTEMATIC REVIEW OF THE BODY OF EVIDENCE

1a.6.1. Citation (*including date*) and **URL** (*if available online*):

1a.6.2. Citation and URL for methodology for evidence review and grading (*if different from 1a.6.1*)**:**

Complete section 1a.7

1a.7. FINDINGS FROM SYSTEMATIC REVIEW OF BODY OF THE EVIDENCE SUPPORTING THE MEASURE

If more than one systematic review of the evidence is identified above, you may choose to summarize the one (or more) for which the best information is available to provide a summary of the quantity, quality, and consistency of the body of evidence. Be sure to identify which review is the basis of the responses in this section and if more than one, provide a separate response for each review.

1a.7.1. What was the specific structure, treatment, intervention, service, or intermediate outcome addressed in the evidence review?

1a.7.2. Grade assigned for the quality of the quoted evidence with definition of the grade:

1a.7.3. Provide all other grades and associated definitions for strength of the evidence in the grading system.

1a.7.4. What is the time period covered by the body of evidence? (*provide the date range, e.g., 1990-2010*).
Date range: Click here to enter date range

QUANTITY AND QUALITY OF BODY OF EVIDENCE

1a.7.5. How many and what type of study designs are included in the body of evidence? (*e.g., 3 randomized controlled trials and 1 observational study*)

1a.7.6. What is the overall quality of evidence across studies in the body of evidence? (*discuss the certainty or confidence in the estimates of effect particularly in relation to study factors such as design flaws, imprecision due to small numbers, indirectness of studies to the measure focus or target population*)

ESTIMATES OF BENEFIT AND CONSISTENCY ACROSS STUDIES IN BODY OF EVIDENCE

1a.7.7. What are the estimates of benefit—magnitude and direction of effect on outcome(s) across studies in the body of evidence? (*e.g., ranges of percentages or odds ratios for improvement/ decline across studies, results of meta-analysis, and statistical significance*)

1a.7.8. What harms were studied and how do they affect the net benefit (benefits over harms)?

UPDATE TO THE SYSTEMATIC REVIEW(S) OF THE BODY OF EVIDENCE

1a.7.9. If new studies have been conducted since the systematic review of the body of evidence, provide for <u>each</u> new study: 1) citation, 2) description, 3) results, 4) impact on conclusions of systematic review.

1a.8 OTHER SOURCE OF EVIDENCE

If source of evidence is NOT from a clinical practice guideline, USPSTF, or systematic review, please describe the evidence on which you are basing the performance measure.

1a.8.1 What process was used to identify the evidence?

1a.8.2. Provide the citation and summary for each piece of evidence.

1. Evidence, Performance Gap, Priority – Importance to Measure and Report

Extent to which the specific measure focus is evidence-based, important to making significant gains in healthcare quality, and improving health outcomes for a specific high-priority (high-impact) aspect of healthcare where there is variation in or overall less-than-optimal performance. ***Measures must be judged to meet all subcriteria to pass this criterion and be evaluated against the remaining criteria.***

1a. Evidence to Support the Measure Focus – See attached Evidence Submission Form
AMI_mortality_NQF_Evidence_Attachment_06-29-15.docx

1b. Performance Gap

Demonstration of quality problems and opportunity for improvement, i.e., data demonstrating:

- considerable variation, or overall less-than-optimal performance, in the quality of care across providers; and/or
- disparities in care across population groups.

1b.1. **Briefly explain the rationale for this measure** *(e.g., the benefits or improvements in quality envisioned by use of this measure)*
The goal of this measure is to improve patient outcomes by providing patients, physicians, and hospitals with information about hospital-level, risk-standardized mortality rates following hospitalization for AMI. Measurement of patient outcomes allows for a broad view of quality of care that encompasses more than what can be captured by individual process-of-care measures. Complex and critical aspects of care, such as communication between providers, prevention of and response to complications, patient safety, and coordinated transitions to the outpatient environment, all contribute to patient outcomes but are difficult to measure by individual process measures. The goal of outcomes measurement is to risk-adjust for patients' conditions at the time of hospital admission and then evaluate patient outcomes. This measure was developed to identify institutions whose performance is better or worse than what would be expected based on their patient case mix, and therefore promote hospital quality improvement and better inform consumers about care quality.

Additionally, AMI mortality is a priority area for outcomes measure development as it is a costly and common condition. Hospital mortality is an outcome that is likely attributable to care processes and is an important outcome for patients. Measuring and reporting mortality rates will inform health care providers about opportunities to improve care, strengthen incentives for quality improvement, and ultimately improve the quality of care received by Medicare patients. The measure will also provide patients with information that could guide their choices. Furthermore, the measure will increase transparency for consumers and has the potential to lower health care costs associated with mortality.

1b.2. **Provide performance scores on the measure as specified (current and over time) at the specified level of analysis.** *(This is required for endorsement maintenance. Include mean, std dev, min, max, interquartile range, scores by decile. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities included). This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*

Distribution of Hospital AMI RSMRs over Different Time Periods:

Characteristic	July 2011- June 2012	July 2012- June 2013	July 2013-June 2014	July 2011-June 2014
Number of Hospitals	4, 166	4,102	3,997	4,490
Number of Admissions	167,291	169,885	160,374	497,550
Mean Number of Admissions	40.2	41.4	40.1	110.8
Range (min. – max.)	11.2-19.4	11.0-19.4	10.9-16.3	9.9-20.6%
Minimum	11.2	11.0	10.9	9.9
10th percentile	13.9	13.7	12.8	13.0
20th percentile	14.3	14.1	13.1	13.6
30th percentile	14.5	14.3	13.2	13.9
40th percentile	14.7	14.4	13.3	14.1
50th percentile	14.7	14.5	13.3	14.2
60th percentile	14.9	14.7	13.4	14.4
70th percentile	15.0	14.9	13.5	14.6
80th percentile	15.2	15.0	13.6	14.9
90th percentile	15.6	15.4	13.9	15.4
Maximum	19.4	19.4	16.2	20.6

1b.3. **If no or limited performance data on the measure as specified is reported in 1b2, then provide a summary of data from the literature that indicates opportunity for improvement or overall less than optimal performance on the specific focus of measurement.**

N/A

1b.4. **Provide disparities data from the measure as specified (current and over time) by population group, e.g., by race/ethnicity, gender, age, insurance status, socioeconomic status, and/or disability.** *(This is required for endorsement maintenance. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities include.) This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*

Distribution of AMI RSMRs by Proportion of Medicaid Patients:
Dates of Data: July 2011 through June 2014
Data Source: Medicare FFS claims

Characteristic	Hospitals with a low proportion (=8.4%) Medicaid patients	Hospitals with a high proportion (=30.5%) Medicaid patients
Number of Measures Entities (Hospitals)	242	243
Number of Patients	49,022 in low-proportion hospitals	37,060 in high-proportion hospitals
Maximum	18.9	18.1
90th percentile	15.3	15.7
75th percentile	14.6	15.1
Median (50th percentile)	13.7	14.3
25th percentile	13.1	13.5
10th percentile	12.5	12.9
Minimum	10.0	11.0

Distribution of RSMRs by Proportion of African-American Patients:
Dates of Data: July 2011 through June 2014
Data Source: Medicare FFS claims

Characteristic	Hospitals with a low Proportion (=0%) African-American patients	Hospitals with a high proportion (=23.7%) African-American patients
Number of Measures Entities (Hospitals)	244	245
Number of Patients	28,674 patients in low-proportion hospitals	38,275 in high-proportion hospitals
Maximum	17.5	17.9

90th percentile// 16.0 // 15.8
75th percentile// 15.2 // 15.1
Median (50%)// 14.3 // 14.2
25th percentile// 13.5 // 13.4
10th percentile// 12.7 // 12.7
Minimum// 11.5 // 10.4

1b.5. **If no or limited data on disparities from the measure as specified is reported in 1b4, then provide a summary of data from the literature that addresses disparities in care on the specific focus of measurement. Include citations.**
N/A

1c. High Priority (previously referred to as High Impact)

The measure addresses:

- a specific national health goal/priority identified by DHHS or the National Priorities Partnership convened by NQF; OR
- a demonstrated high-priority (high-impact) aspect of healthcare (e.g., affects large numbers of patients and/or has a substantial impact for a smaller population; leading cause of morbidity/mortality; high resource use (current and/or future); severity of illness; and severity of patient/societal consequences of poor quality).

1c.1. **Demonstrated high priority aspect of healthcare**
Affects large numbers, A leading cause of morbidity/mortality, High resource use, Patient/societal consequences of poor quality, Severity of illness
1c.2. **If Other:**

1c.3. **Provide epidemiologic or resource use data that demonstrates the measure addresses a high priority aspect of healthcare. List citations in 1c.4.**
Acute myocardial infarction (AMI) is one of the most common principal hospital discharge diagnoses among older adults and is associated with high mortality. The high prevalence and considerable morbidity and mortality associated with AMI create an economic burden on the healthcare system (American Heart Association, 2010). In 2005, AMI was the fourth most expensive condition treated in US hospitals, accounting for nearly 4% of the national hospital bill. It was also the fourth most expensive condition billed to Medicare that year, accounting for 4.5% of Medicare´s hospital bill (Andrews and Elixhauser, 2007).

Approximately 635,000 Americans will have AMI and approximately 280,000 will have a recurrent attack. It is estimated that an additional 150,000 MIs occur each year, creating an estimated total of 1,065,000 AMI related events a year. It is estimated that the combination of direct and indirect health care costs of coronary heart disease reached over $195.2 billion (2009).

Many current hospital interventions are known to decrease the risk of death within 30 days of hospital admission (Jha et al. 2007; Rathore et al. 2009). Current process-based performance measures, however, cannot capture all the ways that care within the hospital might influence outcomes. As a result, many stakeholders, including patient organizations, are interested in outcomes measures that allow patients and providers to assess relative outcomes performance for hospitals.

1c.5. **If a PRO-PM (e.g. HRQoL/functional status, symptom/burden, experience with care, health-related behaviors), provide evidence that the target population values the measured PRO and finds it meaningful.** *(Describe how and from whom their input was obtained.)*
N/A

2. Reliability and Validity—Scientific Acceptability of Measure Properties

Extent to which the measure, as specified, produces consistent (reliable) and credible (valid) results about the quality of care when implemented. ***Measures must be judged to meet the subcriteria for both reliability and validity to pass this criterion and be evaluated against the remaining criteria.***

2a.1. Specifications The measure is well defined and precisely specified so it can be implemented consistently within and across organizations and allows for comparability. eMeasures should be specified in the Health Quality Measures Format (HQMF) and the Quality Data Model (QDM).

De.5. **Subject/Topic Area** *(check all the areas that apply):*
Cardiovascular, Cardiovascular : Acute Myocardial Infarction

De.6. **Cross Cutting Areas** *(check all the areas that apply):*
Safety

S.1. **Measure-specific Web Page** *(Provide a URL link to a web page specific for this measure that contains current detailed specifications including code lists, risk model details, and supplemental materials. Do not enter a URL linking to a home page or to general information.)*
https://www.qualitynet.org/dcs/ContentServer?c=Page&pagename=QnetPublic%2FPage%2FQnetTier4&cid=1163010421830 &
http://www.cms.gov/Medicare/Quality-Initiatives-Patient-Assessment-Instruments/HospitalQualityInits/Measure-Methodology.html

S.2a. **If this is an eMeasure**, HQMF specifications must be attached. Attach the zipped output from the eMeasure authoring tool (MAT) - if the MAT was not used, contact staff. (Use the specification fields in this online form for the plain-language description of the specifications)
This is not an eMeasure **Attachment:**

S.2b. **Data Dictionary, Code Table, or Value Sets** *(and risk model codes and coefficients when applicable) must be attached. (Excel or csv file in the suggested format preferred - if not, contact staff)*
Attachment **Attachment:** AMI_Mortality_NQF_Data_Dictionary_06-22-15_FINAL.xlsx

S.3. **For endorsement maintenance**, please briefly describe any changes to the measure specifications since last endorsement date and explain the reasons.
Annual Updates
1. Updated CC map.
a. Rationale: The ICD-9-CM CC map is updated annually to capture all relevant comorbidities coded in patient administrative claims data.

No other updates made after 2013 Measure Updates except for use of new years of data for public reporting.

S.4. **Numerator Statement** *(Brief, narrative description of the measure focus or what is being measured about the target population, i.e., cases from the target population with the target process, condition, event, or outcome)*
IF an OUTCOME MEASURE, state the outcome being measured. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
The outcome for this measure is 30-day all-cause mortality. We define mortality as death from any cause within 30 days of the index admission date for patients 18 and older discharged from the hospital with a principal diagnosis of AMI.

S.5. **Time Period for Data** *(What is the time period in which data will be aggregated for the measure, e.g., 12 mo, 3 years, look back*

to August for flu vaccination? Note if there are different time periods for the numerator and denominator.)
Numerator time window: We define the time period for death from any cause within 30 days from the date of admission of the index AMI hospitalization.

Denominator time window: This measure was developed with 12 months of data. The time window can be specified from one to three years. Currently, the measure is publicly reported with three years of index hospitalizations.

S.6. **Numerator Details** *(All information required to identify and calculate the cases from the target population with the target process, condition, event, or outcome such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
IF an OUTCOME MEASURE, describe how the observed outcome is identified/counted. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
The measure counts deaths for any cause within 30 days of the date of admission of the index AMI hospitalization.

Identifying deaths in the FFS measure
As currently reported, we identify deaths for FFS Medicare patients 65 years and older in the Medicare Enrollment Database (EDB).

Identifying deaths in the all-payer measure
For the purposes of development, deaths were identified using the California vital statistics data file. Nationally, post-discharge deaths can be identified using an external source of vital status, such as the Social Security Administration's Death Master File (DMF) or the Centers for Disease Control and Prevention's National Death Index (NDI).

S.7. **Denominator Statement** *(Brief, narrative description of the target population being measured)*
This claims-based measure can be used in either of two patient cohorts: (1) patients aged 65 years or older or (2) patients aged 18 years or older. The cohort includes admissions for patients discharged from the hospital with a principal discharge diagnosis of AMI and with a complete claims history for the 12 months prior to admission. Currently, the measure is publicly reported by CMS for those patients 65 years and older who are either Medicare FFS beneficiaries admitted to non-federal hospitals or patients admitted to VA hospitals. Additional details are provided in S.9 Denominator Details.

S.8. **Target Population Category** *(Check all the populations for which the measure is specified and tested if any):*
Populations at Risk, Senior Care

S.9. **Denominator Details** *(All information required to identify and calculate the target population/denominator such as definitions, specific data collection items/responses , code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
To be included in the measure cohort used in public reporting, patients must meet the following additional inclusion criteria:
1. Having a principal discharge diagnosis of AMI;
2. Enrolled in Medicare FFS;
3. Aged 65 or over;
4. Not transferred from another acute care facility; and
5. Enrolled in Part A and Part B Medicare for the 12 months prior to the date of index admission, and enrolled in Part A during the index admission.

VA beneficiaries/hospitalizations are also included in the AMI mortality measure. Enrollment in Medicare FFS is not required for these patients.

International Classification of Diseases, 9th Revision, Clinical Modification (ICD-9-CM) codes used to define the cohort for each measure are:
410.00 AMI (anterolateral wall) – episode of care unspecified
410.01 AMI (anterolateral wall) – initial episode of care
410.10 AMI (other anterior wall) – episode of care unspecified
410.11 AMI (other anterior wall) – initial episode of care
410.20 AMI (inferolateral wall) – episode of care unspecified
410.21 AMI (inferolateral wall) – initial episode of care
410.30 AMI (inferoposterior wall) – episode of care unspecified
410.31 AMI (inferoposterior wall) – initial episode of care

410.40 AMI (other inferior wall) – episode of care unspecified
410.41 AMI (other inferior wall) – initial episode of care
410.50 AMI (other lateral wall) – episode of care unspecified
410.51 AMI (other lateral wall) – initial episode of care
410.60 AMI (true posterior wall) – episode of care unspecified
410.61 AMI (true posterior wall) – initial episode of care
410.70 AMI (subendocardial) – episode of care unspecified
410.71 AMI (subendocardial) – initial episode of care
410.80 AMI (other specified site) – episode of care unspecified
410.81 AMI (other specified site) – initial episode of care
410.90 AMI (unspecified site) – episode of care unspecified
410.91 AMI (unspecified site) – initial episode of care

ICD-10 Codes that define the patient cohort:
I2109 ST elevation (STEMI) myocardial infarction involving other coronary artery of anterior wall
I2119 ST elevation (STEMI) myocardial infarction involving other coronary artery of inferior wall
I2111 ST elevation (STEMI) myocardial infarction involving right coronary artery
I2119 ST elevation (STEMI) myocardial infarction involving other coronary artery of inferior wall
I2129 ST elevation (STEMI) myocardial infarction involving other sites
I214 Non-ST elevation (NSTEMI) myocardial infarction
I213 ST elevation (STEMI) myocardial infarction of unspecified site

An ICD-9 to ICD-10 crosswalk is attached in field S.2b. (Data Dictionary or Code Table).

S.10. **Denominator Exclusions** *(Brief narrative description of exclusions from the target population)*
The mortality measures exclude index admissions for patients:
1. Discharged alive on the day of admission or the following day who were not transferred to another acute care facility.
2. With inconsistent or unknown vital status or other unreliable demographic (age and gender) data;
3. Enrolled in the Medicare hospice program or used VA hospice services any time in the 12 months prior to the index admission, including the first day of the index admission; or
4. Discharged against medical advice (AMA).

For patients with more than one admission for a given condition in a given year, only one index admission for that condition is randomly selected for inclusion in the cohort.

For Medicare FFS patients, the measure additionally excludes admissions for patients without at least 30 days post-discharge enrollment in FFS Medicare (because the 30-day mortality outcome cannot be assessed in this group).

S.11. **Denominator Exclusion Details** *(All information required to identify and calculate exclusions from the denominator such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
1. The discharge disposition indicator is used to identify patients alive at discharge. Transfers are identified in the claims when a patient with a qualifying admission is discharged from an acute care hospital and admitted to another acute care hospital on the same day or next day. In addition, patient length of stay and condition is identified from the admission claim.
2. Inconsistent vital status or unreliable data are identified if any of the following conditions are met 1) the patient's age is greater than 115 years; 2) if the discharge date for a hospitalization is before the admission date; and 3) if the patient has a sex other than 'male' or 'female'.
3. Hospice enrollment in the 12 months prior to or on the index admission is identified using hospice data and the Inpatient standard analytic file (SAF). This exclusion applies when the measure is used in Medicare FFS patients only.
4. Discharges against medical advice (AMA) are identified using the discharge disposition indicator.

Additional exclusions:
• AMI admissions within 30 days of discharge from a qualifying index admission, which are identified by comparing the discharge date from the index admission with the readmission date.
• Admissions without at least 30 days post-discharge enrollment in FFS Medicare, which is determined by examining the Medicare Enrollment Database (EDB)

S.12. **Stratification Details/Variables** *(All information required to stratify the measure results including the stratification variables, definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format with at S.2b)*
N/A

S.13. **Risk Adjustment Type** (Select type. Provide specifications for risk stratification in S.12 and for statistical model in S.14-15)
Statistical risk model
If other:

S.14. **Identify the statistical risk model method and variables** *(Name the statistical method - e.g., logistic regression and list all the risk factor variables. Note - risk model development and testing should be addressed with measure testing under Scientific Acceptability)*
Our approach to risk adjustment is tailored to and appropriate for a publicly reported outcome measure, as articulated in the American Heart Association (AHA) Scientific Statement, "Standards for Statistical Models Used for Public Reporting of Health Outcomes" (Krumholz et. al., 2006).

The measure employs a hierarchical logistic regression model to create a hospital level 30-day RSMR. In brief, the approach simultaneously models data at the patient and hospital levels to account for the variance in patient outcomes within and between hospitals (Normand & Shahian, 2007). At the patient level, the model adjusts the log-odds of mortality within 30-days of admission for age, sex, and selected clinical covariates. At the hospital level, the approach models the hospital-specific intercepts as arising from a normal distribution. The hospital intercept represents the underlying risk of a death at the hospital, after accounting for patient risk. If there were no differences among hospitals, then after adjusting for patient risk, the hospital intercepts should be identical across all hospitals.

Candidate and Final Risk-adjustment Variables:
Candidate variables were patient-level risk-adjustors that were expected to be predictive of mortality, based on empirical analysis, prior literature, and clinical judgment including age, sex, and indicators of comorbidity and disease severity. For each patient, covariates are obtained from Medicare claims extending 12 months prior to and including the index admission. However, in the all-payer hospital discharge database measure, the risk-adjustment variables can be obtained only from inpatient claims in the prior 12 months and the index admission (this was tested explicitly in our all-payer testing, as many all-payer datasets do not include outpatient claims).

The model adjusts for case-mix differences based on the clinical status of patients at the time of admission. We used condition categories (CCs), which are clinically meaningful groupings of more than 15,000 ICD-9-CM diagnosis codes, and combinations of CCs as candidate variables (Pope et al., 2000). A file that contains a list of the ICD-9-CM codes and their groupings into CCs is attached in data field S.2b (Data Dictionary or Code Table). In addition, only comorbidities that convey information about the patient at admission or in the 12-months prior, and not complications that arise during the course of the hospitalization, are included in the risk-adjustment. Hence, we do not risk adjust for CCs that may represent adverse events of care and that are only recorded in the index admission.

The final set of risk adjustment variables are:
Demographics
Male
Age-65 (years above 65, continuous) for 65 and over cohorts; or Age (years, continuous) for 18 and over cohorts.

Comorbidities
Congestive heart failure (CC 80)
Acute myocardial infarction (CC 81)
Other acute/subacute forms of ischemic heart disease (CC 82)
Anterior myocardial infarction (ICD-9 codes 410.00-410.19)
Other location of myocardial infarction (ICD-9 codes 410.20-410.69)
Coronary atherosclerosis or angina (CC 83, 84)
Cardio-respiratory failure and shock (CC 79)
Valvular and rheumatic heart disease (CC 86)
Hypertension (CC 89, 91)
Stroke (CC 95-96)
Cerebrovascular disease (CC 97-99, 103)

Renal failure (CC 131)
Chronic obstructive pulmonary disease (COPD) (CC 108)
Pneumonia (CC 111-113)
Diabetes mellitus (DM) or DM complications except proliferative retinopathy (CC 15-20, 120)
Protein-calorie malnutrition (CC 21)
Dementia or other specified brain disorders (CC 49, 50)
Hemiplegia, paraplegia, paralysis, functional disability (CC 67-69, 100-102, 177, 178)
Vascular disease and complications (CC 104, 105)
Metastatic cancer, acute leukemia and other severe cancers (CC 7, 8)
Trauma in last year (CC 154-156, 158-162)
Major psychiatric disorders (CC 54-56)
Chronic Liver Disease (CC 25-27)
History of CABG (ICD-9-CM V45.81, 36.10-36.16)
History of PTCA (ICD-9-CM V45.82, 00.66, 36.01, 36.02, 36.05, 36.06, 36.07)

S.15. Detailed risk model specifications *(must be in attached data dictionary/code list Excel or csv file. Also indicate if available at measure-specific URL identified in S.1.)*
Note: Risk model details (including coefficients, equations, codes with descriptors, definitions), should be provided on a separate worksheet in the suggested format in the Excel or csv file with data dictionary/code lists at S.2b.
Provided in response box S.15a

S.15a. Detailed risk model specifications (*if not provided in excel or csv file at S.2b*)
Available at measure-specific web page URL identified in S.1.

S.16. Type of score:
Rate/proportion
If other:

S.17. Interpretation of Score *(Classifies interpretation of score according to whether better quality is associated with a higher score, a lower score, a score falling within a defined interval, or a passing score)*
Better quality = Lower score

S.18. Calculation Algorithm/Measure Logic *(Describe the calculation of the measure score as an ordered sequence of steps including identifying the target population; exclusions; cases meeting the target process, condition, event, or outcome; aggregating data; risk adjustment; etc.)*
The measure estimates hospital-level 30-day all-cause RSMRs following hospitalization for AMI using hierarchical logistic regression models. In brief, the approach simultaneously models data at the patient and hospital levels to account for variance in patient outcomes within and between hospitals (Normand and Shahian, 2007). At the patient level, it models the log-odds of mortality within 30 days of discharge using age, sex, selected clinical covariates, and a hospital-specific intercept. At the hospital level, it models the hospital-specific intercepts as arising from a normal distribution. The hospital intercept represents the underlying risk of mortality at the hospital, after accounting for patient risk. The hospital-specific intercepts are given a distribution to account for the clustering (non-independence) of patients within the same hospital. If there were no differences among hospitals, then after adjusting for patient risk, the hospital intercepts should be identical across all hospitals.

The RSMR is calculated as the ratio of the number of "predicted" to the number of "expected" deaths, multiplied by the national unadjusted mortality rate. For each hospital, the numerator of the ratio ("predicted") is the number of deaths within 30 days

predicted on the basis of the hospital's performance with its observed case mix, and the denominator ("expected") is the number of deaths expected on the basis of the nation's performance with that hospital's case mix. This approach is analogous to a ratio of "observed" to "expected" used in other types of statistical analyses. It conceptually allows for a comparison of a particular hospital's performance given its case mix to an average hospital's performance with the same case mix. Thus, a lower ratio indicates lower-than-expected mortality or better quality and a higher ratio indicates higher-than-expected mortality or worse quality.

The "predicted" number of deaths (the numerator) is calculated by using the coefficients estimated by regressing the risk factors and the hospital-specific intercept on the risk of mortality. The estimated hospital specific intercept is added coefficients multiplied by the patient characteristics. The results are transformed and summed over all patients attributed to a hospital to get a predicted value. The "expected" number of deaths (the denominator) is obtained in the same manner, but a common intercept using all hospitals in our sample is added in place of the hospital specific intercept. The results are transformed and summed over all patients in the hospital to get an expected value. To assess hospital performance for each reporting period, we re-estimate the model coefficients using the years of data in that period.

This calculation transforms the ratio of predicted over expected into a rate that is compared to the national observed readmission rate. The hierarchical logistic regression models are described fully in the original methodology report (Krumholz et al., 2005).

S.19. **Calculation Algorithm/Measure Logic Diagram URL or Attachment** *(You also may provide a diagram of the Calculation Algorithm/Measure Logic described above at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
Available at measure-specific web page URL identified in S.1

S.20. **Sampling** *(If measure is based on a sample, provide instructions for obtaining the sample and guidance on minimum sample size.)*
IF a PRO-PM, identify whether (and how) proxy responses are allowed.
N/A. This measure is not based on a sample or survey.

S.21. **Survey/Patient-reported data** *(If measure is based on a survey, provide instructions for conducting the survey and guidance on minimum response rate.)*
IF a PRO-PM, specify calculation of response rates to be reported with performance measure results.
N/A. This measure is not based on a sample or survey.

S.22. **Missing data** (specify how missing data are handled, e.g., imputation, delete case.)
Required for Composites and PRO-PMs.
Missing values are rare among variables used from claims data in this measure.

S.23. **Data Source** *(Check ONLY the sources for which the measure is SPECIFIED AND TESTED).*
If other, please describe in S.24.
Administrative claims, Other, Paper Medical Records

S.24. **Data Source or Collection Instrument** *(Identify the specific data source/data collection instrument e.g. name of database, clinical registry, collection instrument, etc.)*
IF a PRO-PM, identify the specific PROM(s); and standard methods, modes, and languages of administration.
Data sources for the Medicare FFS measure:
1. Medicare Part A inpatient and Part B outpatient claims: This data source contains claims data for fee-for service inpatient and outpatient services including: Medicare inpatient hospital care, outpatient hospital services, skilled nursing facility care, some home health agency services, as well as inpatient and outpatient physician claims for the 12 months prior to an index admission.
2. Medicare Enrollment Database (EDB): This database contains Medicare beneficiary demographic, benefit/coverage, and vital status information. This data source was used to obtain information on several inclusion/exclusion indicators such as Medicare status on admission as well as vital status. These data have previously been shown to accurately reflect patient vital status (Fleming et al., 1992).
3. Veterans Health Administration Data: This data source contains claims data for VA inpatient and outpatient services including: inpatient hospital care, outpatient hospital services, skilled nursing facility care, some home health agency services, as well as inpatient and outpatient physician claims for the 12 months prior to and including each index admission. Unlike Medicare FFS

patients, VA patients are not required to have been enrolled in Part A and Part B Medicare for the 12 months prior to the date of admission.

All-payer data sources:
For our analyses to examine use in all-payer data, we used all-payer data from California in addition to CMS data for Medicare FFS 65+ patients in California hospitals. California is a diverse state, and, with more than 37 million residents, California represents 12% of the US population. We used the California Patient Discharge Data, a large, linked database of patient hospital admissions. In 2006, there were approximately 3 million adult discharges from more than 450 non-Federal acute care hospitals. Records are linked by a unique patient identification number, allowing us to determine patient history from previous hospitalizations and to evaluate rates of both readmission and mortality (via linking with California vital statistics records).

Using all-payer data from California as well as CMS Medicare FFS data for California hospitals, we performed analyses to determine whether the AMI mortality measure can be applied to all adult patients, including not only FFS Medicare patients aged 65+ but also non-FFS Medicare patients aged 65+ and younger patients aged 18-64 years at the time of admission.

NATIONAL QUALITY FORUM—Measure Testing (subcriteria 2a2, 2b2-2b7)

Measure Number (*if previously endorsed*)**:** 0230
Measure Title: Hospital 30-day, all-cause, risk-standardized mortality rate (RSMR) following acute myocardial infarction (AMI) hospitalization for patients 18 and older
Date of Submission: Click here to enter a date
Type of Measure:

☐ Composite – ***STOP – use composite testing form***	☒ Outcome (*including PRO-PM*)
☐ Cost/resource	☐ Process
☐ Efficiency	☐ Structure

Instructions

- Measures must be tested for all the data sources and levels of analyses that are specified. ***If there is more than one set of data specifications or more than one level of analysis, contact NQF staff*** about how to present all the testing

information in one form.

- **For all measures, sections 1, 2a2, 2b2, 2b3, and 2b5 must be completed.**
- **For outcome and resource use measures**, section **2b4** also must be completed.
- If specified for **multiple data sources/sets of specificaitons** (e.g., claims and EHRs), section **2b6** also must be completed.
- Respond to all questions as instructed with answers immediately following the question. All information on testing to demonstrate meeting the subcriteria for reliability (2a2) and validity (2b2-2b6) must be in this form. An appendix for *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 20 pages (*incuding questions/instructions;* minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.
- For information on the most updated guidance on how to address sociodemographic variables and testing in this form refer to the release notes for version 6.6 of the Measure Testing Attachment.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the testing results for this measure meet NQF's evaluation criteria for testing.

2a2. Reliability testing [10] demonstrates the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise. For **PRO-PMs and composite performance measures**, reliability should be demonstrated for the computed performance score.

2b2. Validity testing [11] demonstrates that the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality. For **PRO-PMs and composite performance measures**, validity should be demonstrated for the computed performance score.

2b3. Exclusions are supported by the clinical evidence; otherwise, they are supported by evidence of sufficient frequency of occurrence so that results are distorted without the exclusion; [12]

AND

If patient preference (e.g., informed decisionmaking) is a basis for exclusion, there must be evidence that the exclusion impacts performance on the measure; in such cases, the measure must be specified so that the information about patient preference and the effect on the measure is transparent (e.g., numerator category computed separately, denominator exclusion category computed separately). [13]

2b4. For outcome measures and other measures when indicated (e.g., resource use):

- **an evidence-based risk-adjustment strategy** (e.g., risk models, risk stratification) is specified; is based on patient factors (including clinical and sociodemographic factors) that influence the measured outcome and are present at start of care; [14,15] and has demonstrated adequate discrimination and calibration

OR

- rationale/data support no risk adjustment/ stratification.

2b5. Data analysis of computed measure scores demonstrates that methods for scoring and analysis of the specified measure allow for **identification of statistically significant and practically/clinically meaningful [16] differences in performance**;

OR

there is evidence of overall less-than-optimal performance.

2b6. If multiple data sources/methods are specified, there is demonstration they produce comparable results.

2b7. For **eMeasures, composites, and PRO-PMs** (or other measures susceptible to missing data), analyses identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias.

Notes

10. Reliability testing applies to both the data elements and computed measure score. Examples of reliability testing for data elements include, but are not limited to: inter-rater/abstractor or intra-rater/abstractor studies; internal consistency for multi-item scales; test-retest for survey items. Reliability testing of the measure score addresses precision of measurement (e.g., signal-to-noise).

11. Validity testing applies to both the data elements and computed measure score. Validity testing of data elements typically analyzes agreement with another authoritative source of the same information. Examples of validity testing of the measure score include, but are not limited to: testing hypotheses that the measures scores indicate quality of care, e.g., measure scores are different for groups known to have differences in quality assessed by another valid quality measure or method; correlation of measure scores with another valid indicator of quality for the specific topic; or relationship to conceptually related measures (e.g., scores on process measures to scores on outcome measures). Face validity of the measure score as a quality indicator may be adequate if accomplished through a systematic and transparent process, by identified experts, and explicitly addresses whether performance scores resulting from the measure as specified can be used to distinguish good from poor quality.

12. Examples of evidence that an exclusion distorts measure results include, but are not limited to: frequency of occurrence, variability of exclusions across providers, and sensitivity analyses with and without the exclusion.

13. Patient preference is not a clinical exception to eligibility and can be influenced by provider interventions.

14. Risk factors that influence outcomes should not be specified as exclusions

15. With large enough sample sizes, small differences that are statistically significant may or may not be practically or clinically meaningful. The substantive question may be, for example, whether a statistically significant difference of one percentage point in the percentage of patients who received smoking cessation counseling (e.g., 74 percent v. 75 percent) is clinically meaningful; or whether a statistically significant difference of $25 in cost for an episode of care (e.g., $5,000 v. $5,025) is practically meaningful. Measures with overall less-than-optimal performance may not demonstrate much variability across providers.

1. DATA/SAMPLE USED FOR ALL TESTING OF THIS MEASURE

Often the same data are used for all aspects of measure testing. In an effort to eliminate duplication, the first five questions apply to all measure testing. If there are differences by aspect of testing,(e.g., reliability vs. validity) be sure to indicate the specific differences in question 1.7.

1.1. What type of data was used for testing? (*Check all the sources of data identified in the measure specifications and data used for testing the measure*. *Testing must be provided for all the sources of data specified and intended for measure implementation.* ***If different data sources are used for the numerator and denominator, indicate N [numerator] or D [denominator] after the checkbox.***)

Measure Specified to Use Data From: **(*must be consistent with data sources entered in S.23*)**	**Measure Tested with Data From:**
☐ abstracted from paper record	☒ abstracted from paper record

☒ administrative claims	☒ administrative claims
☐ clinical database/registry	☐ clinical database/registry
☐ abstracted from electronic health record	☐ abstracted from electronic health record
☐ eMeasure (HQMF) implemented in EHRs	☐ eMeasure (HQMF) implemented in EHRs
☐ other: Click here to describe	☒ other: Census data/American Community Survey

1.2. If an existing dataset was used, identify the specific dataset (*the dataset used for testing must be consistent with the measure specifications for target population and healthcare entities being measured; e.g., Medicare Part A claims, Medicaid claims, other commercial insurance, nursing home MDS, home health OASIS, clinical registry*).

The datasets used for testing included Medicare Parts A and B claims, Veterans' Health Administration claims, as well as the Medicare Enrollment Database (EDB). Additionally, census data were used to assess socio-demographic factors. The dataset used varies by testing type; see Section 1.7 for details.

1.3. What are the dates of the data used in testing? Click here to enter date range

The dates used vary by testing type; see Section 1.7 for details.

1.4. What levels of analysis were tested? (*testing must be provided for <u>all</u> the levels specified and intended for measure implementation, e.g., individual clinician, hospital, health plan*)

Measure Specified to Measure Performance of: **(*must be consistent with levels entered in item S.26*)**	**Measure Tested at Level of:**
☐ individual clinician	☐ individual clinician
☐ group/practice	☐ group/practice
☒ hospital/facility/agency	☒ hospital/facility/agency
☐ health plan	☐ health plan
☐ other: Click here to describe	☐ other: Click here to describe

1.5. How many and which <u>measured entities</u> were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of measured entities included in the analysis (e.g., size, location, type); if a sample was used, describe how entities were selected for inclusion in the sample*)

For this measure, hospitals are the measured entities. All non-federal, acute inpatient US hospitals (including territories) with Medicare fee-for-service (FFS) beneficiaries over the age of 65 are included. All Veteran's Health Administration Hospitals are also included in the current publically reported measure. The number of measured entities (hospitals) varies by testing type; see Section 1.7 for details.

1.6. How many and which <u>patients</u> were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of patients included in the analysis (e.g., age, sex, race, diagnosis); if a sample was used, describe how patients were selected for inclusion in the sample*)

The number of admissions/patients varies by testing type: see Section 1.7 for details

1.7. If there are differences in the data or sample used for different aspects of testing (e.g., reliability, validity, exclusions, risk adjustment), identify how the data or sample are different for each aspect of testing reported below.

The datasets, dates, number of measured entities and number of admissions used in each type of testing are as follows:

For reliability testing (Section 2a2: Dataset 1), measure exclusions (Section 2b3; Dataset 1), and testing to identify meaningful differences in performance (Section 2b5; Dataset 1):
The reliability of the model was tested by randomly selecting 50% of the Medicare FFS patients aged 65+ in the most recent 3-year cohort and developing a risk-adjusted model for this group. We then developed a second model for the remaining 50% of patients and compared the two. In each year of measure maintenance we also re-fit the model and compare the frequencies and model coefficients of risk variables (condition categories for patient comorbidities) and model fit across 3 years (Dataset 1 below).

Dataset 1 (current public reporting cohort): Medicare Part A Inpatient and Outpatient and Part B Outpatient claims
Dates of Data: July 1, 2011 – June 30, 2014 (current public reporting cohort)
Number of admissions: 497,550
Number of patients in sample A = 247,641
Number of patients in sample B = 249,909
Patient Descriptive Characteristics: average age= 78.9, % male= 52.4
Number of measured entities: 4,490

For validity testing (Section 2b2; Datasets 2 and 4):
Dataset 2 (Chart validation sample data): Cooperative Cardiovascular Project (CCP) initiative medical chart-abstracted AMI cases, linked to the corresponding Medicare Part A Inpatient and Outpatient and Part B Outpatient claims, and mortality data from the Medicare enrollment database.
Dates of Data: 1994-1995
Number of Admissions: 181,032
Number of Measured Entities: 4,668

Dataset 4 (California discharge data): Medicare FFS and all-payer data
Dates of Data: January 1, 2006- December 31, 2006
Number of Admissions:
Total discharges of all payer (18+): 39,481
Total discharges of Medicare FFS 65+ patients: 11,418
Patient Descriptive Characteristics (for FFS 65+): average age=80, % male=50
Number of Measured Entities: >450 non-Federal acute care hospitals

For testing of measure risk adjustment (Section 2b4; Datasets 1, 3 and 4)
Dataset 1: Please see description above

Dataset 3 (Original development dataset from 1998): Medicare Part A Inpatient and Outpatient and Part B Outpatient claims
Dates of Data: 1998
Number of Admissions: 134, 661
Number of Measured Entities: 4,646

Dataset 4 (California discharge data): Please see description above.

1.8 What were the patient-level sociodemographic (SDS) variables that were available and analyzed in the data or sample used? For example, patient-reported data (e.g., income, education, language), proxy variables when SDS data are not collected from each patient (e.g. census tract), or patient community characteristics (e.g. percent vacant housing, crime rate).

We selected sociodemographic status (SDS) variables to analyze after reviewing the literature and examining available national data sources. Few patient-level SDS variables that can be linked to Medicare data are available nationally. We found both race [black vs. non-black] and dual-eligible status, e.g. enrolled in both Medicare and Medicaid, [obtained from CMS claims enrollment data] as the only two patient-level SDS variables available to examine directly. While some

argue against consideration of race in risk-adjustment, we felt it was important to understand the association with race as well as more traditional socio-economic variables.

We also considered neighborhood-level variables, linked by patient zip code level data that could serve in a risk model as a proxy for patient-level SDS. A range of census-collected SDS variables [collected annually as part of American Community Survey and aggregated over 5-years] including income and education, were available. Currently we are only able to link the data at a 5-digit zip code level. Nine-digit zip code data may provide a more granular view of patient sociodemographic status, but this data is not available to us at this time and we therefore cannot ascertain the incremental, if any, value of greater geographic discrimination for risk adjustment purposes.

Our conceptual model and the literature regarding how SDS may influence post-discharge mortality did not identify a single SDS concept as predominant in the pathway. There is a large body of literature linking various SDS factors to worse health status and higher mortality over a lifetime (Adler and Newman 2002, Mackenbach et al. 2000, Tonne et al. 2005, van Oeffelen et al. 2012). Income, education, and occupational level are the most commonly examined variables. However, literature directly examining how different SDS factors might influence the likelihood of mortality in older, insured, Medicare patients within 30 days of an admission for cardiovascular disease is much more limited. Assuming that the risk imparted based on zip code level data may reflect multiple different SDS variables, we chose to analyze a validated AHRQ composite index of SDS, which has been used and tested among Medicare beneficiaries (Blum et al. 2014; Bonito et al. 2008). This index is a composite of 7 different variables found in the census data which may capture SDS better than any single variable. The index variables include rates of unemployment, percent of person living below poverty, education level (percent below 12^{th} grade education and percent with college education), crowding (average of more than one person per room), median household income, and median housing value. We identified patients as low SDS if they lived in a neighborhood in the lowest quartile of this index.

Other variables can be found at a county or regional level and could represent the hospital's community. We did not directly test any such variables because they are not as closely related to patients' sociodemographic status given the wide scope of a county and seemed unlikely to be ideal for patient-level risk adjustment.

2a2. RELIABILITY TESTING

***Note**: If accuracy/correctness (validity) of data elements was empirically tested, separate reliability testing of data elements is not required – in 2a2.1 check critical data elements; in 2a2.2 enter "see section 2b2 for validity testing of data elements"; and skip 2a2.3 and 2a2.4.*

2a2.1. What level of reliability testing was conducted? (*may be one or both levels*)
☒ **Critical data elements used in the measure** (*e.g., inter-abstractor reliability; data element reliability must address ALL critical data elements*)
☒ **Performance measure score** (e.g., *signal-to-noise analysis*)

2a2.2. For each level checked above, describe the method of reliability testing and what it tests (*describe the steps—do not just name a method; what type of error does it test; what statistical analysis was used*)

Data Element Reliability

In constructing the measure, we aim to utilize only those data elements from the claims that have both face validity and reliability. We avoid the use of fields that are thought to be coded inconsistently across hospitals or providers. Specifically, we use fields that are consequential for payment and which are audited. We identify such variables through empiric analyses and our understanding of CMS auditing and billing policies while seeking to avoid variables that do not meet this standard. For example, "discharge disposition" is a variable in Medicare claims data that is not thought to be a reliable variable for identifying a transfer between two acute care facilities. Thus, we derive a variable using admission and discharge dates as a surrogate for "discharge disposition" to identify hospital admissions involving transfers. This allows us to identify these admissions using variables in the claims data which have greater reliability than the "discharge disposition" variable. In addition, CMS has several hospital auditing programs used to assess overall claims code accuracy in order to ensure appropriate billing and assist with overpayment recoupment. CMS routinely conducts data analyses to identify potential problem areas and detect fraud. Audits are important data fields used in our measures including diagnosis, procedure codes, and other elements that are consequential to payment.

Finally, we assess the reliability of the data elements by comparing model variable frequencies and odds ratios from logistic regression models across three years of data.

Measure Score reliability

The reliability of a measurement is the degree to which repeated measurements of the same entity agree with each other. For measures of hospital performance, the measured entity is naturally the hospital and the reliability is the extent to which repeated measurements of the same hospital give similar results. In line with this thinking, our approach to assessing reliability is to consider the extent to which assessments of a hospital using different but randomly selected subsets of patients produces similar measures of hospital performance. That is, we take a "test-retest" approach in which hospital performance is measured once using a random subset of patients, then measured again using a second random subset exclusive of the first, and finally comparing the agreement between the two resulting performance measures across hospitals (Rousson et al., 2002).

For test-retest reliability, we combined index admissions from successive measurement periods into one dataset, randomly sampled half of the patients within each hospital, calculated the measure for each hospital, and repeated the calculation using the second half. Thus, each hospital is measured twice but each measurement is made using an entirely distinct set of patients. To the extent that the calculated measures of these two subsets agree, we have evidence that the measure is assessing an attribute of the hospital, not of the patients. As a metric of agreement, we calculated the intra-class correlation coefficient (ICC) (Shrout and Fleiss, 1979), and assessed the values according to conventional standards (Landis and Koch, 1977). Specifically, we used Dataset 1 to randomly split the samples, and calculated the RSMR for each hospital within each sample. The agreement of the two RSMRs was quantified for hospitals in each sample using the intra-class correlation as defined by ICC (2,1) by Shrout and Fleiss (1979).

Using two independent samples provides a stringent estimate of the measure's reliability, compared with using two random but potentially overlapping samples which would exaggerate the agreement. Moreover, because our final measure is derived using hierarchical logistic regression, and a known property of hierarchical logistic regression models is that smaller volume hospitals contribute less ´signal´, a split sample using a single measurement period would introduce extra noise. This leads to an underestimate in the actual test-retest reliability that would be achieved if the measure were reported using the full measurement period, as evidenced by the Spearman Brown prophecy formula (Spearman 1910, Brown 1910), which estimates the reliability of the measure if the whole cohort were used, based on an estimate from half the cohort.

2a2.3. For each level of testing checked above, what were the statistical results from reliability testing? (e.*g., percent agreement and kappa for the critical data elements; distribution of reliability statistics from a signal-to-noise analysis*)

Data element reliability results (Dataset 1)

The frequency of some model variables increased. The increase may reflect an increased rate of comorbidities in the fee-for-service population but is also due, in part, to increased hospital coding of comorbidities. In the 2012 update to the measures, we increased the number of diagnosis codes and procedure codes to align with the Version 5010 format changes required by the Department of Health and Human Services (DHHS). Beginning in 2010, hospitals could submit up to 25 diagnosis and procedure codes. Over time (from July 2011-June 2012 to July 2013-June2014), more hospitals have submitted increased numbers of codes, which translate into increased frequencies for some model variables. Some notable decreases occurred in congestive heart failure (CC 80) (31.0% to 29.3%), pneumonia (CC 111-113) (23.7% to 22.3%), and dementia or other specific brain disorders (CC 49-50) (20.8% to 19.8%), while notable increases occurred in history of percutaneous transluminal coronary angioplasty (PTCA) (15.9% to 17.5%), renal failure (CC 131) (26.3% to 27.3%), and % males (51.7% to 53.3%).

Measure Score Reliability Results (Dataset 1)

There were 497,550 admissions in the combined three-year sample, with 247,641 patients in one sample and 249,909 patients in the other randomly selected sample. The agreement between the two RSMRs for each hospital was 0.41, which according to the conventional interpretation is “moderate” (Landis & Koch, 1977).

Note that this analysis was limited to hospitals with 12 or more cases in each split sample. The intra-class correlation coefficient is based on a split sample of three years of data, resulting in a volume of patients in each sample equivalent to only 1.5 years of data, whereas the measure is reported with the full three years of data. The correlation coefficient is expected to be higher using the full three-year sample since it would include more patients.

Landis J, Koch G. The measurement of observer agreement for categorical data, Biometrics 1977;33:159-174.

2a2.4 What is your interpretation of the results in terms of demonstrating reliability? (i.*e., what do the results mean and what are the norms for the test conducted?*)

The stability over time of the risk factor odds ratios suggests that the underlying data elements are reliable. Additionally, the ICC score demonstrates moderate agreement across samples using a conservative approach to assessment.

2b2. VALIDITY TESTING

2b2.1. What level of validity testing was conducted? (*may be one or both levels*)

☐ **Critical data elements** (*data element validity must address ALL critical data elements*)

☒ **Performance measure score**

☒ **Empirical validity testing**

☐ **Systematic assessment of face validity of performance measure score as an indicator** of quality or resource use (*i.e., is an accurate reflection of performance on quality or resource use and can distinguish good from poor performance*)

2b2.2. For each level of testing checked above, describe the method of validity testing and what it tests (*describe the steps—do not just name a method; what was tested, e.g., accuracy of data elements compared to authoritative source, relationship to another measure as expected; what statistical analysis was used)*

During original measure development, we validated the AMI mortality administrative model against a medical record model in the same cohort of patients for which hospital-level AMI mortality medical record data were available.

For the derivation of the chart-based model, we used cases identified through the Cooperative Cardiovascular Project (CCP) initiative and provided by the Health Care Financing Administration (now CMS). The CCP initiative included more than 200,000 admissions to non-governmental, acute care hospitals in the United States and Puerto Rico (Krumholz et al., 1998; Marciniak et al., 1998). In the CCP study, CMS sampled all claims from FFS Medicare patients during an approximately 8-month period (varying by state) in 1994 and 1995 who were discharged with a principal diagnosis of AMI (ICD-9-CM code 410, excluding 410.x2). These patients were matched to the Medicare enrollment database to determine survival and, where applicable, the date of death. Corresponding medical records were abstracted by 2 clinical data abstraction centers (DynKePRO [York, PA] and FMAS Corporation [Rockville, MD]), and the clinical data used to confirm the diagnosis of AMI.

The test sample contained 178,188 cases with an unadjusted mortality rate of 19.0%.

The medical record model validation included clinician and hospital outpatient data. The same coding and transfer rules described in the AMI administrative dataset were used in defining the AMI medical record dataset.

Validity Indicated by Established Measure Development Guidelines:
We developed this measure in consultation with national guidelines for publicly reported outcomes measures, with outside experts, and with the public. The measure is consistent with the technical approach to outcomes measurement set forth in NQF guidance for outcomes measures (National Quality Forum, 2010), CMS Measure Management System (MMS) guidance, and the guidance articulated in the American Heart Association scientific statement, “Standards for Statistical Models Used for Public Reporting of Health Outcomes” (Krumholz, Brindis, et al. 2006).

ICD-9 to ICD-10 Conversion

Statement of Intent

[X] Goal was to convert this measure to a new code set, fully consistent with the intent of the original measure.
[ ] Goal was to take advantage of the more specific code set to form a new version of the measure, but fully consistent with the original intent.
[ ] The intent of the measure has changed.

Process of Conversion

ICD-10 codes were initially identified using 2015 General Equivalence Mapping (GEM) software. Clinicians with expertise in relevant areas were enlisted to select and evaluate which ICD-10 codes map to the ICD-9 codes currently in use for this measure. An ICD-9 to ICD-10 crosswalk is attached in field S.2b. (Data Dictionary or Code Table).

2b2.3. What were the statistical results from validity testing? (*e.g., correlation; t-test*)

Dataset 2 (see section 1.7 above):
The performance of the administrative and medical record models is similar. The areas under the receiver operating characteristic (ROC) curve are 0.69 and 0.77, respectively, for the two models. In addition, they are similar with respect to predictive ability. For the administrative model, the predicted readmission rate ranges from 4.79%, in the lowest predicted decile, to 39.33%, in the highest predicted decile, with a range of 36%. For the medical record model, the corresponding range is 2.9% to 57.7%with a range of 54.8%.

We estimated hospital-level RSMRs using the corresponding hierarchical logistic regression administrative and medical record models for the linked patient sample. We then examined the linear relationship between the two sets of estimates using regression techniques and weighting by the total number of cases in each hospital. The correlation coefficient of the standardized rates from the administrative and medical record models is 0.91.

2b2.4. What is your interpretation of the results in terms of demonstrating validity? (i*.e., what do the results mean and what are the norms for the test conducted?*)

The results between the administrative and medical record models proved to be similar in each of the model testing that was performed. The ROC results were similar and in line with other mortality models. The correlation between the resulting RSMRs calculated from both models was 0.91 which shows that there was a strong correlation in rates calculated from the clinical and admin models.

2b3. EXCLUSIONS ANALYSIS

NA ☐ no exclusions — *skip to section 2b4*

2b3.1. Describe the method of testing exclusions and what it tests (*describe the steps—do not just name a method; what was tested, e.g., whether exclusions affect overall performance scores; what statistical analysis was used*)

All exclusions were determined by careful clinical review and have been made based on clinically relevant decisions and to ensure accurate calculation of the measure. To ascertain impact of exclusions on the cohort, we examined overall frequencies and proportions of the total cohort excluded for each exclusion criterion. These exclusions are consistent with similar NQF-endorsed outcome measures. Rationales for the exclusions are detailed in data field S.10 (Denominator Exclusions).

2b3.2. What were the statistical results from testing exclusions? (*include overall number and percentage of individuals excluded, frequency distribution of exclusions across measured entities, and impact on performance measure scores*)

Among 4,490 hospitals with at least 25 index stays in [July 1, 2011- June 30, 2014] (Dataset 1):

Exclusion	N	%	Distribution across hospitals: Min, 25th, 50th, 75th percentile, max
1. Discharged alive on the day of admission or the following day who were not transferred to another acute care facility.	34,657	6.17%	Min: 0.00% 25th: 0.00% 50th: 4.04% 75th: 8.20% Max: 100.00%
2. With inconsistent or unknown vital status or other unreliable demographic (age and gender) data.	26	<0.01%	Min: 0.00% 25th: 0.00% 50th: 0.00% 75th: 0.00% Max: 4.35%
3. Enrolled in the Medicare hospice program or used VA hospice services any time in the 12 months prior to the index admission, including the first day of the index admission.	4,770	0.85%	Min: 0.00% 25th: 0.00% 50th: 0.00% 75th: 1.13% Max: 100.00%
4. Discharged against medical advice (AMA).	2,630	0.47%	Min: 0.00% 25th: 0.00% 50th: 0.00% 75th: 0.34% Max: 100.00%

2b3.3. What is your interpretation of the results in terms of demonstrating that exclusions are needed to prevent unfair distortion of performance results? (*i.e., the value outweighs the burden of increased data collection and analysis. Note: **If patient preference is an exclusion**, the measure must be specified so that the effect on the performance score is transparent, e.g., scores with and without exclusion*)

Exclusion 1 (patients who were discharged alive on the day of admission or the following day who were not transferred to another acute care facility) is meant to ensure a clinically coherent cohort (excludes 6.2% of cohort). This exclusion prevents the inclusion of patients who likely did not suffer a clinically significant AMI. For most hospitals, this results in very few patients being excluded. For those hospitals with greater proportions of excluded patients, the measure is likely excluding less severe patients that may not be considered as AMI at other hospitals. This exclusion was guided by the input of clinical experts at the time of measure development. Exclusion 2 (patients with inconsistent or unknown vital status or other unreliable demographic (age and gender) data) and Exclusion 3 (patients enrolled in the Medicare hospice program or used VA hospice services any time in the 12 months prior to the index admission), including the first day of the index admission, are necessary for valid calculation of the measure. Exclusion 4 (patients who leave AMA) is needed for acceptability of the measure to hospitals who do not have the opportunity to adequately prepare such patients for discharge. The aforementioned exclusions are unlikely to affect the measure score because they exclude a very small percentage of patients.

After all exclusions are applied, the measure randomly selects one index admission per patient per year for inclusion in the cohort so that each episode of care is mutually independent with the same probability of the outcome. For each patient, the probability of death increases with each subsequent admission and therefore the episodes of care are not mutually independent. Similarly, for the three year combined data, when index admissions occur during the transition between measure reporting periods (June and July of each year) and both are randomly selected for inclusion in the measure, the measure includes only the June admission. The July admissions are excluded to avoid assigning a single death to two admissions.

2b4. RISK ADJUSTMENT/STRATIFICATION FOR OUTCOME OR RESOURCE USE MEASURES
If not an intermediate or health outcome, or PRO-PM, or resource use measure, skip to section 2b5.

2b4.1. What method of controlling for differences in case mix is used?
☐ **No risk adjustment or stratification**
☒ **Statistical risk model with 27 risk factors**
☐ **Stratification by** Click here to enter number of categories **risk categories**
☐ **Other,** Click here to enter description

2b4.2. If an outcome or resource use measure is not risk adjusted or stratified, provide rationale and analyses to demonstrate that controlling for differences in patient characteristics (case mix) is not needed to achieve fair comparisons across measured entities.

2b4.3. Describe the conceptual/clinical and statistical methods and criteria used to select patient factors (clinical factors or sociodemographic factors) used in the statistical risk model or for stratification by risk (*e.g., potential factors identified in the literature and/or expert panel; regression analysis; statistical significance of p<0.10; correlation of x or higher; patient factors should be present at the start of care*)

Our approach to risk adjustment was tailored to and appropriate for a publicly reported outcome measure, as articulated in the American Heart Association (AHA) Scientific Statement, "Standards for Statistical Models Used for Public Reporting of Health Outcomes" (Krumholz et al. 2006).

The measure employs a hierarchical logistic regression model (a form of hierarchical generalized linear model [HGLM]) to create a hospital level 30-day RSMR. This approach to modeling appropriately accounts for the structure of the data (patients clustered within hospitals), the underlying risk due to patients' comorbidities, and the sample size at a given hospital when estimating hospital mortality rates. In brief, the approach simultaneously models two levels (patient and

hospital) to account for the variance in patient outcomes within and between hospitals (Normand and Shahian et al. 2007). At the patient level, each model adjusts the log-odds of mortality within 30 days of admission for age, sex, selected clinical covariates, and a hospital specific intercept. The second level models the hospital-specific intercepts as arising from a normal distribution. The hospital intercept, or hospital specific effect, represents the hospital contribution to the risk of mortality, after accounting for patient risk and sample size, and can be inferred as a measure of quality. The hospital-specific intercepts are given a distribution in order to account for the clustering (non-independence) of patients within the same hospital. If there were no differences among hospitals, the hospital intercepts should be identical across all hospitals after adjusting for patient risk.

Clinical Factors

Candidate and Final Risk-adjustment Variables:

The measure was developed using Medicare FFS claims data. Candidate variables were patient-level risk-adjustors that are expected to be predictive of mortality based on empirical analysis, prior literature, and clinical judgment including demographic factors (age, sex) and indicators of comorbidity and disease severity. For each patient, covariates were obtained from Medicare claims extending 12 months prior to and including the index admission. The model adjusted for case differences based on the clinical status of the patient at the time of admission. We used condition categories (CCs), which are clinically meaningful groupings of more than 15,000 ICD-9-CM diagnosis codes. We did not risk-adjust for CCs that were possible adverse events of care and that were only recorded in the index admission. In addition, only comorbidities that conveyed information about the patient at that time or in the 12 months prior, and not complications that arose during the course of the hospitalization, were included in the risk-adjustment.

The final set of risk-adjustment variables is:

Demographic

- Age-65 (years above 65, continuous) for 65 and over cohorts; or Age (years, continuous) for 18 and over cohorts.
- Male

Cardiovascular

- History of PTCA
- History of CABG
- Congestive heart failure
- History of AMI
- Unstable angina
- Anterior myocardial infarction
- Other location of myocardial infarction
- Chronic atherosclerosis
- Cardio-respiratory failure and shock
- Valvular and rheumatic heart disease

Comorbidity

- Hypertension
- Stroke
- Cerebrovascular disease
- Renal failure
- Chronic Obstructive Pulmonary Disease
- Pneumonia
- Diabetes and DM complications
- Protein-calorie malnutrition
- Dementia and senility

• Hemiplegia, paraplegia, paralysis, functional disability
• Peripheral vascular disease
• Metastatic cancer, acute leukemia and other severe cancers
• Trauma in the last year
• Major psychiatric disorders
• Chronic liver disease

Sociodemographic Factors

We selected candidate sociodemographic factors for examination based on a review of the literature, conceptual pathways, and feasibility. In section 1.8, we describe the variables that we considered and analyzed based on this review. Below we describe the pathways by which SDS may influence 30-day mortality.

Our conceptualization of the pathways by which patient SDS affects 30-day mortality is informed by the literature. Although there is a long list of studies showing a relationship between lower SDS status and mortality rates generally, there is relatively little literature directly examining how SDS might influence the likelihood of older, insured, Medicare patients dying within 30 days of a admission for cardiovascular disease and even less literature to directly illuminate the pathways by which SDS influences this outcome. The ability to distinguish between these pathways is challenging but important for making decisions regarding risk adjustment.

One important pathway by which patient SDS influences 30-day mortality is through health status at the time of admission. SDS factors can influence admission health status both due to the impact of multiple related stressors over a lifetime contributing to overall worse health as well as through poor access to care and potentially delayed presentation. This results in low SDS patients, when compared with other patients, often arriving for hospital admission with greater levels of illness or comorbidity burden. This pathway should be largely accounted for in our current clinical risk-adjustment.

However, there are a number of other pathways by which patient SDS may influence 30-day mortality that are related to hospital quality. The first, sometimes referred to as contextual effects, is that patients of low SDS may present at lower quality institutions for care. Therefore, some part of the apparent relationship between SDS and mortality may be due to clustering of patients of low SDS at poorer quality institutions (Barnato et al. 2005; Hasnain-Wynia et al. 2010; Jha et al. 2011; Skinner et al. 2005).

Next, within the hospital, patients of low SDS may receive differentiated care as compared to counterparts of higher SDS – this can occur for a variety of reasons and in some cases differentiated care could be worse quality and in others better quality. For example, providers may be less likely to offer guideline-concordant care to patients of low SDS – perhaps based on discrimination or misunderstanding of patients' wishes and values (Institute of Medicine, 2009). However, in other cases, differentiated care may be that patients of low SDS appropriately need different types of care or services such as low literacy information, social worker support or transportation at discharge. Providing needed differentiated care is patient-centered and appropriate – the equivalent to ensuring a diabetic goes home with insulin – however, low SDS patients may not always receive needed differentiated care. This lack of needed differentiated care may also contribute to relatively worse outcomes.

Finally, there may be pathways by which SDS influences 30-day mortality risk outside of health care quality and admission health status. Some SDS factors may affect the likelihood of mortality without directly affecting health status on admission or the quality of care received during the hospital stay. For instance, despite a hospital making appropriate care decisions and providing tailored care and education, a lower-income patient may elect not to follow prescribed care (e.g. refill a prescription or keep a follow-up visit with a primary care provider) because limited resources create competing priorities for the patient.

These sets of proposed pathways are complex to distinguish analytically. We, therefore, first assessed if there was evidence of a meaningful effect on the risk model to warrant efforts to distinguish among these pathways. First we evaluated the variation in the prevalence of low SDS patients among providers. We then assessed the relationship

between the SDS variables and the outcome and examined the incremental effect of SDS in a multivariable model. For these measures, we also examined the extent to which the addition of any one of these variables improved model performance or changed hospital results. Given no meaningful improvement in the risk-model or change in performance scores, we did not further seek to distinguish the causal pathways for these measures.

Based on this model and the considerations outlines in 1.8, the following SDS variables were considered:

- Dual eligible status
- African American race
- AHRQ SES index

2b4.4a. What were the statistical results of the analyses used to select risk factors?

A table of candidate variables and odds ratios associated with each variable in the model are available in the attached Excel file (referenced in data field S.2b) (Dataset 1).

2b4.4b. Describe the analyses and interpretation resulting in the decision to select SDS factors (e.g. prevalence of the factor across measured entities, empirical association with the outcome, contribution of unique variation in the outcome, assessment of between-unit effects and within-unit effects)

Variation in prevalence of the factor across measured entities

The prevalence of SDS factors in the AMI cohort varies substantially across hospitals. The median percent of dual eligible patients is 10.8% (interquartile range [IQR] 6.9%-16.8%). The median percentage of black patients is 3.6% (IQR 0.7%-10.6%). The median frequency of low SES AHRQ indicator patients is 16.4% (IQR 4.1%-40.3%).

Empirical association with the outcome (bivariate)

The patient-level observed AMI unadjusted mortality rate for dual-eligible patients was somewhat higher, at 16.1% compared with 14.0% for all other patients. The mortality rate for black patients was lower at 12.6% compared with 14.4% for patients of all other races. The mortality rate for patients in the lowest SES quartile by AHRQ Index was slightly higher at 14.4% compared with 13.9% for patients in the highest SES quartile.

Incremental effect of SDS variables in a multivariable model

We then examined the strength and significance of the SDS variables in the context of a multivariable model. Each of the variables remained significantly associated in the multivariable model.

For dual eligibility and the AHRQ SES indicator, the variable is associated with higher risk of modest strength. Odds ratios are on the order of 1.12 for dual eligibility and 1.09 for AHRQ SES. This is similar to the odds ratio for comorbidities such as COPD and substantially lower than the risk associated with comorbidities such as metastatic cancer. For race, black race is associated with a lower risk of mortality, with an odds ratio of 0.81. In all cases, the c-statistic for the AMI patient-level multivariate model with the SDS variable in the model is essentially unchanged from that without.

To further understand the relative importance of these risk-factors in the measure we compared hospital performance with and without the addition of each SDS variable. We found that the addition of any of these variables into the model has little to no effect on hospital performance. The mean absolute change in hospitals' RSMRs when adding a dual eligibility indicator is -0.00039% with a correlation coefficient between RSMRs for each hospital with and without dual eligibility added of 0.9996. The mean absolute change in hospitals' RSMRs when adding a race indicator is 0.00087% with a correlation coefficient between RSMRs for each hospital with and without race added of 0.9971. The mean absolute change in hospitals' RSMRs when adding a low SES AHRQ indicator is -0.00205% with a correlation coefficient between RSMRs for each hospital with and without low SES added of 0.9982.

Overall we found that among the SDS variables that could be feasibly incorporated into this model, 1) the relationship with mortality is small and 2) the relative effect of black race is stronger than the other two SDS variables in the opposite direction than what has been the expressed concern of stakeholders interested in adding such adjustment to the models. We also found that the impact of adding any of these indicators is very small to negligible on model performance and hospital profiling.

Given these findings and complex pathways that could explain any relationship between SDS and mortality, which do not all support risk-adjustment, we did not incorporate SDS variables into the measure.

2b4.5. Describe the method of testing/analysis used to develop and validate the adequacy of the statistical model <u>or</u> stratification approach (*describe the steps—do not just name a method; what statistical analysis was used*)

Provide the statistical results from testing the approach to controlling for differences in patient characteristics (case mix) below.

If stratified, skip to 2b4.9

Approach to assessing model performance

During measure development, we computed three summary statistics for assessing model performance (Harrell and Shih, 2001) for the development and validation cohort:

Discrimination Statistics:

(1) Area under the receiver operating characteristic (ROC) curve (the c-statistic (also called ROC) is the probability that predicting the outcome is better than chance, which is a measure of how accurately a statistical model is able to distinguish between a patient with and without an outcome)

(2) Predictive ability (discrimination in predictive ability measures the ability to distinguish high-risk subjects from low-risk subjects. Therefore, we would hope to see a wide range between the lowest decile and highest decile)

Calibration Statistics:

(3) Over-fitting indices (over-fitting refers to the phenomenon in which a model accurately describes the relationship between predictive variables and an outcome in the development dataset but fails to provide valid predictions in new patients)

We tested the performance of the model in all four datasets described in section 1.7.

Citation

F.E. Harrell and Y.C.T. Shih, Using full probability models to compute probabilities of actual interest to decision makers, *Int. J. Technol. Assess. Health Care* **17** (2001), pp. 17–26.

2b4.6. Statistical Risk Model Discrimination Statistics (*e.g., c-statistic, R-squared*)**:**

For the development cohort the results are summarized below (Dataset 3):

1st half of randomly split development sample: C statistic = 0.71

Predictive ability (lowest decile %, highest decile %) = (4.0%, 40.0%)

2st half of randomly split development sample: C statistic = 0.70

Predictive ability (lowest decile %, highest decile %) = (4.2%, 40.1%)

For the current measure cohort the results are summarized below (Dataset 1):

C statistic = 0.72

Predictive ability (lowest decile %, highest decile %) = (2.8%, 33.3%)

For comparision of model with and without inclusion of SDS factors see above section.

2b4.7. Statistical Risk Model Calibration Statistics (*e.g., Hosmer-Lemeshow statistic*):

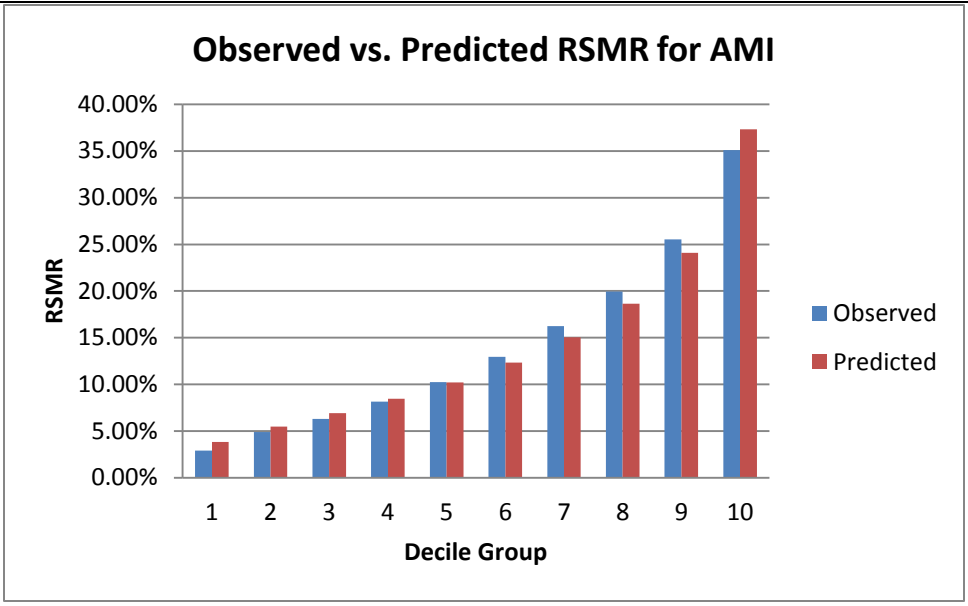
Development spilt dataset (Dataset 3):

1st half of randomly split development sample: Calibration: (0.000, 1.000)

1st half of randomly split development sample: Calibration: (-0.030, 0.994)

2b4.8. Statistical Risk Model Calibration – Risk decile plots or calibration curves:

The risk decile plot is a graphical depiction of the deciles calculated to measure predictive ability. Below, we present the risk decile plot showing the distributions for the [Observed vs. Predicted RSMR for AMI] for Medicare FFS data from July 2011 to June 2014 (Dataset 1).



Plots for other datasets were similar.

2b4.9. Results of Risk Stratification Analysis:

2b4.10. What is your interpretation of the results in terms of demonstrating adequacy of controlling for differences in patient characteristics (case mix)? (i.*e., what do the results mean and what are the norms for the test conducted*)

Discrimination Statistics
The C-statistic of 0.72 indicates good model discrimination. The model indicated a wide range between the lowest decile and highest decile, indicating the ability to distinguish high-risk subjects from low-risk subjects.

Calibration Statistics
Over-fitting (Calibration γ0, γ1)
If the γ0 in the validation samples are substantially far from zero and the γ1 is substantially far from one, there is potential evidence of over-fitting. The calibration value of close to 0 at one end and close to 1 at the other end indicates good calibration of the model.

Risk Decile Plots
Higher deciles of the predicted outcomes are associated with higher observed outcomes, which show a good calibration of the model. This plot indicates very good discrimination of the model and good predictive ability.

Overall Interpretation
Interpreted together, our diagnostic results demonstrate that the risk-adjustment model adequately controls for differences in patient characteristics (case mix).

2b4.11. Optional Additional Testing for Risk Adjustment (*not required, but would provide additional support of adequacy of risk model, e.g., testing of risk model in another data set; sensitivity analysis for missing data; other methods that were assessed*)

Application to Medicare FFS Beneficiaries Using Inpatient Data Only for Risk Adjustment

As part of the testing for the model in the all-payer data, we also applied the model to CMS data for Medicare FFS 65+ patients in California hospitals using only inpatient data for risk adjustment. Specifically, we created a 2006 measure cohort with complete one-year history data and 30-day follow-up data (N= 39,481).

To help determine whether the measure could be applied to Medicare FFS 65+ patients using only Medicare Part A data, we performed analyses to assess how the model performs when using only inpatient claims data for risk adjustment, as all-payer hospital discharge databases do not have outpatient claims. To assess the validity of using only admission claims data for risk adjustment, we fit the model separately using the full dataset and using only admission claims data and (a) compared the odds ratios (ORs) for the various risk factors; (b) conducted a reclassification analysis to compare risk prediction at the patient level; (c) compared model performance in terms of the c-statistic (discrimination); and (d) compared hospital-level risk-standardized rates (scatterplot, correlation coefficient, and R2) to assess whether the model with only admission claims data is different from the current model in profiling hospital rates.

Analyzing CMS data for Medicare FFS 65+ beneficiaries in California hospitals: (a) the magnitude of odds ratios for most risk factors was similar when comparing the model using the full dataset and using only admission claims data; (b) when comparing the model with the full dataset and with only admission claims data, the reclassification analysis demonstrated good patient-level risk prediction; (c) the c-statistic was similar (0.713 vs. 0.725); and (d) hospital-level risk-standardized rates were highly correlated (ICC=0.984).

Application to Patients Aged 18 and Older

We also applied the model to all-payer data from California. The analytic sample included 39,481 cases aged 18 and older in the 2006 California Patient Discharge Data. When used in all-payer data, only admission claims data are used for risk adjustment, as the hospital discharge databases do not have outpatient claims.

To help determine whether the measure could be applied to a population of patients aged 18+, we examined the interaction terms between age (18-64 vs. 65+) and each of the other risk factors. Specifically, we fit the model in all patients 18+ with and without interaction terms and (a) conducted a reclassification analysis to compare risk prediction at the patient level; (b) compared the c-statistic; and (c) compared hospital-level risk-standardized rates (scatterplot, correlation coefficient, and R-square) to assess whether the model with interactions is different from the current model in profiling hospital rates.

When the model was applied to all patients 18+, overall discrimination was good (c-statistic=0.765). In addition, there was good discrimination and predictive ability in both those aged 18-64 and those aged 65+. Moreover, the distribution of Pearson residuals was comparable across the patient subgroups. When comparing the model with and without interaction terms, (a) the reclassification analysis demonstrated that nearly all patients were found to be in a similar risk category; (b) the c-statistic was nearly identical (0.767 vs. 0.765); and (c) hospital-level risk-standardized rates were highly correlated (ICC=0.998). Thus, the inclusion of the interactions did not substantively affect either patient-level model performance or hospital-level results.

Therefore, the measure can be applied to all-payer data for patients 18 and older.

2b5. IDENTIFICATION OF STATISTICALLY SIGNIFICANT & MEANINGFUL DIFFERENCES IN PERFORMANCE

2b5.1. Describe the method for determining if statistically significant and clinically/practically meaningful differences in performance measure scores among the measured entities can be identified (*describe the steps—do not just name a method; what statistical analysis was used? Do not just repeat the information provided related to performance gap in 1b)*

For public reporting of the measure, CMS characterizes the uncertainty associated with the RSMR by estimating the 95% interval estimate. This is similar to a 95% confidence interval but is calculated differently. If the RSMR's interval estimate does not include the national observed AMI mortality rate (is lower or higher than the rate), then CMS is confident that the hospital's RSMR is different from the national rate, and describes the hospital on the Hospital Compare website as "better than the U.S. national rate" or "worse than the U.S. national rate." If the interval includes the national rate, then CMS describes the hospital's RSMR as "no different than the U.S. national rate" or "the difference is uncertain." CMS does not classify performance for hospitals that have fewer than 25 cases in the three-year period.

2b5.2. What were the statistical results from testing the ability to identify statistically significant and/or clinically/practically meaningful differences in performance measure scores across measured entities? (e.g., *number and percentage of entities with scores that were statistically significantly different from mean or some benchmark, different from expected; how was meaningful difference defined*)

Recent analyses of Medicare FFS data show substantial variation in RSMRs among hospitals. Using data from July 2011-June 2014 (Dataset 1) the mean hospital RSMR was 14.3%, with a range of 9.9% to 20.6%. The interquartile range was 13.8%-14.8%.

Of 4,490 hospitals in the study cohort, 41 performed "better than the U.S. national rate," 2,474 performed "no different from the U.S. national rate," 21 performed "worse than the U.S. national rate," and 1,954 were classified as "number of cases too small" (fewer than 25) to reliably tell how well the hospital is performing.

2b5.3. What is your interpretation of the results in terms of demonstrating the ability to identify statistically significant and/or clinically/practically meaningful differences in performance across measured entities? (i*.e., what do the results mean in terms of statistical and meaningful differences?*)

Despite recent decreases in mortality rates nationally, the mortality rate for AMI remains high at 13.3%.

The variation in rates and number of performance outliers suggests there are differences in the quality of care received across hospitals for AMI mortality that support measurement to reduce the variation.

2b6. COMPARABILITY OF PERFORMANCE SCORES WHEN MORE THAN ONE SET OF SPECIFICATIONS
If only one set of specifications, this section can be skipped.

Note*: This criterion is directed to measures with more than one set of specifications/instructions (e.g., one set of specifications for how to identify and compute the measure from medical record abstraction and a different set of specifications for claims or eMeasures). It does not apply to measures that use more than one source of data in one set of specifications/instructions (e.g., claims data to identify the denominator and medical record abstraction for the numerator).* ***If comparability is not demonstrated, the different specifications should be submitted as separate measures.***

2b6.1. Describe the method of testing conducted to demonstrate comparability of performance scores for the same entities across the different data sources/specifications (*describe the steps—do not just name a method; what statistical analysis was used*)

N/A

2b6.2. What were the statistical results from testing comparability of performance scores for the same entities when using different data sources/specifications? (*e.g., correlation, rank order*)

N/A

2b6.3. What is your interpretation of the results in terms of demonstrating comparability of performance measure scores for the same entities across the different data sources/specifications? (i.*e., what do the results mean and what are the norms for the test conducted*)

N/A

2b7. MISSING DATA ANALYSIS AND MINIMIZING BIAS

2b7.1. Describe the method of testing conducted to identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias (*describe the steps—do not just name a method; what statistical analysis was used*)

2b7.2. What is the overall frequency of missing data, the distribution of missing data across providers, and the results from testing related to missing data? (*e.g., results of sensitivity analysis of the effect of various rules for missing data/nonresponse; if no empirical sensitivity analysis, identify the approaches for handling missing data that were considered and pros and cons of each*)

2b7.3. What is your interpretation of the results in terms of demonstrating that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias**?** (i.*e., what do the results mean in terms of supporting the selected approach for missing data and what are the norms for the test conducted; if no empirical analysis, provide rationale for the selected approach for missing data*)

3. Feasibility

Extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

3a. Byproduct of Care Processes

For clinical measures, the required data elements are routinely generated and used during care delivery (e.g., blood pressure, lab test, diagnosis, medication order).

3a.1. Data Elements Generated as Byproduct of Care Processes.

Coded by someone other than person obtaining original information (e.g., DRG, ICD-9 codes on claims)

If other:

3b. Electronic Sources

The required data elements are available in electronic health records or other electronic sources. If the required data are not in electronic health records or existing electronic sources, a credible, near-term path to electronic collection is specified.

3b.1. **To what extent are the specified data elements available electronically in defined fields?** *(i.e., data elements that are needed to compute the performance measure score are in defined, computer-readable fields)*

ALL data elements are in defined fields in electronic claims

3b.2. **If ALL the data elements needed to compute the performance measure score are not from electronic sources, specify a credible, near-term path to electronic capture, OR provide a rationale for using other than electronic sources.**

3b.3. **If this is an eMeasure, provide a summary of the feasibility assessment in an attached file or make available at a measure-specific URL.**

Attachment:

3c. Data Collection Strategy

Demonstration that the data collection strategy (e.g., source, timing, frequency, sampling, patient confidentiality, costs associated with fees/licensing of proprietary measures) can be implemented (e.g., already in operational use, or testing demonstrates that it is ready to put into operational use). For eMeasures, a feasibility assessment addresses the data elements and measure logic and demonstrates the eMeasure can be implemented or feasibility concerns can be adequately addressed.

3c.1. **Describe what you have learned/modified as a result of testing and/or operational use of the measure regarding data collection, availability of data, missing data, timing and frequency of data collection, sampling, patient confidentiality, time and cost of data collection, other feasibility/implementation issues.**

IF a PRO-PM, consider implications for both individuals providing PROM data (patients, service recipients, respondents) and those whose performance is being measured.

Administrative data are routinely collected as part of the billing process.

3c.2. **Describe any fees, licensing, or other requirements to use any aspect of the measure as specified** *(e.g., value/code set, risk model, programming code, algorithm)*.

There are no fees associated with the use of this measure.

4. Usability and Use

Extent to which potential audiences (e.g., consumers, purchasers, providers, policy makers) are using or could use performance results for both accountability and performance improvement to achieve the goal of high-quality, efficient healthcare for individuals or populations.

4a. Accountability and Transparency

Performance results are used in at least one accountability application within three years after initial endorsement and are publicly reported within six years after initial endorsement (or the data on performance results are available). If not in use at the time of initial endorsement, then a credible plan for implementation within the specified timeframes is provided.

4.1. **Current and Planned Use**

NQF-endorsed measures are expected to be used in at least one accountability application within 3 years and publicly reported within 6 years of initial endorsement in addition to performance improvement.

Planned	Current Use (for current use provide URL)
	Public Reporting Hospital Inpatient Quality Reporting (IQR) Program http://cms.gov/Medicare/Quality-Initiatives-Patient-Assessment-Instruments/HospitalQualityInits/HospitalRHQDAPU.html

	Payment Program Hospital Value Based Purchasing (HVBP) Program http://www.cms.gov/Medicare/Quality-Initiatives-Patient-Assessment-Instruments/hospital-value-based-purchasing/index.html

4a.1. For each CURRENT use, checked above, provide:

- Name of program and sponsor
- Purpose
- Geographic area and number and percentage of accountable entities and patients included

Public Reporting

1. Program Name, Sponsor: Hospital Inpatient Quality Reporting (IQR) Program, Centers for Medicare and Medicaid Services (CMS)

Purpose: The Hospital Inpatient Quality Reporting (Hospital IQR) program was originally mandated by Section 501(b) of the Medicare Prescription Drug, Improvement, and Modernization Act (MMA) of 2003. This section of the MMA authorized CMS to pay hospitals that successfully report designated quality measures a higher annual update to their payment rates. Initially, the MMA provided for a 0.4 percentage point reduction in the annual market basket (the measure of inflation in costs of goods and services used by hospitals in treating Medicare patients) update for hospitals that did not successfully report. The Deficit Reduction Act of 2005 increased that reduction to 2.0 percentage points.

In addition to giving hospitals a financial incentive to report the quality of their services, the hospital reporting program provides CMS with data to help consumers make more informed decisions about their health care. Some of the hospital quality of care information gathered through the program is available to consumers on the Hospital Compare website at: http://www.medicare.gov/hospitalcompare/search.html.

Geographic area and number and percentage of accountable entities and patients included: The IQR program includes all non-federal acute care hospitals and VA hospitals in the United States. The number and percentage of accountable entities included in the program, as well as the number of patients included in the measure, varies by reporting year. For 2015 public reporting, the RSMR will be reported for 4,490 hospitals across the US. The final index cohort includes 497,550 admissions.

2. Program Name, Sponsor: Hospital Value-Based Purchasing (HVBP) Program, Centers for Medicare and Medicaid Services (CMS)

Purpose: The Hospital Value-Based Purchasing (VBP) Program is a CMS initiative that rewards acute-care hospitals with incentive payments for the quality of care they provide to people with Medicare. It was established by the Affordable Care Act of 2010 (ACA), which added Section 1886(o) to the Social Security Act. The law requires the Secretary of the Department of Health and Human Services (HHS) to establish a value-based purchasing program for inpatient hospitals. To improve quality, the ACA builds on earlier legislation—the 2003 MMA and the 2005 Deficit Reduction Act. These earlier laws established a way for Medicare to pay hospitals for reporting on quality measures, a necessary step in the process of paying for quality rather than quantity.

Geographic area and number and percentage of accountable entities and patients included: More than 3,000 hospitals across the country are eligible to participate in Hospital VBP. The program applies to subsection (d) hospitals located in the 50 states and the District of Columbia and acute-care hospitals in Maryland. Hospital VBP is based on data collected through the IQR Program.

The following hospitals are excluded from Hospital VBP:
• Hospitals and hospital units excluded from the Inpatient Prospective Payment System, such as psychiatric, rehabilitation, long-term care, children's, and cancer hospitals;
• Hospitals that do not participate in Hospital IQR during the Hospital VBP performance period;
• Hospitals cited by the Secretary of HHS for deficiencies during the performance period that pose an immediate jeopardy to patients' health or safety; and
• Hospitals that do not meet the minimum number of cases, measures, or surveys required by Hospital VBP.

4a.2. If not currently publicly reported OR used in at least one other accountability application (e.g., payment program, certification, licensing) what are the reasons? (*e.g., Do policies or actions of the developer/steward or accountable entities restrict access to performance results or impede implementation?*)
N/A, this measure is currently publicly reported

4a.3. If not currently publicly reported OR used in at least one other accountability application, provide a credible plan for

implementation within the expected timeframes -- any accountability application within 3 years and publicly reported within 6 years of initial endorsement. (*Credible plan includes the specific program, purpose, intended audience, and timeline for implementing the measure within the specified timeframes. A plan for accountability applications addresses mechanisms for data aggregation and reporting.*)
N/A, this measure is currently publicly reported

4b. Improvement

Progress toward achieving the goal of high-quality, efficient healthcare for individuals or populations is demonstrated. If not in use for performance improvement at the time of initial endorsement, then a credible rationale describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.

4b.1. **Progress on Improvement. (Not required for initial endorsement unless available.)**
Performance results on this measure (current and over time) should be provided in 1b.2 and 1b.4. Discuss:

- **Progress (trends in performance results, number and percentage of people receiving high-quality healthcare)**
- **Geographic area and number and percentage of accountable entities and patients included**

There has been significant progress in 30-day RSMR for AMI. The median 30-day RSMR decreased by 1.4% from 2011-2012 (median RSMR: 14.7%) to 2013-2014 (median RSMR: 13.3%). The median hospital RSMR from 2011-2014 was 14.3% (Interquartile Range [IQR] 13.8% - 14.8%). In addition, hospitals with a high proportion of Medicaid and African American patients achieve a similar range of performance as compared with hospitals with a low proportion of these patients, indicating that both groups of hospitals can perform well on the measure.

4b.2. **If no improvement was demonstrated, what are the reasons? If not in use for performance improvement at the time of initial endorsement, provide a credible rationale that describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.**
N/A

4c. Unintended Consequences

The benefits of the performance measure in facilitating progress toward achieving high-quality, efficient healthcare for individuals or populations outweigh evidence of unintended negative consequences to individuals or populations (if such evidence exists).

4c.1. **Were any unintended negative consequences to individuals or populations identified during testing; OR has evidence of unintended negative consequences to individuals or populations been reported since implementation? If so, identify the negative unintended consequences and describe how benefits outweigh them or actions taken to mitigate them.**
We did not identify any unintended consequences during measure development or model testing. However, we are committed to monitoring this measure's use and assessing potential unintended consequences over time, such as the inappropriate shifting of care, increased patient morbidity and mortality, and other negative unintended consequences for patients.

5. Comparison to Related or Competing Measures

If a measure meets the above criteria and there are endorsed or new related measures (either the same measure focus or the same target population) or competing measures (both the same measure focus and the same target population), the measures are compared to address harmonization and/or selection of the best measure.

5. Relation to Other NQF-endorsed Measures
Are there related measures (conceptually, either same measure focus or target population) or competing measures (conceptually both the same measure focus and same target population)? If yes, list the NQF # and title of all related and/or competing measures.
Yes

5.1a. **List of related or competing measures (selected from NQF-endorsed measures)**
0229 : Hospital 30-day, all-cause, risk-standardized mortality rate (RSMR) following heart failure (HF) hospitalization for patients 18 and older
0330 : Hospital 30-day, all-cause, risk-standardized readmission rate (RSRR) following heart failure (HF) hospitalization
0468 : Hospital 30-day, all-cause, risk-standardized mortality rate (RSMR) following pneumonia hospitalization

0505 : Hospital 30-day all-cause risk-standardized readmission rate (RSRR) following acute myocardial infarction (AMI) hospitalization.
0506 : Hospital 30-day, all-cause, risk-standardized readmission rate (RSRR) following pneumonia hospitalization
1551 : Hospital-level 30-day, all-cause risk-standardized readmission rate (RSRR) following elective primary total hip arthroplasty (THA) and/or total knee arthroplasty (TKA)
1789 : Hospital-Wide All-Cause Unplanned Readmission Measure (HWR)
1891 : Hospital 30-Day, All-Cause, Risk-Standardized Readmission Rate (RSRR) following Chronic Obstructive Pulmonary Disease (COPD) Hospitalization
1893 : Hospital 30-Day, All-Cause, Risk-Standardized Mortality Rate (RSMR) following Chronic Obstructive Pulmonary Disease (COPD) Hospitalization
2431 : Hospital-level, risk-standardized payment associated with a 30-day episode-of-care for Acute Myocardial Infarction (AMI)

5.1b. **If related or competing measures are not NQF endorsed please indicate measure title and steward.**

5a. Harmonization

The measure specifications are harmonized with related measures;
OR
The differences in specifications are justified

5a.1. **If this measure conceptually addresses EITHER the same measure focus OR the same target population as NQF-endorsed measure(s):**
Are the measure specifications completely harmonized?
Yes

5a.2. **If the measure specifications are not completely harmonized, identify the differences, rationale, and impact on interpretability and data collection burden.**
We did not include in our list of related measures any non-outcome (e.g., process) measures with the same target population as our measure. Our measure cohort was heavily vetted by clinical experts. Additionally, the measure, with the specified cohort, has been publicly reported since 2008. Because this is an outcome measure, clinical coherence of the cohort takes precedence over alignment with related non-outcome measures. Furthermore, non-outcome measures are limited due to broader patient exclusions. This is because they typically only include a specific subset of patients who are eligible for that measure (for example, patients who receive a specific medication or undergo a specific procedure).

5b. Competing Measures

The measure is superior to competing measures (e.g., is a more valid or efficient way to measure);
OR
Multiple measures are justified.

5b.1. **If this measure conceptually addresses both the same measure focus and the same target population as NQF-endorsed measure(s):**
Describe why this measure is superior to competing measures (e.g., a more valid or efficient way to measure quality); OR provide a rationale for the additive value of endorsing an additional measure. (Provide analyses when possible.)
N/A

Appendix

A.1 Supplemental materials may be provided in an appendix. All supplemental materials (such as data collection instrument or methodology reports) should be organized in one file with a table of contents or bookmarks. If material pertains to a specific submission form number, that should be indicated. Requested information should be provided in the submission form and required attachments. There is no guarantee that supplemental materials will be reviewed.

MEASURE WORKSHEET

This document summarizes the evaluation of the measure as it progresses through NQF's Consensus Development Process (CDP). The information submitted by measure developers/stewards is included after the Brief Measure Information, Preliminary Analysis, and Pre-meeting Public and Member Comments sections.

To navigate the links in the worksheet: Ctrl + click link to go to the link; ALT + LEFT ARROW to return

Brief Measure Information

NQF #: 0669
De.2. **Measure Title:** Cardiac Imaging for Preoperative Risk Assessment for Non-Cardiac, Low Risk Surgery
Co.1.1. **Measure Steward:** Centers for Medicare & Medicaid Services
De.3. **Brief Description of Measure:** This measure calculates the percentage of stress echocardiography, single photon emission computed tomography myocardial perfusion imaging (SPECT MPI), or stress magnetic resonance (MR) imaging studies performed at each facility in the 30 days prior to an ambulatory non-cardiac, low-risk surgery performed at any location. The measure is calculated based on a one-year window of Medicare claims data. The measure has been publicly reported, annually, by the Centers for Medicare & Medicaid Services (CMS), since 2011, as a component of its Hospital Outpatient Quality Reporting (HOQR) Program.
1b.1. **Developer Rationale:** This measure aims to reduce overuse of cardiac imaging prior to low-risk non-cardiac surgeries, for patients with low or moderate cardiac risk, as cardiac imaging in this population can result in increased exposure to radiation with little or no clinical benefit. The measure score will guide patient selection of providers, assess quality, and inform quality improvement.

S.4. **Numerator Statement:** The number of stress echocardiography, SPECT MPI, and stress MR studies performed in a hospital outpatient department within 30 days of an ambulatory non-cardiac, low-risk surgery performed at any location (e.g., same hospital, other hospital, or physician office).
S.7. **Denominator Statement:** The number of stress echocardiography, SPECT MPI, and stress MR studies performed in a hospital outpatient department on Medicare beneficiaries within a 12-month time window.
S.10. **Denominator Exclusions:** Studies are excluded for any patients with diagnosis codes in at least three of the following categories: diabetes mellitus, renal insufficiency, stroke or transient ischemic attack, prior heart failure, or ischemic heart disease.

De.1. **Measure Type:** Process.
S.23. **Data Source:** Administrative claims
S.26. **Level of Analysis:** Facility, Population : National, Population : State

IF Endorsement Maintenance – Original Endorsement Date: Apr 26, 2011 **Most Recent Endorsement Date:** Apr 26, 2011
Is this a MAINTENANCE measure submission? ☒ **Yes** ☐ **No, this is a NEW measure submission.**
For MAINTENANCE, state the Original Endorsement Date: 4/26/11 **Most Recent Endorsement Date:** 4/26/11

Previous Measure Evaluation - Public & Member Comments, Developer Responses & Steering Committee Recommendations are available from Standards for Imaging Efficiency: A Consensus Report for Outpatient Imaging (See Measure IEP-010-10 on Page 14)

Preliminary Analysis

The preliminary analysis was developed in response to recommendations from NQF's Consensus Task Force and measurement stakeholders as a way to enhance and streamline the measures evaluation and voting processes. The preliminary analysis will help to guide the Standing Committee evaluation of each measure by summarizing the measure developer submission, guide measure evaluation discussion, and identify topic areas for additional input. **NQF staff would like to stress that the preliminary analysis is intended to be used as a guide to facilitate the Committee's discussion and evaluation.**

Criteria 1: Importance to Measure and Report

1a. Evidence

1a. Evidence. The evidence requirements for a *process* measure is that it is based on a systematic review (SR) and grading of the body of empirical evidence where the specific focus of the evidence matches what is being measured. Per NQF's submission criteria, this appropriate use criteria (AUC) measure is a *process* measure, rather than an efficiency measure as defined by the developer.

The developer provides the following evidence for this process measure:

- This is a facility level measure calculates the % of stress echocardiography, single photon emission computed tomography myocardial perfusion imaging (SPECT MPI), or stress magnetic resonance (MR) imaging studies performed at each facility in the 30 days prior to an ambulatory non-cardiac, low-risk surgery performed at any location for low-risk patients.
- The developer provides the path from identifying low-risk non-cardiac surgical patients to reduced exposure to radiation, contrast agents, and more efficient use of imaging resources.
- The developer provides 2 separate guidelines with 9 guideline statements for the recommendation that patients undergoing low-risk, non-cardiac surgery should not have stress image testing. Guideline 1 recommendations ranged from Class I through Class III, Level C. Guideline 2 recommendations ranged from Class IIa through Class III, Level B & C.
- The developers provided a summary of the quantity, quality, and consistency of the evidence for the ACC/AHA guideline., and provides an additional 14 articles that support the measure's intent.

Questions for the Committee:

- *Questions specific to the measure information provided on evidence*
- *For process measures:*
  - *Is the evidence directly applicable to the process of care being measured?*
  - *Is the process of care proximal and closely related to desired outcomes?*
- *For possible exception to the evidence criteria:*
  - *Are there, or could there be, performance measures of a related health outcome, OR evidence-based intermediate clinical outcomes, intervention/treatment?*
  - *Is there evidence of a systematic assessment of expert opinion beyond those involved in developing the measure?*
  - *Does the SC agree that it is acceptable (or beneficial) to hold providers accountable without empiric evidence?*

1b. Gap in Care/Opportunity for Improvement and 1b. Disparities

1b. Performance Gap. The performance gap requirements include demonstrating quality problems and opportunity for improvement.

- The developer provides an analysis of Medicare fee-for-service data for 1,953 facilities for 2009-2014.
  - The maximum performance rates ranged from 14.5% in 2009 to 18.0% July 2013 through June 2014 (weighted mean = 5.07%).
  - The mean performance ranged from 5.1% in 2009 to 5.0% from July 2013 through June 2014.
- The developer states that one of the intentions of this measure is to identify facilities with significant outlying performance as demonstrated in the table.
- Using 2013 data, the developers found that race/ethnicity and facility characteristics such as size and location (urban vs. rural) had a statistically significant effect on the likelihood that a patient underwent inappropriate preoperative imaging.
- The developer also provides additional evidence from the literature demonstrating differences in the use of cardiac imaging prior to surgery based on sex, race, and age.
- Despite statistically significant differences in imaging prior to low-risk, non-cardiac surgery based on race and facility, the developer believes these differences are driven by a variation in provider practice, therefore, risk adjustment/stratification is not necessary or appropriate.

Questions for the Committee:

- *Is there a gap in care that warrants a national performance measure?*

○ *If no disparities information is provided, are you aware of evidence that disparities exist in this area of healthcare?*

○ *Should this measure be indicated as disparities sensitive?*

1c. Priority

1c. High Priority (previously "High Impact") requires measures to address national health goal/priority or a demonstrated high-impact aspect of care.

○ *Beginning in 2015, priority is no longer an NQF measure evaluation criterion.*

Committee pre-evaluation comments

Criteria 1: Importance to Measure and Report (including 1a, 1b, 1c)

1. ***Committee's Overview Comments***:
   - There is evidence to support this measure from a process standpoint. It is guideline based and provides appropriate quantity, quality and consistency of evidence to assess the inappropriate utilization of cardiac imaging fro preoperative risk assessment for non-cardiac, low risk surgery.

1a. ***Committee's Comments on Evidence to Support Measure Focus:***
   - It measures the overuse of cardiac imaging prior to non-cardiac surgery and can be applied directly.

1b. ***Committee's Comments on Performance Gap:***
   - Performance data was provided.
   - Based on the 2013 data, race/ethnicity and facility location (urban vs. rural) had a statistically significant likelihood of undergoing inappropriate imaging therefore indicating a gap in care. Subgroup data was provided indicating a disparity in care.

1c. ***Committee's Comments on Composite Performance Measure:***
   - All performance measures were stated and logical.

Criteria 2: Scientific Acceptability of Measure Properties

2a. Reliability

2a1. Reliability Specifications

2a1. Specifications requires the measure, as specified, to produce consistent (reliable) and credible (valid) results about the quality of care when implemented.

- The data source includes administrative claims. HCPCS, ICD-9, ICD-10, and CPT codes provided for the numerator denominator and exclusions, with "look-back" timing as applicable. An ICD-10 conversion methodology is not provided. A clear calculation algorithm is provided.
- Since initial endorsement in 2011, 48 new codes added to the list of low-risk surgical procedures included in the numerator.
- Based on a 2013 update to the ACC/AHA guidelines on Perioperative Cardiovascular Evaluation and Care for Non-Cardiac Surgery an exclusion from the measure's denominator was added in 2014 for those patients with 3 of 5 clinical risk factors (i.e., diabetes mellitus, renal insufficiency, stroke or transient ischemic attack, prior heart failure, or ischemic heart disease) to determine non-low risk patients.
- The measure is not risk adjusted, though the developers state the testing sample includes unique patient and facility characteristic coding.
- For this measure, better quality equates to lower scores.

Questions for the Committee:

○ *Are all the data elements clearly defined? Are all appropriate codes included?*

○ *Is the logic or calculation algorithm clear?*

○ *Is it likely this measure can be consistently implemented?*

2a2. Reliability Testing Testing attachment

2a2. Reliability testing demonstrates if the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise enough to distinguish differences in performance across providers.

- Reliability testing for this measure was conducted at the level of the performance measure score, using the data source and level of analysis specified. The primary analysis was conducted at the facility level and included 2013 Medicare FFS data from 2,759 facilities.
- Reliability was calculated using *two* tests: the ability to identify statistical outliers and a signal-to-noise analysis.
  - The statistical outliers – As previously mentioned, one of the intentions of this measure is to identify statistical outliers. Of the 2,759 facilities having met an undetermined minimum count of studies, 137 were classified as outliers (defined as falling outside of the confidence interval (± 1.96 standard deviations) for the measure mean or benchmark value, in 2013; these facilities were reported as having statistically significant rates of overuse.
  - The signal-to-noise analysis, which is appropriate for the measure, quantifies the amount of variation in performance that is due to differences between different facilities (as opposed to differences that are due to random measurement error). The method results in a reliability statistic for each facility. The developers state that the beta-binomial model determined a mean reliability score of 43.0%, which the developer states is indicative of moderate reliability.

Questions for the Committee:

- *Is the test sample adequate to generalize for widespread implementation?*
- *Do the results demonstrate sufficient reliability so that differences in performance can be identified?*

2b. Validity

2b1. Validity: Specifications

2b1. Validity Specifications. This section should determine if the measure specifications are consistent with the evidence.

- The clinical practice guidelines supporting this measure recommend that patients undergoing low-risk, non-cardiac surgery should not have stress image testing.

Question for the Committee:

- *Are the specifications consistent with the evidence?*

2b2. Validity testing

2b2. Validity Testing should demonstrate the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality.

- Face validity of the measure score and data element was systematically assessed through a 7 member Technical Expert Panel (TEP), majority who were not involved in the development of the measure.
- Overall, the TEP members support the validity of the measure, as specified. 75% of the TEP members agreed the 30-day window used to look forward for a low-risk non-cardiac surgery from the date of the imaging procedure accurately captures preoperative testing. 86% and 71% agreed that the imaging procedures and exclusions, respectively, are accurately captured using claims data.
- The developers state that the TEP was not able to reach a consensus on which clinical conditions should be excluded from the measure. The TEP members felt they did not have the clinical knowledge to provide a definitive response. However, these exclusions are based on the revised AHA/ACC clinical guideline.

Questions for the Committee:

- *Is the test sample adequate to generalize for widespread implementation?*
- *Do the results demonstrate sufficient validity so that conclusions about quality can be made?*
- *Do you agree that the score from this measure as specified is an indicator of quality?*

2b3-2b7. Threats to Validity

2b3. Exclusions:

- The measure excludes patients with three or more of the listed risk factors in the prior three years (diabetes, renal insufficiency, stroke or transient ischemic attack, prior heart failure or ischemic heart disease) as determinants of non-low risk patients.
- The developers tested the prevalence of each exclusion by facility and at an aggregate level; they also tested the aggregate risk factor exclusion to determine the effect on facility performance scores using 2013 data.
- A total of 2,770 facilities in 2013 met an undetermined minimum case count which included a patient population of 647,957 and 633,195 cardiac imaging studies. Overall, there were 395,577 (37.9%) occurrences of any three of the risk factors.
- The developer also calculated descriptive statistics for the measure scores of each facility, with and without, the exclusion for patients with three or more risk factors.
- The frequency of the exclusion for patients with three or more risk factors varied substantially across facilities (IQR: 13.7%). Despite the variation across facilities, the developers state exclusion of patients with 3 or more risk factors is appropriate.

Questions for the Committee:

- *Are the exclusions consistent with the evidence?*
- *Are any patients or patient groups inappropriately excluded from the measure?*
- *Are the exclusions/exceptions of sufficient frequency and variation across providers to be needed (and outweigh the data collection burden)?*

2b4. Risk adjustment:

- This process measure is not risk adjusted.
- Despite statistically significant differences in imaging prior to low-risk, non-cardiac surgery based on race and facility, the developer believes these differences are driven by a variation in provider practice, therefore, risk adjustment/stratification is not necessary or appropriate.

Questions for the Committee:

- *Does the SC feel the measure is appropriate for risk-adjustment?*

2b5. Meaningful difference:

- The developers state that many facilities had a performance score between 4% and 5% in 2013 and more than 7% of facilities continued to have an outlying performance.
- The developers state that by reporting a measure mean (benchmark value), outlying facilities have the opportunity to identify their high rate of overuse and implement quality improvement strategies to reduce the rate of overuse of imaging studies.

Question for the Committee:

- *Does this measure identify meaningful differences about quality?*

2b6. Comparability of data sources/methods:

- N/A

2b7. Missing Data

- The developer states that the analytic files used for measure testing and measure calculation include post-adjudicated claims, and do not include missing data.

Committee pre-evaluation comments

Criteria 2: Scientific Acceptability of Measure Properties (including all 2a, 2b, and 2d)

2a1. &2b1.: ***Committee's Comments on Reliability-Specifications:***

- Data elements are provided , codes are provided. The 5 clinical risk factors provided although covered in the ACC/AHA guidelines do not comment on patient functional status which may be the most important preoperative assessment.

2a2.: ***Committee's Comments on Reliability-Testing:***

- Yes, reliability testing was performed looking at both statistical outliers and signal-to-noise analysis. The results demonstrate moderate reliability with a score of 43%.

2b1.: ***Committee's Comments on Validity-Specifications***:

- They are not inconsistent with the evidence.
- None

2b2.: ***Committee's Comments on Validity-Testing:***

- Yes validity testing was performed with adequate scope. A 7 member TEP was used and found that 75% agreed on the 30 day window would adequate capture preoperative testing. 86% and 71% agreed that imaging procedures and exclusions were accurately captured.

2b3-7.: ***Committee's Comments on Threats to Validity:***

- The measure excludes patients with 3 or more of the listed risk factors diagnosed in the prior 3 years as determinants of non-low risk patients.
- 2770 facilities met an undetermined minimum case count and overall 395,577 (37%) had occurrences of any three.
- Process measure is not risk adjusted
- Comparibility is not applicable

2d.: ***Committee's Comments on Composite Performance Measure:***

- Not Applicable

Criterion 3. Feasibility

3. Feasibility is the extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

- The data source includes administrative claims and uses CMS hospital outpatient claims as its data source; all data elements are in defined fields in electronic claims.
- This is not an eMeasure.

Questions for the Committee:

- *Are the required data elements routinely generated and used during care delivery?*
- *Are the required data elements available in electronic form, e.g., EHR or other electronic sources?*
- *Is the data collection strategy ready to be put into operational use?*
- *If an eMeasure, does the eMeasure Feasibility Score Card demonstrate acceptable feasibility in multiple EHR systems and sites?*

Committee pre-evaluation comments

Criteria 3: Feasibility

3.: ***Committee's Comments on Feasibility:***

- The data source would include administrative claims using CMS hospital outpatient claims as its data source, so thus feasible.

Criterion 4: Usability and Use

4. Usability and Use evaluate the extent to which audiences (e.g., consumers, purchasers, providers, policymakers) use or could use performance results for both accountability and performance improvement activities.

- The measure is currently publicly reported in CMS' Hospital Outpatient Quality Reporting program.
- The developers state that they did not identify any untended consequences during measure testing.
- NQF's Measure Application Partnership (MAP) reviewed the measure with the following recommendations:

MAP Report Year	Measure Set	Care Setting	Level of Analysis	MAP Finding
2012	Acute Cardiovascular Conditions	Urgent Care	Facility, National	None Provided

***Questions for the Committee**:*

- *Is the measure publicly reported?*
- *For maintenance measures – is the measure used in at least one accountability application?*
- *How can the performance results be used to further the goal of high-quality, efficient healthcare?*
- *Do the benefits of the measure outweigh any potential unintended consequences?*

Committee pre-evaluation comments

Criteria 4: Usability and Use

4.: ***Committee's Comments on Usability and Use:***

- The measure is currently reported in the CMS HOQR
- No unintended consequences.
- It can reduce unnecessary stress testing.

Criterion 5: Related and Competing Measures

- 0670 : Cardiac stress imaging not meeting appropriate use criteria: Preoperative evaluation in low risk surgery patients
- The developer states that although NQF #0669 is similar to NQF #0670, there are several differences that would make measure harmonization infeasible and reduce the effectiveness of both currently endorsed measures.

Pre-meeting public and member comments

-

NATIONAL QUALITY FORUM—Evidence (subcriterion 1a)

Measure Number (*if previously endorsed*)**:** 0669
Measure Title: Cardiac Imaging for Preoperative Risk Assessment for Non-Cardiac, Low Risk Surgery
IF the measure is a component in a composite performance measure, provide the title of the Composite Measure here: Click here to enter composite measure #/ title

Date of Submission: <Date>

Instructions

- *For composite performance measures:*
  - *A separate evidence form is required for each component measure unless several components were studied together.*
  - *If a component measure is submitted as an individual performance measure, attach the evidence form to the individual*

measure submission.

- Respond to all questions as instructed with answers immediately following the question. All information needed to demonstrate meeting the evidence subcriterion (1a) must be in this form. An appendix of *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 10 pages (*incudes questions/instructions*; minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the evidence for this measure meets NQF's evaluation criteria.

1a. Evidence to Support the Measure Focus

The measure focus is evidence-based, demonstrated as follows:

- Health outcome: [3] a rationale supports the relationship of the health outcome to processes or structures of care. Applies to patient-reported outcomes (PRO), including health-related quality of life/functional status, symptom/symptom burden, experience with care, health-related behavior.
- Intermediate clinical outcome: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured intermediate clinical outcome leads to a desired health outcome.
- Process: [5] a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured process leads to a desired health outcome.
- Structure: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured structure leads to a desired health outcome.
- Efficiency: [6] evidence not required for the resource use component.

Notes

3. Generally, rare event outcomes do not provide adequate information for improvement or discrimination; however, serious reportable events that are compared to zero are appropriate outcomes for public reporting and quality improvement.

4. The preferred systems for grading the evidence are the U.S. Preventive Services Task Force (USPSTF) grading definitions and methods, or Grading of Recommendations, Assessment, Development and Evaluation (GRADE) guidelines.

5. Clinical care processes typically include multiple steps: assess → identify problem/potential problem → choose/plan intervention (with patient input) → provide intervention → evaluate impact on health status. If the measure focus is one step in such a multistep process, the step with the strongest evidence for the link to the desired outcome should be selected as the focus of measurement. Note: A measure focused only on collecting PROM data is not a PRO-PM.

6. Measures of efficiency combine the concepts of resource use and quality (see NQF's Measurement Framework: Evaluating Efficiency Across Episodes of Care; AQA Principles of Efficiency Measures).

1a.1.This is a measure of: (*should be consistent with type of measure entered in De.1*)

Outcome

☐ Health outcome: Click here to name the health outcome

☐Patient-reported outcome (PRO): Click here to name the PRO

PROs include HRQoL/functional status, symptom/symptom burden, experience with care, health-related behaviors

☐ Intermediate clinical outcome (*e.g., lab value*): Click here to name the intermediate outcome

☒ Process: Overuse of cardiac imaging prior to non-cardiac, low-risk surgery for patients at low or moderate risk of cardiac involvement.

☐ Structure: Click here to name the structure

☐ Other:

_____

HEALTH OUTCOME/PRO PERFORMANCE MEASURE *If not a health outcome or PRO, skip to 1a.3*

1a.2. Briefly state or diagram the path between the health outcome (or PRO) and the healthcare structures, processes, interventions, or services that influence it.

This measure is not a health outcome/PRO performance measure.

1a.2.1. State the rationale supporting the relationship between the health outcome (or PRO) to at least one healthcare structure, process, intervention, or service (*i.e., influence on outcome/PRO*).

This measure is not a health outcome/PRO performance measure.

Note: For health outcome/PRO performance measures, no further information is required; however, you may provide evidence for any of the structures, processes, interventions, or service identified above.

INTERMEDIATE OUTCOME, PROCESS, OR STRUCTURE PERFORMANCE MEASURE

1a.3. Briefly state or diagram the path between structure, process, intermediate outcome, and health outcomes. Include all the steps between the measure focus and the health outcome.

The process of identifying low-risk patients undergoing surgeries for which there is low or moderate risk of cardiac involvement prior to performing preoperative cardiac imaging is related to improved outcomes, including reduced exposure to radiation, reduced exposure to contrast agents, and more efficient use of imaging resources.

1a.3.1. What is the source of the systematic review of the body of evidence that supports the performance measure?

☒ Clinical Practice Guideline recommendation – ***complete sections 1a.4, and 1a.7***

☐ US Preventive Services Task Force Recommendation – ***complete sections 1a.5 and 1a.7***

☐ Other systematic review and grading of the body of evidence (*e.g., Cochrane Collaboration, AHRQ Evidence Practice Center*) – ***complete sections 1a.6 and 1a.7***

☒ Other – ***complete section 1a.8***

Please complete the sections indicated above for the source of evidence. You may skip the sections that do not apply.

1a.4. CLINICAL PRACTICE GUIDELINE RECOMMENDATION

1a.4.1. Guideline citation (*including date*) and **URL for guideline** (*if available online*):

Two clinical practice guidelines are provided based on their relevance and sample size for the measure. The first guideline, developed by the European Society of Cardiology and the European Society of Anaesthesiology, evaluates cardiovascular assessment and management for non-cardiac surgery. The second guideline, from the American College of Cardiology and American Heart Association, evaluates preoperative cardiovascular evaluation and management of the adult patient undergoing non-cardiac surgery. Citations for the two guidelines follow:

2 – ACC/AHA 2014 Guidelines on Perioperative Cardiovascular Evaluation and Care for Non- cardiac Surgery: a report of the American College of Cardiology/American Heart Association task force on practice guidelines. J Am Coll Cardiol. 2007; 50: e159-e242. Guideline available at: http://content.onlinejacc.org/article.aspx?articleid=1893784.

1a.4.2. Identify guideline recommendation number and/or page number and **quote verbatim, the specific guideline recommendation**.

Guideline 1 recommends that patients undergoing low-risk, non-cardiac surgery should not have stress image testing. For intermediate- to high-risk, non-cardiac surgeries, only patients with one to two clinical risk factors and poor functional capacity should undergo imaging stress testing prior to the non-cardiac surgery. *Guideline 1* provides four recommendations to support the measure's clinical intent.

Guideline 2 recommends that patients undergoing low-risk, non-cardiac surgery should not have stress image testing. For patients with elevated risk and poor/unknown functional capacity, it may be reasonable to perform exercise stress-image testing. *Guideline 2* provides five recommendations to support the measure's clinical intent.

Guideline 1 Recommendations:

A. Selected patients with cardiac disease undergoing low-and intermediate-risk non-cardiac surgery may be referred by the anaesthesiologist for cardiological evaluation and medical optimization (Class IIb, Level C; pg. 2388).
B. Imaging stress testing is recommended before high-risk surgery in patients with more than two clinical risk factors and poor functional capacity (<4 METs) (Class I, Level C; pg. 2394).
C. Imaging stress testing may be considered before high- or intermediate-risk surgery in patients with one or two clinical risk factors and poor functional capacity (<4 METs) (Class IIb, Level C; pg. 2394).
D. Imaging stress testing is not recommended before low-risk surgery, regardless of the patient's clinical risk (Class III, Level C; pg. 2394).

Guideline 1: European Society of Cardiology/European Society of Anaesthesiology

Surgical risk estimate according to type of surgery or intervention:

Low Risk (<1%)

- Superficial surgery
- Breast
- Dental
- Endocrine: thyroid
- Eye
- Reconstructive
- Carotid asymptomatic (CEA or CAS)
- Gynaecology: minor
- Orthopaedic: minor (meniscectomy)
- Urological: minor (transurethral resection of the prostate)

Intermediate Risk (1% to 5%)

- Intraperitoneal: splenectomy, hiatal hernia repair, cholecystectomy
- Carotid symptomatic (CEA or CAS)
- Peripheral arterial angioplasty
- Endovascular aneurysm repair
- Head and neck surgery
- Neurological or orthopaedic: major (hip and spine surgery)
- Urological or gynaecological: major
- Renal transplant
- Intra-thoracic: non-major

High-risk (>5%)

- Aortic and major vascular surgery
- Open lower limb revascularization or amputation or thromboembolectomy
- Duodeno-pancreatic surgery
- Liver resection, bile duct surgery
- Oesophagectomy
- Repair of perforated bowel
- Adrenal resection
- Total cystectomy
- Pneumonectomy
- Pulmonary or liver transplant

Guideline #2 Recommendations: American College of Cardiology/American Heart Association

A. For patients with elevated risk and excellent functional capacity, it is reasonable to forgo further exercise testing and proceed to surgery (Class IIa, Level B; pg. e96).
B. For patients with elevated risk and unknown functional capacity it may be reasonable to perform exercise testing to assess for functional capacity if it will change management (Class IIb, Level B; pg. 396).
C. For patients with elevated risk and moderate to good functional capacity, it may be reasonable to forgo further exercise testing and proceed to surgery (Class IIb, Level B; pg. e96).
D. For patients with elevated risk and poor or unknown functional capacity it may be reasonable to perform exercise testing with cardiac imaging to assess for myocardial ischemia (Class IIb, Level C; pg. e96).
E. Routine screening with noninvasive stress testing is not useful for low-risk noncardiac surgery (Class III, Level B; pg. e96).

1a.4.3. Grade assigned to the quoted recommendation with definition of the grade:

Recommendations made within *Guideline 1* ranged from Class I through Class III. The evidence supporting these recommendations demonstrates that cardiac imaging is appropriate for patients with a history of cardiac disease or for whom cardiac involvement is likely, and that it is unnecessary for those patients for whom no risk factors exist.

Recommendations made within *Guideline 2* ranged from Class IIa through Class III. The evidence for these recommendations is supported by either a single randomized control trial or a non-randomized study. Generally, the evidence available suggests consensus within the clinical community that cardiac imaging in patients with low likelihood of cardiac involvement is well accepted (though there may be some conflicting evidence within single randomized or non-randomized studies).

The following grading scale applies to recommendations from *Guideline 1*:
Recommendation A: Class IIb: Usefulness/efficacy is less well established by evidence/opinion.
Recommendation B: Class I: Evidence and/or general agreement that a given treatment or procedure is beneficial, useful, and effective.
Recommendation C: Class IIb: Usefulness/efficacy is less well established by evidence/opinion.
Recommendation D: Class III: Evidence or general agreement that the given treatment or procedure is not useful/effective, and in some cases may be harmful.

The following evidence scales apply to recommendations from *Guideline 1*:
Three levels of evidence: Level A, Level B, and Level C.
Level A: Data derived from multiple randomized clinical trials or meta-analyses.
Level B: Data derived from a single randomized clinical trial or large non-randomized studies.
Level C: Consensus of opinion of the experts and/or small studies, retrospective studies, registries.

Five classes of recommendations: Class I, Class II, Class IIA, Class IIB, and Class III.
Class I: Evidence and/or general agreement that given treatment or procedure is beneficial, useful, and effective.
Class II: Conflicting evidence and/or a divergence of opinion about the usefulness/efficacy of the given treatment or procedure.
Class IIA: Weight of evidence/opinion is in favor of usefulness/efficacy.
Class IIB: Usefulness/efficacy is less well established by evidence/opinion.
Class III: Evidence or general agreement that the given treatment or procedure is not useful/effective, and in some cases may be harmful.

The following grading scale applies to recommendations from *Guideline 2*:
Recommendation A: Class IIa, Level B: Recommendation in favor of treatment or procedure being useful/effective; some conflicting evidence from single randomized trial or nonrandomized studies
Recommendation B: Class IIb, Level B: Recommendation's usefulness/efficacy less well established; Greater conflicting evidence from single randomized trial or nonrandomized studies.

Recommendation C: Class IIb, Level B: Recommendation's usefulness/efficacy less well established; Greater conflicting evidence from single randomized trial or nonrandomized studies.
Recommendation D: Class IIb, Level C: Recommendation's usefulness/efficacy less well established; only diverging expert opinion, case studies, or standard of care.
Recommendation E: Class III, Level B: Recommendation that procedure or treatment is not useful/ineffective and may be harmful; evidence from single randomized trial or nonrandomized studies.

The following evidence scales apply to recommendations from Guideline 2:
Three levels of evidence: Level A, Level B, and Level C.
Level A: Multiple populations evaluated. Data derived from multiple randomized clinical trials or meta-analyses.
Level B: Limited populations evaluated. Data derived from single randomized trial or nonrandomized studies.
Level C: Very limited populations evaluated. Only consensus opinion of experts, case studies or standard of care.

Four classes of recommendations: Class I, Class IIa, Class IIb, Class III.
Class I: Benefit >>> Risk. Procedure/treatment SHOULD be performed/administered.
Class IIa: Benefit >> Risk. Additional studies with focused objectives needed. IT IS REASONABLE to perform procedure/administer treatment.
Class IIb: Benefit ≥ Risk. Additional studies with broad objectives needed; additional registry data would be helpful. Procedure/treatment MAY BE CONSIDERED.
Class III: No benefit or harmful.

- Procedure/Test – Not helpful OR Excess cost with no benefit or harmful
- Treatment – No proven benefit OR harmful to patients

1a.4.4. Provide all other grades and associated definitions for recommendations in the grading system. (*Note: If separate grades for the strength of the evidence, report them in section 1a.7.*)
All relevant information about the grades and associated definitions for the two guidelines provided has been included in **section 1a.4.3.**

1a.4.5. Citation and URL for methodology for grading recommendations (*if different from 1a.4.1*)**:**
Citations and URLs are the same as those noted in **section 1a.4.1**.

1a.4.6. If guideline is evidence-based (rather than expert opinion), are the details of the quantity, quality, and consistency of the body of evidence available (e.g., evidence tables)?
☒ Yes → ***complete section 1a.7***
☐ No → ***report on another systematic review of the evidence in sections 1a.6 and 1a.7; if another review does not exist, provide what is known from the guideline review of evidence in 1a.7***

1a.5. UNITED STATES PREVENTIVE SERVICES TASK FORCE RECOMMENDATION
1a.5.1. Recommendation citation (*including date*) and **URL for recommendation** (*if available online*):
This measure is not based on a United States Preventive Services Task Force Recommendation.

1a.5.2. Identify recommendation number and/or page number and **quote verbatim, the specific recommendation**.
This measure is not based on a United States Preventive Services Task Force Recommendation.

1a.5.3. Grade assigned to the quoted recommendation with definition of the grade:
This measure is not based on a United States Preventive Services Task Force Recommendation.

1a.5.4. Provide all other grades and associated definitions for recommendations in the grading system. (*Note: the grading system for the evidence should be reported in section 1a.7.*)
This measure is not based on a United States Preventive Services Task Force Recommendation.

1a.5.5. Citation and URL for methodology for grading recommendations (*if different from 1a.5.1*)**:**
This measure is not based on a United States Preventive Services Task Force Recommendation.

1a.7. FINDINGS FROM SYSTEMATIC REVIEW OF BODY OF THE EVIDENCE SUPPORTING THE MEASURE
If more than one systematic review of the evidence is identified above, you may choose to summarize the one (or more) for which the best information is available to provide a summary of the quantity, quality, and consistency of the body of evidence. Be sure to identify which review is the basis of the responses in this section and if more than one, provide a separate response for each review.

1a.7.1. What was the specific structure, treatment, intervention, service, or intermediate outcome addressed in the evidence review?
The clinical focus of *Guideline #2*, for which this systematic review was performed, is the perioperative cardiovascular evaluation and management of the adult patient undergoing non-cardiac surgery, including preoperative risk assessment and cardiac imaging. Preoperative cardiac imaging can serve three purposes, including 1) assessment of perioperative risk, 2) determination of the need for changes in management, and 3) identification of cardiovascular conditions or risk factors requiring longer-term management. Results of the cardiac imaging may lead to recommendations and discussions with the perioperative team about the optimal location and timing of surgery (e.g., ambulatory surgery center versus outpatient hospital, or inpatient admission) or alternative strategies to approaching patient care.

Methodologic Approach for the Systematic Review that Supports *Guideline #2*:
In April 2013, the American College of Cardiology/American Heart Association task force on practice guidelines conducted an extensive evidence review, which included a literature review for evidence published through July 2013. Other selected references published through May 2014 were also incorporated by the guideline writing committee (GWC). Literature included was derived from research involving human subjects, published in English, and indexed in MEDLINE (through PubMed), EMBASE, the Cochrane Library, Agency for Healthcare Research and Quality Reports, and other selected databases relevant to this clinical practice guideline (CPG). The relevant data are included in evidence tables in the ACC/AHA Data Supplement available online (link here: http://jaccjacc.cardiosource.com/acc_documents/2014_Periop_GL_Data_Supplement_Tables.pdf); seven articles were identified by the ACC/AHA task force that were relevant to *preoperative exercise stress testing for myocardial ischemia and functional capacity*, which are located on Data Supplement 11.

Key search words included, but were not limited to, the following: anesthesia protection; arrhythmia; atrial fibrillation; atrioventricular block; bundle branch block; cardiac ischemia; cardioprotection; cardiovascular implantable electronic device; conduction disturbance; dysrhythmia; electrocardiography; electrocautery; electromagnetic interference; heart disease; heart failure; implantable cardioverter-defibrillator; intraoperative; left ventricular ejection fraction; left ventricular function; myocardial infarction; myocardial protection; National Surgical Quality Improvement Program; pacemaker; perioperative; perioperative pain management; perioperative risk; postoperative; preoperative; preoperative evaluation; surgical procedures; ventricular premature beats; ventricular tachycardia; and volatile anesthetics.

An independent evidence review committee (ERC) was commissioned to perform a systematic review of a key question, the results of which were considered by the GWC for incorporation into this CPG. Please refer to the ACC/AHA task force's systematic review report, published in conjunction with this CPG and its respective data supplements.

1a.7.2. Grade assigned for the quality of the quoted evidence with definition of the grade:
Grade for the evidence provided from *Guideline #2* can be found in **section 1a.4.3.**

1a.7.3. Provide all other grades and associated definitions for strength of the evidence in the grading system.
Grade for the evidence provided from *Guideline 2* can be found in section **1a.4.3.**

1a.7.4. What is the time period covered by the body of evidence? (*provide the date range, e.g., 1990-2010*). Date range: Guideline #2: 2007 - 2013

QUANTITY AND QUALITY OF BODY OF EVIDENCE

1a.7.5. How many and what type of study designs are included in the body of evidence? (*e.g., 3 randomized controlled trials and 1 observational study*)
Guideline #2: 213 articles were included in the body of evidence, 7 of which were directly related to preoperative stress testing for noncardiac low-risk surgery. Of these seven, two of the studies were observational, two were prospective, two were consecutive case series, and one was a retrospective analysis.

1a.7.6. What is the overall quality of evidence across studies in the body of evidence? (*discuss the certainty or confidence in the estimates of effect particularly in relation to study factors such as design flaws, imprecision due to small numbers, indirectness of studies to the measure focus or target population*)
Consistency was seen in the outcomes of the seven studies cited by *Guideline 2* within the ACC/AHA task force Data Supplement. Of the seven studies cited, some limitations were identified, including small sample sizes for each study and potential concerns with patient assignment into the experimental and control arms. Collectively, however, the results cited within the body of evidence for the recommendations made in *Guideline #2* were consistent across studies and were of moderate quality.

ESTIMATES OF BENEFIT AND CONSISTENCY ACROSS STUDIES IN BODY OF EVIDENCE

1a.7.7. What are the estimates of benefit—magnitude and direction of effect on outcome(s) across studies in the body of evidence? (*e.g., ranges of percentages or odds ratios for improvement/ decline across studies, results of meta-analysis, and statistical significance*)
Given the high costs associated with performing unnecessary cardiac stress testing prior to non-cardiac, low-risk surgeries, the increased level of radiation to which these patients are exposed unnecessarily, and the fact that preoperative stress testing prior to non-cardiac, low-risk surgery is unlikely to change the outcome of the patient's operative or treatment plan. The overall net benefit in reducing overuse of cardiac stress testing prior to non-cardiac, low-risk surgery is a reduction in cost, a reduction in radiation exposure, and a reduction in the number of procedures performed, per beneficiary.

1a.7.8. What harms were studied and how do they affect the net benefit (benefits over harms)?
No harms in measure implementation were identified to counter the net benefit of the measure.

UPDATE TO THE SYSTEMATIC REVIEW(S) OF THE BODY OF EVIDENCE

1a.7.9. If new studies have been conducted since the systematic review of the body of evidence, provide for each new study: 1) citation, 2) description, 3) results, 4) impact on conclusions of systematic review.
In addition to the two guidelines cited above, a review of the clinical literature was conducted during the measure contractor's annual review of the literature for additional evidence and/or new studies that substantiate the measure's intent. Citations and summaries for the 14 items included in this review can be found in **Section 1a.8.2**. Some of these 14 studies have been published since the period of guideline development. Results cited in these studies are consistent across studies and with the guidelines cited above.

1a.8 OTHER SOURCE OF EVIDENCE

If source of evidence is NOT from a clinical practice guideline, USPSTF, or systematic review, please describe the evidence on which you are basing the performance measure.

1a.8.1 What process was used to identify the evidence?

In addition to the two guidelines cited above, a review of the clinical literature was conducted during the measure contractor's annual review of the literature for additional evidence and/or new studies that support the measure's intent. The measure contractor identified relevant peer-reviewed publications by searching the PubMed MEDLINE database from January 1, 2013 to January 16, 2015, limiting included results to those published in the English language and that had abstracts available in PubMed. The search initially identified 96 articles; a further review by the contractor's clinical and measure-development team resulted in the inclusion of 14 articles in the body of evidence below. Citations and summaries for the 14 items included in this review can be found in **Section 1a.8.2**.

1a.8.2. Provide the citation and summary for each piece of evidence.

Augoustides JG, Neuman MD, Al-Ghofaily L, Silvay G. Preoperative cardiac risk assessment for non-cardiac surgery: defining costs and risks. J Cardiothorac Vasc Anesth. 2013; 27(2):395-9.

Augoustides et al. reviewed literature on the appropriateness of preoperative cardiac risk assessment prior to non-cardiac surgery. The review notes that cardiac stress testing in Ontario acute care hospitals was associated with harm in low-risk patients (hazard ratio 1.35; 95% CI 1.05–1.74). However, preoperative cardiac stress testing was associated with benefits for intermediate-risk (hazard ratio 0.92; 95% CI 0.85–0.99) and high-risk patients (hazard ratio 0.80; 95% CI 0.67–0.97). Reducing cardiac stress testing prior to non-cardiac surgery for low-risk cases presents a cost-saving opportunity and a reduction in unnecessary testing. The study also notes that risk stratification tools such as the thoracic risk index effectively stratify patient risks and identify patients for whom additional cardiac stress testing may be appropriate.

Carryer D, Hodge D, Miller T, Askew J, Gibbons R. Application of appropriateness criteria to stress single photon emission computed tomography sestamibi studies: a comparison of the 2009 revised appropriateness criteria to the 2005 original criteria. Am Heart J. 2010; 160:244–9.

Carryer et al. retrospectively examined 281 patients who underwent stress SPECT MPI at the Mayo Clinic between May 1, 2005, and May 15, 2005. Using the revised 2009 ACCF/ASNC AUC, the researchers compared these findings to previously published results in this same cohort using the 2005 AUC. The most common broad indication for testing was post-revascularization (34 percent of the group), followed by evaluation of chest pain or ischemic equivalent (25 percent), follow-up of prior testing (20 percent), and screening of asymptomatic patients (14 percent). Evaluation for preoperative assessment for non-cardiac surgery (6 percent) was uncommon. Compared to the 2005 AUC, the 2009 AUC resulted in a highly significant overall change ($P < .001$) in the classification of appropriateness. The 2009 AUC eliminated unclassified patients, reduced appropriate studies (59.8 percent versus 63.7 percent, $P = .02$), increased studies of uncertain appropriateness (16.0 percent versus 10.7 percent, $P = .01$), and increased inappropriate studies (24.2 percent versus 14.6 percent, $P < .001$).

Colla CH, Morden NE, Sequist TD. Choosing Wisely: prevalence and correlates of low-value health care services in the United States. J Gen Intern Med. 2014; 30(2): 221-228.

Colla et al. aimed to develop claims-based algorithms to estimate the prevalence of select Choosing Wisely services and to examine the relationship between low-value care at the regional level and demographic, health, and healthcare system differences. The study team developed claims-based algorithms to measure the prevalence of 11 low-value services as identified by Choosing Wisely and examined geographic variation across hospital referral regions for these services. The study team found that the national average annual prevalence of the measured Choosing Wisely low-value services ranged from 1.2 percent to 46.5 percent and that prevalence across hospital referral regions varied significantly. For preoperative cardiac testing for non-cardiac surgery, specifically, the study team found that the average annual prevalence was 46.5 percent, with an estimated waste of $3.2 million. The study team stated that potential implications of these findings are that non-indicated

preoperative cardiac testing could lead to patient harm from additional testing or an increase in false positive results. The study team concluded that identifying and measuring low-value health services could help increase the value of healthcare and improve services and areas with greater use of potentially inappropriate care.

Ghadri JR, Fietcher M, Veraguth K, et al. Coronary calcium score as an adjunct to nuclear myocardial perfusion imaging for risk stratification before non-cardiac surgery. J Nucl Med. 2012; 53(7):1081-6.

Ghadri et al. studied the value of coronary artery calcium score (CACS) as an addition to SPECT MPI for cardiac risk stratification prior to non-cardiac surgery. The study included 326 patients referred for SPECT MPI prior to elective non-cardiac surgery, who then also underwent a low-dose CT scan to determine the CACS. CACS was found to be a strong preoperative risk predictor independent of the SPECT MPI study. CACS was also found to add additional risk stratification information to the results of SPECT MPI studies. In particular, patients with a normal SPECT MPI result, were still at increased risk for a major adverse cardiac event if the result of the CACS test was found to be above the normal threshold ($p = 0.003$).

Gibbons RJ, Miller TD, Hodge D, Urban L, Araoz PA, Pellikka P, McCully RB. Application of appropriateness criteria to stress single-photon emission computed tomography sestamibi studies and stress echocardiograms in an academic medical center. J Am Coll Cardiol. 2008; 51(13).

Gibbons et al. retrospectively applied the 2005 ACCF/ASNC AUC to 284 patients who underwent stress SPECT MPI and 298 patients who underwent stress echocardiography in a single academic medical center. Fourteen percent of stress SPECT studies and 18 percent of stress echo studies were performed for inappropriate reasons. Stress SPECT patients were more likely to be referred for follow-up testing post-revascularization and for follow-up testing after prior SPECT testing. In contrast, stress echo patients were more likely to be referred for preoperative assessment before non-cardiac surgery and the assessment of symptoms. Very few patients were referred for risk assessment after acute coronary syndromes. Similar percentages (14–15 percent) of both groups were asymptomatic patients without other indications, who were being screened for suspected coronary artery disease.

Hashimoto J, Nakahara T, Bai J, et al. Preoperative risk stratification with myocardial perfusion imaging in intermediate and low-risk non-cardiac surgery. Circ J. 2007; 71:1395–1400.

Hashimoto et al., in a retrospective cohort study, examined data collected from patients referred for preoperative stress myocardial perfusion SPECT before non-cardiac surgery and concluded that preoperative SPECT provides an incremental prognostic value in intermediate, but not in low-risk surgery. More than 1,200 consecutive patients underwent electrocardiography-gated dipyridamole stress SPECT to evaluate myocardial perfusion and cardiac function before intermediate- or low-risk non-cardiac surgery. Perfusion or cardiac function yielded significant risk stratification in intermediate- but not low-risk surgery. Adding functional data to perfusion variables offered an incremental prognostic value for patients with an intermediate clinical risk and scheduled intermediate risk surgery.

Hendel RC, Cerqueira M, Douglas PS, Caruth KC, Allen JM, Jensen NC, Pan W, Brindis R, Wolk M. A multicenter assessment of the use of single-photon emission computed tomography myocardial perfusion imaging with appropriateness criteria. J Am Coll Cardiol. 2010; 55(2).

Hendel et al. assessed the feasibility of evaluation for appropriate use of SPECT MPI in multiple clinical sites to determine use patterns as well as to identify areas of apparent inappropriate use. Six diverse clinical sites enrolled consecutive patients undergoing MPI. An automated algorithm assigned a specific indication from the 2005 ACCF/ASNC appropriateness criteria for SPECT MPI. Of the 6,351 patients enrolled in the study, 93 percent were successfully assigned an appropriateness level. Inappropriate use of MPI was found in 14.4 percent of patients, with a range of 4–22 percent among practices. Women and patients less than 65 years of age were more likely to undergo inappropriate MPI. Asymptomatic, low-risk patients accounted for 44.5 percent of inappropriate testing.

Henzlova M, Savino J, Levine EJ, Croft L, Einstein A, Hermann L, Duvall W. Comparative effectiveness of coronary CT angiography versus stress testing using high-efficiency SPECT myocardial perfusion imaging and stress-only imaging in the emergency department. J Am Coll Cardiol. 2013; 61(10_S).

Henzlova et al. compared CT angiography (CTA) and stress testing with SPECT MPI. During a period of two years, 1,458 individuals underwent testing in the emergency department (ED). A total of 192 CTAs and 1,266 stress tests (939 MPIs and 327 exercise treadmill testing (ETTs) were performed. In general, patients undergoing CTA were a lower risk group, based on age, risk factors, and known presence of heart disease. Within the MPI cohort, 708 underwent stress-only imaging. The percentage of patients discharged directly from the ED by stress-testing group, as compared with CTA group, was 82 percent versus 73 percent. However, the time to disposition was significantly longer for the stress-testing group as compared with the CTA group (20.5 ± 7 versus 11.0 ± 5 hrs, $p < 0.0001$). Additionally, there were more cardiac return visits to the ED in individuals who underwent CTA as opposed to stress testing (47 percent versus 10 percent, $p = 0.0002$). In general, the study concluded that stress testing with ETT, high-efficiency SPECT MPI, had significantly lower patient radiation dose, fewer cardiac return visits, and fewer follow-up diagnostic testing than CTA. Additionally, while CTA had a lower time to disposition than stress testing, there was a trend toward more discharges from the ED with stress testing.

Kerr EA, Chen J, Sussman JB, et al. Stress testing before low-risk surgery: so many recommendations, so little overuse. JAMA Internal Medicine. 2015; E1-E2.

Kerr et al. sought to determine the prevalence of cardiac stress testing before low-risk surgeries, prior to commencement of the Choosing Wisely campaign, to estimate the effect of the recommendations on future use of resources. The study team performed a retrospective cohort study using data from the Department of Veterans Affairs (VA) and from a nationally representative five percent sample of Medicare fee-for-service claims. The study team found that a routine preoperative stress test preceded 1 of the 3 low-risk surgeries in only 0.67 percent of VA patients and 2.14 percent of Medicare patients. The study team concluded that routine preoperative stress testing before low-risk surgery in both VA and Medicare patients is low and shows little variance across geographic regions. These trends existed even prior to the Choosing Wisely campaign, so the study team postulated that most physicians had already been incorporating guidelines about appropriate preoperative stress testing into their practices before the Choosing Wisely recommendations were developed.

Koh AS, Flores JL, Keng FY, Tan RS, Chua TS. Correlation between clinical outcomes and appropriateness grading for referral to myocardial perfusion imaging for preoperative evaluation prior to non-cardiac surgery. J Nucl Cardiol. 2012; 19(2):277–84.

Koh et al. studied the correlation of appropriateness of grading with both the outcome of MPI as well as the clinical outcomes of patients post-surgery. Patients visiting the MPI laboratory from March 2009 to July 2009 were studied and, based on their medical records, stress data, and imaging results, MPI scans were classified as appropriate, inappropriate, uncertain, or unclassified. Based on AUC, MPI referrals in intermediate- and high-risk groups with poor functional class were graded as appropriate, while MPI referrals in low-risk and intermediate risk groups with normal functional class were graded as inappropriate referrals. Out of 176 referrals for preoperative evaluation, 39.8 percent were graded as inappropriate. The study concluded that MPI results predicted outcome in appropriately tested patients, but not in patients whose tests were classified as inappropriate.

Koh AS, Flores JL, Keng FY, Tan RS, Chua TS. Evaluation of the American College of Cardiology Foundation/American Society of Nuclear Cardiology appropriateness criteria for SPECT myocardial perfusion imaging in an Asian tertiary cardiac center. J Nucl Cardiol. 2011 Apr; 18(2):324–30.

Koh et al. studied the pattern of referrals for SPECT MPI in an Asian tertiary cardiac center. Medical records and stress data were studied for 1,623 consecutive patients (mean age 61 years, 61 percent males) who were referred to the MPI laboratory between February 16 and June 19, 2009. MPI studies were categorized into appropriate, inappropriate, uncertain, or unclassified according to the 2009 ACCF/ASNC appropriateness criteria for SPECT MPI. Most common indications for SPECT were evaluation of ischemic equivalent for coronary artery disease, risk assessment post-revascularization, and preoperative evaluation for non-cardiac surgery. Ten percent of referrals were classified as inappropriate, 5 percent as uncertain, and 3 percent as unclassified. The

preoperative group had the highest proportion of inappropriate studies (59 percent). The authors concluded that preoperative evaluation for low-risk surgery appeared to be the most common source of inappropriate referrals for SPECT MPI in their institution.

McCully RB, Pellikka PA, Hodge DO, Araoz PA, Miller TD, Gibbons RJ. Applicability of appropriateness criteria for stress imaging: similarities and differences between stress echocardiography and single-photon emission computed tomography myocardial perfusion imaging criteria. Circ Cardiovasc Imaging. 2009; 2:213–8.

McCully et al. evaluated the application of the stress echocardiography appropriateness criteria to patients undergoing stress echocardiography in an academic medical center. The stress echocardiography criteria were applied to 298 consecutive patients who underwent stress echocardiography. Results were compared with those of a previous analysis in the same patients using the SPECT MPI criteria. Overall, 54 percent of patients were classified as appropriate, 8 percent as uncertain, and 19 percent as inappropriate; 19 percent were not classifiable. By the SPECT MPI criteria, 64 percent of patients were classified as appropriate, 9 percent as uncertain, and 18 percent as inappropriate; 9 percent were not classifiable ($P < .001$ compared with stress echocardiography criteria). By the stress echocardiography criteria, preoperative evaluation for low-risk surgery in patients with minor or intermediate clinical risk predictors was among six clinical situations or indications that accounted for more than 90 percent of the inappropriate tests. Most of these involved asymptomatic patients.

Placanica G, Merola R, Placanica A, Pecoraro A, Fusco L, Placanica P, Pasta V. Cardiological assessment of cardiac patients undergoing non-cardiac surgery (usefulness of surveys). Ann Ital Chir. 2011 May–Jun; 82(3):179–84.

Placanica et al. studied the effective usefulness of preoperative stress test and echocardiography in adult patients with coronary artery disease, undergoing non-cardiac surgery. Two-hundred patients age 58–85, affected by stable ischemic pathology, undergoing non-cardiac surgery, and treated with oral drugs, were enrolled for an assessment protocol including a preliminary case history (anamnesis); objective examination; blood pressure; race, class, and gender blood chemistry analysis; and cardiac risk evaluation. A second cohort of 50 patients with similar characteristics was subjected to the same tests and preoperative and exercise stress test. All patients showed a good hemodynamic compensation and a quick recovery. The group of 200 patients, for whom the risk assessment was performed without preoperative and stress test, concluded the process three days prior, on average, before undergoing an echocardiography and exercise stress test. The authors concluded that when patients are hemodynamically stable and their conditions controlled by appropriate therapy, it is sufficient to perform first-level tests for the preoperative stratification of cardiovascular risk. It is recommended to perform echocardiogram and stress test when the first level tests are abnormal, when there is a worsening of the conditions prior to admission, or when the patient is not hemodynamically stable.

Sumin AN, Korok EV, Kokov AN, et al. Role of multidetector computed tomography and stress- echocardiography in assessment of risk of cardiological complications of non-cardiac surgery. Kardiologiia. 2014; 54(5): 39-47.

Sumin et al. sought to compare results of coronary angiography with data of multi-slice computed tomography (MSCT) angiography, and analyzed the rate of detection of hemodynamically significant coronary artery lesions during preoperative examination of patients. The investigators analyzed case histories of 92 patients [median age 59 years] examined prior to surgery on non-coronary vessels, or for exclusion of ischemic heart disease. All patients were subjected to selective coronary angiography (CA) and MSCT angiography. According to results of CA patients were divided into two groups – those with coronary artery stenoses >70% (n=55, group 1) and <70% (n=37, group 2). In 46 patients (50%), dobutamine stress echocardiography was performed for detection of concealed coronary insufficiency. The study concluded that the diagnostic value of MSCT for detection of coronary artery stenoses >70% have better sensitivity, specificity, and negative and positive predictive value compared with stress echocardiography. The authors concluded that the study confirms the value of MSCT angiography for diagnosis of coronary atherosclerosis preoperatively, and recommended it as a screening method for detecting hemodynamically significant coronary artery involvement before extracardiac surgery.

1. Evidence, Performance Gap, Priority – Importance to Measure and Report

Extent to which the specific measure focus is evidence-based, important to making significant gains in healthcare quality, and improving health outcomes for a specific high-priority (high-impact) aspect of healthcare where there is variation in or overall less-than-optimal performance. ***Measures must be judged to meet all subcriteria to pass this criterion and be evaluated against the remaining criteria.***

1a. Evidence to Support the Measure Focus – See attached Evidence Submission Form
NQF_0669_Measure_Evidence_Form_2015-06-30.docx

1b. Performance Gap

Demonstration of quality problems and opportunity for improvement, i.e., data demonstrating:

- considerable variation, or overall less-than-optimal performance, in the quality of care across providers; and/or
- disparities in care across population groups.

1b.1. **Briefly explain the rationale for this measure** *(e.g., the benefits or improvements in quality envisioned by use of this measure)*
This measure aims to reduce overuse of cardiac imaging prior to low-risk non-cardiac surgeries, for patients with low or moderate cardiac risk, as cardiac imaging in this population can result in increased exposure to radiation with little or no clinical benefit. The measure score will guide patient selection of providers, assess quality, and inform quality improvement.

1b.2. **Provide performance scores on the measure as specified (current and over time) at the specified level of analysis.** *(This is required for endorsement maintenance. Include mean, std dev, min, max, interquartile range, scores by decile. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities included). This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*
Analysis of Medicare fee-for-service (FFS) claims data indicates variation in the use of cardiac imaging prior to non-cardiac, low-risk surgery. For the time period (July 2013 through June 2014), performance rates ranged from 0.00 percent to 18.0 percent, with a weighted mean of 5.07 percent.

The data presented below represent information for the 1,953 facilities whose denominator counts met minimum case count requirements for all years included in the table.

Further details on the descriptive statistics for longitudinal facility performance are included below:

	2009*	2010*	2011*	2012-2013**	2013-2014**	% Change (2009-2014)
Facilities	1,953	1,953	1,953	1,953	1,953	-
Minimum Value	0.0%	0.0%	0.0%	0.0%	0.0%	0.0%
1st Percentile	0.9%	1.2%	1.4%	1.2%	0.0%	-0.9%
5th Percentile	2.2%	2.4%	2.7%	2.5%	1.7%	-0.5%
10th Percentile	2.8%	3.1%	3.3%	3.1%	2.5%	-0.3%
25th Percentile	3.8%	4.2%	4.3%	4.1%	3.7%	-0.1%
Median	4.9%	5.5%	5.4%	5.2%	4.8%	-0.1%
75th Percentile	6.3%	6.7%	6.7%	6.4%	6.1%	-0.2%
90th Percentile	7.7%	8.1%	8.0%	7.7%	7.5%	-0.2%
95th Percentile	8.7%	9.2%	8.9%	8.5%	8.5%	-0.2%
99th Percentile	10.5%	11.6%	11.6%	10.7%	11.1%	0.6%
Maximum Value	14.5%	16.0%	17.0%	15.1%	18.0%	3.5%
Mean Performance (Standard Deviation)	5.1% (2.0)	5.6% (2.1)	5.6% (2.1)	5.3% (1.9)	5.0% (2.1)	-0.1% (0.1)
Number of Imaging Studies (Denom)	622,774	676,847	791,191	845,928	556,825	-65,949

*The measurement period for HOQR data reported from 2009 through 2011 ran from January to December.
**Beginning in 2012, the measurement period for HOQR was adjusted to run from July to June; consequently, data are not reported for January through June 2012.

One of the intentions for reporting this measure is to identify facilities with significant outlying performance. As shown in the table above, many facilities cluster around a value of 4 to 5 percent; however, outlying performance persists, indicating there are facilities for which there is a notable rate of overuse.

1b.3. **If no or limited performance data on the measure as specified is reported in 1b2, then provide a summary of data from the literature that indicates opportunity for improvement or overall less than optimal performance on the specific focus of**

measurement.
Data have been included in Section 1b.2; these data represent national performance over time, from 2009 to 2014.

1b.4. **Provide disparities data from the measure as specified (current and over time) by population group, e.g., by race/ethnicity, gender, age, insurance status, socioeconomic status, and/or disability.** *(This is required for endorsement maintenance. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities include.) This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*
Using 2013 performance data, we evaluated the effect of patient and facility characteristics on the likelihood of each beneficiary having a cardiac imaging procedure occur prior to a non-cardiac, low-risk surgery. Using a logistic regression model, we assessed the impact of patient and facility characteristics for the 662,905 cardiac-imaging procedures performed in 2013 and found that race/ethnicity and facility characteristics had a significant relationship with the rate of inappropriate preoperative cardiac imaging.

The primary finding from the regression model is that patient race/ethnicity has a statistically significant effect on the likelihood that a patient undergoes inappropriate preoperative imaging. African-Americans were slightly less likely to undergo inappropriate preoperative cardiac imaging compared to White beneficiaries (OR 0.948, p=0.021); conversely, Asian beneficiaries were slightly more likely to undergo inappropriate preoperative cardiac imaging prior to a low-risk surgery (OR 1.112, p=0.023).

Facility characteristics also played a role in determining whether a non-cardiac, low-risk surgery was performed following a cardiac-imaging study. When compared to facilities with fewer than 50 beds (a proxy for facility size), facilities with 101 to 250 beds (OR 1.151, p=0.018) and 500 or more beds (OR 1.148, p=0.029) were more likely to perform pre-operative imaging. Similarly, a facility's urbanicity impacted a beneficiary's likelihood of having cardiac imaging performed preoperatively—urban facilities were more likely than rural facilities to be associated with pre-surgical imaging (OR 1.067, p=0.006).

While the regression model identified subpopulations of patients and facilities for which there are statistically significant differences in imaging prior to low-risk, non-cardiac surgery, these disparities do not indicate a need for adjustment of the measure specifications. Adjusting for these differences would mask underlying differences in quality of care. As this is a process measure, there should be no difference in the standard of care for these patients; we believe these statistically significant differences are driven by variation in provider practice. Consequently, we do not believe risk adjustment or stratification is necessary or appropriate for this measure.

1b.5. **If no or limited data on disparities from the measure as specified is reported in 1b4, then provide a summary of data from the literature that addresses disparities in care on the specific focus of measurement. Include citations.**
A review of the literature for population-based disparities in the inappropriate use of cardiac imaging prior to low-risk, non-cardiac surgery found one study on the topic. Sheffield et al. (2013) analyzed the overuse of preoperative stress testing and found that inappropriate stress testing prior to low-risk surgery was more likely for females. The study also found that living in a region with higher Medicare expenditures was associated with higher rates of preoperative stress testing.

There is additional literature on population disparities for the use of diagnostic imaging more broadly. Hendel et al (2010) assessed the use of single photon emission computed tomography myocardial perfusion imaging (SPECT MPI), finding that women and younger patients were more likely to undergo inappropriate SPECT MPI studies. This study, however, is not restricted to the Medicare population, and examines inappropriate SPECT MPI use for a variety of cases, not just prior to low-risk surgery.

Lucas et al. (2006) evaluated the utilization of imaging stress tests in the Medicare population, finding that non-black males have the highest rate of utilization, followed by non-black females, black males, and finally black females. The study indicates a disparity in utilization based on both race and gender; one limitation of this study is that it does not report outcomes based on income, age, or other factors. While the study demonstrates a gap in utilization of diagnostic imaging, it does not indicate whether the utilization is considered appropriate or inappropriate.

Sistrom et al. (2012) examined diagnostic imaging utilization, finding that race was a determinant in the likelihood of receiving a diagnostic imaging test. While these disparities were noted within the literature, a review of the measure's specifications did not identify conceptual or empirical evidence suggesting that adjustment based on patient racial or ethnic identification would be indicated for the calculation of provider performance. Thus, this process measure does not require additional adjustment based on sociodemographic factors.

1c. High Priority (previously referred to as High Impact)

The measure addresses:

- a specific national health goal/priority identified by DHHS or the National Priorities Partnership convened by NQF; OR
- a demonstrated high-priority (high-impact) aspect of healthcare (e.g., affects large numbers of patients and/or has a substantial impact for a smaller population; leading cause of morbidity/mortality; high resource use (current and/or future); severity of illness; and severity of patient/societal consequences of poor quality).

1c.1. Demonstrated high priority aspect of healthcare

Affects large numbers, Frequently performed procedure, High resource use, Patient/societal consequences of poor quality, Other

1c.2. If Other: Safety

1c.3. Provide epidemiologic or resource use data that demonstrates the measure addresses a high priority aspect of healthcare. List citations in 1c.4.

Cardiac imaging is among the most common imaging services in the Medicare population; its use has grown significantly in the past decade. In 2008, hospital outpatient settings performed over 760,000 stress echocardiography, SPECT MPI, and stress MRI procedures. Between 1998 and 2006, the rate of MPI use in Medicare beneficiaries increased 51 percent among cardiologists in the hospital setting, and 215 percent in private offices (Levin 2009). During this period, total Medicare Part B payments for MPI across all settings of care increased by 227 percent (The Lewin Group 2009).

Concomitant with the growth in cardiac imaging, the number of non-cardiac, low-risk surgeries and procedures has progressively increased over the past twenty years (Hernandez 2004). Elderly patients undergo at least four million major, non-cardiac operations annually (Gregoratos 2008). Increased utilization of imaging services also poses a safety concern for patients. Radiation exposure from medical imaging procedures has increased rapidly in recent years, though the growth was fairly consistent across sociodemographic groups from 1997 to 2007. Annual radiation exposure per radiation inducing imaging service procedure increased by 164 percent in emergency departments and 90 percent in physician offices from 1997 to 2007 (Brenner 2007).

While it is important to perform a cardiac risk assessment prior to surgery to identify high-risk patients, in most patients, an extensive cardiac workup is unnecessary, costly, and delays definitive patient care. Perioperative risk is proportional both to the severity of the patient's heart failure and the surgical risk (Savino 2007).

A study evaluating measure concepts included in the Choosing Wisely campaign demonstrated that there is national overuse of cardiac imaging prior to low-risk surgery. Colla et al. (2014) found that the national average annual prevalence of the measured Choosing Wisely low-value services ranged from 1.2 percent to 46.5 percent and that prevalence across hospital referral regions varied significantly. In terms of preoperative cardiac testing for non-cardiac surgery specifically, the study team found that the average annual prevalence was 46.5 percent, with an estimated waste of $3.2 million. Potential implications of these findings suggest non-indicated, preoperative cardiac testing could lead to patient harm from additional testing or an increase in false-positive results. The study team concluded that identifying and measuring low-value health services could help increase the value of health care, improving services and areas with greater use of potentially inappropriate care (Colla et al. 2014).

In general, as evidenced in clinical guidelines and the peer-reviewed literature, preoperative cardiac tests should be performed only if their results are likely to influence patient treatment. Cardiac intervention is rarely necessary to reduce the risk of surgery. The Cleveland Clinic states that, "there are very few cases in which the surgical outcomes and treatments are affected by extensive preoperative cardiac testing. Although preoperative testing is indicated in some cases, it does not always lead to a scientifically measurable improvement in outcome. Indiscriminate and extensive preoperative cardiac testing is an ineffective way of using health care funds and can lead to more unwarranted and risky procedures. In addition to the inappropriate expenditure of resources, unnecessary testing could cause harm to the patient by delaying surgery. For a test to be considered useful, it should be accurate, influence patient outcomes, and have a favorable risk-to-benefit ratio. Therefore, it is essential for the physician to identify patients who will benefit most from an in-depth preoperative cardiac evaluation. It is important for the physician to explore noncardiac issues (e.g., chronic lung disease, coagulopathy, anemia, renal and cerebrovascular disease, diabetes) that can negatively affect the

outcome of the surgery" (Grasso and Wael 2014).

1c.5. **If a PRO-PM (e.g. HRQoL/functional status, symptom/burden, experience with care, health-related behaviors), provide evidence that the target population values the measured PRO and finds it meaningful.** *(Describe how and from whom their input was obtained.)*

This measure is not a PRO-PM measure.

2. Reliability and Validity—Scientific Acceptability of Measure Properties

Extent to which the measure, as specified, produces consistent (reliable) and credible (valid) results about the quality of care when implemented. ***Measures must be judged to meet the subcriteria for both reliability and validity to pass this criterion and be evaluated against the remaining criteria.***

2a.1. Specifications The measure is well defined and precisely specified so it can be implemented consistently within and across organizations and allows for comparability. eMeasures should be specified in the Health Quality Measures Format (HQMF) and the Quality Data Model (QDM).

De.5. **Subject/Topic Area** *(check all the areas that apply):*

Cardiovascular, Cardiovascular : Screening, Surgery, Surgery : General Surgery

De.6. **Cross Cutting Areas** *(check all the areas that apply):*

Overuse, Safety

S.1. **Measure-specific Web Page** *(Provide a URL link to a web page specific for this measure that contains current detailed specifications including code lists, risk model details, and supplemental materials. Do not enter a URL linking to a home page or to general information.)*

https://www.qualitynet.org/dcs/ContentServer?c=Page&pagename=QnetPublic%2FPage%2FQnetTier2&cid=1228695266120

S.2a. **If this is an eMeasure**, HQMF specifications must be attached. Attach the zipped output from the eMeasure authoring tool (MAT) - if the MAT was not used, contact staff. (Use the specification fields in this online form for the plain-language description of the specifications)

This is not an eMeasure **Attachment:**

S.2b. **Data Dictionary, Code Table, or Value Sets** *(and risk model codes and coefficients when applicable) must be attached. (Excel or csv file in the suggested format preferred - if not, contact staff)*

Attachment **Attachment:** NQF_0669_Measure_Value_Sets_2015-06-30.xlsx

S.3. **For endorsement maintenance**, please briefly describe any changes to the measure specifications since last endorsement date and explain the reasons.

As part of the annual measure maintenance and review process, several new codes for low-risk surgeries were added to the numerator in 2012. The 48 new codes added to the list of surgical procedures included in the numerator (see Other Surgeries sub-heading) align the procedure-code list with NQF measure #0670 (cardiac stress imaging not meeting appropriate use criteria: preoperative evaluation in low risk surgery patients). All 48 new surgical procedures fall into the low risk surgical category (i.e., each procedure has a less than one percent surgical-risk estimate). When presented to the contractor's Technical Expert Panel (TEP), the TEP supported the addition of these codes to the numerator, based on a desire to harmonize the list of procedure codes with NQF #0670 and the surgery-risk estimate for each procedure.

Similarly, exclusion from the measure's denominator for those patients identified as at high risk for cardiac involvement was added to the specifications in 2014, based on evidence from the literature and review by the contractor's TEP. The 2013 update to the Guidelines on Perioperative Cardiovascular Evaluation and Care for Non-Cardiac Surgery, developed by the American College of Cardiology/American Heart Association task force on practice guidelines, indicated that patients presenting with three of five concomitant clinical risk factors (i.e., diabetes mellitus, renal insufficiency, stroke or transient ischemic attack, prior heart failure, or ischemic heart disease) were at increased cardiac risk during surgery; consequently, pre-operative cardiac imaging for these patients may be appropriate. Based on this updated evidence, the contractor's TEP recommended adding patients with at least three of these five risk factors to the list of denominator exclusions.

S.4. **Numerator Statement** *(Brief, narrative description of the measure focus or what is being measured about the target population, i.e., cases from the target population with the target process, condition, event, or outcome)*
IF an OUTCOME MEASURE, state the outcome being measured. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.

The number of stress echocardiography, SPECT MPI, and stress MR studies performed in a hospital outpatient department within 30 days of an ambulatory non-cardiac, low-risk surgery performed at any location (e.g., same hospital, other hospital, or physician office).

S.5. **Time Period for Data** *(What is the time period in which data will be aggregated for the measure, e.g., 12 mo, 3 years, look back to August for flu vaccination? Note if there are different time periods for the numerator and denominator.)*

Numerator: Stress echocardiography, SPECT MPI, or stress MR procedures, occurring within 30 days of an ambulatory non-cardiac, low-risk surgery, within a 12-month time window (July 1 – June 30).
Denominator: Stress echocardiography, SPECT MPI, or stress MR procedures within an 11-month time window (July 1 – May 31).

S.6. **Numerator Details** *(All information required to identify and calculate the cases from the target population with the target process, condition, event, or outcome such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
IF an OUTCOME MEASURE, describe how the observed outcome is identified/counted. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.

The numerator is defined by the following categories of surgical procedures:

-Surgery/Integumentary System: Breast
-Surgery/Respiratory System: Accessory Sinuses
-Surgery/Respiratory System: Larynx
-Surgery/Respiratory System: Trachea and Bronchi
-Surgery/Respiratory System: Lungs and Pleura
-Surgery/Digestive System: Esophagus
-Surgery/Digestive System: Intestines (Except Rectum)
-Surgery/Digestive System: Rectum
-Surgery/Digestive System: Anus
-Surgery/Digestive System: Biliary Tract
-Surgery/Digestive System: Abdomen, Peritoneum, and Omentum
-Surgery/Urinary System: Kidney
-Surgery/Urinary System: Ureter
-Surgery/Urinary System: Bladder
-Surgery/Female Genital System: Cervix Uteri
-Surgery/Female Genital System: Corpus Uteri

-Surgery/Female Genital System: Oviduct/Ovary
-Surgery/Eye and Ocular Adnexa: Anterior Segment
-Other Surgeries

(Specific CPT codes for each condition class are included in the value set for this measure; this detailed list can be found in the Excel workbook provided for Section S2b.)

S.7. **Denominator Statement** *(Brief, narrative description of the target population being measured)*
The number of stress echocardiography, SPECT MPI, and stress MR studies performed in a hospital outpatient department on Medicare beneficiaries within a 12-month time window.

S.8. **Target Population Category** *(Check all the populations for which the measure is specified and tested if any):*
Senior Care

S.9. **Denominator Details** *(All information required to identify and calculate the target population/denominator such as definitions, specific data collection items/responses , code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
The denominator is defined by the following CPT codes:

SPECT MPI
CPT 78464, 78451, 78465, 78452

Stress Echocardiography
CPT 93350 C8928 and 93351 C8930

Stress MR
CPT 75559, 75560, 75563, 75564

Global and technical-component (TC) claims should be considered to capture all outpatient volume facility claims, typically paid under the Outpatient Prospective Payment System(OPPS)/Ambulatory Payment Classifications (APC) methodology, and to avoid double counting of professional-component claims (i.e., 26 modifier). A technical unit can be identified by a modifier code of TC. A global unit can be identified by the absence of a TC or 26 modifier code.

SPECT MPI, stress echocardiography, and stress MR studies can be billed separately for the technical and professional components or billed globally, which includes both the professional and technical components.

Professional component claims will outnumber technical component claims due to over-reads.

S.10. **Denominator Exclusions** *(Brief narrative description of exclusions from the target population)*
Studies are excluded for any patients with diagnosis codes in at least three of the following categories: diabetes mellitus, renal insufficiency, stroke or transient ischemic attack, prior heart failure, or ischemic heart disease.

S.11. **Denominator Exclusion Details** *(All information required to identify and calculate exclusions from the denominator such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
Studies are excluded for any patients with diagnosis codes in at least three of the following categories:

Diabetes (look back of one year)
Diabetes mellitus
ICD-9 codes 249, 250, and 648.0X
ICD-10 codes E08.00-E13.9
Diabetes mellitus in pregnancy, childbirth, and the puerperium
ICD-10 codes O24.011-O24.33, O24.811-O24.93

Renal Insufficiency (look back of one year)
Renal insufficiency

ICD-9 codes 403, 404, 580, 582, 583, 584, 585, 586, and 593.9
Hypertensive chronic kidney disease
ICD-10 codes I12.0-I12.9
Hypertensive heart and chronic kidney disease
ICD-10 codes I13.0-I13.2
Glomerular diseases
ICD-10 codes N00.0-N01.9, N03.0-N03.9, N05.0-N08
Acute kidney failure and chronic kidney disease
ICD-10 codes N17.0-N19
Other disorders of kidney and ureter
ICD-10 codes N28.9-N29

Stroke or transient ischemic attack (look back of three years)
ICD-9 codes 430, 431, 432, 433, 434, 435, 436, 437, 438, 674.0X, and 997.02
Transient cerebral ischemic attacks and related syndromes
ICD-10 codes G45.0-G45.2, G45.8-G45.9
Vascular syndromes of brain in cerebrovascular diseases
ICD-10 codes G46.0-G46.2
Cerebrovascular diseases
ICD-10 codes I60.00-I63.9, I65.21-I65.29, I66.01-I66.9, I67.1, I67.841-I67.89, I69.00-I69.998
Diseases of the circulatory system complicating pregnancy, childbirth and the puerperium
ICD-10 codes O99.411-O99.43

Prior heart failure (look back of three years)
Prior heart failure
ICD-9 codes 425, 428, and 429
Other forms of heart disease
ICD-10 codes I42.0-I43
Heart failure
ICD-10 codes I50.1-I50.9
Intraoperative and post-procedural complications and disorders of circulatory system, not elsewhere classified
ICD-10 codes I97.0-I97.191
Complications and ill-defined descriptions of heart disease
ICD-10 codes I51.0-I51.9

Ischemic heart disease (look back of three years)
Ischemic heart disease
ICD-9 codes 410, 411, 412, 413, and 414
ICD-10 codes I20.0-I22.9, I24.8-I25.119, I25.700-I25.799

S.12. **Stratification Details/Variables** *(All information required to stratify the measure results including the stratification variables, definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format with at S.2b)*
Not applicable; this measure does not stratify its results.

S.13. **Risk Adjustment Type** (Select type. Provide specifications for risk stratification in S.12 and for statistical model in S.14-15)
No risk adjustment or risk stratification
If other:

S.14. **Identify the statistical risk model method and variables** *(Name the statistical method - e.g., logistic regression and list all the risk factor variables. Note - risk model development and testing should be addressed with measure testing under Scientific Acceptability)*
Not applicable; this measure does not risk adjust.

S.15. **Detailed risk model specifications** *(must be in attached data dictionary/code list Excel or csv file. Also indicate if available at measure-specific URL identified in S.1.)*
Note: Risk model details (including coefficients, equations, codes with descriptors, definitions), should be provided on a separate

worksheet in the suggested format in the Excel or csv file with data dictionary/code lists at S.2b.
Provided in response box S.15a

S.15a. **Detailed risk model specifications** (*if not provided in excel or csv file at S.2b*)
No risk model specifications are provided, as risk adjustment or stratification are not necessary for this measure.

S.16. **Type of score:**
Other (specify):
If other: Percentage

S.17. **Interpretation of Score** *(Classifies interpretation of score according to whether better quality is associated with a higher score, a lower score, a score falling within a defined interval, or a passing score)*
Better quality = Lower score

S.18. **Calculation Algorithm/Measure Logic** *(Describe the calculation of the measure score as an ordered sequence of steps including identifying the target population; exclusions; cases meeting the target process, condition, event, or outcome; aggregating data; risk adjustment; etc.)*
This measure calculates the percentage of SPECT MPI, stress echocardiography, or stress MR studies that are performed within the 30 days preceding a non-cardiac, low-risk surgery, out of all SPECT MPI, stress echocardiography, and stress MR studies performed. The measure is calculated based on one year of hospital outpatient claims data, as follows:

1. Select hospital outpatient claims with a CPT code for any SPECT MPI, stress echocardiography, or stress MR on a revenue line item
2. Exclude professional component only claims with modifier =´26´
3. Exclude cases with three or more exclusion diagnoses occurring during the look back period for each diagnosis
4. Set denominator counter = 1
5. Set numerator counter = 1 if a non-cardiac, low-risk surgery occurs within the 30 days following the SPECT MPI, stress echocardiography, or stress MR from step 1, above
6. Aggregate denominator and numerator counts by Medicare provider number
7. Measure = numerator counts / denominator counts [The value should be recorded as a percentage]

S.19. **Calculation Algorithm/Measure Logic Diagram URL or Attachment** *(You also may provide a diagram of the Calculation Algorithm/Measure Logic described above at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
No diagram provided

S.20. **Sampling** *(If measure is based on a sample, provide instructions for obtaining the sample and guidance on minimum sample size.)*
IF a PRO-PM, identify whether (and how) proxy responses are allowed.
This measure relies exclusively on 100 percent Medicare fee-for-service (FFS) standard analytical file (SAF) data; no sampling of beneficiaries was performed.

S.21. **Survey/Patient-reported data** *(If measure is based on a survey, provide instructions for conducting the survey and guidance on minimum response rate.)*
IF a PRO-PM, specify calculation of response rates to be reported with performance measure results.
This measure does not use survey data.

S.22. **Missing data** (specify how missing data are handled, e.g., imputation, delete case.)
Required for Composites and PRO-PMs.
The measure does not make any adjustments for missing data. The measure relies on Medicare claims data, which are used for payment purposes for services rendered by a provider. The data undergo prepayment claims analysis and post payment audits, as part of the CMS administrative process. The analytic files used by the measure developer are post-adjudicated claims.

S.23. **Data Source** *(Check ONLY the sources for which the measure is SPECIFIED AND TESTED).*
If other, please describe in S.24.
Administrative claims

S.24. **Data Source or Collection Instrument** *(Identify the specific data source/data collection instrument e.g. name of database,*

clinical registry, collection instrument, etc.)
IF a PRO-PM, identify the specific PROM(s); and standard methods, modes, and languages of administration.
This measure was initially constructed using the 100-percent FFS outpatient standard analytical files (SAFs) from 2009. These outpatient SAFs contain the claims data on imaging utilization and low-risk surgical procedures performed in hospital outpatient departments (including emergency department services), which are necessary to attribute the measure to specific facilities. Public reporting of the measure currently uses the 100 percent Medicare FFS outpatients SAFs from 2013 and 2014.

S.25. **Data Source or Collection Instrument** *(available at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
No data collection instrument provided

S.26. **Level of Analysis** *(Check ONLY the levels of analysis for which the measure is SPECIFIED AND TESTED)*
Facility, Population : National, Population : State

S.27. **Care Setting** *(Check ONLY the settings for which the measure is SPECIFIED AND TESTED)*
Ambulatory Care : Clinician Office/Clinic, Hospital/Acute Care Facility, Imaging Facility
If other:

S.28. **COMPOSITE Performance Measure** - Additional Specifications *(Use this section as needed for aggregation and weighting rules, or calculation of individual performance measures if not individually endorsed.)*
Not applicable; this is not a composite measure.

2a. Reliability – See attached Measure Testing Submission Form
2b. Validity – See attached Measure Testing Submission Form
NQF_0669_Measure_Testing_Form_2015-06-30.docx

NATIONAL QUALITY FORUM—Measure Testing (subcriteria 2a2, 2b2-2b7)

Measure Number (*if previously endorsed*)**:** 0669
Measure Title: Cardiac Imaging for Preoperative Risk Assessment for Non-Cardiac, Low-Risk Surgery
Date of Submission: 6/30/2015
Type of Measure:

☐ Composite – ***STOP – use composite testing form***	☐ Outcome (*including PRO-PM*)
☐ Cost/resource	☒ Process
☐ Efficiency	☐ Structure

Instructions

- Measures must be tested for all the data sources and levels of analyses that are specified. ***If there is more than one set of data specifications or more than one level of analysis, contact NQF staff*** about how to present all the testing information in one form.
- **For all measures, sections 1, 2a2, 2b2, 2b3, and 2b5 must be completed.**
- **For outcome and resource use measures**, section **2b4** also must be completed.
- If specified for **multiple data sources/sets of specificaitons** (e.g., claims and EHRs), section **2b6** also must be completed.
- Respond to all questions as instructed with answers immediately following the question. All information on testing to demonstrate meeting the subcriteria for reliability (2a2) and validity (2b2-2b6) must be in this form. An appendix for *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 20 pages (*incuding questions/instructions;* minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.
- For information on the most updated guidance on how to address sociodemographic variables and testing in this form refer to the release notes for version 6.6 of the Measure Testing Attachment.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the testing results for this measure meet NQF's evaluation criteria for testing.

2a2. Reliability testing [10] demonstrates the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise. For **PRO-PMs and composite performance measures**, reliability should be demonstrated for the computed performance score.

2b2. Validity testing [11] demonstrates that the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality. For **PRO-PMs and composite performance measures**, validity should be demonstrated for the computed performance score.

2b3. Exclusions are supported by the clinical evidence; otherwise, they are supported by evidence of sufficient frequency of occurrence so that results are distorted without the exclusion; [12]

AND

If patient preference (e.g., informed decisionmaking) is a basis for exclusion, there must be evidence that the exclusion impacts performance on the measure; in such cases, the measure must be specified so that the information about patient preference and the effect on the measure is transparent (e.g., numerator category computed separately, denominator exclusion category computed separately). [13]

2b4. For outcome measures and other measures when indicated (e.g., resource use):

- **an evidence-based risk-adjustment strategy** (e.g., risk models, risk stratification) is specified; is based on patient factors (including clinical and sociodemographic factors) that influence the measured outcome and are present at start of care; [14,15] and has demonstrated adequate discrimination and calibration

OR

- rationale/data support no risk adjustment/ stratification.

2b5. Data analysis of computed measure scores demonstrates that methods for scoring and analysis of the specified measure allow for **identification of statistically significant and practically/clinically meaningful [16] differences in performance**;

OR

there is evidence of overall less-than-optimal performance.

2b6. If multiple data sources/methods are specified, there is demonstration they produce comparable results.

2b7. For **eMeasures, composites, and PRO-PMs** (or other measures susceptible to missing data), analyses identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias.

Notes

10. Reliability testing applies to both the data elements and computed measure score. Examples of reliability testing for data elements include, but are not limited to: inter-rater/abstractor or intra-rater/abstractor studies; internal consistency for multi-item scales; test-retest for survey items. Reliability testing of the measure score addresses precision of measurement (e.g., signal-to-noise).

11. Validity testing applies to both the data elements and computed measure score. Validity testing of data elements typically analyzes agreement with another authoritative source of the same information. Examples of validity testing of the measure score include, but are not limited to: testing hypotheses that the measures scores indicate quality of care, e.g., measure scores are different for groups known to have differences in quality assessed by another valid quality measure or method; correlation of measure scores with another valid indicator of quality for the specific topic; or relationship to conceptually related measures (e.g., scores on process measures to scores on outcome measures). Face validity of the measure score as a quality indicator may be adequate if accomplished through a systematic and transparent process, by identified experts, and explicitly addresses whether performance scores resulting from the measure as specified can be used to distinguish good from poor quality.

12. Examples of evidence that an exclusion distorts measure results include, but are not limited to: frequency of occurrence, variability of exclusions across providers, and sensitivity analyses with and without the exclusion.

13. Patient preference is not a clinical exception to eligibility and can be influenced by provider interventions.

14. Risk factors that influence outcomes should not be specified as exclusions

15. With large enough sample sizes, small differences that are statistically significant may or may not be practically or clinically meaningful. The substantive question may be, for example, whether a statistically significant difference of one percentage point in the percentage of patients who received smoking cessation counseling (e.g., 74 percent v. 75 percent) is clinically meaningful; or whether a statistically significant difference of $25 in cost for an episode of care (e.g., $5,000 v. $5,025) is practically meaningful. Measures with overall less-than-optimal performance may not

demonstrate much variability across providers.

1. DATA/SAMPLE USED FOR ALL TESTING OF THIS MEASURE

Often the same data are used for all aspects of measure testing. In an effort to eliminate duplication, the first five questions apply to all measure testing. If there are differences by aspect of testing,(e.g., reliability vs. validity) be sure to indicate the specific differences in question 1.7.

1.1. What type of data was used for testing? (*Check all the sources of data identified in the measure specifications and data used for testing the measure. Testing must be provided for all the sources of data specified and intended for measure implementation.* ***If different data sources are used for the numerator and denominator, indicate N [numerator] or D [denominator] after the checkbox.***)

Measure Specified to Use Data From: (***must be consistent with data sources entered in S.23***)	**Measure Tested with Data From:**
☐ abstracted from paper record	☐ abstracted from paper record
☒ administrative claims	☒ administrative claims
☐ clinical database/registry	☐ clinical database/registry
☐ abstracted from electronic health record	☐ abstracted from electronic health record
☐ eMeasure (HQMF) implemented in EHRs	☐ eMeasure (HQMF) implemented in EHRs
☐ other: Click here to describe	☐ other: Click here to describe

1.2. If an existing dataset was used, identify the specific dataset (*the dataset used for testing must be consistent with the measure specifications for target population and healthcare entities being measured; e.g., Medicare Part A claims, Medicaid claims, other commercial insurance, nursing home MDS, home health OASIS, clinical registry*).

We tested the measure using 2010 - 2013 Medicare fee-for-service (FFS) data from the 100% samples from the Outpatient Standard Analytic File (SAF-O), Inpatient Standard Analytic File (SAF-I), and Carrier File.

a. Datasets used to define the initial patient population (denominator):
   - *SAF-O:* The initial patient population was defined based on the 2013 100% SAF-O file. The initial patient population includes all claims for a cardiac imaging study from January 1, 2013 – December 1, 2013, provided in a hospital outpatient setting. This dataset also includes unique patient and facility identifiers.
   - *Enrollment database and denominator files:* This dataset contains Medicare FFS enrollment, demographic, and death information for patients identified in the above file.
   - *Provider of services (POS) file:* The POS file contains data on facility characteristics including urbanicity, bed count, and teaching status.

b. Datasets used to capture the numerator:
   - *SAF-O and Carrier:* For patients included in the initial patient population, numerator cases are identified by searching the 2013 100% SAF-O and Carrier files for one or more claims for low-risk, non-cardiac surgery in the 30 days following the cardiac imaging study.

c. Datasets used to identify measure exclusions:

- *SAF-O, SAF-I, and Carrier:* For patients included in the initial patient population, denominator exclusions are identified by searching the 2010 – 2013 100% SAF-O, SAF-I, and Carrier files for risk factor diagnoses in the three years preceding the cardiac imaging study.

1.3. What are the dates of the data used in testing? 2010-2013

1.4. What levels of analysis were tested? (*testing must be provided for all the levels specified and intended for measure implementation, e.g., individual clinician, hospital, health plan*)

Measure Specified to Measure Performance of: (***must be consistent with levels entered in item S.26***)	**Measure Tested at Level of:**
☐ individual clinician	☐ individual clinician
☐ group/practice	☐ group/practice
☒ hospital/facility/agency	☒ hospital/facility/agency
☐ health plan	☐ health plan
☒ other: state, national	☒ other: state, national

1.5. How many and which measured entities were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of measured entities included in the analysis (e.g., size, location, type); if a sample was used, describe how entities were selected for inclusion in the sample*)
The number of measured entities (hospital outpatient departments) varies by testing type; see Section **1.7** for details.

1.6. How many and which patients were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of patients included in the analysis (e.g., age, sex, race, diagnosis); if a sample was used, describe how patients were selected for inclusion in the sample*)
The number of patients varies by testing type; see Section **1.7** for details.

1.7. If there are differences in the data or sample used for different aspects of testing (e.g., reliability, validity, exclusions, risk adjustment), identify how the data or sample are different for each aspect of testing reported below.
The data sources, dates, number of measured entities, number of cardiac imaging studies, number of surgeries, level of analysis, and demographic profile for the patients used in each type of testing are as follows:

Reliability Testing
Data Source: Denominator: SAF-O; Numerator: SAF-O and Carrier; Exclusions: SAF-O, SAF-I, and Carrier
Dates: Denominator: January 1, 2013 – December 1, 2013; Numerator: January 1, 2013 – December 31, 2013; Exclusions: January 1, 2010 – December 1, 2013
Number of Facilities: 2,759
Number of Cardiac Imaging Studies: 1,042,496
Number of Surgeries: 53,579
Level of Analysis: Facility
Patient Characteristics: Gender (% Male): 46.4; Median Age (Years): 70.3 (St. Dev.: 10.2); Race/Ethnicity (% Minority): 14.9

Validity Testing
Data Source: Structured qualitative survey questions completed by Technical Expert Panel members

Date Collected: June 2015
Number of Responses: 7
Respondent Characteristics: Respondents were asked to select at least one of the following categories: insurer/purchaser (2); clinician (4); management/administration (2); patient/patient advocate/caregiver (3).

Exclusions Analysis
Data Source: Denominator: SAF-O; Numerator: SAF-O and Carrier; Exclusions: SAF-O, SAF-I, and Carrier
Dates: Denominator: January 1, 2013 – December 1, 2013; Numerator: January 1, 2013 – December 31, 2013; Exclusions: January 1, 2010 – December 1, 2013
Number of Facilities: 2,770
Number of Cardiac Imaging Studies: 1,043,534
Number of Surgeries: 53,824
Level of Analysis: Observation, Facility
Patient Characteristics: Gender (% Male): 46.4; Median Age (Years): 70.2 (St. Dev.: 10.2); Race/Ethnicity (% Minority): 14.9

Risk Adjustment/Stratification
N/A

Identification of Statistically Significant & Meaningful Differences in Performance
Data Source: Denominator: SAF-O; Numerator: SAF-O and Carrier; Exclusions: SAF-O, SAF-I, and Carrier
Dates: Denominator: January 1, 2013 – December 1, 2013; Numerator: January 1, 2013 – December 31, 2013; Exclusions: January 1, 2010 – December 1, 2013
Number of Facilities: 2,759
Number of Cardiac Imaging Studies: 1,042,496
Number of Surgeries: 53,579
Level of Analysis: Facility
Patient Characteristics: Gender (% Male): 46.4; Median Age (Years): 70.3 (St. Dev.: 10.2); Race/Ethnicity (% Minority): 14.9

Comparability of Performance Scores when more than one Set of Specifications
N/A

Missing Data Analysis and Minimizing Bias
N/A

1.8 What were the patient-level sociodemographic (SDS) variables that were available and analyzed in the data or sample used? For example, patient-reported data (e.g., income, education, language), proxy variables when SDS data are not collected from each patient (e.g. census tract), or patient community characteristics (e.g. percent vacant housing, crime rate).

2a2. RELIABILITY TESTING
Note*: If accuracy/correctness (validity) of data elements was empirically tested, separate reliability testing of data elements is not required – in 2a2.1 check critical data elements; in 2a2.2 enter "see section 2b2 for validity testing of data elements"; and skip 2a2.3 and 2a2.4.*

2a2.1. What level of reliability testing was conducted? (*may be one or both levels*)
☐ **Critical data elements used in the measure** (*e.g., inter-abstractor reliability; data element reliability must address ALL critical data elements*)
☒ **Performance measure score** (e.g., *signal-to-noise analysis*)

2a2.2. For each level checked above, describe the method of reliability testing and what it tests (*describe the steps—do not just name a method; what type of error does it test; what statistical analysis was used*)
Reliability was calculated using two tests. We first assessed the ability of the measure to identify statistical outliers. As a secondary assessment, we calculate reliability in accordance with the methods discussed in *The Reliability of Provider Profiling: A Tutorial* (2009). The reliability testing calculates the ability of the measure to distinguish between the performance of different facilities. Specifically, the testing calculated the signal-to-noise ratio for each facility meeting the minimum case count in 2013. The reliability score is estimated using a beta-binomial model, which is appropriate for the reliability testing of pass/fail measures. The reliability score for each facility is a function of the facility's sample size and score on the measure, and the variance across facilities.

Reference:
Adams JL. The reliability of provider profiling: a tutorial. Santa Monica, CA: RAND Corporation. 2009. Retrieved from http://www.rand.org/pubs/technical_reports/TR653.

2a2.3. For each level of testing checked above, what were the statistical results from reliability testing?
(e.*g., percent agreement and kappa for the critical data elements; distribution of reliability statistics from a signal-to-noise analysis*)
Of the 2,759 facilities in 2013 meeting the minimum case count, 137 (5.0 percent) facilities had a performance value that was statistically significantly different from the weighted mean (or benchmark value). Statistically meaningful difference was defined as when the facility score fell outside of the confidence interval (± 1.96 standard deviations) for the measure mean (benchmark value).

Figure 1 (below) is a histogram of the distribution of the reliability scores for the facilities meeting the minimum case count in 2013. Reliability scores ranged from 4.9 percent to 100.0 percent, with a median reliability score of 43.0 percent.

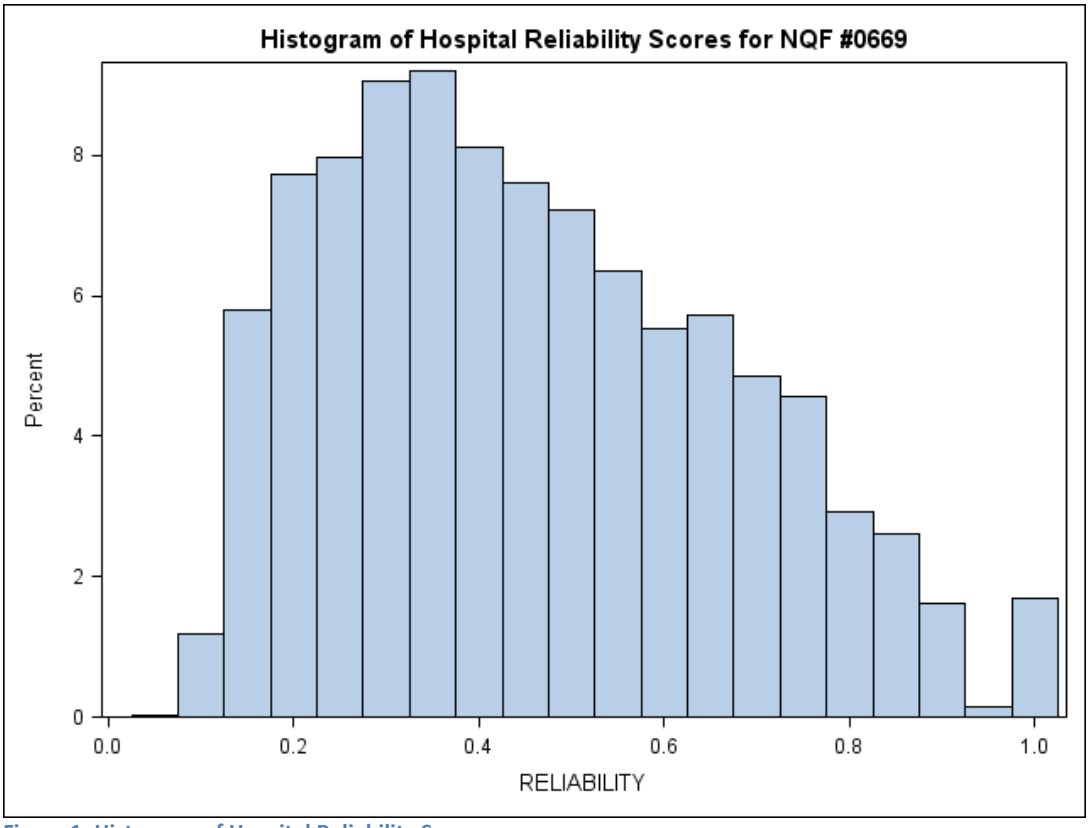

Figure 1: Histogram of Hospital Reliability Scores

2a2.4 What is your interpretation of the results in terms of demonstrating reliability? (i.*e., what do the results mean and what are the norms for the test conducted?*)
As the intent of the measure is to identify differences from the mean (or threshold value), the ability of the measure to identify statistical outliers is indicative of strong reliability. As noted above, 137 facilities were classified as outliers in 2013, indicating that these facilities had a rate of overuse that was statistically significant and meaningfully different from the measure mean.

Calculated using a beta-binomial model, a median reliability score of 43.0 percent is indicative of moderate measure reliability and further supports the findings of the test to identify statistical outliers. A beta-binomial model is intended to assess the ability of the measure to identify true differences in performance between individual facilities.

2b2. VALIDITY TESTING

2b2.1. What level of validity testing was conducted? (*may be one or both levels*)

☐ **Critical data elements** (*data element validity must address ALL critical data elements*)

☒ **Performance measure score**

☐ **Empirical validity testing**

☒ **Systematic assessment of face validity of performance measure score as an indicator** of quality or resource use (*i.e., is an accurate reflection of performance on quality or resource use and can distinguish good from poor performance*)

2b2.2. For each level of testing checked above, describe the method of validity testing and what it tests (*describe the steps—do not just name a method; what was tested, e.g., accuracy of data elements compared to authoritative source, relationship to another measure as expected; what statistical analysis was used)*
Face validity of the measure score was systematically assessed through survey of the Technical Expert Panel (TEP). Seven TEP members participated in the data collection. Respondent perspectives include insurers/purchasers, clinicians, management or administration, patients/patient advocates, and caregivers. Prior to responding to questions related to measure-score and data-element face validity, TEP members were provided detailed measure specifications.

The following questions and statements related to measure-score face validity were posed to the TEP:
1. To gather data, the measure uses claims to look 30 days forward from the date of the cardiac imaging test to determine if the patient had a low-risk surgery. Thirty days is an appropriate time period to capture a surgery related to the preoperative imaging test.
2. This measure helps assess the inappropriate use of pre-operative cardiac imaging.

Data-element face validity was also assessed, using the following questions and statements:
1. The following tests can be accurately captured using claims data: stress echocardiography, SPECT MPI, and stress MRI.
2. Do you foresee any challenges in capturing any of these exclusions in claims data?
3. For this measure, indications for measure exclusion include any patients with diagnosis codes from the following categories: diabetes mellitus, renal insufficiency, stroke or transient ischemic attack, prior heart failure, or ischemic heart disease. Please indicate how well the following patient exclusions identify high-risk patients.

Responses to questions *1* and *2* in the measure-score face-validity section and question *1* in the data-element face-validity section were collected using a five-point scale: strongly agree, agree, undecided, disagree, strongly disagree, and do not know. For data-element face validity, responses to question *2* were collected using yes/no response options; responses to question *3* were collected using keep/remove response options.

2b2.3. What were the statistical results from validity testing? (*e.g., correlation; t-test*)
Results of the face-validity assessment indicate that a diverse group of stakeholders, a majority of whom were not involved in the measure's development, support the validity of the measure. Results for each of the questions provided above follow.

Measure-Score Face Validity

1. *To gather data, the measure uses claims to look 30 days forward from the date of the cardiac imaging test to determine if the patient had a low-risk surgery. Thirty days is an appropriate time period to capture a surgery related to the preoperative imaging test.*

Response Option	Response Percentage	Response Count
Strongly Agree	42.9%	3
Agree	28.6%	2
Undecided	0.0%	0
Disagree	0.0%	0
Strongly Disagree	0.0%	0
Do Not Know or Not Applicable	28.6%	2

2. *This measure helps assess the inappropriate use of pre-operative cardiac imaging.*

Response Option	Response Percentage	Response Count
Strongly Agree	42.9%	3
Agree	28.6%	2
Undecided	14.3%	1
Disagree	0.0%	0
Strongly Disagree	0.0%	0
Do Not Know or Not Applicable	14.3%	1

Data-Element Face Validity

1a. The following test can be accurately captured using claims data: stress echocardiography

Response Option	Response Percentage	Response Count
Strongly Agree	42.9%	3
Agree	42.9%	3
Undecided	0.0%	0
Disagree	0.0%	0
Strongly Disagree	0.0%	0
Do Not Know or Not Applicable	14.3%	1

1b. The following test can be accurately captured using claims data: SPECT MPI

Response Option	Response Percentage	Response Count
Strongly Agree	42.9%	3
Agree	42.9%	3
Undecided	0.0%	0

Disagree	0.0%	0
Strongly Disagree	0.0%	0
Do Not Know or Not Applicable	14.3%	1

1c. The following test can be accurately captured using claims data: stress MRI

Response Option	Response Percentage	Response Count
Strongly Agree	42.9%	3
Agree	42.9%	3
Undecided	0.0%	0
Disagree	0.0%	0
Strongly Disagree	0.0%	0
Do Not Know or Not Applicable	14.3%	1

2. *Do you foresee any challenges in capturing any of these exclusions in claims data?*

Response Option	Response Percentage	Response Count
No	71.4%	5
Not Sure/ Do Not Know	14.3%	1
Yes (please explain)	14.3%	1: ICD-9 is not robust enough to capture all of the clinical nuances that would be required to differentiate which of these patients should be excluded.

3. *For this measure, indications for measure exclusion include any patients with diagnosis codes from the following categories: diabetes mellitus, renal insufficiency, stroke or transient ischemic attack, prior heart failure, or ischemic heart disease. Please indicate how well the following patient exclusions identify high-risk patients.*

Exclusion	Keep this Exclusion	Remove this Exclusion	Do Not Know/ Not Applicable
Diabetes mellitus	2	2	3
Renal insufficiency	3	1	3
Stroke or transient ischemic attack	3	0	4
Prior heart failure	3	0	4
Ischemic heart disease	3	0	4

2b2.4. What is your interpretation of the results in terms of demonstrating validity? (i.*e., what do the results mean and what are the norms for the test conducted?*)

The face validity of this measure was evaluated by our Technical Expert Panel. Results for four of the questions listed above indicate that the measure is appropriately specified. Seventy-one percent of respondents believe the 30-day window used to look forward for a low-risk, non-cardiac surgery from the date of the imaging procedure accurately captures imaging related to pre-surgical testing. Eighty-six percent of those who responded believe

stress echocardiography, SPECT MPI, and stress MRI are accurately captured using claims data. Seventy-one percent of respondents believe the exclusions are accurately captured using claims data.

For one question listed above, no consensus was reached related to which clinical conditions should be excluded from the measure; this lack of consensus was driven by *do not know* responses. For both this question (and for others for which a response of *Do Not Know* was selected), respondents did not have feel they had the clinical knowledge to provide a definitive response. Though TEP members did not reach consensus for this question, related to the clinical conditions to be excluded from the measure, evidence from the literature and data included in Section **2b3** support continued exclusion of these five clinical categories. The European Society of Cardiology recommends stress testing only in patients with three or more clinical risk factors for cardiac complications after surgery, in accordance with Lee Index preoperative risk stratification model.

Historically, measures that rely on claims data for calculation of performance are assumed to have strong face validity. This assumption of face validity is due in part to the rigor with which data are cleaned and audited prior to payment and subsequent use in measure calculation. For other public reporting programs for which payment is adjusted based on provider performance, few concerns about use of claims data for face validity have been raised.

2b3. EXCLUSIONS ANALYSIS

NA ☐ no exclusions — *skip to section 2b4*

2b3.1. Describe the method of testing exclusions and what it tests (*describe the steps—do not just name a method; what was tested, e.g., whether exclusions affect overall performance scores; what statistical analysis was used*)

We tested measure exclusions to determine the prevalence of each exclusion, by facility, and at an aggregate level. We also tested the aggregate risk factor exclusion to determine the effect on facility performance score, both by reporting summary statistics and by calculating a spearman rank correlation coefficient. The analysis tested the following categories of measure exclusions using 2013 performance data:

- Diabetes
- Renal insufficiency
- Stroke or transient ischemic attack
- Prior heart failure
- Ischemic heart disease
- Three or more of the above risk factors

Currently, the measure excludes patients with three or more of the listed risk factors in the prior three years, in accordance with the Lee Index (European Society of Cardiology, 2009).

Reference:

European Society of Cardiologists. Guidelines for pre-operative cardiac risk assessment and perioperative cardiac management in non-cardiac surgery. Eur Heart J. 2009; 30: 2769–812.

2b3.2. What were the statistical results from testing exclusions? (*include overall number and percentage of individuals excluded, frequency distribution of exclusions across measured entities, and impact on performance measure scores*)

We examined overall frequencies and proportions of the studies excluded for each exclusion criterion in all cardiac imaging studies for a sample of 2,770 facilities meeting the minimum case count in 2013 if no exclusions were imposed. The initial patient population included 647,957 cardiac imaging studies. The final initial patient population included 633,195 cardiac imaging studies. The total number of exclusion occurrences exceeded the number of studies excluded because a single patient might meet multiple exclusion criteria.

Exclusion	Overall Occurrence (N)	Overall Occurrence (%)	Distribution Across Facilities (%)		
			25th	50th	75th
Diabetes	461,534	44.2	38.6	43.8	50.0
Renal Insufficiency	292,409	28.0	22.9	27.2	31.9
Stroke or Transient Ischemic Attack	338,431	32.4	25.9	30.9	36.6
Prior Heart Failure	449,600	43.1	35.1	41.7	49.2
Ischemic Heart Disease	643,962	61.7	50.9	58.7	67.2
Any three of the risk factors	395,577	37.9	29.9	36.4	43.6

Additionally, we calculated descriptive statistics for the measure scores of each facility, with and without the exclusion for patients with three or more risk factors.

Descriptive Statistic	With Exclusions (%)	Without Exclusions (%)
Minimum	0.0	0.0
Maximum	22.1	23.0
Mean	4.9	5.1
Standard Deviation	2.3	2.2
25th Percentile	3.4	3.7
50th Percentile (Median)	4.7	4.9
75th Percentile	6.2	6.3

Finally, we calculated a spearman rank correlation coefficient for facility score with and without the exclusion for patients with three or more risk factors:

$r_S = 0.8304$
$p = 0.0000$

2b3.3. What is your interpretation of the results in terms of demonstrating that exclusions are needed to prevent unfair distortion of performance results? (*i.e., the value outweighs the burden of increased data collection and analysis.* <u>*Note*</u>*:* ***If patient preference is an exclusion****, the measure must be specified so that the effect on the performance score is transparent, e.g., scores with and without exclusion*)

The frequency of the exclusion for patients with three or more risk factors varied substantially across facilities (IQR: 13.7 percent). While median performance does not change significantly, exclusion of these patients is appropriate, as inclusion would noticeably alter the initial patient population for select facilities. As noted in the 2009 European Society of Cardiology guideline, patients risk should be determined by evaluating clinical risk factors, test results and intensity of the planned surgical procedure to arrive at an individualized cardiac risk assessment. Using the six-variable Lee Index preoperative risk stratification model, the European Society of Cardiology recommends stress testing only in patients with three or more clinical risk factors for cardiac complications after surgery. The six clinical risk factors used for preoperative cardiac risk stratification in the Lee Index model are:

- IHD (angina pectoris and/or MI)
- Surgical risk: high-risk surgery
- Heart failure
- Stroke/transient ischemic attack
- Diabetes mellitus requiring insulin therapy
- Renal dysfunction/hemodialysis

2b4. RISK ADJUSTMENT/STRATIFICATION FOR OUTCOME OR RESOURCE USE MEASURES

If not an intermediate or health outcome, or PRO-PM, or resource use measure, skip to section 2b5.

2b4.1. What method of controlling for differences in case mix is used?

☒ **No risk adjustment or stratification**

☐ **Statistical risk model with** Click here to enter number of factors **risk factors**

☐ **Stratification by** Click here to enter number of categories **risk categories**

☐ **Other,** Click here to enter description

2b4.2. If an outcome or resource use measure is not risk adjusted or stratified, provide rationale and analyses to demonstrate that controlling for differences in patient characteristics (case mix) is not needed to achieve fair comparisons across measured entities.

This measure is a process measure for which we provide no risk adjustment or risk stratification. We determined risk adjustment and risk stratification were not appropriate based on the measure evidence base and the measure construct. During the measure development and maintenance process, we performed an annual review of the literature, which included a scan for potential patient subpopulations for which there are differences in the clinical decision to perform cardiac imaging prior to low-risk, non-cardiac surgery; this review identified no clear evidence of an empirical relationship between sociodemographic status (SDS) and facility-level measure performance.

In addition to the evidence gathered from the literature, stakeholder feedback obtained during the four years of implementation and public reporting has not identified concerns related to SDS factors and need for risk adjustment. This supports the conceptual model upon which the measure is based. As a process-of-care measure, the decision to image a patient prior to surgery should not be influenced by SDS factors; rather, adjustment would risk masking such important inequities in care delivery. Variation across patient populations is reflective of differences in the quality of care provided to the disparate patient population included in the measure's denominator.

2b4.3. Describe the conceptual/clinical and statistical methods and criteria used to select patient factors (clinical factors or sociodemographic factors) used in the statistical risk model or for stratification by risk (*e.g., potential factors identified in the literature and/or expert panel; regression analysis; statistical significance of p<0.10; correlation of x or higher; patient factors should be present at the start of care*)

No risk adjustment or stratification was performed.

2b4.4a. What were the statistical results of the analyses used to select risk factors?

No risk adjustment or stratification was performed.

2b4.4b. Describe the analyses and interpretation resulting in the decision to select SDS factors (e.g. prevalence of the factor across measured entities, empirical association with the outcome, contribution of unique variation in the outcome, assessment of between-unit effects and within-unit effects)

No risk adjustment or stratification was performed.

2b4.5. Describe the method of testing/analysis used to develop and validate the adequacy of the statistical model or stratification approach (*describe the steps—do not just name a method; what statistical analysis was used*)
Provide the statistical results from testing the approach to controlling for differences in patient characteristics (case mix) below.
No risk adjustment or stratification was performed.

2b4.6. Statistical Risk Model Discrimination Statistics (*e.g., c-statistic, R-squared*)**:**
No risk adjustment or stratification was performed.

2b4.7. Statistical Risk Model Calibration Statistics (*e.g., Hosmer-Lemeshow statistic*):
No risk adjustment or stratification was performed.

2b4.8. Statistical Risk Model Calibration – Risk decile plots or calibration curves:
No risk adjustment or stratification was performed.

2b4.9. Results of Risk Stratification Analysis:
No risk adjustment or stratification was performed.

2b4.10. What is your interpretation of the results in terms of demonstrating adequacy of controlling for differences in patient characteristics (case mix)? (i.*e., what do the results mean and what are the norms for the test conducted*)
No risk adjustment or stratification was performed.

2b4.11. Optional Additional Testing for Risk Adjustment (*not required, but would provide additional support of adequacy of risk model, e.g., testing of risk model in another data set; sensitivity analysis for missing data; other methods that were assessed*)
No risk adjustment or stratification was performed.

2b5. IDENTIFICATION OF STATISTICALLY SIGNIFICANT & MEANINGFUL DIFFERENCES IN PERFORMANCE

2b5.1. Describe the method for determining if statistically significant and clinically/practically meaningful differences in performance measure scores among the measured entities can be identified (*describe the steps—do not just name a method; what statistical analysis was used? Do not just repeat the information provided related to performance gap in 1b)*
The measure calculation contractor takes a number of steps to ensure precision and accuracy of publicly reported values. One step in this process is through application of a minimum case count to exclude facilities that do not perform a high volume of services contained within the measure's specifications. In the situation where a facility provides only a handful of the relevant services that are eligible for this measure, the results of the measure may be significantly impacted and skewed by one or two cases. Minimum case count requirements were developed for each facility in order to assure a 90 percent confidence level for the observed facility rate. There are two different processes for determining required case counts depending on whether the facility rate is less than 0.05 or greater than 0.95 (i.e., towards the end of the range of possible rate values), or somewhere between 0.05 and 0.95 (inclusive). Each process has three steps: (1) determine reasonable levels of precision; (2) determine the level of confidence to be required for the measures; and, (3) calculate the case counts needed to meet the precision requirements. For facility rates less than 0.05 or greater than 0.95, the case count needed to attain the required precision was calculated to be 45 cases. For facility rates between 0.05 and 0.95, the case count needed to attain the required precision ranges from 31 to 67 cases. For more details on the minimum case count requirements determinations, please see the supplemental materials.

Following the application of the minimum case count, we also tested the statistical significance of the difference between facility performance scores and the mean performance value. For the 2013 data, this included 2,383 facilities. For each facility, the facility performance score and standard deviation was calculated. This analysis identified more than 130 facilities as statistical outliers. Additional details of this analysis are provided in Section **2b5.2**.

Methodology explaining the minimum case count calculations for this measure can be found at https://www.qualitynet.org/dcs/BlobServer?blobkey=id&blobnocache=true&blobwhere=1228889854907&blobheader=multipart%2Foctet-stream&blobheadername1=Content-Disposition&blobheadervalue1=attachment%3Bfilename%3D2012_OIE_MCC.pdf&blobcol=urldata&blobtable=MungoBlobs.

2b5.2. What were the statistical results from testing the ability to identify statistically significant and/or clinically/practically meaningful differences in performance measure scores across measured entities? (e.g., *number and percentage of entities with scores that were statistically significantly different from mean or some benchmark, different from expected; how was meaningful difference defined*)
Of the 2,759 facilities in 2013 meeting the minimum case count, 137 (5.0 percent) facilities had a performance value that was statistically significantly different from the weighted mean (or benchmark value). Statistically meaningful difference was defined as when the facility score fell outside of the confidence interval (± 1.96 standard deviations) for the measure mean (benchmark value). Thus, this calculation identifies statistical outliers.

2b5.3. What is your interpretation of the results in terms of demonstrating the ability to identify statistically significant and/or clinically/practically meaningful differences in performance across measured entities? (i.*e., what do the results mean in terms of statistical and meaningful differences?*)
Analysis of the 2013 performance data, and the subsequent rate of identification of statistically different performance for 7.4 percent of measured entities, demonstrates the ability of the measure to identify outlying performance. While many facilities have converged around a performance score of between 4 and 5 percent, more than 7 percent of facilities continue to have outlying performance. By reporting a measure mean (benchmark value), this provides an opportunity for outlying facilities to identify their high rate of overuse and work to implement quality improvement mechanisms to reduce the rate of overuse of cardiac imaging studies.

2b6. COMPARABILITY OF PERFORMANCE SCORES WHEN MORE THAN ONE SET OF SPECIFICATIONS

If only one set of specifications, this section can be skipped.

Note: *This criterion is directed to measures with more than one set of specifications/instructions (e.g., one set of specifications for how to identify and compute the measure from medical record abstraction and a different set of specifications for claims or eMeasures). It does not apply to measures that use more than one source of data in one set of specifications/instructions (e.g., claims data to identify the denominator and medical record abstraction for the numerator).* ***If comparability is not demonstrated, the different specifications should be submitted as separate measures.***

2b6.1. Describe the method of testing conducted to demonstrate comparability of performance scores for the same entities across the different data sources/specifications (*describe the steps—do not just name a method; what statistical analysis was used*)
This measure only uses one set of specifications.

2b6.2. What were the statistical results from testing comparability of performance scores for the same entities when using different data sources/specifications? (*e.g., correlation, rank order*)
This measure only uses one set of specifications.

2b6.3. What is your interpretation of the results in terms of demonstrating comparability of performance measure scores for the same entities across the different data sources/specifications? (i.*e., what do the results mean and what are the norms for the test conducted*)
This measure only uses one set of specifications.

2b7. MISSING DATA ANALYSIS AND MINIMIZING BIAS

2b7.1. Describe the method of testing conducted to identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias (*describe the steps—do not just name a method; what statistical analysis was used*)
This measure is calculated from claims data submitted by facilities for purposes of payment. The administrative claims data used to calculate the measure are maintained by CMS's Office of Information Services; these data undergo additional quality assurance checks during measure development and maintenance. Thus, the analytic files used for measure testing and measure calculation include post-adjudicated claims, and do not include missing data.

2b7.2. What is the overall frequency of missing data, the distribution of missing data across providers, and the results from testing related to missing data? (*e.g., results of sensitivity analysis of the effect of various rules for missing data/nonresponse; if no empirical sensitivity analysis, identify the approaches for handling missing data that were considered and pros and cons of each*)
As described in Section **2b7.1**, the analytic files used for measure testing and measure calculation include post-adjudicated claims, and do not include missing data.

2b7.3. What is your interpretation of the results in terms of demonstrating that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias**?** (i.*e., what do the results mean in terms of supporting the selected approach for missing data and what are the norms for the test conducted; if no empirical analysis, provide rationale for the selected approach for missing data*)
As described in Section **2b7.1**, the analytic files used for measure testing and measure calculation include post-adjudicated claims, and do not include missing data. As such, missing data does not bias the performance results.

3. Feasibility

Extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

3a. Byproduct of Care Processes
For clinical measures, the required data elements are routinely generated and used during care delivery (e.g., blood pressure, lab test, diagnosis, medication order).

3a.1. **Data Elements Generated as Byproduct of Care Processes.**
Coded by someone other than person obtaining original information (e.g., DRG, ICD-9 codes on claims)
If other:

3b. Electronic Sources
The required data elements are available in electronic health records or other electronic sources. If the required data are not in electronic health records or existing electronic sources, a credible, near-term path to

electronic collection is specified.

3b.1. To what extent are the specified data elements available electronically in defined fields? *(i.e., data elements that are needed to compute the performance measure score are in defined, computer-readable fields)*
ALL data elements are in defined fields in electronic claims

3b.2. If ALL the data elements needed to compute the performance measure score are not from electronic sources, specify a credible, near-term path to electronic capture, OR provide a rationale for using other than electronic sources.

3b.3. If this is an eMeasure, provide a summary of the feasibility assessment in an attached file or make available at a measure-specific URL.
Attachment:

3c. Data Collection Strategy

Demonstration that the data collection strategy (e.g., source, timing, frequency, sampling, patient confidentiality, costs associated with fees/licensing of proprietary measures) can be implemented (e.g., already in operational use, or testing demonstrates that it is ready to put into operational use). For eMeasures, a feasibility assessment addresses the data elements and measure logic and demonstrates the eMeasure can be implemented or feasibility concerns can be adequately addressed.

3c.1. Describe what you have learned/modified as a result of testing and/or operational use of the measure regarding data collection, availability of data, missing data, timing and frequency of data collection, sampling, patient confidentiality, time and cost of data collection, other feasibility/implementation issues.
IF a PRO-PM, consider implications for both individuals providing PROM data (patients, service recipients, respondents) and those whose performance is being measured.
This measure is claims based and uses CMS hospital outpatient claims as its data source.

Special attention needs to be taken when counting procedures on the Medicare claims files. The biggest issue is how to deal with modifier codes. Modifiers are two digit indicators (alpha or numeric) that represent a service or procedure that has been altered by some specific circumstance, which typically will impact the payment amount.

Procedure modifier code “26” represents the professional component of a procedure and includes the clinician work (i.e., the reading of the image by a physician), associated overhead and professional liability insurance costs. This modifier corresponds to the human involvement in a given service or procedure.

The procedure modifier code “TC” represents the technical component of a service or procedure and includes the cost of equipment and supplies to perform that service or procedure. This modifier corresponds to the equipment/facility part of a given service or procedure.

In most cases, unmodified codes represent a global procedure which includes both the professional and technical components. There are also other modifier codes. All other modifier codes have been counted as a technical code for our purposes. When calculating the measures, we are only concerned with procedures associated with technical and global modifiers, as these modifiers refer to services provided by the facility. This reduces the possibility of double-counting procedures, since a single procedure may result in both a technical and professional record on the claims files. There were very few instances when this occurred as it related to procedures applicable to the measure.

When developing counts of procedures, the objective is to avoid double-counting procedures that may have been billed through multiple revenue centers within a facility. Billing through multiple centers leads to multiple records in the Medicare claims files (i.e., the SAFs). For instance, there may be multiple bills for a single SPECT MPI. On one bill, the charges relate to the application of a radiopharmaceutical, which could have a technical modifier code and come from the pharmacy revenue center. On the other bill, the charges relate to the imaging study and may fall under a technical bill from the imaging center revenue center. In this case, we only count the SPECT MPI once, since only one SPECT MPI was performed. However, if we were summing up the Medicare paid amounts for this procedure, we would include the Medicare paid amounts from both bills, as they each represent payments for

services directly related to the particular SPECT MPI procedure.

3c.2. **Describe any fees, licensing, or other requirements to use any aspect of the measure as specified** *(e.g., value/code set, risk model, programming code, algorithm)*.
No fees, licensure, or other requirements are necessary to use this measure; however, CPT codes, descriptions, and other data are copyright 2013 American Medical Association. All rights reserved. CPT is a registered trademark of the American Medical Association. Applicable FARS\DFARS Restrictions Apply to Government Use. Fee schedules, relative value units, conversion factors, and/or related components are not assigned by the AMA, are not part of CPT, and the AMA is not recommending their use. The AMA does not directly or indirectly practice medicine or dispense medical services. The AMA assumes no liability for data contained or not contained herein.

4. Usability and Use

Extent to which potential audiences (e.g., consumers, purchasers, providers, policy makers) are using or could use performance results for both accountability and performance improvement to achieve the goal of high-quality, efficient healthcare for individuals or populations.

4a. Accountability and Transparency

Performance results are used in at least one accountability application within three years after initial endorsement and are publicly reported within six years after initial endorsement (or the data on performance results are available). If not in use at the time of initial endorsement, then a credible plan for implementation within the specified timeframes is provided.

4.1. **Current and Planned Use**

NQF-endorsed measures are expected to be used in at least one accountability application within 3 years and publicly reported within 6 years of initial endorsement in addition to performance improvement.

Planned	Current Use (for current use provide URL)
	Public Reporting Hospital Outpatient Quality Reporting http://www.medicare.gov/hospitalcompare/search.html Hospital Outpatient Quality Reporting https://www.qualitynet.org/dcs/ContentServer?c=Page&pagename=QnetPublic%2FPage%2FQnetTier2&cid=1228695266120 Quality Improvement with Benchmarking (external benchmarking to multiple organizations) Hospital Outpatient Quality Reporting http://www.medicare.gov/hospitalcompare/search.html Hospital Outpatient Quality Reporting https://www.qualitynet.org/dcs/ContentServer?c=Page&pagename=QnetPublic%2FPage%2FQnetTier2&cid=1228695266120

4a.1. **For each CURRENT use, checked above, provide:**

- Name of program and sponsor
- Purpose
- Geographic area and number and percentage of accountable entities and patients included

Public Reporting:
Name of program and sponsor: The CMS Hospital Outpatient Quality Reporting (HOQR) Program
Purpose: The HOQR Program is a pay for quality data reporting program implemented by CMS for outpatient hospital services. In addition to providing hospitals with a financial incentive to report their quality of care measure data, the HOQR Program provides CMS with data to help Medicare beneficiaries make more informed decisions about their health care. Hospital quality of care information gathered through the HOQR Program is publicly available on the Hospital Compare website.
Accountable entities and patients: The publicly reported values (on Hospital Compare) are calculated for all facilities in the United States that meet minimum case count requirements. For the period of 2009 to 2014, 1,953 facilities met the minimum case count each year. Additional facilities met the minimum case count requirements in some, but not all, years. The claims included in the publicly reported calculations are for Medicare FFS patients whose claims are subject to the Outpatient Prospective Payment System

(OPPS).

Quality Improvement with Benchmarking (external benchmarking to multiple organizations):
Name of program and sponsor: The CMS HOQR Program
Purpose: The HOQR Program is a pay for quality data reporting program implemented by CMS for outpatient hospital services. In addition to providing hospitals with a financial incentive to report their quality of care measure data, the data is publicly reported on the Hospital Compare Website. The data reported on Hospital Compare not only shows the hospital's score on the measure, but also provides state and national averages for the measure. This enables consumers to compare the hospital's performance to other facilities and determine if the facility is an outlier.
Accountable entities and patients: The publicly reported values (on Hospital Compare) are calculated for all facilities in the United States that meet minimum case count requirements. For the period of 2009 to 2014, 1,953 facilities met the minimum case count each year. Additional facilities met the minimum case count requirements in some, but not all, years. The claims included in the publicly reported calculations are for Medicare FFS patients whose claims are subject to the OPPS.

4a.2. **If not currently publicly reported OR used in at least one other accountability application (e.g., payment program, certification, licensing) what are the reasons?** (*e.g., Do policies or actions of the developer/steward or accountable entities restrict access to performance results or impede implementation?*)
This measure is publicly reported.

4a.3. **If not currently publicly reported OR used in at least one other accountability application, provide a credible plan for implementation within the expected timeframes -- any accountability application within 3 years and publicly reported within 6 years of initial endorsement.** (*Credible plan includes the specific program, purpose, intended audience, and timeline for implementing the measure within the specified timeframes. A plan for accountability applications addresses mechanisms for data aggregation and reporting.*)
This measure is publicly reported.

4b. Improvement

Progress toward achieving the goal of high-quality, efficient healthcare for individuals or populations is demonstrated. If not in use for performance improvement at the time of initial endorsement, then a credible rationale describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.

4b.1. **Progress on Improvement. (Not required for initial endorsement unless available.)**
Performance results on this measure (current and over time) should be provided in 1b.2 and 1b.4. Discuss:

- **Progress (trends in performance results, number and percentage of people receiving high-quality healthcare)**
- **Geographic area and number and percentage of accountable entities and patients included**

Summary statistics for performance scores from 2009 - 2014 are provided in Section 1b.2.

The median rate of overuse increased from 2009 to 2011 (4.92 percent to 5.50 percent); however, the rate of overuse has declined since that point. From July 2013 – June 2014 the median rate of overuse fell to 4.88 percent. Over the period of January 2009 – June 2014, 1,953 facilities met the minimum case count to be eligible for public reporting in all years. Additional facilities met the minimum case count requirements in some, but not all, years. During the July 2012-June 2013 reporting period, there were more than 45,000 inappropriate cardiac imaging studies performed for Medicare FFS beneficiaries. This number fell to approximately 28,000 potentially inappropriate imaging studies in the most recent year of publicly reported data, July 2013-June 2014.

4b.2. **If no improvement was demonstrated, what are the reasons? If not in use for performance improvement at the time of initial endorsement, provide a credible rationale that describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.**
Not applicable as there is demonstrated improvement in measure performance.

4c. Unintended Consequences

The benefits of the performance measure in facilitating progress toward achieving high-quality, efficient healthcare for individuals or populations outweigh evidence of unintended negative consequences to individuals or populations (if such evidence exists).

4c.1. **Were any unintended negative consequences to individuals or populations identified during testing; OR has evidence of unintended negative consequences to individuals or populations been reported since implementation? If so, identify the negative unintended consequences and describe how benefits outweigh them or actions taken to mitigate them.**
We did not identify any unintended consequences during measure testing. Similarly, no evidence of unintended consequences to

individuals or populations have been reported since implementation. We will continue to monitor the potential for unintended consequences through an annual review of the literature as well as an ongoing review of stakeholder comments and inquiries.

5. Comparison to Related or Competing Measures

If a measure meets the above criteria and there are endorsed or new related measures (either the same measure focus or the same target population) or competing measures (both the same measure focus and the same target population), the measures are compared to address harmonization and/or selection of the best measure.

5. Relation to Other NQF-endorsed Measures
Are there related measures (conceptually, either same measure focus or target population) or competing measures (conceptually both the same measure focus and same target population)? If yes, list the NQF # and title of all related and/or competing measures.
Yes

5.1a. **List of related or competing measures (selected from NQF-endorsed measures)**
0670 : Cardiac stress imaging not meeting appropriate use criteria: Preoperative evaluation in low risk surgery patients

5.1b. **If related or competing measures are not NQF endorsed please indicate measure title and steward.**
Institute for Clinical Systems Improvement (ICSI) - Perioperative protocol: percentage of patients undergoing elective non-high-risk surgery having laboratory tests/imaging unrelated to positive findings on preoperative basic health assessment

5a. Harmonization

The measure specifications are harmonized with related measures;
OR
The differences in specifications are justified

5a.1. **If this measure conceptually addresses EITHER the same measure focus OR the same target population as NQF-endorsed measure(s):**
Are the measure specifications completely harmonized?
No

5a.2. **If the measure specifications are not completely harmonized, identify the differences, rationale, and impact on interpretability and data collection burden.**
Although NQF #0669 is similar to NQF #0670, there are several differences that would make measure harmonization infeasible and reduce the effectiveness of both currently endorsed measures. First, the measures serve different target populations and purposes: the CMS measure is used for public reporting and the measure calculations only include CMS FFS claims; on the other hand, the ACC measure is not restricted to the Medicare population and the measure calculations are sold to hospitals as part of a quality improvement package, rather than used for public reporting. Second, the measures include different stress testing procedures: the ACC measure (NQF #0670) includes SPECT MPI, stress echocardiography, CCTA, and CMR procedures codes in the denominator, whereas the CMS measure (NQF #0669) includes SPECT MPI, stress echocardiography, and stress MR procedure codes. Finally, the ACC measure relies on a different data source than does the CMS measure: unlike the CMS measure, the ACC measure does not account for instances where the imaging and low risk surgery occur at different facilities. While NQF #0669 is related to the ICSI measure, significant structural differences makes measure harmonization inappropriate for these measures. The denominator of the ICSI measure is defined by low-risk surgery cases, whereas the denominator of the CMS measure is defined by cardiac imaging studies. The ICSI measure also relies on test results for measure calculation, a data element not available in CMS administrative claims data. Finally, the ICSI measure includes patients aged 2 years and older while the CMS measure is targeted to the Medicare population.

5b. Competing Measures

The measure is superior to competing measures (e.g., is a more valid or efficient way to measure);
OR
Multiple measures are justified.

5b.1. **If this measure conceptually addresses both the same measure focus and the same target population as NQF-endorsed measure(s):**

Describe why this measure is superior to competing measures (e.g., a more valid or efficient way to measure quality); OR provide a rationale for the additive value of endorsing an additional measure. (Provide analyses when possible.)
We did not identify any competing measures that address both the same measure focus and target population as NQF #0669.

Appendix

A.1 Supplemental materials may be provided in an appendix. All supplemental materials (such as data collection instrument or methodology reports) should be organized in one file with a table of contents or bookmarks. If material pertains to a specific submission form number, that should be indicated. Requested information should be provided in the submission form and required attachments. There is no guarantee that supplemental materials will be reviewed.

Additional Information

Ad.1 **Workgroup/Expert Panel involved in measure development**
Provide a list of sponsoring organizations and workgroup/panel members' names and organizations. Describe the members' role in measure development.
The contractor has convened a Technical Expert Panel (TEP), which will evaluate and provide feedback on measure-development and maintenance efforts for the imaging efficiency measures. Specifically, the TEP will provide direction and feedback through all phases of project activities, including expansion of imaging efficiency measures to additional CMS quality reporting programs, updates to the current specifications of the seven imaging efficiency measures, review of quantitative testing results, feedback on qualitative testing questions (i.e., results of TEP member questionnaires), and support for endorsement of the measures by the National Quality Forum (NQF).

The following is a list of the contractor's TEP members:

Meenu Arora, MBA
Quality Improvement Leader , Sequoia Hospital

Brian Baker
Chief Executive Officer, Carealytics

Peter Benner
Vice Chair, MNSure

Martha Deed, Ph.D
Safe Patient Project´s Patient Advocacy Network

Lawrence Feinberg, MD
Attending Physician, University of Colorado Hospital

Elliott Fishman, MD
Professor of Radiology and Oncology, Johns Hopkins School of Medicine

Marian Hollingsworth
Patient Advocate

Michael Hutchinson, MD Ph.D

Clinical Associate Professor of Neurology, Icahn School of Medicine at Mount Sinai

Gregory M. Kusiak, MBA FRBMA
President, California Medical Business Services, Inc.

Barbara Landreth, RN MBA
Clinical Information Analyst , St. Louis Area Business Health Coalition

Barbara McNeil, MD Ph.D
Head Professor of Radiology, Harvard University

Michael J. Pentecost, MD
Chief Medical Officer, NIA Magellan

David Seidenwurm, MD
Medical Staff Consultant, Sutter Medical Group

Adam Sharp, MD MS
Research Scientist , Kaiser Permanente Southern California

Paul R. Sierzenski, MD RDMS FACEP FAAEM
Medical Director, Christian Health Care System

Brief Measure Information

NQF #: 0694
Measure Title: Hospital Risk-Standardized Complication Rate following Implantation of Implantable Cardioverter-Defibrillator (ICD)
Measure Steward: American College of Cardiology
Brief Description of Measure: This measure provides hospital specific risk-standardized rates of procedural complications following the implantation of an ICD in patients at least 65 years of age. The measure uses clinical data available in the National Cardiovascular Data Registry (NCDR) ICD Registry for risk adjustment linked with administrative claims data using indirect patient identifiers to identify procedural complications.
Developer Rationale: The goal of this measure is to improve patient outcomes by providing patients, physicians, and hospitals with information about hospital-level, risk-standardized procedural complication rates following hospitalization for an ICD implantation. Measurement of patient outcomes allows for a broad view of quality of care that encompasses more than what can be captured by individual process-of-care measures. Complex and critical aspects of care, such as operator and hospital procedural expertise, communication among providers, prevention of and response to complications, patient safety, and coordinated transitions to the outpatient environment all contribute to patient outcomes but are difficult to measure by individual process measures. The goal of outcomes measurement is to risk-adjust for patients' conditions at the time of hospital admission and then evaluate patient outcomes. This measure was developed to identify institutions whose performance is better or worse than would be expected based on their patient case mix, and therefore promote hospital quality improvement and better inform consumers about care quality.

Numerator Statement: The outcome for this measure is one or more complications within 30 or 90 days (depending on the complication) following initial ICD implantation. The measure treats complications as a dichotomous (yes/no) variable; we are interested in whether or not a complication has occurred and not how many complications occurred in each hospital.
Denominator Statement: The target population for this measure includes inpatient and outpatient hospital stays with ICD implants for patients at least 65 years of age who have matching information in the National Cardiovascular Disease Registry (NCDR) ICD Registry. The time window can be specified from one to three years. This measure was developed with Medicare claims and CathPCI Registry data from one calendar year (2007).
Denominator Exclusions: (1) Previous ICD placement. Hospital stays in which the patient had an ICD implanted prior to the index hospital stay are excluded.
Rationale: Ideally, the measure would include patients with a prior ICD, as this is a population known to be at high risk of adverse outcomes. However, for these patients it is difficult to distinguish in the administrative data whether adverse events such as infection were present on admission or complications of the second ICD placement. In order to avoid misclassification, we exclude these patients from the measure.
(2) Previous pacemaker placement, Hospital stays in which the patient had a previous pacemaker placement prior to the index hospital stay are excluded.
Rationale: Some complications (infection or mechanical complication) may be related to a pacemaker that was removed prior to placement of an ICD. Ideally, the measure would include patients with a prior pacemaker, as this is a population known to be at higher risk of adverse outcomes. However, for these patients it is difficult to distinguish in the administrative data whether adverse events such as infection were present on admission or complications of the ICD placement. In order to avoid misclassification, we exclude these patients from the measure.
(3) Not Medicare FFS patient on admission. Patient admissions in which the patient is not enrolled in Medicare FFS at the time of the ICD procedure.
Rationale: Outcome data are being derived only for Medicare fee-for-service patients.
(4) Lack 90-day follow-up in Medicare FFS post-discharge. Patients who cannot be tracked for 90 days following discharge are excluded.
Rationale: There will not be adequate follow-up data to assess complications
(5) Not the first claim in the same claim bundle. There are cases when several claims in the same hospital representing a single

episode of care exist in the data together. These claims are bundled together and any claim other than the first is excluded. Rationale: Inclusion of additional claims could lead to double counting of an index ICD procedure.

Measure Type: Composite
Data Source: Administrative claims, Electronic Clinical Data : Registry
Level of Analysis: Facility, Population : National
Is this an eMeasure? ☐ **Yes** ☒ **No** **If Yes, was it re-specified from a previously endorsed measure?** ☐ **Yes** ☐ **No**

1d.1. **Composite Measure Construction:** any-or-none measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient)

Is this a MAINTENANCE measure submission? ☒ **Yes** ☐ **No, this is a NEW measure submission.**
For MAINTENANCE, state the Original Endorsement Date: 1/17/11 **Most Recent Endorsement Date:** 1/17/11

Previous Measure Evaluation - Public & Member Comments, Developer Responses & Steering Committee Recommendations from National Voluntary Consensus Standards for Patient Outcomes 2009

This measure provides hospital-specific risk-standardized rates of procedural complications following the implantation of an ICD in patients at least 65 years of age. The measure uses clinical data available in the National Cardio- vascular Data Registry (NCDR) ICD Registry for risk-adjustment that has been linked with CMS administrative claims data used to identify procedural complications. This measure can be applied to all Medicare patients at least 65 years of age.

This measure was designed to combine clinical data from the National Cardiovascular Data Registry (NCDR)6 ICD Registry and administrative data. All patients over age 65 years are required to be entered into the registry, and 70 percent of hospitals report all patients to NCDR. The Committee and TAP agreed that the measure is important in addressing a costly procedure that has a high complication rate (18 percent). The TAP also commended the strong performance charac- teristics of the risk model. Committee members were interested in including patients below age 65 years. The measure developers advised the Committee that the measure was developed in the Medicare 65 and older fee-for-service population because this is the only cohort of patients for whom the data are available to reliably identify outcomes (complications and vital status) beyond the index hospitalization. The measure could be applied to a broader population of patients undergoing ICD implantation if the required data elements were available with some additional work to optimize the risk-adjustment methodology.

A Committee member noted that the variation of values in the technical report is very narrow due to hierarchical modeling and therefore will not discriminate among providers. Others suggested that clustering of the complication rate at 18 percent represents opportunity for improvement overall. This measure addresses the National Priority of safety.

Preliminary Analysis

The preliminary analysis was developed in response to recommendations from NQF's Consensus Task Force and measurement stakeholders as a way to enhance and streamline the measures evaluation and voting processes. The preliminary analysis will help to guide the Standing Committee evaluation of each measure by summarizing the measure developer submission, guide measure evaluation discussion, and identify topic areas for additional input. **NQF staff would like to stress that the preliminary analysis is intended to be used as a guide to facilitate the Committee's discussion and evaluation.**

Criteria 1: Importance to Measure and Report

1a. Evidence

1a. Evidence. The evidence requirements for a health outcomes measure include providing a rationale that supports the relationship of the outcome to at least one healthcare structure, process, intervention, or service.

- This measure calculates hospital-specific risk-standardized rates of procedural complications for patients at least 65 years of age within 30 or 90 days (depending on the complication) following initial ICD implantation.
- The developer provides the following rationale for measuring this outcome:
  - The developer notes that a complication following placement of an Implantable Cardioverter Defibrillator (ICD) is an undesirable outcome, and suggests that complications in the ICD patient population can be reduced through comprehensive, personalized risk assessment, competency of the physician and/or hospital treating the patient and appropriate follow up.

- The developer states that the risk of adverse outcomes following ICD implantation varies markedly by the experience and training of the implanting physician, the device implanted, and the characteristics of the facility in which the procedure is performed.
- The developer also states that this measure was developed to identify institutions whose performance is better or worse than would be expected based on their patient case mix, and therefore promote hospital quality improvement and better inform consumers about care quality.
- The developer provides a number of references to support their rationale.

Question for the Committee:

- *Does the Committee agree that hospitals have the ability to influence rates of procedural complications following ICD implantation?*

1b. Gap in Care/Opportunity for Improvement and 1b. Disparities

1b. Performance Gap. The performance gap requirements include demonstrating quality problems and opportunity for improvement.

- The developer states that reported complication rates following ICD implantation vary from 4% to 30%, depending on how complications are defined, the period of assessment and data source.
- The developer reports that in the ACC's NCDR ICD Registry, the incidence of in-hospital complications is approximately 4%, while also noting that complications such as device infection, malfunction, or cardiac tamponade may only become evident following hospital discharge.
- The developer does not provide performance scores for the measure as specified; however, as part of the measure's development, the developer analyzed unadjusted rates of ICD-related complications in 2007 Medicare inpatient claims data, which included 67,532 ICD admissions for 67,080 patients at 1,792 hospitals.
  - In these preliminary analyses, complications were seen in **5.7% of ICD admissions** (3,818 complications); the median complication rate following ICD implantation **ranged from 0% to 17.8% across deciles** of hospitals grouped by their all-cause complication rate.
- The developer examined health disparities associated with this measure by race/ethnicity [percentage of African American patients] and by socioeconomic status (SES) [from AHRQ SES Index data]. For both sets of analyses, the distribution of race and SES were stratified by quintiles.
  - This information was derived from CMS fee-for-service (FFS) data from the time period of 2010Q2 – 2011Q4, comprising 1,279 hospitals and 43,711 patients.
- The developer provides the results of these analyses in the form of box-and-whisker plots that are included in the testing attachment.

Questions for the Committee:

- *Is there a gap in care that warrants a national performance measure?*
- *Should this measure be indicated as disparities sensitive?*

1c. Priority

1c. High Priority (previously "High Impact") requires measures to address national health goal/priority or a demonstrated high-impact aspect of care.

- *Beginning in 2015, priority is no longer an NQF measure evaluation criterion.*

1d. Composite - Quality Construct and Rationale

1c. Composite Quality Construct and Rationale. The quality construct and rationale should be explicitly articulated and logical; a description of how the aggregation and weighting of the components is consistent with the quality construct and rationale also should be explicitly articulated and logical.

- This is an 'any-or-none' composite measure, meaning that the measure treats complications as a dichotomous (yes/no) variable; if any of the specified complications occurs in a given patient, that patient is included in the measure numerator.
- The developer notes that their interest is in whether or not a complication has occurred and not how many

complications occurred in each hospital.

- The developer states that the goal of this measure is to improve patient outcomes by providing patients, physicians, and hospitals with information about hospital-level, risk-standardized procedural complication rates following hospitalization for an ICD implantation.

Questions for the Committee:

○ *Are the quality construct and rationale for the composite explicitly stated and logical?*

Committee pre-evaluation comments

Criteria 1: Importance to Measure and Report (including 1a, 1b, 1c)

1. ***Committee's Overview Comments***:
   - Acknowledge that measure was developed with Medicare claims and CathPCI registry data, but this measure has limits to its evidence based only on evaluating patients 65 years of age or older. Exclusion criteria are logical except for the issue of excluding all patients who are not Medicare FFS based on the outcome data being derived from Medicare FFS patients. Also, patients who cannot be tracked for 90 days are excluded which could be an issue as patients could have an a complication even if not followed for 90 days. It is an important measure to evaluate quality within hospitals, but is limited by its scope focused on patients 65 years of age or older based on available data.

1a. ***Committee's Comments on Evidence to Support Measure Focus:***

- This is an any-or-non composite outcome measure: Any complication within 30 or 90 days of a first ICD implantation.
- Evidence presented from 2007 Medicare inpatient claims showed a 5.7% complication rate in ICD admissions with a range of 0% to 17.8% which indicates a huge range of complication rates amongst hospitals and a reason to evaluate this measure.

1b. ***Committee's Comments on Performance Gap:***

- Performance analysis shows that RSCRs vary from about 3% to 14%
- There is a performance gap with the range of complications being as high as 18% in some hospitals and as low as 0% in other with a average of 5.7% overall. When looking at SES and AA race there was no difference in average complication rates across hospitals.

1c. ***Committee's Comments on Composite Performance Measure:***

- The quality construct is logical. An any-or-none composite measure makes differences among hospitals much more clear while each single complication may not draw attention to differences in performance.
- The construct is appropriate based on looking whether a complication occurred in individual patients vs looking at how many overall complications occurred. This allows for evaluation to compare hospital to hospital and the overall mean complication rate.

Criteria 2: Scientific Acceptability of Measure Properties

2a. Reliability

2a1. Reliability Specifications

2a1. Specifications requires the measure, as specified, to produce consistent (reliable) and credible (valid) results about the quality of care when implemented.

- This measure calculates complications within 30 or 90 days (depending on the complication) following initial ICD implantation.
- The measure employs a hierarchical logistic regression model to create a hospital-level 30 or 90 day risk-standardized complication rate (RSCR).
- The measure cohort includes inpatient and outpatient hospital stays with ICD implants for patients at least 65 years of age who have matching information in the National Cardiovascular Disease Registry (NCDR) ICD

Registry.

- The denominator is defined using ICD-9 procedure codes from inpatient claims and HCPCS/CPT procedure codes from outpatient claims. A list of relevant codes is included in the submission form.
- The numerator is defined using ICD-9 diagnosis and procedure codes, HCPCS/CPT procedure codes, and vital status data from the Medicare Enrollment Database. A list of complications included in the numerator within 30 days and 90 days is included in the submission form.

Questions for the Committee:

- *Are all the data elements clearly defined? Are all appropriate codes included?*
- *Is it likely this measure can be consistently implemented?*

2a2. Reliability Testing Testing attachment

2a2. Reliability testing demonstrates if the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise enough to distinguish differences in performance across providers.

- The developer notes that the ACC's National Cardiovascular Data Registry (NCDR), from which measure data are also derived, includes two programs to ensure data quality. The developer states hospitals must achieve >95% completeness of "core field" data elements for warehouse analysis, though descriptive characteristics are not provided. The 2 programs include:
  - The Data Quality Program (DQP), which assesses the completeness and validity of electronic data submitted by participating hospitals; and
  - The Data Audit Program (DAP), which consists of annual on-site chart review and data abstraction.
- With regard to data element reliability, the developers note that the measure has been developed to utilize only claims data elements that have both face validity and reliability, avoiding the use of fields that are thought to be coded inconsistently across hospitals or providers; the developer also cites hospital auditing programs used by CMS to assess overall claims code accuracy. NQF guidance indicates that if data element validity testing has been conducted, additional data element reliability testing is not required.
- The developer also assesses data element reliability by comparing model variable frequencies and odds ratios in two years of data to determine their degree of consistency over time. [*Note: NQF does not typically consider temporal consistency to be a valid method of demonstrating reliability of data elements.*]
  - Data were drawn from the National Cardiovascular Data Registry (NCDR) ICD Registry and from Medicare Part A claims over the time period 2010Q2-2011Q4. The combined two-year sample included a total of 43,711 admissions to 1,279 hospitals.
  - The developer does not provide specific frequencies and odds ratios for each data element in the submission form, but states that overall, risk factor frequencies changed little across years and there were no notable differences in the odds ratios across years of data.
- The developer defines performance score reliability as the degree to which repeated measurements of the same entity agree with each other.
- In line with this thinking, the developer's approach to assessing score-level reliability was to consider the extent to which assessments of a hospital using different but randomly-selected subsets of patients produce similar measures of hospital performance. For testing purposes, each hospital is measured twice, but each measurement is made using an entirely distinct set of patients.
- The developers refer to this as a "test-retest" approach; it may also be called a "split-half" method. [*Note: NQF considers this to be an appropriate method of assessing reliability*.]
  - Data were drawn from the National Cardiovascular Data Registry (NCDR) ICD Registry and from Medicare Part A claims over the time period 2010Q2-2011Q4. The combined two-year sample included a total of 43,711 admissions to 1,279 hospitals.
  - The developer randomly split this sample into two groups, leaving 21,856 admissions to 1,254 hospitals in one randomly selected sample and 21,855 admissions to 1,246 hospitals in the remaining sample.
  - The developer calculated the measure for each hospital in the first sample, and then repeated the calculation using the second sample; thus, each hospital is measured twice, but each measurement is

made using an entirely distinct set of patients.
    - A table is provided showing the distribution of risk-standardized complication rates (RSCRs) within these randomly-split samples.
    - The developer suggests that, to the extent that the calculated measures of these two subsets agree, it shows that the measure is assessing an attribute of the hospital, not of the patients. Agreement was calculated using an intra-class correlation coefficient (ICC).
        - However, the developer seems to suggest that hospitals with fewer than 25 cases were excluded from the sample for purposes of calculating agreement; after excluding these hospitals, the first sample contained 297 hospitals and the second sample contained 298 hospitals. [*Note: The developer does not specify how many patients were included in the testing sample after excluding hospitals with fewer than 25 cases; it is also unclear whether the measure itself excludes hospitals with fewer than 25 cases*.]
    - The developer reports that the agreement between the two RSCRs for each hospital was **0.1494**; the developer notes that, according to the conventional interpretation, this is considered "slight" agreement.
    - The developer also notes that the ICC is based on a split sample of 2 years of data, resulting in a volume of patients in each sample equivalent to only 1 year of data, whereas the measure is likely to be reported with a full two years of data.
- The developer's interpretation of reliability testing results is that the stability over time of the risk factor frequencies and odds ratios indicate that the underlying data elements are reliable, and that the ICC score demonstrates fair agreement across samples using a "strict" approach to assessment that would likely improve with greater sample size.

Questions for the Committee:

- *Is the test sample adequate to generalize for widespread implementation?*
- *Do the results demonstrate sufficient reliability so that differences in performance can be identified?*

2b. Validity

2b1. Validity: Specifications

2b1. Validity Specifications. This section should determine if the measure specifications are consistent with the evidence.

- For each measured entity, this measure calculates a risk-standardized rate of complications within 30 or 90 days (depending on the complication) following initial ICD implantation. The measure treats complications as a dichotomous (yes/no) variable; the developer notes that their interest is in whether or not a complication has occurred and not how many complications occurred in each hospital.
- As a rationale for measuring this outcome, the developer suggests that complications in the ICD patient population can be reduced through comprehensive, personalized risk assessment and competency of the physician and/or hospital treating the patient.

Question for the Committee:

- *Are the specifications consistent with the evidence?*

2b2. Validity testing

2b2. Validity Testing should demonstrate the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality.

- With regard to data element validity, the developer refers to programs established within ACC's National Cardiovascular Data Registry (NCDR) that are intended to ensure data quality:
    - The Data Quality Program (DQP), which assesses the completeness and validity of electronic data submitted by participating hospitals; and
    - The Data Audit Program (DAP), which consists of annual on-site chart review and data abstraction.
- In addition, the developer conducted a chart validation study to determine whether ICD-9-CM diagnosis

and procedure codes reported on Medicare claims and used in the measure specifications accurately identify patients experiencing ICD complications within 30 or 90 days of ICD implantation as reported in the medical charts.

- The developer notes that achieving a "substantial" degree of agreement (based on the conventional interpretation of a Kappa coefficient) would have required a sample size of approximately 1,000 charts. However, this was beyond the developer's budgetary restraints; for the final analysis, a sample of 411 medical records from eight hospitals was reviewed.
    - The developers report that the study found an overall agreement between chart and claims (based on paired ratings) of **91.5%**, with a Kappa coefficient of **0.83** (0.7865 – 0.8907) which the developer notes is in the "almost perfect" range, according to the conventional interpretation. The developer states the data comparison included all applicable claims and clinical information, though they do not state all critical data elements (numerator, denominator and exclusions) were tested separately.
- The developer also refers to analyses conducted as part of their risk model diagnostics.
    - For results, see the section on Risk Adjustment below.
- Interpreting their validity testing results, the developer suggests that the audits conducted by the ACC support the overall validity of the data elements included in this measure, and that the data elements used for risk adjustment were consistently found for all patients and were accurately extracted from the medical record.

Questions for the Committee:

- *Is the test sample adequate to generalize for widespread implementation?*
- *Do the results demonstrate sufficient validity so that conclusions about quality can be made?*
- *Do you agree that the score from this measure as specified is an indicator of quality?*

2b3-2b7. Threats to Validity

2b3. Exclusions:

- This measure has the following exclusions:
    - Hospital stays in which the patient had an ICD implanted prior to the index hospital stay
    - Hospital stays in which the patient had a previous pacemaker placement prior to the index hospital stay
    - Patient admissions in which the patient is not enrolled in Medicare FFS at the time of the ICD procedure
    - Patients who cannot be tracked for 90 days following discharge
    - Not the first claim in the same claim bundle
- The developer provides a brief rationale for each of these exclusions in the submission form as well as details on how the exclusions are identified.
- To ascertain the impact of exclusions on the cohort, the developer examined overall frequencies and proportions of the total cohort excluded for each exclusion criterion.
- A table showing exclusions from the target cohort for the combined 2010-2011 study sample is included in the submission form; the table appears to show the number of patients excluded by each criterion, and the resulting number of patients and hospitals remaining in the analysis after each exclusion criterion is applied sequentially.
- The developer states that the majority of exclusions are necessary to 1) link registry and administrative data (e.g. excluding patient not enrolled in Medicare FFS) and 2) identify patients eligible for complication (e.g. excluding patients who died before discharge).
- The developer suggests that as a result, these exclusions are not discretionary and do not require further testing.

Questions for the Committee:

- *Are the exclusions consistent with the evidence?*
- *Are any patients or patient groups inappropriately excluded from the measure?*
- *Are the exclusions/exceptions of sufficient frequency and variation across providers to be needed (and outweigh the*

data collection burden)?

2b4. Risk adjustment:

Clinical risk-adjustment:

- The developer states that their risk-adjustment approach uses a parsimonious model that included key variables previously shown to be associated with complications following ICD implantation.
- The developer considered 15 variables for inclusion in their risk-adjustment model, using logistic regression with stepwise selection (entry p<0.05; retention with p<0.01) for variable selection, meaning variables were retained in the model if they met a certain threshold of statistical significance within the model.
- The developer notes that the variables included in the risk model were fully harmonized with the NCDR's existing risk model for in-hospital adverse events; several variables were not clinically significantly associated with risk of complications at 30/90 days, but the developer elected to retain them in the model for consistency with the NCDR's existing model.

Adjustment for Sociodemographic Status (SDS) Factors:

- The developer states that SDS factors were carefully considered by the stewards of this measure, and upon clinical review from the expert panel, found to be less associated with complications.
- The developer argues that routine inclusion of SDS variables in risk models has the potential to explain away meaningful and actionable differences in hospital performance, that analyses have shown that many hospitals caring for a higher proportion of disadvantaged patients still perform well on the measure, and that literature shows that the inclusion of SDS does not consistently meaningfully improve the discriminatory capacity of risk adjustment models.
- The developer notes that the Agency for Healthcare Research and Quality (AHRQ)-validated SES index score provides an analytic approach to accounting for SDS status.
- The developer used this index score to show the distribution of risk standardized complication rates (RSCR) by SES status; the results of this analysis are provided in the form of a box-and-whiskers chart.
- The developer states that the results show little appreciable variation in distribution of risk standardized complication rates, and demonstrate that adjustment for socioeconomic status does not have a statistically meaningful impact on the complication measure results.
- The developer states this as the conceptual reason and justification for **not including SDS status** as a variable within the model.

Risk Model Diagnostics:

- To assess the overall performance of their risk-adjustment model, the developers computed several summary statistics, including:
    - Area under the receiver operating characteristic (ROC) curve (also known as a c-statistic, which measures the probability that the model's prediction of the outcome is better than chance)
        - A c-statistic of 0.64 means that for 64% of all possible pairs of patients—one who suffered a complication and one who didn't—the model correctly assigned a higher probability to those who had a complication. Generally, a c-statistic of at least 0.70 is considered acceptable.
    - Predictive ability (the model's ability to distinguish high-risk subjects from low-risk subjects)
        - The developer notes that a wide range between the lowest decile and highest decile is an indication that the model has good predictive ability.
    - Over-fitting indices (to ensure that the model is not only describing the relationship between predictive variables and outcome in the development dataset but also providing valid predictions in new patients)
        - Presented as $(\gamma 0, \gamma 1)$ – the developer suggests that if the γ0 in the validation samples are substantially far from zero and the γ1 is substantially far from 1, there is potential evidence of over-fitting. A calibration value close to 0 at one end and close to 1 on the other end indicates good calibration of the model.
- The results of these analyses are as follows:
    - Derivation sample:
        - C-statistic = **0.640**

        - Predictive ability (lowest decile %, highest decile %): **4.05%, 25.08%**
    - Validation sample:
        - C-statistic = **0.642**
        - Predictive ability (lowest decile %, highest decile %): **3.80%, 23.80%**
    - Over-fitting indices [model calibration]: **(0.03, 1.02)**
- The developer states that the C-statistics of 0.640 and 0.642 indicate "fair" model discrimination in the derivation and validation cohorts, suggesting that complications, as opposed to other outcomes such as mortality, consistently have a lower c-statistic, likely because complications are less determined by patient comorbidities and more by health system factors.
- The developer notes that the model showed a wide range between the lowest decile and highest decile, indicating the ability to distinguish high-risk patients from low-risk patients.
- The developer suggests that, interpreted together, their diagnostic results demonstrate the risk-adjustment model adequately controls for differences in patient characteristics (case mix).

Questions for the Committee:

- *Are the candidate and final variables included in the risk adjustment model adequately described for the measure to be implemented?*
- *Are all of the risk adjustment variables present at the start of care?*
- *Does the Standing Committee agree with the developer's rationale that there is no conceptual basis for adjusting this measure for SDS factors?*
- *Do you agree with the developer's decision, based on their analysis, to not include SDS factors in their risk-adjustment model?*

2b5. Meaningful difference:

- The developer notes that for public reporting purposes, an interval estimate for each hospital's risk-standardized complication rate is estimated to characterize the amount of uncertainty associated with the rate; these interval estimates are then compared to the national crude rate for the outcome, with hospitals being categorized as "better than," "worse than," or "no different than" the U.S. national rate.
- To assess variation in RSCRs among hospitals, the developer examined the distribution of hospital RSCRs and plotted these values in the form of a histogram.
- The developer states that recent analyses of Medicare FFS data show variation in RSCRs among hospitals, noting that based on data from 2010Q2-2011Q4, the mean hospital RSCR was 6.8%, with a range of 5.42% to 9.52% and an interquartile range of 6.55% to 6.99%.
- The developer states that the variation in rates suggests there are clinically meaningful differences across hospitals for 30/90 day risk-standardized complications after ICD insertion.

Question for the Committee:

- *Does this measure identify meaningful differences about quality?*

2b6. Comparability of data sources/methods:

- N/A

2b7. Missing Data

- To identify the extent and distribution of missing data, the developer examined rates of missing data for all candidate variables and examined histograms of the frequency of missing data by hospital.
- The developer reports that overall, the percentage of missing values for all categorical variables was very small (<1%) and were imputed to specific categories based on the developer's previous experience.
- The developer suggests that model performance was comparable when they included or excluded cases with missing data.

2d.Composite measure: construction

2d. Empirical analysis to support composite construction. Empirical analysis should demonstrate that the component measures add value to the composite and that the aggregation and weighting rules are consistent with the quality

construct.

- The developer states that the empirical analysis demonstrating the individual component measures fit the overall quality construct is currently underway. The developer reports that this data can be provided at the next maintenance review, once testing is completed.
- The empirical analysis will focus on construct validation which will test the hypothesis on the theory of the construct that following these processes for patients with ICD implantations lead to better outcomes.
- The developer believes they have achieved parsimony by including as few elements as possible without impacting the psychometric properties of the measure.

Questions for the Committee:

- *Do the component measures fit the quality construct?*
- *Are the objectives of parsimony and simplicity achieved while supporting the quality construct?*

Committee pre-evaluation comments

Criteria 2: Scientific Acceptability of Measure Properties (including all 2a, 2b, and 2d)

2a1. &2b1.: ***Committee's Comments on Reliability-Specifications:***

- The elements are clearly defined. They all come from the NCDR.
- Use ICD-9 diagnosis and procedure codes to identify values in both the numerator and denominator. Will need to address how to use ICD-10 codes moving forward. Match Medicare FFS patients with NCDR ICD registry. The only concern is it looks at patients who are Medicare FFS patients. Utilize claims data elements with face reliability.

2a2.: ***Committee's Comments on Reliability-Testing:***

- Reliability was tested with a development sample and a test sample. Numerically, the results were very similar. The developer reports that the agreement between the two RSCRs for each hospital was 0.1494. I am surprised that this statistic is so small given the similarity of the distributions of the two samples.
- Agreement rate for scores for each hospital was 0.1494 and this is determined as slight agreement.

2b1.: ***Committee's Comments on Validity-Specifications***:

- I didn't see any threats to validity. This is not a PRO
- The outcome is measured as a dichotmous variable (Y/N) rather than how many complications which they authors conclude that it makes this measure valid as it allows for complication rate comparisons across hospitals.

2b2.: ***Committee's Comments on Validity-Testing:***

- The data are drawn from the NCDR which has both a Data Quality Program (DQP) and a Data Audit Program (DAP). CMS audits the codes that a hospital submits. In a sample of 411 medical records from 8 hospitals, overall agreement between chart and claims was 0.83. "nearly perfect"
- Yes, validity was tested and showed an overall agreement between chart and claims (based on paired ratings) of 91.5%, with a Kappa coefficient of 0.83 (0.7865 – 0.8907) which the developer notes is in the "almost perfect" range.

2b3-7.: ***Committee's Comments on Threats to Validity:***

- Exclusions are appropriate as is the risk adjustment model.
- The problem that the developer is having in using the data is that they have been told by ResDAT that they can't use ResDAT for quality assessment. The ACC is currently in the process of establishing an agreement that will give them access to claims data--access that is necessary if this measure is to be implemented.
- The way in which missing data and empty fields will be handled is clearly specified and is appropriate.
- The measure steward has not analyzed the performance of every component (because they didn't realize that this was a composite measure until a few days ago), but because each of the components is based on a claim, I don't see that this is a significant issue.
- One potential threat to validity is that patients are excluded if they do not have 90 day follow-up which could underrepresent the rate of complications. Also, patients are excluded if they are not Medicare FFS patients based on the data linkage and tracking of outcomes
- Considered 15 variables for a risk-adjustment model using logistic regression with stepwise selection for each

variable (retention with [< 0.01).
- The developer states that the C-statistics of 0.640 and 0.642 indicate "fair" model discrimination in the derivation and validation cohorts
- Recent analyses of Medicare FFS data show variation in RSCRs among hospitals, noting that based on data from 2010Q2-2011Q4, the mean hospital RSCR was 6.8%, with a range of 5.42% to 9.52% and an interquartile range of 6.55% to 6.99%.
- Missing data is less than 1% of patients analyzed

2d.: ***Committee's Comments on Composite Performance Measure:***
- All of the analysis is, in fact, directed at the composite. The analysis demonstrates that the measure is reliable and valid.
- An empirical analysis demonstrating the individual component measures fit the overall quality construct is currently underway and will be available at the live meeting per the submission information.

Criterion 3. Feasibility

3. Feasibility is the extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

- The data sources for this measure are ICD-9 diagnosis and procedure codes, HCPCS/CPT procedure codes, and vital status data from the Medicare Enrollment Database.
- The developer states that all data elements are in defined fields in electronic clinical data.
- The measure is specified to collect data through the ACC's National Cardiovascular Data Registry (NCDR) ICD Registry, which requires fees for participation; however, the developer notes that the ACCF also allows for licensing of the measure specifications outside of the Registry.
- The developer also suggests that centers already have to participate in this specific registry for reimbursement purposes, so that currently almost all hospitals that implant ICDs in Medicare populations already participate in the Registry.

Questions for the Committee:
- *Are the required data elements routinely generated and used during care delivery?*
- *Are the required data elements available in electronic form, e.g., EHR or other electronic sources?*

Committee pre-evaluation comments
Criteria 3: Feasibility

3.: ***Committee's Comments on Feasibility:***
- All of the data elements are generated either from the NCDR or CMS claims. The measure is only for patients who were enrolled in Medicare before the beginning of the episode. The measure is not feasible for the commercial population because of impracticality of following patients after discharge from hospital.
- Data is available through the Medicare Enrollment Database and thus it is feasible to extract this data. In addition data can be extracted from the NCDR ICD registry.

Criterion 4: Usability and Use

4. Usability and Use evaluate the extent to which audiences (e.g., consumers, purchasers, providers, policymakers) use or could use performance results for both accountability and performance improvement activities.

- This measure is not currently in use, but the developer states their commitment to implementing the measure, and notes that ACC is currently in the process of applying to be a Qualified Entity for Medicare data reporting purposes.
- With regard to potential unintended consequences, the developer notes that publicly reporting hospital risk-standardized ICD complication rates requires that the data submitted by hospitals be complete, consistent, and

accurate.

- The developer refers to methods used to ensure data quality as part of the NCDR's existing Data Quality Program (DQP) to address these issues.

Questions for the Committee (as appropriate) *:*

- *Is the measure publicly reported?*
- *For maintenance measures – is the measure used in at least one accountability application?*
- *How can the performance results be used to further the goal of high-quality, efficient healthcare?*
- *Do the benefits of the measure outweigh any potential unintended consequences?*

Committee pre-evaluation comments

Criteria 4: Usability and Use

4.: ***Committee's Comments on Usability and Use:***

- The measure is not being used at this time because the steward has not been able to gain access to Medicare data. The steward is working with CMS to gain access to the data.
- Planned use includes Public Reporting; Quality Improvement with Benchmarking (external benchmarking to multiple organizations); and Quality Improvement (Internal to the specific organization)
- The measure is not currently in use and discusses using NCDR data quality program requirements in order to maintain reliability and usability of the data.

Criterion 5: Related and Competing Measures

- List any related or competing measures based on harmonization protocol.
- Summarize any harmonization efforts, i.e., responses from the developers regarding harmonization.
- Briefly summarize next steps according to protocol

Pre-meeting public and member comments

-

NATIONAL QUALITY FORUM—Evidence (subcriterion 1a)

Measure Number (*if previously endorsed*)**:** 0694

Measure Title: Hospital Risk-Standardized Complication Rate following Implantation of Implantable Cardioverter-Defibrillator (ICD)

IF the measure is a component in a composite performance measure, provide the title of the Composite Measure here: Click here to enter composite measure #/ title

Date of Submission: Click here to enter a date

Instructions

- *For composite performance measures:*
  - *A separate evidence form is required for each component measure unless several components were studied together.*

- *If a component measure is submitted as an individual performance measure, attach the evidence form to the individual measure submission.*

- Respond to all questions as instructed with answers immediately following the question. All information needed to demonstrate meeting the evidence subcriterion (1a) must be in this form. An appendix of *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 10 pages (*incudes questions/instructions*; minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the evidence for this measure meets NQF's evaluation criteria.

1a. Evidence to Support the Measure Focus

The measure focus is evidence-based, demonstrated as follows:

- Health outcome: [3] a rationale supports the relationship of the health outcome to processes or structures of care. Applies to patient-reported outcomes (PRO), including health-related quality of life/functional status, symptom/symptom burden, experience with care, health-related behavior.
- Intermediate clinical outcome: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured intermediate clinical outcome leads to a desired health outcome.
- Process: [5] a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured process leads to a desired health outcome.
- Structure: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured structure leads to a desired health outcome.
- Efficiency: [6] evidence not required for the resource use component.

Notes

3. Generally, rare event outcomes do not provide adequate information for improvement or discrimination; however, serious reportable events that are compared to zero are appropriate outcomes for public reporting and quality improvement.

4. The preferred systems for grading the evidence are the U.S. Preventive Services Task Force (USPSTF) grading definitions and methods, or Grading of Recommendations, Assessment, Development and Evaluation (GRADE) guidelines.

5. Clinical care processes typically include multiple steps: assess → identify problem/potential problem → choose/plan intervention (with patient input) → provide intervention → evaluate impact on health status. If the measure focus is one step in such a multistep process, the step with the strongest evidence for the link to the desired outcome should be selected as the focus of measurement. Note: A measure focused only on collecting PROM data is not a PRO-PM.

6. Measures of efficiency combine the concepts of resource use and quality (see NQF's Measurement Framework: Evaluating Efficiency Across Episodes of Care; AQA Principles of Efficiency Measures).

1a.1.This is a measure of: (*should be consistent with type of measure entered in De.1*)

Outcome

☒ Health outcome: Avoidance of complications

☐ Patient-reported outcome (PRO): Click here to name the PRO

PROs include HRQoL/functional status, symptom/symptom burden, experience with care, health-related behaviors

☐ Intermediate clinical outcome (*e.g., lab value*): Click here to name the intermediate outcome

☐ Process: Click here to name the process

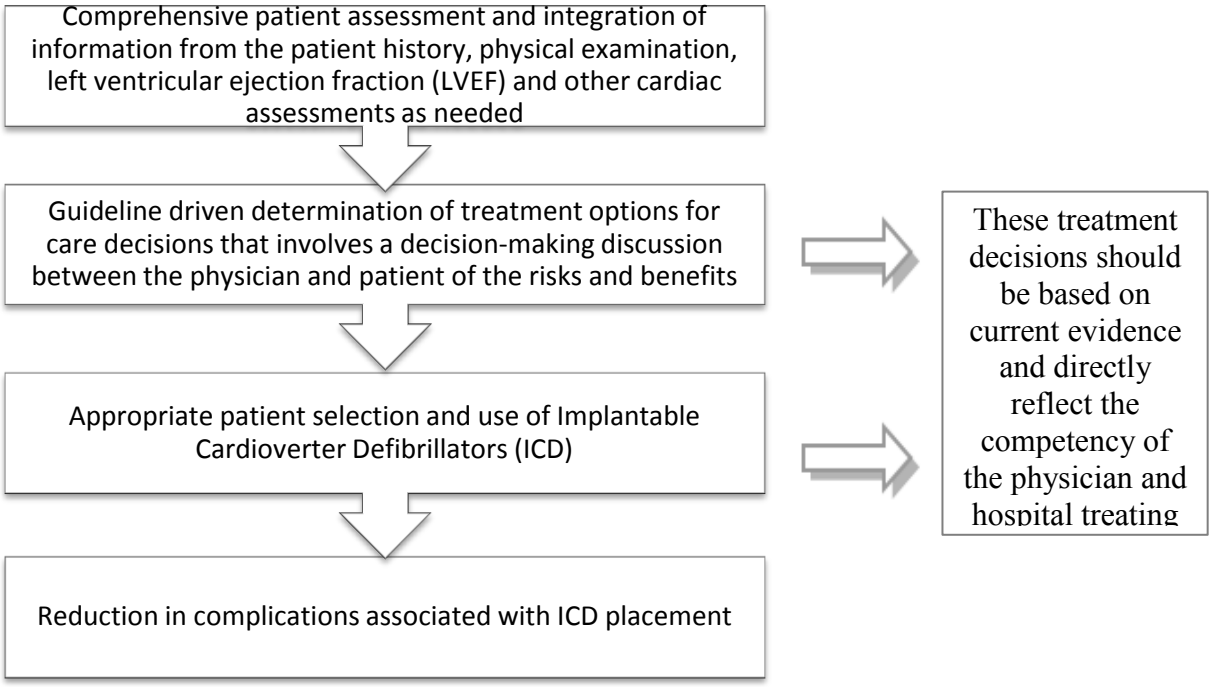
☐ Structure: Click here to name the structure

☐ Other: Click here to name what is being measured

HEALTH OUTCOME/PRO PERFORMANCE MEASURE *If not a health outcome or PRO, skip to 1a.3*

1a.2. Briefly state or diagram the path between the health outcome (or PRO) and the healthcare structures, processes, interventions, or services that influence it.

A complication following placement of an Implantable Cardioverter Defibrillator (ICD) is an undesirable outcome. Comprehensive, personalized risk assessment and competency of the physician and hospital treating the patient can lead to decreased complications in the ICD patient population.



1a.2.1. State the rationale supporting the relationship between the health outcome (or PRO) to at least one healthcare structure, process, intervention, or service (*i.e., influence on outcome/PRO*).

Complications following insertion of Implantable Cardioverter Defibrillators (ICD) are an important patient outcome (Al-Khatib 2005, 2008; Curtis 2009, Peterson, 2013) that reflects the quality of care delivered to patients.

ICDs are expensive and are utilized in patients with high cost conditions such as coronary artery disease or heart failure. Reynolds, et al (2006) found that just over 10% of all patients with an ICD placed had a complication deemed attributable the procedure. The cost to treat these unexpected complications was more than $7,000 for each patient and frequently extended a patient's hospital stay.

The risk of adverse outcomes following ICD implantation varies markedly by the experience and training of the implanting physician, the device implanted, and the characteristics of the facility in which the procedure is performed (Curtis, 2009). These structures and processes of care that prevent these costly and undesirable

complications are difficult to measure in a way that is reliable, valid and meaningful to providers and patients. It is important that ICDs are provided to those patients for whom it is deemed appropriate based on guideline-based assessments and evaluations and hospitals ensure provision of the highest quality of care. Reporting the rate of procedure-related complications provides relevant information on whether these characteristics were achieved.

Note: For health outcome/PRO performance measures, no further information is required; however, you may provide evidence for any of the structures, processes, interventions, or service identified above.

INTERMEDIATE OUTCOME, PROCESS, OR STRUCTURE PERFORMANCE MEASURE

1a.3. Briefly state or diagram the path between structure, process, intermediate outcome, and health outcomes. Include all the steps between the measure focus and the health outcome.

1a.3.1. What is the source of the systematic review of the body of evidence that supports the performance measure?

☐ Clinical Practice Guideline recommendation – ***complete sections 1a.4, and 1a.7***

☐ US Preventive Services Task Force Recommendation – ***complete sections 1a.5 and 1a.7***

☐ Other systematic review and grading of the body of evidence (*e.g., Cochrane Collaboration, AHRQ Evidence Practice Center*) – ***complete sections 1a.6 and 1a.7***

☐ Other – ***complete section 1a.8***

Please complete the sections indicated above for the source of evidence. You may skip the sections that do not apply.

1a.4. CLINICAL PRACTICE GUIDELINE RECOMMENDATION

1a.4.1. Guideline citation (*including date*) and **URL for guideline** (*if available online*):

1a.4.2. Identify guideline recommendation number and/or page number and **quote verbatim, the specific guideline recommendation**.

1a.4.3. Grade assigned to the quoted recommendation with definition of the grade:

1a.4.4. Provide all other grades and associated definitions for recommendations in the grading system. (*Note: If separate grades for the strength of the evidence, report them in section 1a.7.*)

1a.4.5. Citation and URL for methodology for grading recommendations (*if different from 1a.4.1*)**:**

1a.4.6. If guideline is evidence-based (rather than expert opinion), are the details of the quantity, quality, and consistency of the body of evidence available (e.g., evidence tables)?

☐ Yes → ***complete section 1a.7***

☐ No → ***report on another systematic review of the evidence in sections 1a.6 and 1a.7; if another review does not exist, provide what is known from the guideline review of evidence in 1a.7***

1a.5. UNITED STATES PREVENTIVE SERVICES TASK FORCE RECOMMENDATION

1a.5.1. Recommendation citation (*including date*) and **URL for recommendation** (*if available online*):

1a.5.2. Identify recommendation number and/or page number and **quote verbatim, the specific recommendation**.

1a.5.3. Grade assigned to the quoted recommendation with definition of the grade:

1a.5.4. Provide all other grades and associated definitions for recommendations in the grading system.
(*Note: the grading system for the evidence should be reported in section 1a.7.*)

1a.5.5. Citation and URL for methodology for grading recommendations (*if different from 1a.5.1*)**:**

Complete section 1a.7

1a.6. OTHER SYSTEMATIC REVIEW OF THE BODY OF EVIDENCE

1a.6.1. Citation (*including date*) and **URL** (*if available online*):

1a.6.2. Citation and URL for methodology for evidence review and grading (*if different from 1a.6.1*)**:**

Complete section 1a.7

1a.7. FINDINGS FROM SYSTEMATIC REVIEW OF BODY OF THE EVIDENCE SUPPORTING THE MEASURE

If more than one systematic review of the evidence is identified above, you may choose to summarize the one (or more) for which the best information is available to provide a summary of the quantity, quality, and consistency of the body of evidence. Be sure to identify which review is the basis of the responses in this section and if more than one, provide a separate response for each review.

1a.7.1. What was the specific structure, treatment, intervention, service, or intermediate outcome addressed in the evidence review?

1a.7.2. Grade assigned for the quality of the quoted evidence with definition of the grade:

1a.7.3. Provide all other grades and associated definitions for strength of the evidence in the grading system.

1a.7.4. What is the time period covered by the body of evidence? (*provide the date range, e.g., 1990-2010*).
Date range: Click here to enter date range

QUANTITY AND QUALITY OF BODY OF EVIDENCE

1a.7.5. How many and what type of study designs are included in the body of evidence? (*e.g., 3 randomized controlled trials and 1 observational study*)

1a.7.6. What is the overall quality of evidence <u>across studies</u> in the body of evidence? (*discuss the certainty or confidence in the estimates of effect particularly in relation to study factors such as design flaws, imprecision due to small numbers, indirectness of studies to the measure focus or target population*)

ESTIMATES OF BENEFIT AND CONSISTENCY ACROSS STUDIES IN BODY OF EVIDENCE

1a.7.7. What are the estimates of benefit—magnitude and direction of effect on outcome(s) <u>across studies</u> in the body of evidence? (*e.g., ranges of percentages or odds ratios for improvement/ decline across studies, results of meta-analysis, and statistical significance*)

1a.7.8. What harms were studied and how do they affect the net benefit (benefits over harms)?

UPDATE TO THE SYSTEMATIC REVIEW(S) OF THE BODY OF EVIDENCE

1a.7.9. If new studies have been conducted since the systematic review of the body of evidence, provide for <u>each</u> new study: 1) citation, 2) description, 3) results, 4) impact on conclusions of systematic review.

1a.8 OTHER SOURCE OF EVIDENCE

If source of evidence is NOT from a clinical practice guideline, USPSTF, or systematic review, please describe the evidence on which you are basing the performance measure.

1a.8.1 What process was used to identify the evidence?

1a.8.2. Provide the citation and summary for each piece of evidence.

1. Evidence, Performance Gap, Priority – Importance to Measure and Report
Extent to which the specific measure focus is evidence-based, important to making significant gains in healthcare quality, and improving health outcomes for a specific high-priority (high-impact) aspect of healthcare where there is variation in or overall less-than-optimal performance. ***Measures must be judged to meet all subcriteria to pass this criterion and be evaluated against the remaining criteria.***

1a. Evidence to Support the Measure Focus – See attached Evidence Submission Form
0694_ACC_Hospital_Complication_ICD_evidence_submission_061715_submitted.docx

1b. Performance Gap

Demonstration of quality problems and opportunity for improvement, i.e., data demonstrating:

- considerable variation, or overall less-than-optimal performance, in the quality of care across providers; and/or
- disparities in care across population groups.

1b.1. **Briefly explain the rationale for this measure** *(e.g., the benefits or improvements in quality envisioned by use of this measure)*
The goal of this measure is to improve patient outcomes by providing patients, physicians, and hospitals with information about hospital-level, risk-standardized procedural complication rates following hospitalization for an ICD implantation. Measurement of patient outcomes allows for a broad view of quality of care that encompasses more than what can be captured by individual process-of-care measures. Complex and critical aspects of care, such as operator and hospital procedural expertise, communication among providers, prevention of and response to complications, patient safety, and coordinated transitions to the outpatient environment all contribute to patient outcomes but are difficult to measure by individual process measures. The goal of outcomes measurement is to risk-adjust for patients' conditions at the time of hospital admission and then evaluate patient outcomes. This measure was developed to identify institutions whose performance is better or worse than would be expected based on their patient case mix, and therefore promote hospital quality improvement and better inform consumers about care quality.

1b.2. **Provide performance scores on the measure as specified (current and over time) at the specified level of analysis.** *(This is required for endorsement maintenance. Include mean, std dev, min, max, interquartile range, scores by decile. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities included). This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*
Reported complication rates following ICD implantation vary from 4% to 30%, depending on how complications are defined and the period of assessment. In the ACC's NCDR ICD Registry, the incidence of in-hospital complications is approximately 4%. However, complications such as device infection, malfunction, or cardiac tamponade may only become evident following hospital discharge. Al-Khatib et al. (2008) found overall rates of complication within 90 days of ICD implantation ranged from 18.8% in 2002 to 14.2% in 2005. Additional updated evidence and peer-reviewed publications can be found in the evidence supplement.

Preliminary analyses confirm that serious complications, including death, can occur after ICD implantation, and that there is substantial variation in complication rates across hospitals. As the foundation of this measure, we conducted analyses to determine unadjusted ICD-related complication rates in Medicare inpatient claims data for 2007, which included 67,532 ICD admissions for 67,080 patients at 1,792 hospitals. Administrative codes identifying ICD-related complications were identified through review of the literature and subsequently refined in conjunction with input from topic experts to capture the most significant complications. Complications were identified from CMS claims data using ICD-9-CM diagnosis and procedure codes or mortality within specified timeframe (30 days or 90 days following implantation depending on the specific complication). In these preliminary analyses, complications were seen in 5.7% of ICD admissions (3,818 complications).

In addition to clinically important rates of complications following ICD implantation, there is substantial variability in rates across hospitals. The median complication rate following ICD implantation ranges from 0% to 17.8% across deciles of hospitals grouped by their all-cause complication rate.

These findings suggest that these complications are reasonably attributable to the ICD, potentially preventable, and thus, actionable.

1b.3. **If no or limited performance data on the measure as specified is reported in 1b2, then provide a summary of data from the literature that indicates opportunity for improvement or overall less than optimal performance on the specific focus of measurement.**
Al-Khatib SM, Greiner MA, Peterson ED, Hernandez AF, Schulman KA, Curtis LH. Patient and Implanting Physician Factors Associated With Mortality and Complications After Implantable Cardioverter-Defibrillator Implantation, 2002-2005. Circ Arrhythmia Electrophysiol. 2008;1:240-249.

1b.4. **Provide disparities data from the measure as specified (current and over time) by population group, e.g., by race/ethnicity, gender, age, insurance status, socioeconomic status, and/or disability.** *(This is required for endorsement maintenance. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities include.) This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*
We examined health disparities associated with this measure by race/ethnicity and by socioeconomic status (SES). For both sets of analyses, the distribution of race and SES were stratified by quintiles. SES status (SES score) was determined from AHRQ SES Index

data, and the percentage of African American patients was derived from CMS FFS patients for any condition during 2010 and 2011.

Dates of Data: 2010Q2 – 2011Q4
Number of Measured Entities (Hospitals): 1279
Number of Patients: 43711

A box and whisker plots depiction can be found in the testing supplement.

1b.5. **If no or limited data on disparities from the measure as specified is reported in 1b4, then provide a summary of data from the literature that addresses disparities in care on the specific focus of measurement. Include citations.**
N/A

1c. High Priority (previously referred to as High Impact)

The measure addresses:

- a specific national health goal/priority identified by DHHS or the National Priorities Partnership convened by NQF; OR
- a demonstrated high-priority (high-impact) aspect of healthcare (e.g., affects large numbers of patients and/or has a substantial impact for a smaller population; leading cause of morbidity/mortality; high resource use (current and/or future); severity of illness; and severity of patient/societal consequences of poor quality).

1c.1. **Demonstrated high priority aspect of healthcare**
Patient/societal consequences of poor quality, Frequently performed procedure, High resource use
1c.2. **If Other:**

1c.3. **Provide epidemiologic or resource use data that demonstrates the measure addresses a high priority aspect of healthcare. List citations in 1c.4.**
Over the past two decades, clinical trials have demonstrated that ICDs reduce the risk of sudden cardiac death for select high risk patients. As a result of these trials, there is a large increase in the number of patients undergoing ICD implantation, with an estimated increase in the number of inpatient implantations from 5,600 in 1990 to 108,680 by 2005 (Brown, Croft et al. 2008). Although ICD therapy can improve the survival of appropriately selected patients, device implantation carries a low but unavoidable risk of significant complications, which are associated with increased cost, length of stay, and higher risk of mortality (Al-Khatib, Greiner et al. 2008).

ICD implantation is an expensive procedure performed on patients with advanced cardiovascular disease and, often, significant comorbidities. Despite improvements in technology and increasing experience with device implantation, the procedure carries a significant risk of complications (Hammill, Curtis, 2008).

--Roughly 150,000 ICDs are implanted each year and approximately two thirds of implantations are performed on Medicare patients

--Direct total medical cost per device (2005) (Sanders et al, 2005) is $68,000-$100,000. The total costs to payers ranges from $10-$15 billion, of which $7-$10 billion is fee-for-service Medicare

-- Costly complications are common with 11% of Medicare patients having early complications

--In one study (Reynolds et al, 2006) complications increased length of stay 1-10 days and raised costs $5,000 – 20,000 (mean $7,251), adding roughly $80 million in Medicare costs

1c.4. **Citations for data demonstrating high priority provided in 1a.3**

1c.5. **If a PRO-PM (e.g. HRQoL/functional status, symptom/burden, experience with care, health-related behaviors), provide evidence that the target population values the measured PRO and finds it meaningful.** *(Describe how and from whom their input was obtained.)*

1d. Composite Quality Construct and Rationale

1d.1. **A composite performance measure is a combination of two or more component measures, each of which individually reflects quality of care, into a single performance measure with a single score.**

For purposes of NQF measure submission, evaluation, and endorsement, the following will be considered composites:

- Measures with two or more individual performance measure scores combined into one score for an accountable entity.
- Measures with two or more individual component measures assessed separately for each patient and then aggregated into one score for an accountable entity:
    - all-or-none measures (e.g., all essential care processes received, or outcomes experienced, by each patient); or
    - any-or-none measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient).

1d.1. Please identify the composite measure construction: any-or-none measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient)

1d.2. **Describe the quality construct, including:**

- the overall area of quality
- included component measures and
- the relationship of the component measures to the overall composite and to each other.

Research strongly suggests that the complications--as identified in this application--are reasonably attributable to the ICD, potentially preventable, and thus actionable.

1) In defining the complications, we sought clinically sensible definitions which were, to the extent possible, likely attributable to ICD implantation. In consultation with an expert panel, it was agreed that restricting outcomes to complications requiring an intervention would enhance measure acceptance as these complications represent the most clinically significant adverse events.
The original list of complications routinely captured in administrative data included:

1. Pneumothorax
2. Hematoma
3. Tamponade
4. Mechanical complications
5. Pulmonary embolism
6. Infection
7. Other cardiac complication
8. Acute renal failure requiring hemodialysis
9. Death

For several of the complications identified in this measure, we chose to refine the definitions following ICD implantation (as discussed in the literature) to include associated interventions. The resulting modified definitions represent the most clinically significant complications. For example, the claims code used to identify "mechanical complications" in the claims data is broad, including both lead dislodgement requiring open revision as well as minor lead abnormalities that can be addressed simply by reprogramming the device. As such, restricting to mechanical complications with a system revision narrows the focus of the measure on complications of device implantation that require intervention. Similarly, restricting "pneumothorax or hemothorax" and "hematoma" complications to those requiring an intervention was deemed important because those events vary widely in identification, clinical severity, and recommended treatment. "Pulmonary embolism" and "acute renal failure requiring hemodialysis" were dropped from the list of complications as the observed rates were low (less than 0.15%) and they were deemed less clearly attributable to the ICD implantation itself. "Other cardiac complication" was also dropped because it was deemed to be too broad for

this measure. Finally, we added two additional complications to the original list: additional ICDs implanted within 90 days of the index procedure and death within 30 days of the index procedure. In both cases, the event would be an unplanned, adverse event. The final list of complications is as follows:

1. Pneumothorax or hemothorax, with chest tube
2. Hematoma with blood transfusion or evacuation
3. Cardiac tamponade or pericardiocentesis
4. Mechanical complications requiring a system revision
5. Infection that is device related
6. Second ICD within 90 days of the index procedure
7. Death

(2) In consultation with an expert panel, we chose a hybrid complication-specific approach for the outcome time period. Review of preliminary analyses revealed that most complications occur within the initial 15 days following implantation, and qualitatively plateaued between 30 and 45 days following ICD implantation. Accordingly, we initially considered a 30-day time period for follow-up. However, feedback from topic experts suggested that using a single period of assessment for such a wide range of outcomes may not be the optimal approach. For example, device related infections may not become apparent for weeks or months following implantation, suggesting a 90 day time period would be best for this outcome. In contrast, however, hematomas due to the procedure would most likely be recognized and treated within 30 days of implantation, and hematomas identified after that point are more likely due to other procedures (e.g., cardiac catheterization). Given these considerations, we adopted timeframes specific to each complication. The timeframes are as follows:

30-day timeframe
- Pneumothorax or hemothorax, plus chest tube
- Hematoma plus blood transfusion or evacuation
- Cardiac tamponade or pericardiocentesis
- Death

90-day timeframe
- Mechanical complications requiring system revision
- Device related infections
- Additional ICD implantations

1d.3. Describe the rationale for constructing a composite measure, including how the composite provides a distinctive or additive value over the component measures individually.

Composite performance measures have a variety of uses.

Data reduction. A large and growing array of individual indicators makes it possible for users to become overloaded with data. A composite measure reduces the information burden by distilling the available indicators into a simple summary.

Scope expansion. The information in a composite measure is highly condensed, making it feasible to track a broader range of metrics than would be possible otherwise. Composite measures have been described as a tool for making provider assessments more comprehensive

Provider performance valuation. Performance indicators are used for various decisions about providers, including the allocation of pay-for-performance incentives, designation of preferred provider status, and assignment of letter grades and star rating categories. If a decision is to be based on multiple indicators instead of a single indicator, a method of translating several variables into a single decision is needed. Composite measures serve this function by assigning providers to 1 position on a scale of better-to-worse performance.

Each complication, when viewed in isolation, offers a narrow perspective of the performance of the given hospital (s). This measure attempts to focus on various key clinical negative outcomes where the locus of control is within the given operator or site.

1d.4. Describe how the aggregation and weighting of the component measures are consistent with the stated quality construct and rationale.

Each of the components of this measure address key patient outcomes. Many factors go into the care of patients. This measure was developed to identify institutions whose performance is better or worse than would be expected based on their patient case mix, regardless of complications. The clinical subject matter experts believed that no complication should be treated less "severe". The measure specifications reflect this notion.

2. Reliability and Validity—Scientific Acceptability of Measure Properties

Extent to which the measure, as specified, produces consistent (reliable) and credible (valid) results about the quality of care when implemented. ***Measures must be judged to meet the subcriteria for both reliability and validity to pass this criterion and be evaluated against the remaining criteria.***

2a.1. Specifications The measure is well defined and precisely specified so it can be implemented consistently within and across organizations and allows for comparability. eMeasures should be specified in the Health Quality Measures Format (HQMF) and the Quality Data Model (QDM).

De.5. **Subject/Topic Area** *(check all the areas that apply):*
Cardiovascular, Cardiovascular : Ischemic Heart Disease, Coronary Artery Disease

De.6. **Cross Cutting Areas** *(check all the areas that apply):*

S.1. **Measure-specific Web Page** *(Provide a URL link to a web page specific for this measure that contains current detailed specifications including code lists, risk model details, and supplemental materials. Do not enter a URL linking to a home page or to general information.)*
N/A

S.2a. **If this is an eMeasure**, HQMF specifications must be attached. Attach the zipped output from the eMeasure authoring tool (MAT) - if the MAT was not used, contact staff. (Use the specification fields in this online form for the plain-language description of the specifications)
This is not an eMeasure **Attachment:**

S.2b. **Data Dictionary, Code Table, or Value Sets** *(and risk model codes and coefficients when applicable) must be attached. (Excel or csv file in the suggested format preferred - if not, contact staff)*
Attachment **Attachment:** icd_v2_datadictionary_codersdictionary_2-1-635699788053782318.pdf

S.3. **For endorsement maintenance**, please briefly describe any changes to the measure specifications since last endorsement date and explain the reasons.
Since this measure was last endorsed on 01/2011, ACC has updated this measure to a more parsimonious version. The original 13 variables have been reduced to 9 variables. Over the next years, it is a priority of the ACC to focus the development of measures that require less variables while ensuring statistical reliability and validity properties are not reduced. One additional benefit for sites is that the burden of data capture may be less resource intensive and could result in less “missing” data.

S.4. **Numerator Statement** *(Brief, narrative description of the measure focus or what is being measured about the target population, i.e., cases from the target population with the target process, condition, event, or outcome)*
IF an OUTCOME MEASURE, state the outcome being measured. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
The outcome for this measure is one or more complications within 30 or 90 days (depending on the complication) following initial ICD implantation. The measure treats complications as a dichotomous (yes/no) variable; we are interested in whether or not a complication has occurred and not how many complications occurred in each hospital.

S.5. **Time Period for Data** *(What is the time period in which data will be aggregated for the measure, e.g., 12 mo, 3 years, look back to August for flu vaccination? Note if there are different time periods for the numerator and denominator.)*
The time period for aggregating data for public reporting has not been determined. Other outcome measures have been calculated using 2 or 3 years of data, and it is likely that this will provide a sufficient volume of cases needed to calculate hospital RSCR.

S.6. **Numerator Details** *(All information required to identify and calculate the cases from the target population with the target process, condition, event, or outcome such as definitions, specific data collection items/responses, code/value sets – Note: lists of*

individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)
IF an OUTCOME MEASURE, describe how the observed outcome is identified/counted. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
Complications are identified using International Classification of Diseases, 9th Revision, Clinical Modification (ICD-9-CM) diagnosis and procedure codes or Healthcare Common Procedure Coding System/Current Procedural Terminology (HCPCS/CPT) procedure codes as well as the Medicare Enrollment Database (vital status) as indicated below. This approach was developed by a CMS Technical Expert Panel of clinicians and methodologists who were charged with identifying a comprehensive claims-based approach to identifying serious procedural complications:

Complications identified within 30 days of device implant

(1) Pneumothorax or hemothorax plus a chest tube
Definition: (a) Pneumothorax / hemothorax: 512.0, 512.1x, 512.8, or 511.8x (diagnosis code) AND
(b) Chest tube: 34.04, 34.05, 34.06, or 34.09 (procedure code)
(2) Hematoma plus a blood transfusion or evacuation
Definition: (a) Hematoma: 998.1x (diagnosis code) AND
(b) Blood transfusion: 518.7x, 287.4x, V59.01, V58.2x (diagnosis code), or
99.00, 99.03, 99.04 (procedure code) OR
Evacuation: 34.04, 34.09 (procedure code)
(3) Cardiac tamponade or pericardiocentesis
Definition: (a) Cardiac tamponade: 420.xx, 423.0x, 423.3x, 423.9x (diagnosis code) OR
37.0, 37.12 (procedure code)
(4) Death
Source: Medicare enrollment database

Complications identified within 90 days of device implant

(5) Mechanical complications requiring a system revision
Definition: (a) Mechanical complications with system revision: 996.0x, 996.72 (diagnosis code) AND
(b) System revision: 37.75, 37.77, 37.79, 37.97, 37.94, 37.99, 39.94, or
00.52(procedure code)
(6) Device related infection
Definition: (a) Infection: 996.61 (diagnosis code)
(7) Additional ICD implantation
Definition: (a) Inpatient or outpatient ICD implantation: 00.50, 00.51, 00.52, 00.53,00.54, or 37.94 (procedure codes) OR
(b) Outpatient ICD implantation: 33216, 33217, 33218, 33220, 33223, 33230, 33231, 33240, 33241, or 33249, 33262, 33263, 33264 (CPT procedure codes)

We used the General Equivalence Mapping (GEM) crosswalk between ICD-9-CM and ICD-10-CM/PCS to create specifications for the ICD complication measure in ICD-10-CM/PCS. Additionally, our process for mapping procedural codes in the measures to ICD-10 included detailed clinical review, including manual review of related ICD-10 codes to determine that all appropriate codes were included, rather than relying exclusively on the GEM. See appendix A.1. supplemental files.

S.7. **Denominator Statement** *(Brief, narrative description of the target population being measured)*
The target population for this measure includes inpatient and outpatient hospital stays with ICD implants for patients at least 65 years of age who have matching information in the National Cardiovascular Disease Registry (NCDR) ICD Registry. The time window can be specified from one to three years. This measure was developed with Medicare claims and CathPCI Registry data from one calendar year (2007).

S.8. **Target Population Category** *(Check all the populations for which the measure is specified and tested if any):*
Populations at Risk, Senior Care

S.9. **Denominator Details** *(All information required to identify and calculate the target population/denominator such as definitions, specific data collection items/responses , code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
We use this field to define the measure cohort, defined by ICD-9 procedures codes from inpatient claims and HCPCS/CPT procedure

codes from outpatient claims as outlined below:
ICD-9 codes
00.50 Implantation of cardiac resynchronization pacemaker without mention of defibrillation, total system (crt-p)
00.51 Implantation of cardiac resynchronization defibrillator, total system (crt-d)
00.52 Implantation or replacement of transvenous lead (electrode) into left ventricular coronary venous system
00.53 Implantation or replacement of cardiac resynchronization pacemaker pulse generator only (crt-p)
00.54 Implantation or replacement of cardiac resynchronization defibrillator pulse generator device only (crt-d)
37.94 Implantation or replacement of automatic cardioverter/defibrillator, total system (aicd)
CPT codes33216 Insertion, single chamber transvenous electrode ICD
33217 Insertion, dual chamber transvenous electrode ICD
33218 Repair, single chamber transvenous electrode ICD
33220 Repair, dual chamber transvenous electrode ICD
33223 Pocket revision ICD
33230 Initial pulse generator insertion only with existing dual leads
33231 Initial pulse generator insertion only with existing multiple leads 33240 Insertion of single or dual chamber ICD pulse generator
33241 Removal of single or dual chamber ICD pulse generator
33249 Insertion or repositioning of electrode lead(s) for single or dual chamber pacing ICD and insertion of pulse generator
33262 Removal pulse generator with replacement pulse generator only single lead system (transvenous)
33263 Removal pulse generator with replacement pulse generator only dual lead system (transvenous)
33264 Removal pulse generator with replacement pulse generator only multiple lead system (transvenous)

S.10. **Denominator Exclusions** *(Brief narrative description of exclusions from the target population)*
(1) Previous ICD placement. Hospital stays in which the patient had an ICD implanted prior to the index hospital stay are excluded.
Rationale: Ideally, the measure would include patients with a prior ICD, as this is a population known to be at high risk of adverse outcomes. However, for these patients it is difficult to distinguish in the administrative data whether adverse events such as infection were present on admission or complications of the second ICD placement. In order to avoid misclassification, we exclude these patients from the measure.
(2) Previous pacemaker placement, Hospital stays in which the patient had a previous pacemaker placement prior to the index hospital stay are excluded.
Rationale: Some complications (infection or mechanical complication) may be related to a pacemaker that was removed prior to placement of an ICD. Ideally, the measure would include patients with a prior pacemaker, as this is a population known to be at higher risk of adverse outcomes. However, for these patients it is difficult to distinguish in the administrative data whether adverse events such as infection were present on admission or complications of the ICD placement. In order to avoid misclassification, we exclude these patients from the measure.
(3) Not Medicare FFS patient on admission. Patient admissions in which the patient is not enrolled in Medicare FFS at the time of the ICD procedure.
Rationale: Outcome data are being derived only for Medicare fee-for-service patients.
(4) Lack 90-day follow-up in Medicare FFS post-discharge. Patients who cannot be tracked for 90 days following discharge are excluded.
Rationale: There will not be adequate follow-up data to assess complications
(5) Not the first claim in the same claim bundle. There are cases when several claims in the same hospital representing a single episode of care exist in the data together. These claims are bundled together and any claim other than the first is excluded.
Rationale: Inclusion of additional claims could lead to double counting of an index ICD procedure.

S.11. **Denominator Exclusion Details** *(All information required to identify and calculate exclusions from the denominator such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
Denominator exclusions are identified based on variables contained in the Standard Analytic File (SAF) or Enrollment Database (EDB). Of note, a hospital stay may satisfy multiple exclusion criteria.
(1) Previous ICD placement is a flag in the NCDR-ICD registry that indicates whether or not a patient has an ICD present on admission.
(2) Previous pacemaker is a flag in the NCDR-ICD registry that indicates whether or not a patient has a pacemaker present on

admission.
(3) Not Medicare FFS patient on admission is determined by patient enrollment in both Part A and Part B in FFS using CMS' EDB.
(4) Lack 90-day follow-up in Medicare FFS post-discharge is determined by patient enrollment status in both Part A and Part B and in FFS using CMS' EDB; the enrollment indicators must be appropriately marked for any month which falls within 90 days of hospital discharge or enrollment end date (this does not apply for patients who die within 90 days of the index hospital stay).
(5) Not the first claim in the same claim bundle is derived by examining inpatient claims located in the SAF; specifically the fields for admit discharge date and provider ID.

S.12. **Stratification Details/Variables** *(All information required to stratify the measure results including the stratification variables, definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format with at S.2b)*
This measure is not stratified.

S.13. **Risk Adjustment Type** (Select type. Provide specifications for risk stratification in S.12 and for statistical model in S.14-15)
Statistical risk model
If other:

S.14. **Identify the statistical risk model method and variables** *(Name the statistical method - e.g., logistic regression and list all the risk factor variables. Note - risk model development and testing should be addressed with measure testing under Scientific Acceptability)*
Our approach to risk adjustment conforms to the scientific standards for a publicly reported outcome measure as articulated in the American Heart Association (AHA) Scientific Statement, "Standards for Statistical Models Used for Public Reporting of Health Outcomes" (Krumholz et al., 2006).
The measure employs a hierarchical logistic regression model to create a hospital-level 30 or 90 day RSCR. In brief, the approach simultaneously models data at the patient and hospital levels to account for the variance in patient outcomes within and between hospitals (Normand & Shahian, 2007). At the patient level, it models the log-odds of hospital complications within 30 or 90 days of discharge using age, selected clinical covariates, and a hospital-specific intercept. At the hospital level, the approach models the hospital-specific intercepts as arising from a normal distribution. The hospital intercept represents the underlying risk of complication at the hospital, after accounting for patient risk. If there were no differences among hospitals, then after adjusting for patient risk, the hospital intercepts should be identical across all hospitals.
Candidate and Final Risk-adjustment Variables: Candidate variables were patient-level risk-adjustors that were expected to be predictive of procedural complications, based on empirical analysis, prior literature, and clinical judgment, including age, sex, and indicators of comorbidity and disease severity. For each patient, covariates are obtained from claims records extending 12 months prior to and including the index admission. For the measure currently implemented by CMS, these risk-adjusters are identified using both inpatient and outpatient Medicare FFS claims data.

The model adjusts for case-mix differences based on the clinical status of patients at the time of admission. We use condition categories (CCs), which are clinically meaningful groupings of more than 15,000 ICD-9-CM diagnosis codes (Pope et al., 2000). A file that contains a list of the ICD-9-CM codes and their groupings into CCs is attached in the supplemental materials. In addition, only comorbidities that convey information about the patient at admission or in the 12 months prior, and not complications that arise during the course of the index hospitalization, are included in the risk adjustment. Hence, we do not risk adjust for CCs that may represent adverse events of care and that are only recorded in the index admission.

The 9 variables included in the risk model are listed below.

(1) Sex
Male
Female
(2) Reason for admission
Admitted for procedure
Cardiac heart failure
Other
(3) NYHA class
I/II
III
IV
(4) Prior Coronary Artery Bypass Graft (CABG)

(5) Abnormal conduction
No
Yes-left bundle
Yes-other
(6) ICD type
Single chamber
Dual chamber
CRT-D
(7) Sodium
<135
135-145
>145
(8) Hemoglobin (5 g/Dl)
(9) BUN (10 mg/Dl)

S.15. **Detailed risk model specifications** *(must be in attached data dictionary/code list Excel or csv file. Also indicate if available at measure-specific URL identified in S.1.)*
Note: Risk model details (including coefficients, equations, codes with descriptors, definitions), should be provided on a separate worksheet in the suggested format in the Excel or csv file with data dictionary/code lists at S.2b.
Provided in response box S.15a

S.15a. **Detailed risk model specifications** (*if not provided in excel or csv file at S.2b*)
See appendix A.1. supplemental files.

S.16. **Type of score:**
Rate/proportion
If other:

S.17. **Interpretation of Score** *(Classifies interpretation of score according to whether better quality is associated with a higher score, a lower score, a score falling within a defined interval, or a passing score)*
Better quality = Lower score

S.18. **Calculation Algorithm/Measure Logic** *(Describe the calculation of the measure score as an ordered sequence of steps including identifying the target population; exclusions; cases meeting the target process, condition, event, or outcome; aggregating data; risk adjustment; etc.)*
The measure employs a hierarchical logistic regression model to create a hospital-level 30 or 90 day RSCR. In brief, the approach simultaneously models data at the patient and hospital levels to account for the variance in patient outcomes within and between hospitals (Normand & Shahian, 2007). At the patient level, it models the log-odds of hospital complications within 30 or 90 days of discharge using age, selected clinical covariates, and a hospital-specific intercept. At the hospital level, the approach models the hospital-specific intercepts as arising from a normal distribution. The hospital intercept represents the underlying risk of complications at the hospital, after accounting for patient risk. If there were no differences among hospitals, then after adjusting for patient risk, the hospital intercepts should be identical across all hospitals.
The RSCR is calculated as the ratio of the number of "predicted" to the number of "expected" complications, multiplied by the national unadjusted complication rate. For each hospital, the numerator of the ratio ("predicted") is the number of complications within 30 days predicted on the basis of the hospital's performance with its observed case mix, and the denominator ("expected") is the number of complications expected on the basis of the nation's performance with that hospital's case mix. This approach is

analogous to a ratio of "observed" to "expected" used in other types of statistical analyses. It conceptually allows for a comparison of a particular hospital's performance given its case mix to an average hospital's performance with the same case mix. Thus, a lower ratio indicates lower-than-expected complications or better quality and a higher ratio indicates higher-than-expected complications or worse quality.
The "predicted" number of complications (the numerator) is calculated by using the coefficients estimated by regressing the risk factors and the hospital-specific intercept on the risk of complication. The estimated hospital specific intercept is added coefficients multiplied by the patient characteristics. The results are transformed and summed over all patients attributed to a hospital to get a predicted value. The "expected" number of complications (the denominator) is obtained in the same manner, but a common intercept using all hospitals in our sample is added in place of the hospital specific intercept. The results are transformed and summed over all patients in the hospital to get an expected value. To assess hospital performance for each reporting period, we re-estimate the model coefficients using the years of data in that period.

Normand S-LT, Shahian DM. 2007. Statistical and Clinical Aspects of Hospital Outcomes Profiling. Stat Sci 22(2): 206-226.

S.19. **Calculation Algorithm/Measure Logic Diagram URL or Attachment** *(You also may provide a diagram of the Calculation Algorithm/Measure Logic described above at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
No diagram provided

S.20. **Sampling** *(If measure is based on a sample, provide instructions for obtaining the sample and guidance on minimum sample size.)*
IF a PRO-PM, identify whether (and how) proxy responses are allowed.
The measure is not based on a sample or survey.

S.21. **Survey/Patient-reported data** *(If measure is based on a survey, provide instructions for conducting the survey and guidance on minimum response rate.)*
IF a PRO-PM, specify calculation of response rates to be reported with performance measure results.

S.22. **Missing data** (specify how missing data are handled, e.g., imputation, delete case.)
Required for Composites and PRO-PMs.
ACC developed measures generally defaults missing data to "performance not met" However, this proposed measure is not treated like process measures where the measure is attempting to measure the documentation of a given care process. Rather the care that is being measured is—based on a number of variables—if there are certain complications within 30 or 90 days of the implantation. The rates of missing values for different elements in the data vary depending on the specific variable, but are rare (<2%).

Variables for which the missing value defaults to the median of the non-missing values of the corresponding variable are:
BUN
Hemoglobin
Sodium

Variables for which the missing was default to a specific values:

ICD type: single chamber
Reason for Admission defaults to "Admitted for procedure"
NYHA Classification defaults to "NYHA class I or II"
Prior CABG defaults to "no"
Abnormal conduction defaults to "no".

S.23. **Data Source** *(Check ONLY the sources for which the measure is SPECIFIED AND TESTED).*
If other, please describe in S.24.
Administrative claims, Electronic Clinical Data : Registry

S.24. **Data Source or Collection Instrument** *(Identify the specific data source/data collection instrument e.g. name of database, clinical registry, collection instrument, etc.)*
IF a PRO-PM, identify the specific PROM(s); and standard methods, modes, and languages of administration.
The datasets used to create the measures are described below.

(1)NCDR ICD Registry data
The National ICD Registry is a cardiovascular data registry which captures detailed information about patients at least 18 years of age undergoing ICD implantation. This includes demographics, comorbid conditions, cardiac status, and laboratory results. As of May 2015, the registry had collected data from 1,786 hospitals in the United States totaling over 1,330,000 implants (NCDR data outcome reports).

The registry, launched on June 30, 2005, was developed through a partnership of the Heart Rhythm Society (HRS) and the American College of Cardiology Foundation (ACCF) in response to CMS' expanded ICD coverage decision for primary prevention ICD therapy. Data included in the registry are collected by hospitals and submitted electronically on a quarterly basis to NCDR. The patient records submitted to the registry focus on acute episodes of care, from admission to discharge. The NCDR does not currently link patient records longitudinally across episodes of care.

The data collection form and the complete list of variables collected and submitted by hospitals can be found at www.ncdr.com. For more information on these data, please see the attached methodology report.

Of note, hospitals are only required to submit data on all primary prevention ICDs implanted in Medicare patients, and, of the 159 data elements collected by the ICD Registry, only 54 are forwarded to CMS by ACC to determine payment eligibility. Nevertheless, the majority of participating hospitals have opted to participate fully in the quality improvement aspect of the registry, and submit all data elements on all patients undergoing ICD implantation.

(2)Medicare Data
The model was developed in a population of Medicare fee-for-service beneficiaries but can be expanded to all ICD patients at least 65 years of age. We used the administrative claims data to identify complications.

(a) Part A inpatient and outpatient data: Part A data refers to claims paid for Medicare inpatient hospital care, outpatient hospital services, skilled nursing facility care, some home health agency services, and hospice care. For this measure, we used Part A data to identify ICDs implanted for admitted and non-admitted patients (i.e. hospital patients with observation status). For model development, we used 2007 Medicare Part A data to match patient stays associated with an ICD with comparable data from the NCDR ICD Registry.

(b) Medicare Enrollment Database (EDB): This database contains Medicare beneficiary demographic, benefit/coverage, and vital status information. This dataset was used to obtain information on several inclusion/exclusion indicators, such as Medicare status on admission, and provided the ability to retrieve 90 days follow-up, linking patient Health Insurance Claim (HIC) number to the Part A data. These data have previously been shown to accurately reflect patient vital status (Fleming Fisher et al. 1992).

S.25. **Data Source or Collection Instrument** *(available at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
Available in attached appendix at A.1

S.26. **Level of Analysis** *(Check ONLY the levels of analysis for which the measure is SPECIFIED AND TESTED)*
Facility, Population : National

S.27. **Care Setting** *(Check ONLY the settings for which the measure is SPECIFIED AND TESTED)*
Ambulatory Care : Urgent Care, Hospital/Acute Care Facility

2b. Validity – See attached Measure Testing Submission Form
0694_Complications_testing__061715_submitted-635705702135277500.docx

Composite Measure Title: 0694

Measure Title: Hospital-level Risk-Standardized Complication Rate following Implantation of Implantable Cardioverter-Defibrillator

Date of Submission: Click here to enter a date

Composite Construction:

☐Two or more individual performance measure scores combined into one score

☐ All-or-none measures (e.g., all essential care processes received or outcomes experienced by each patient)

☐ Any-or-none measures (e.g., any or none of a list of adverse outcomes experienced, or inappropriate or unnecessary care processes received, by each patient

Instructions

- Measures must be tested for all the data sources and levels of analyses that are specified. ***If there is more than one set of data specifications or more than one level of analysis, contact NQF staff*** about how to present all the testing information in one form.
- **For all measures, sections 1, 2a2, 2b2, 2b3, and 2b5 must be completed.**
- **For outcome and resource use measures**, section **2b4** also must be completed.
- If specified for **multiple data sources/sets of specificaitons** (e.g., claims and EHRs), section **2b6** also must be completed.
- Respond to all questions as instructed with answers immediately following the question. All information on testing to demonstrate meeting the subcriteria for reliability (2a2) and validity (2b2-2b6) must be in this form. An appendix for *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 20 pages (*incuding questions/instructions;* minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the testing results for this measure meet NQF's evaluation criteria for testing.

2a2. Reliability testing [10] demonstrates the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise. For **PRO-PMs and composite performance measures**, reliability should be demonstrated for the computed performance score.

2b2. Validity testing [11] demonstrates that the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality. For **PRO-PMs and composite performance measures**, validity should be demonstrated for the computed performance score.

2b3. Exclusions are supported by the clinical evidence; otherwise, they are supported by evidence of sufficient frequency of occurrence so that results are distorted without the exclusion; [12]

AND

If patient preference (e.g., informed decision-making) is a basis for exclusion, there must be evidence that the exclusion impacts performance on the measure; in such cases, the measure must be specified so that the information about patient preference and the effect on the measure is transparent (e.g., numerator category computed separately, denominator exclusion category computed separately). [13]

2b4. For outcome measures and other measures when indicated (e.g., resource use):

- **an evidence-based risk-adjustment strategy** (e.g., risk models, risk stratification) is specified; is based on patient factors that influence the measured outcome (but not factors related to disparities in care or the quality of care) and are present at start of care; [14,15] and has demonstrated adequate discrimination and calibration

OR

- rationale/data support no risk adjustment/ stratification.

2b5. Data analysis of computed measure scores demonstrates that methods for scoring and analysis of the specified measure allow for **identification of statistically significant and practically/clinically meaningful [16] differences in performance**;

OR

there is evidence of overall less-than-optimal performance.

2b6. If multiple data sources/methods are specified, there is demonstration they produce comparable results.

2b7. For **eMeasures, composites, and PRO-PMs** (or other measures susceptible to missing data), analyses identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and non-responders) and how the specified handling of missing data minimizes bias.

Notes

10. Reliability testing applies to both the data elements and computed measure score. Examples of reliability testing for data elements include, but are not limited to: inter-rater/abstractor or intra-rater/abstractor studies; internal consistency for multi-item scales; test-retest for survey items. Reliability testing of the measure score addresses precision of measurement (e.g., signal-to-noise).

11. Validity testing applies to both the data elements and computed measure score. Validity testing of data elements typically analyzes agreement with another authoritative source of the same information. Examples of validity testing of the measure score include, but are not limited to: testing hypotheses that the measures scores indicate quality of care, e.g., measure scores are different for groups known to have differences in quality assessed by another valid quality measure or method; correlation of measure scores with another valid indicator of quality for the specific topic; or relationship to conceptually related measures (e.g., scores on process measures to scores on outcome measures). Face validity of the measure score as a quality indicator may be adequate if accomplished through a systematic and transparent process, by identified experts, and explicitly addresses whether performance scores resulting from the measure as specified can be used to distinguish good from poor quality.

12. Examples of evidence that an exclusion distorts measure results include, but are not limited to: frequency of occurrence, variability of exclusions across providers, and sensitivity analyses with and without the exclusion.

13. Patient preference is not a clinical exception to eligibility and can be influenced by provider interventions.

14. Risk factors that influence outcomes should not be specified as exclusions.

15. Risk models should not obscure disparities in care for populations by including factors that are associated with differences/inequalities in care, such as race, socioeconomic status, or gender (e.g., poorer treatment outcomes of African American men with prostate cancer or inequalities in treatment for CVD risk factors between men and women). It is preferable to stratify measures by race and socioeconomic status rather than to adjust out the differences.

16. With large enough sample sizes, small differences that are statistically significant may or may not be practically or clinically meaningful. The substantive question may be, for example, whether a statistically significant difference of one percentage point in the percentage of patients who received smoking cessation counseling (e.g., 74 percent v. 75 percent) is clinically meaningful; or whether a statistically significant difference of $25 in cost for an episode of care (e.g., $5,000 v. $5,025) is practically meaningful. Measures with overall less-than-optimal performance may not demonstrate much variability across providers.

1. DATA/SAMPLE USED FOR ALL TESTING OF THIS MEASURE

Often the same data are used for all aspects of measure testing. In an effort to eliminate duplication, the first five questions apply to all measure testing. If there are differences by aspect of testing,(e.g., reliability vs. validity) be sure to indicate the specific differences in question 1.7.

1.1. What type of data was used for testing? (*Check all the sources of data identified in the measure specifications and data used for testing the measure*. *Testing must be provided for <u>all</u> the sources of data specified and intended for measure implementation.* ***If different data sources are used for the numerator and denominator, indicate N [numerator] or D [denominator] after the checkbox.***)

Measure Specified to Use Data From: (*must be consistent with data sources entered in S.23*)	**Measure Tested with Data From:**
☐ abstracted from paper record	☐ abstracted from paper record
☒ administrative claims	☐ administrative claims
☒ clinical database/registry	☐ clinical database/registry
☐ abstracted from electronic health record	☐ abstracted from electronic health record
☐ eMeasure (HQMF) implemented in EHRs	☐ eMeasure (HQMF) implemented in EHRs
☐ other: Click here to describe	☐ other: Click here to describe

1.2. If an existing dataset was used, identify the specific dataset (*the dataset used for testing must be consistent with the measure specifications for target population and healthcare entities being measured; e.g., Medicare Part A claims, Medicaid claims, other commercial insurance, nursing home MDS, home health OASIS, clinical registry*).

We propose to use a clinical registry, the National Cardiovascular Data Registry (NCDR) ICD Registry. This is a national quality improvement registry that is currently participated in >1,600 US hospitals. Some states and healthcare systems mandate participation. Rigorous quality standards are applied to the data and both quarterly and ad hoc performance reports are generated for participating centers to track and improve their performance.

The measure links clinical data from NCDR to Medicare claims data to ascertain complications.

1.3. What are the dates of the data used in testing? Click here to enter date range

1.4. What levels of analysis were tested? (*testing must be provided for <u>all</u> the levels specified and intended for measure implementation, e.g., individual clinician, hospital, health plan*)

Measure Specified to Measure Performance of: (*must be consistent with levels entered in item S.26*)	**Measure Tested at Level of:**
☐ individual clinician	☐ individual clinician
☐ group/practice	☐ group/practice
☒ hospital/facility/agency	☒ hospital/facility/agency
☐ health plan	☐ health plan
☐ other: Click here to describe	☐ other: Click here to describe

1.5. How many and which <u>measured entities</u> were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of measured entities included in the analysis (e.g., size, location, type); if a sample was used, describe how entities were selected for inclusion in the sample*)

For this measure, hospitals are the measured entities. All non-federal, acute inpatient US hospitals (including territories) that participate in the American College of Cardiology (ACC) NCDR's ICD Registry and care for Medicare Fee-for-Service (FFS) beneficiaries who are 65 years of age or older are included. The number of measured entities (hospitals) varies by testing type; see Section 1.7 for details.

1.6. How many and which <u>patients</u> were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of patients included in the analysis (e.g., age, sex, race, diagnosis); if a sample was used, describe how patients were selected for inclusion in the sample*)

1.7. If there are differences in the data or sample used for different aspects of testing (e.g., reliability, validity, exclusions, risk adjustment), identify how the data or sample are different for each aspect of testing reported below.

The measure reliability dataset linked the ICD registry and Medicare Part A claims data from 2010Q2-2011Q4. The combined two-year sample included 43, 711 to 1,279 hospitals with 21,856 admissions to 1,254 hospitals in one randomly selected sample and 21,855 admissions to 1,246 hospitals in the remaining sample for patients aged 65 years and older. After excluding hospitals with fewer than 25 cases in each sample, the first sample contained 297 hospitals and the second sample contained 298 hospitals. In addition to being used for reliability testing, the linked dataset was used for measure exclusions testing (Section 2b3).

These analyses used a cohort of patients undergoing ICD placement for whom NCDR ICD Registry data were linked with corresponding administrative claims data. However, we also conducted additional analyses to meet newer testing requirements, and these analyses were performed using comparable linked data from 2010-2011. Details are provided below.

<u>Reliability testing (Section 2a2) and exclusions testing (Section 2b3)</u>
The measure reliability dataset linked the ICD and Medicare Part A claims data for claims between 2010Q2 and 2011Q4. The sample included ICD placement in a cohort of 43,711 Medicare FFS patients aged 65 years and older performed in 1279 hospitals. We then randomly split the sample, leaving 21,856 admissions to 1,254 hospitals in one randomly selected sample and 21,855 admissions to 1,246 hospitals in the remaining sample for patients aged 65 years and older. After excluding hospitals with fewer than 25 cases in each sample, the first sample contained 297 hospitals and the second sample contained 298 hospitals. The linked dataset was also used for measure exclusions testing (Section 2b3).

<u>Validity testing (Section 2b2)</u>

A summary of validity testing undertaken has been provided in 3c.1 of the application form. A chart validation study has been completed to determine whether ICD-9-CM diagnosis and procedure codes reported on Medicare claims and used in the measure specifications accurately identified patients experiencing ICD complications within 30 and 90 days of ICD implantation as reported in the medical charts. The findings of the study reported an overall agreement between chart and claims (based on paired ratings) of 91.5%.

Measure development and risk-adjustment dataset (Section 2b4)

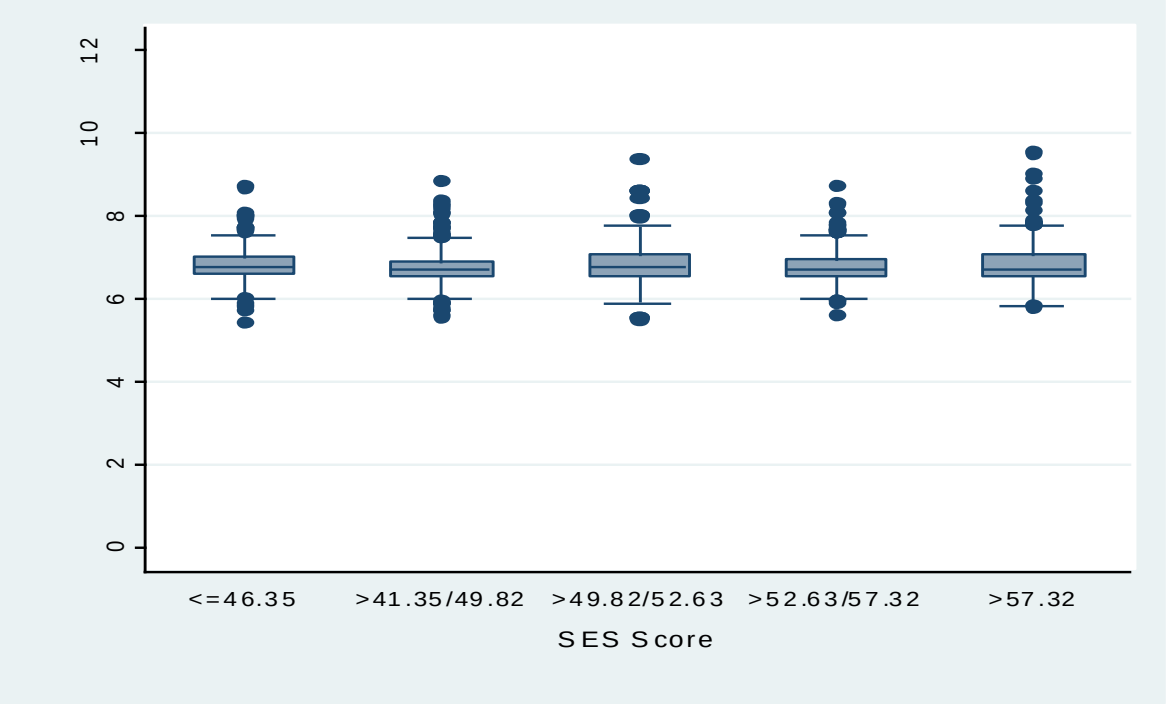
In measure development, we identified ICD procedures in the NCDR ICD Registry in which the patient was released from the hospital between April 2010 and December 2011. We merged ICD admissions in the NCDR ICD Registry data and ICD admissions in Medicare claims data to derive cohorts for development using probabilistic matching methodology. There were 21,855 cases discharged from the 1226 hospitals in the validation sample. This validation sample had a crude complication rate of 6.71%

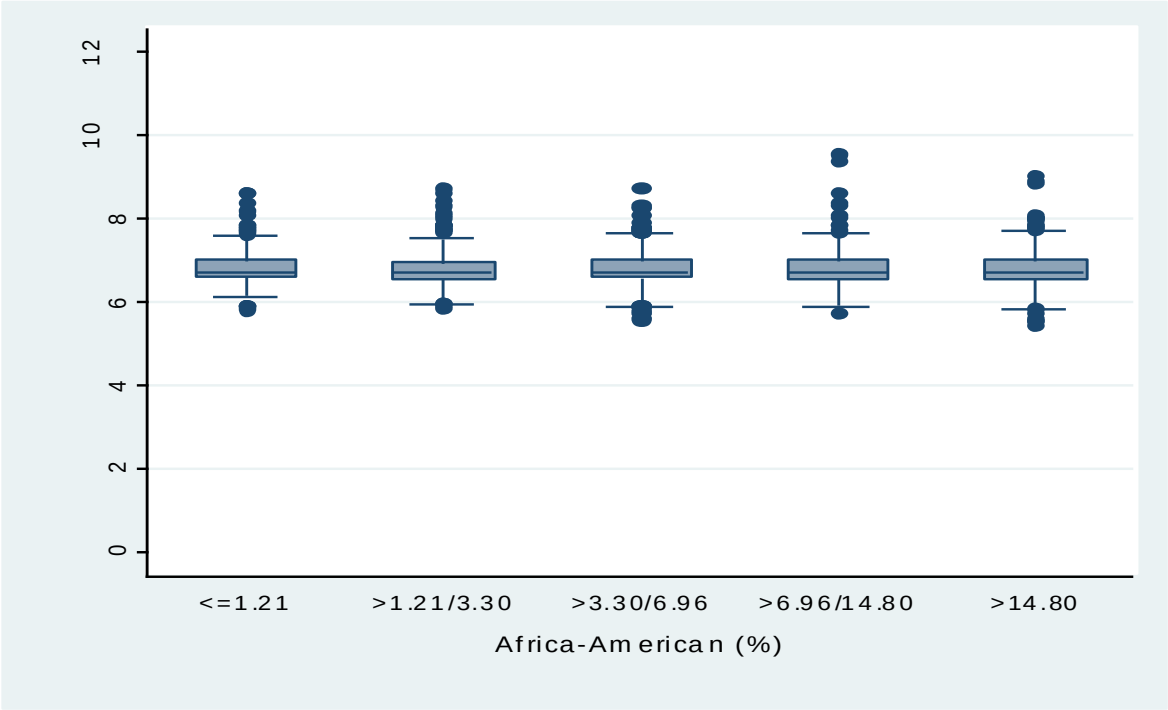
1.8 What were the patient-level sociodemographic (SDS) variables that were available and analyzed in the data or sample used? For example, patient-reported data (e.g., income, education, language), proxy variables when SDS data are not collected from each patient (e.g. census tract), or patient community characteristics (e.g. percent vacant housing, crime rate).

We examined health disparities associated with this measure by race/ethnicity and by socioeconomic status (SES). For both sets of analyses, the hospitals were grouped by quintiles of the rate of Africa Americans or the median SES score within a hospital. SES status (SES score) was determined from AHRQ SES Index data, and the percentage of African American patients was derived from CMS FFS patients for any condition during 2010 and 2011.

Dates of Data: 2010Q2 – 2011Q4
Number of Measured Entities (Hospitals): 1279
Number of Patients: 43711

The box and whisker plots below demonstrate the distribution of risk standardized complication rates (RSCRs) by SES score, and by the percentage of African-American patients.





2a2. RELIABILITY TESTING

Note*: If accuracy/correctness (validity) of data elements was empirically tested, separate reliability testing of data elements is not required – in 2a2.1 check critical data elements; in 2a2.2 enter "see section 2b2 for validity testing of data elements"; and skip 2a2.3 and 2a2.4.*

2a2.1. What level of reliability testing was conducted? (*may be one or both levels*)

☒ **Critical data elements used in the measure** (*e.g., inter-abstractor reliability; data element reliability must address ALL critical data elements*)

☒ **Performance measure score** (e.g., *signal-to-noise analysis*)

2a2.2. For each level checked above, describe the method of reliability testing and what it tests (*describe the steps—do not just name a method; what type of error does it test; what statistical analysis was used*)

Data Element Reliability

In constructing the measure we aim to utilize only those data elements from the claims that have both face validity and reliability. We avoid the use of fields that are thought to be coded inconsistently across hospitals or providers. Specifically, we use fields that are consequential for payment and which are audited. We identify such variables through empiric analyses and our understanding of CMS auditing and billing policies and seek to avoid variables which do not meet this standard. For example, "discharge disposition" is a variable in Medicare claims data that is not thought to be a reliable variable for identifying a transfer between two acute care facilities. Thus, we derive a variable using admission and discharge dates as a surrogate for "discharge disposition" to identify hospital admissions involving transfers. This allows us to identify these admissions using variables in the claims data which have greater reliability than the "discharge disposition" variable. In addition, CMS has in place several hospital auditing programs used to assess overall claims code accuracy, to ensure appropriate billing, and for overpayment recoupment. CMS routinely conducts data analysis to identify potential problem areas and detect fraud, and audits important data fields used in our measures, including diagnosis and procedure codes and other elements that are consequential to payment.

In addition, as an example of some of the methods that could be used to ensure data quality, we describe the NCDR's existing Data Quality Program (DQP). The two main component of the DQP are complementary and consist of the Data Quality Report (DQR) and the Data Audit Program (DAP). The DQR process assesses the completeness and validity of the electronic data submitted by participating hospitals. Hospitals must achieve >95% completeness of specific data elements identified as 'core fields' to be included in the registry's data warehouse for analysis. The 'core fields' include the variables included in 25 our risk adjustment models. The process is iterative, providing hospitals with the opportunity to correct errors and resubmit data for review and acceptance into the data warehouse. The DAP consists of annual on-site chart review and data abstraction. Among participating hospitals that pass the DQ random charts of 10% of submitted cases.

Finally, we assess the reliability of the data elements by comparing model variable frequencies and odds ratios in two years of data.

Measure Score Reliability

The reliability of a measurement is the degree to which repeated measurements of the same entity agree with each other. For measures of hospital performance, the measured entity is naturally the hospital, and reliability is the extent to which repeated measurements of the same hospital give similar results. In line with this thinking, our approach to assess reliability is to consider the extent to which assessments of a hospital using different, but randomly selected subsets of patients, produce similar measures of hospital performance. That is, we take a "test-retest" approach in which hospital performance is measured once using a random subset of patients, then measured again using a second random subset exclusive of the first, and finally comparing the agreement between the two resulting performance measures across hospitals (Rousson et al., 2002).

For test-retest reliability of the measure score, from the study cohort, we randomly sampled half of patients within each hospital, calculated the measure for each hospital in the first half, and then repeated the calculation using the second half. Thus, each hospital is measured twice, but each measurement is made using an entirely distinct set of patients. To the extent that the calculated measures of these two subsets agree, we have evidence that the measure is assessing an attribute of the hospital, not of the patients. As a metric of agreement we calculated the intra-class correlation coefficient (ICC) (Shrout and Fleiss, 1979), and assessed the values according to conventional standards (Landis and Koch, 1977). Specifically, we used the two data samples and calculated the risk-standardized complication rate (RSCR) for each hospital for each sample. The agreement of the two RSCRs was quantified for hospitals in each sample using the intra-class correlation (ICC) as defined by Shrout and Fleiss (1979).

Using two independent samples provides an honest estimate of the measure's reliability, compared with using two random, but potentially overlapping samples, which would exaggerate the agreement. Moreover, because our final measure is derived using hierarchical logistic regression, and a known property of hierarchical logistic regression models is that small volume hospitals contribute less ´signal´. As such a split sample using a single measurement period likely introduces extra noise; potentially underestimating the actual test-retest reliability that would be achieved if the measures were reported using additional years of data. Furthermore, the measure is specified for the entire ICD population, but we tested it only in the subset of Medicare FFS patients for whom information about vital status was available.

2a2.3. For each level of testing checked above, what were the statistical results from reliability testing? (e.*g., percent agreement and kappa for the critical data elements; distribution of reliability statistics from a signal-to-noise analysis*)

Data element reliability results

Overall, risk factor frequencies changed little across years, and there were no notable differences in the odds ratios across years of data.

Split Sample Methodology:

Distribution of RSCR within random split samples

Description	**First (RAND= 1)**	**Second (RAND= 0)**
N	1254	1246
Mean	17.43	17.54
Std. Deviation	18.01	17.99
100% Max	0.0839	0.0836
75% Q3	0.0713	0.0676
50% Median	0.0697	0.0653
25% Q1	0.0684	0.0634

Results of the split sample testing are provided above. The 2 split samples were calculated during the same timeframe to avoid the potential for changes in hospital performance over time. After splitting the cohort into two random samples, we compared measure scores calculated at hospitals with at least 25 cases in both random samples. The distribution of hospital performance was similar in the two samples (figure below), and there was a fair correlation between hospital performances assessed in the two samples (r 0.1494).

Measure score reliability results

In the most recent years of data (2010Q1-2011Q4), there were 43,711 admissions in the combined two-year sample, with 21,856 admissions to 1,254 hospitals in the first randomly selected sample (mean RSCR 7.01%), and 21,855 admissions to 1,246 hospitals in the second randomly-selected sample (mean RSCR 6.58%). The agreement between the two RSCRs for each hospital was 0.1494, which according to the conventional interpretation is “slight” (Landis & Koch, 1977). The intra-class correlation coefficient is based on a split sample of 2 years of data, resulting in a volume of patients in each sample equivalent to only 1 year of data, whereas the measure is likely to be reported with a full two years of data.

Reference.

Landis J, Koch G. The measurement of observer agreement for categorical data, Biometrics 1977;33:159-174..

2a2.4 What is your interpretation of the results in terms of demonstrating reliability? (i*.e., what do the results mean and what are the norms for the test conducted?*)

The stability over time of the risk factor frequencies and odds ratios indicate that the underlying data elements are reliable. Additionally, the ICC score demonstrates fair agreement across samples using a "strict" approach to assessment that would likely improve with greater sample size.

2b2. VALIDITY TESTING

2b2.1. What level of validity testing was conducted? (*may be one or both levels*)

☒ **Critical data elements** (*data element validity must address ALL critical data elements*)

☒ **Performance measure score**

☒ **Empirical validity testing**

☐ **Systematic assessment of face validity of performance measure score as an indicator** of quality or resource use (*i.e., is an accurate reflection of performance on quality or resource use and can distinguish good from poor performance*)

2b2.2. For each level of testing checked above, describe the method of validity testing and what it tests (*describe the steps—do not just name a method; what was tested, e.g., accuracy of data elements compared to authoritative source, relationship to another measure as expected; what statistical analysis was used)*
Measure validity is demonstrated through prior validity testing done on our other measures, through use of established measure development guidelines, by systematic assessment of measure face validity by a technical expert panel (TEP) of national experts and stakeholder organizations, and through registry data validation.

Validity of Registry Data
Data element validity testing was done on the specified measure by comparing with variables in the ACC audit program. The NCDR ICD Registry has an established DQP that serves to assess and improve the quality of the data submitted to the registry. There are two complementary components to the Data Quality Program- the Data Quality Report (DQR) and the Data Audit Program (DAP). The DQR process assesses the completeness of the electronic data submitted by participating hospitals. Hospitals must achieve >95% completeness of specific data elements identified as "core fields" to be included in the registry's data warehouse for analysis. The "core fields" encompass the variables included in our risk adjustment models. The process is iterative, providing hospitals with the opportunity to correct errors and resubmit data for review and acceptance into the data warehouse. All data for this analysis passed the DQR completeness thresholds.

The DAP consists of annual on-site chart review and data abstraction. Among participating hospitals that pass the DQR for a minimum of two quarters, at least 5% are randomly selected to participate in the DAP. At individual sites, auditors review charts of 10% of submitted cases. The audits focus on variables that are used in the NCDR risk-adjusted in-hospital mortality model including demographics, comorbidities, cardiac status, coronary anatomy, and ICD status. However, the scope of the audit could be expanded to include additional fields. The DAP includes an appeals process for hospitals to dispute the audit findings.

We also examined the temporal variation of the standardized estimates and frequencies of the variables in the development and validation models.

To assess the predictive ability of the model, we grouped patients into deciles of predicted 30 or 90 day complication and compared predicted complication with observed complication for each decile in the derivation cohort (figure 2).

As noted in more detail in 3c.1 of the application form, a chart validation study has been completed to determine whether ICD-9-CM diagnosis and procedure codes reported on Medicare claims and used in the measure specifications accurately identified patients experiencing ICD complications within 30 and 90 days of ICD implantation as reported in the medical charts. The findings of the study reported an overall agreement between chart and claims (based on paired ratings) of 91.5%. Table 2 and figure 1 provide a depiction of the agreement and disagreement for patients with complication identified by charts and claims.

Figure 1. Number of Patients with Complication Identified by Charts and/or Claims

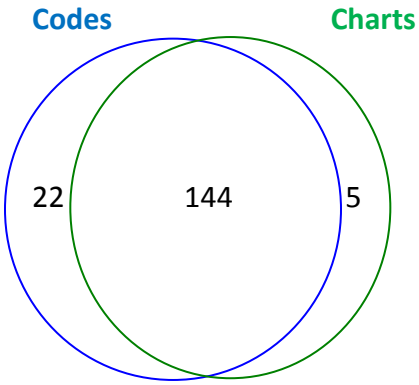

Table 2. Number of Cases of Disagreement and Agreement for Patients with Complication Identified by Charts and Claims

		CHARTS	
		YES	**NO**

	NO	**5**	**145**

Validity as Assessed by External Groups

During original measure development and in alignment with the CMS Measures Management System (MMS), we released a public call for nominations and convened a TEP when originally developing the measure. The purpose of convening the TEP was to provide input and feedback during measure development from a group of recognized experts in relevant fields. The TEP represented physician, consumer, hospital, and purchaser perspectives, chosen to represent a diverse of perspectives and backgrounds.

ICD-9 to ICD-10 Conversion

Statement of Intent

[X] Goal was to convert this measure to a new code set, fully consistent with the intent of the original measure.
[ ] Goal was to take advantage of the more specific code set to form a new version of the measure, but fully consistent with the original intent.
[ ] The intent of the measure has changed.

Process of Conversion

ICD-10 codes were initially identified using 2013 General Equivalence Mapping (GEM) software. We then enlisted the help of clinicians with expertise in relevant areas to select and evaluate which ICD-10 codes map to the ICD-9 codes currently in use for this measure. An ICD-9 to ICD-10 crosswalk is attached in field S.2b.(Data Dictionary or Code Table).

Lead clinical expert

Jeptha Curtis, M.D., Associate Professor of Medicine, Section of Cardiovascular Disease, Yale University

The full list of individuals involved are listed under the main application section Ad.1.

Table 3. 30 / 90 Day Complications Model Performance: Results Based on the GLM

Indices	**Derivation Sample**	**Validation Sample**
Year	2010-11	2010-11
RR Calibration (γ0, γ1)[1]	(0.00, 1.00)	(0.03, 1.02)
Discrimination- Adjusted R-Square[2]	0.07	0.06
Discrimination -Predictive Ability[3] (lowest decile %, highest	(4.05, 25.08)	(3.80, 23.80)
Discrimination – ROC	0.64	0.642
Residuals Lack of Fit (Pearson Residual Fall %)		
<-2	0.00	0.00
[-2, 2)	93.19	93.43
> 2	6.81	6.57
Model χ^2 [Number of Covariates][4]	328 [9]	355 [9]

2b2.3. What were the statistical results from validity testing? (*e.g., correlation; t-test*)

The performance of the derivation and validation samples is similar. The areas under the receiver operating characteristic (ROC) curve are 0.640 and 0.642, respectively, for the two samples. In addition, they are similar with respect to predictive ability. For the derivation sample, the predicted complication rate ranges from 3% in the lowest predicted decile to 14% in the highest predicted decile, a range of 11%. For the validation sample, the corresponding range is 3% to 14%, also a range of 11%.
Additionally, the frequencies and regression coefficients are fairly consistent over the two years of data. Also, there was excellent correlation between predicted and observed complications.

2b2.4. What is your interpretation of the results in terms of demonstrating validity? (i.*e., what do the results mean and what are the norms for the test conducted?*)

_____ The audits conducted by the ACC support the overall validity of the data elements included in this measure. The data elements used for risk adjustment were consistently found for all patients and were accurately extracted from the medical record.

_____

2b3. EXCLUSIONS ANALYSIS

NA ☐ no exclusions — *skip to section 2b4*

2b3.1. Describe the method of testing exclusions and what it tests (*describe the steps—do not just name a method; what was tested, e.g., whether exclusions affect overall performance scores; what statistical analysis was used*)

All exclusions were determined by careful clinical review and have been made based on clinically relevant decisions. To ascertain impact of exclusions on the cohort, we examined overall frequencies and proportions of the total cohort excluded for each exclusion criterion. These exclusions are consistent with similar NQF-endorsed complication measures. Rationales for the exclusions are detailed in data field S.10 (Denominator Exclusions).

2b3.2. What were the statistical results from testing exclusions? (*include overall number and percentage of individuals excluded, frequency distribution of exclusions across measured entities, and impact on performance measure scores*)

We examined overall frequencies and proportions of the admissions excluded for each exclusion criterion in the most recent data (2010Q1-2011Q4). The initial sample without exclusions included 112,341 admissions to 1,319 hospitals. After applying the exclusion criteria as outlined in Table 4, the 2010-2011 study sample included 43,711 patients admitted to 1,279 hospitals.

Table 4. Exclusions from the target cohort for the combined 2010-2011 study sample.

Exclusions	2010Q2 to 2011Q4			
	Patient Stay		Hospitals	
	#	%	#	%

Study Sample	**43711**		**1279**	
Complication		0.00		
Mortality		0.00		
Mortality or Complications		0.00		

2b3.3. What is your interpretation of the results in terms of demonstrating that exclusions are needed to prevent unfair distortion of performance results? (*i.e., the value outweighs the burden of increased data collection and analysis. Note: **If patient preference is an exclusion**, the measure must be specified so that the effect on the performance score is transparent, e.g., scores with and without exclusion*)

The majority of exclusions are necessary to 1) link registry and administrative data (e.g. excluding patient not enrolled in Medicare FFS) and 2) identify patients eligible for complication (e.g. excluding patients who died before discharge). As such, these exclusions are not discretionary and do not require further testing.

2b4. RISK ADJUSTMENT/STRATIFICATION FOR OUTCOME OR RESOURCE USE MEASURES

If not an intermediate or health outcome, or PRO-PM, or resource use measure, skip to section 2b5.

2b4.1. What method of controlling for differences in case mix is used?

2b4.2. If an outcome or resource use measure is not risk adjusted or stratified, provide rationale and analyses to demonstrate that controlling for differences in patient characteristics (case mix) is not needed to achieve fair comparisons across measured entities.
N/A. This measure is risk adjusted.

2b4.3. Describe the conceptual/clinical and statistical methods and criteria used to select patient factors used in the statistical risk model or for stratification by risk (*e.g., potential factors identified in the literature and/or expert panel; regression analysis; statistical significance of p<0.10; correlation of x or higher; patient factors should be present at the start of care and not related to disparities*)

We developed a parsimonious model that included key variables previously shown to be associated with complications following ICD implantation. Importantly, the variables included in the risk model were fully harmonized with the NCDR's existing risk model used to provide hospitals with risk adjusted in-hospital adverse events. In the development of that model, a team of clinicians had reviewed all variables in the NCDR ICD Registry database (a copy of the data collection form and the complete list of variables collected and submitted by hospitals can be found at www.ncdr.com and also in this application).

Based on clinical review informed by the literature, a total of 15 variables were determined to be appropriate for consideration as candidate variables. We used logistic regression with stepwise selection (entry p<0.05; retention with p<0.01) for variable selection. We also assessed the direction and magnitude of the regression coefficients. This resulted in a final risk-adjusted complication model that included 9 variables (table 5). To harmonize the models, we elected to apply this approach to risk adjustment to the 30/90 day complications risk model. Several variables were not clinically significantly associated with risk of complications at 30/90 days, but we elected to retain them in the model for consistency. We compared hospitals' RSCR calculated using this model with the output from a risk model that been developed specifically for 30/90 day complications and found them to be almost identical (correlation coefficient 0.996).

For categorical variables with missing values, the value from the reference group was added. The percentage of missing values for all categorical variables was very small (<1%) and they were imputed to a specific categories based on our previous experience. There were three continuous variables with missing values: **Hemoglobin** (HGB, 1.9%), **BUN** (1.3%), and **Sodium** (1.1%); and these missing values were imputed as the median of the non-missing values of the corresponding variable.

2b4.4. What were the statistical results of the analyses used to select risk factors?

2b4.5. Describe the method of testing/analysis used to develop and validate the adequacy of the statistical model or stratification approach (*describe the steps—do not just name a method; what statistical analysis was used*)

Approach to assessing model performance

During measure development, we computed three summary statistics for assessing model performance (Harrell and Shih, 2001) for the development and validation cohort:

Discrimination Statistics:

(1) Area under the receiver operating characteristic (ROC) curve (the c statistic (also called ROC) is the probability that predicting the outcome is better than chance, which is a measure of how accurately a statistical model is able to distinguish between a patient with and without an outcome.)

(2) Predictive ability (discrimination in predictive ability measures the ability to distinguish high-risk subjects from low-risk subjects. Therefore, we would hope to see a wide range between the lowest decile and highest decile)

Calibration Statistics:

(3) Over-fitting indices (over-fitting refers to the phenomenon in which a model accurately describes the relationship between predictive variables and outcome in the development dataset but fails to provide valid predictions in new patients)

We compared the model performance in the development sample with its performance in another sample of half of the patients randomly selected from the whole 2010Q2-2011Q4 study cohort. There were 21, 856 cases discharged from the 1222 hospitals in the 2010-2011 validation dataset. This validation sample had a crude complication rate of 6.86%. We also computed statistics (1) and (2) for the current measure cohort, which includes discharges from 2010Q2-2011Q4.

Provide the statistical results from testing the approach to controlling for differences in patient characteristics (case mix) below.
If stratified, skip to 2b4.9

2b4.6. Statistical Risk Model Discrimination Statistics (*e.g., c-statistic, R-squared*)**:**

For the derivation cohort the results are summarized below:
C-statistic=0.640
Predictive ability (lowest decile %, highest decile %): 4.05%, 25.08%

For the validation cohort the results are summarized below:
C statistic=0.642
Predictive ability (lowest decile %, highest decile %): 3.80%, 23.80%

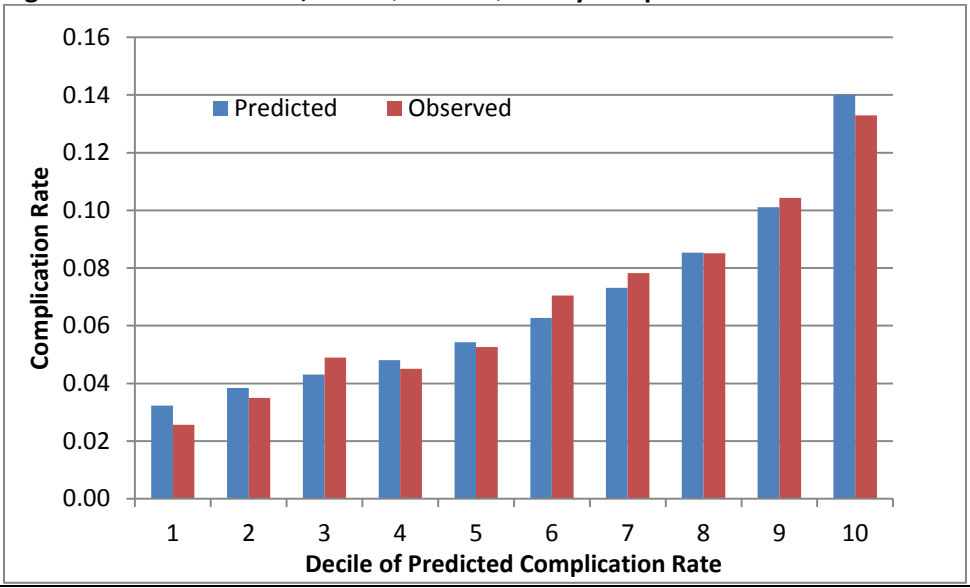
2b4.7. Statistical Risk Model Calibration Statistics (*e.g., Hosmer-Lemeshow statistic*):

For the validation cohort the results are summarized below:
Calibration: (0.03, 1.02)

2b4.8. Statistical Risk Model Calibration – Risk decile plots or calibration curves:

The risk decile plot is a graphical depiction of the deciles calculated to measure predictive ability. Below, we present the risk decile plot showing the distributions for the current measure cohort.

Figure 2. Risk Decile Plot, 2010Q2-2011Q4 study sample.



2b4.9. Results of Risk Stratification Analysis:

n/a

2b4.10. What is your interpretation of the results in terms of demonstrating adequacy of controlling for differences in patient characteristics (case mix)? (i*.e., what do the results mean and what are the norms for the test conducted*)

Discrimination Statistics
The C-statistics of 0.640 and 0.642 indicate fair model discrimination in the derivation and validation cohorts. Complications, as opposed to other outcomes such as mortality consistently have a lower c-statistic, even in medical record models. This is likely because complications are less determined by patient comorbidities and more by health system factors. The model indicated a wide range between the lowest decile and highest decile, indicating the ability to distinguish high-risk patients from low-risk patients.

Calibration Statistics
Over-fitting (Calibration γ0, γ1)
If the γ0 in the validation samples are substantially far from zero and the γ1 is substantially far from 1, there is potential evidence of over-fitting. The calibration value close to 0 at one end and close to 1 on the other end indicates good calibration of the model.

Risk Decile Plots
Higher deciles of the predicted outcomes are associated with higher observed outcomes, which show a good calibration of the model. This plot indicates excellent discrimination of the model and good predictive ability.

Overall Interpretation
Interpreted together, our diagnostic results demonstrate the risk-adjustment model adequately controls for differences in patient characteristics (case mix).

2b4.11. Optional Additional Testing for Risk Adjustment (*not required, but would provide additional support of adequacy of risk model, e.g., testing of risk model in another data set; sensitivity analysis for missing data; other methods that were assessed*)

N/A

2b5. IDENTIFICATION OF STATISTICALLY SIGNIFICANT & MEANINGFUL DIFFERENCES IN PERFORMANCE
2b5.1. Describe the method for determining if statistically significant and clinically/practically meaningful differences in performance measure scores among the measured entities can be identified (*describe the steps—do not just name a method; what statistical analysis was used? Do not just repeat the information provided related to performance gap in 1b)*

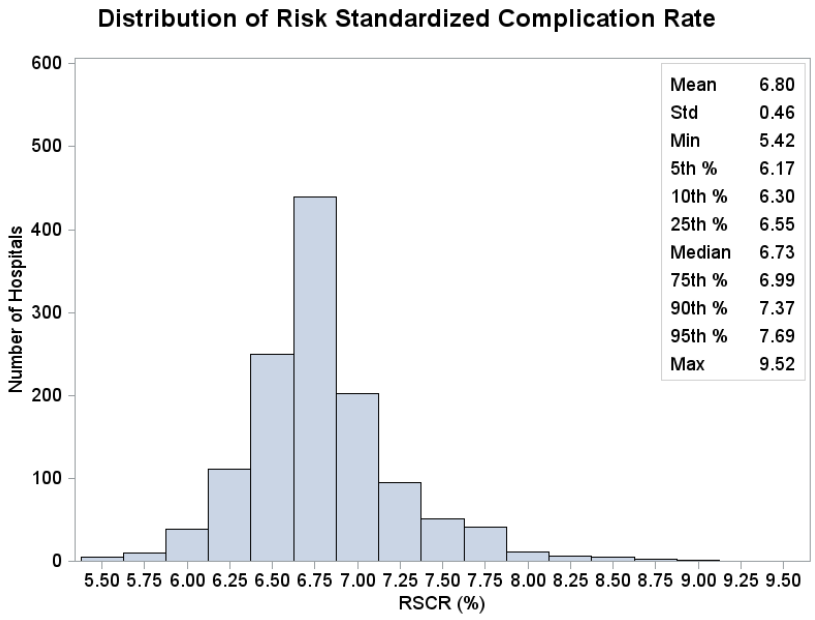
For the currently publicly reported measures of hospital outcomes, including the ICD 30/90 day complication measure, CMS estimates an interval estimate for each risk-standardized rate to characterize the amount of uncertainty associated with the rate. It then compares the interval estimate to the national crude rate for the outcome and categorizes hospitals as “better than,” “worse than,” or “no different than” the U.S. national rate (NCDR registry rate for ICD). We assessed variation in RSCRs among hospitals by examining the distribution of the hospital RSCRs and plotting the histogram of the hospital RSCRs.

2b5.2. What were the statistical results from testing the ability to identify statistically significant and/or clinically/practically meaningful differences in performance measure scores across measured entities? (e.g., *number and percentage of entities with scores that were statistically significantly different from mean or some benchmark, different from expected; how was meaningful difference defined*)

Recent analyses of Medicare FFS data show variation in RSCRs among hospitals. Using the most recent data sample (2010Q2-2011Q4) and updating the measure by applying the complication algorithm, the mean hospital RSCR was 6.8%, with a range of 5.42% to 9.52%. The interquartile range was 6.55% to 6.99%.

Figure 3. Distribution of risk-standardized complication rates (RSCRs); 2010Q2-2011Q4 sample.

Figure 3.



2b5.3. What is your interpretation of the results in terms of demonstrating the ability to identify statistically significant and/or clinically/practically meaningful differences in performance across measured entities? (i*.e., what do the results mean in terms of statistical and meaningful differences?*)

The variation in rates suggests there are clinically meaningful differences across hospitals for 30/90 day risk-standardized complications after ICD insertion.

2b6. COMPARABILITY OF PERFORMANCE SCORES WHEN MORE THAN ONE SET OF SPECIFICATIONS
***If only one set of specifications, this section can be skipped*.**

Note*: This criterion is directed to measures with more than one set of specifications/instructions (e.g., one set of specifications for how to identify and compute the measure from medical record abstraction and a different set of specifications for claims or eMeasures). It does not apply to measures that use more than one source of data in one set of specifications/instructions (e.g., claims data to identify the denominator and medical record abstraction for the numerator).* ***If comparability is not demonstrated, the different specifications should be submitted as separate measures.***

N/A . This measure has only one set of specifications.

2b6.1. Describe the method of testing conducted to demonstrate comparability of performance scores for the same entities across the different data sources/specifications (*describe the steps—do not just name a method; what statistical analysis was used*)

N/A . This measure has only one set of specifications.

2b6.2. What were the statistical results from testing comparability of performance scores for the same entities when using different data sources/specifications? (*e.g., correlation, rank order*)

N/A . This measure has only one set of specifications.

2b6.3. What is your interpretation of the results in terms of demonstrating comparability of performance measure scores for the same entities across the different data sources/specifications? (i.*e., what do the results mean and what are the norms for the test conducted*)

N/A . This measure has only one set of specifications.

2b7. MISSING DATA ANALYSIS AND MINIMIZING BIAS

2b7.1. Describe the method of testing conducted to identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias (*describe the steps—do not just name a method; what statistical analysis was used*)

We examined rates of missing data for all candidate variables and examined histograms of the frequency of missing data by hospital.

2b7.2. What is the overall frequency of missing data, the distribution of missing data across providers, and the results from testing related to missing data? (*e.g., results of sensitivity analysis of the effect of various rules for missing data/nonresponse; if no empirical sensitivity analysis, identify the approaches for handling missing data that were considered and pros and cons of each*)

Overall, the percentage of missing values for all categorical variables was very small (<1%) and they were imputed to a specific categories based on our previous experience. There were three continuous variables with missing values: **Hemoglobin** (HGB, 1.9%), **BUN** (1.3%), and **Sodium** (1.1%); And these missing values were imputed as the median of the non-missing values of the corresponding variable.

2b7.3. What is your interpretation of the results in terms of demonstrating that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias**?** (i.*e., what do the results mean in terms of supporting the selected approach for missing data and what are the norms for the test conducted; if no empirical analysis, provide rationale for the selected approach for missing data*)

As noted above, model performance was comparable when we included or excluded cases with missing data.

Additional analyses and input from the Developers of measure 0694:

Indicators of socioeconomic status are increasingly considered potentially important variables for inclusion in efforts to risk adjust outcomes measures. This is something that has been carefully considered by the stewards of this measure, and upon clinical review from the expert panel, found to be less associated with complications.

The routine inclusion of SDS variables into risk models has the potential to explain away meaningful and actionable differences in hospital performance. Analyses have shown that many hospitals caring for a higher proportion of disadvantaged patients still perform well on the measure. Furthermore, literature shows that the inclusion of SDS does not consistently meaningfully improve the discriminatory capacity of risk adjustment models, shown in urban areas with large disparities in wealth and income (Blum et al., 2014) and even more nationally representative samples (Eapen et al., 2015).

The variables considered for inclusion in the risk model were carefully considered for both clinical significance and strength of association with the primary outcome. Based on clinical review informed by the literature, a total of 15 variables were determined to be appropriate for consideration as candidate variables for the risk model. The final risk-adjusted complication model that included 9 variables was decided on after further logistic regression with stepwise selection for variable selection, as well as assessing the direction and magnitude of the regression coefficients. Importantly, as mentioned in section 2b4.2 of the testing form, variables incorporated in the risk model were fully harmonized with the NCDR's existing risk model used to provide hospitals with risk adjusted in-hospital adverse events.

The Agency for Healthcare Research and Quality (AHRQ)-validated SES index score provides an analytic approach to accounting for SDS status. It incorporates 7 independently weighted socioeconomic variables under 5 domains; occupation, income, wealth, education and housing. The ICD 30/90 day complications measure utilizes this score to show the distribution of risk standardized complication rates (RSCR) by SES status. Section 1.8 of the testing form details the results of this analysis, showing little appreciable variation in distribution of risk standardized complication rates. The conceptual reason and justification for not including SDS status as a variable within the model is demonstrated by these results. In these results, adjustment for socioeconomic status does not have a statistically meaningful impact on the complication measure results.

2d. EMPIRICAL ANALYSIS TO SUPPORT COMPOSITE CONSTRUCTION APPROACH

Note: *If empirical analyses do not provide adequate results—or are not conducted—justification must be provided and accepted in order to meet the must-pass criterion of Scientific Acceptability of Measure Properties. Each of the following questions has instructions if there is no empirical analysis.*

2d1. Empirical analysis demonstrating that the component measures fit the quality construct, add value to the overall composite, and achieve the object of parsimony to the extent possible.

On August 18th, 2015, the developer was informed by NQF staff that measure 0694 should be considered a composite measure. Developers updated the forms where possible. However, no empirical analysis could be performed in the time provided.

We believe the content validity of this measure has been achieved by virtue of the noted expertise of those individuals who developed this measure. The individual components of the composite have already shown to

impact clinical outcomes and specific information on how ACC determined which complications to include is outlined in 1.d.2.

However the empirical analysis demonstrating the individual component measures fit the overall quality construct is currently being researched. The testing will focus on construct validation which will test the hypothesis on the theory of the construct that following these processes for patients with ICD implantations lead to better outcomes. This research is expected to ultimately be published in the medical literature.

Measuring and reporting complications fit the overall construct. Also give the data burden, we believed we achieved the object of parsimony by including as few elements as possible without impacting the psychometric properties of measure 0694.

2d1.1 Describe the method used (*describe the steps—do not just name a method; what statistical analysis was used; if no empirical analysis, provide justification)*

All complications, as clinically defined by the subject matter experts were used with equal weighting and this straightforward approach is based on the current electrophysiology research.

2d1.2. What were the statistical results obtained from the analysis of the components? (e.g., *correlations, contribution of each component to the composite score, etc*.; *if no empirical analysis, identify the components that were considered and the pros and cons of each*)

We can provide data once testing is completed at the next maintenance review.

2d1.3. What is your interpretation of the results in terms of demonstrating that the components included in the composite are consistent with the described quality construct and add value to the overall composite? (i.*e., what do the results mean in terms of supporting inclusion of the components; if no empirical analysis, provide rationale for the components that were selected)*

We can provide data once testing is completed at the next maintenance review.

2d2. Empirical analysis demonstrating that the aggregations and weighting rules are consistent with the quality construct and achieve the objective of simplicity to the extent possible

We can provide data once testing is completed at the next maintenance review.

2d2.1 Describe the method used (*describe the steps—do not just name a method; what statistical analysis was used; if no empirical analysis, provide justification)*

We can provide data once testing is completed at the next maintenance review.

2d2.2. What were the statistical results obtained from the analysis of the aggregation and weighting rules? (e.g., *results of sensitivity analysis of effect of different aggregations and/or weighting rules; if no empirical analysis, identify the aggregation and weighting rules that were considered and the pros and cons of each*)

While no empirical analysis was performed, the developer carefully reviewed the weighing rules. In essence the goal of this measure is to improve patient outcomes by providing patients, physicians, and hospitals with

information about hospital-level, risk-standardized procedural complication rates following hospitalization for an ICD implantation. Measurement of patient outcomes allows for a broad view of quality of care that encompasses more than what can be captured by individual process-of-care measures. Complex and critical aspects of care, such as operator and hospital procedural expertise, communication among providers, prevention of and response to complications, patient safety, and coordinated transitions to the outpatient environment all contribute to patient outcomes but are difficult to measure by individual process measures. The goal of outcomes measurement is to risk-adjust for patients' conditions at the time of hospital admission and then evaluate patient outcomes. This measure was developed to identify institutions whose performance is better or worse than would be expected based on their patient case mix, and therefore promote hospital quality improvement and better inform consumers about care quality. In addition to mortality, all identified complications in the specifications were considered serious enough. If a patient had one or more complications, they get counted as a "complication".

2d2.3. What is your interpretation of the results in terms of demonstrating the aggregation and weighting rules are consistent with the described quality construct? (i.*e., what do the results mean in terms of supporting the selected rules for aggregation and weighting; if no empirical analysis, provide rationale for the selected rules for aggregation and weighting*)

All complications are weighted in the same manner.

2d3. Empirical analysis demonstrating that the approach for handling missing data minimizes bias (*i.e., achieves scores that are an accurate reflection of quality*)**.**

Note: *Applies to the overall composite measure; the focus is on missing data rather than exclusions, which are considered in 2b3.*

2d3.1. What is the overall frequency of missing data and the distribution of missing data across providers?

Please see section 2b7.2.

2d3.2. Describe the method used to compare approaches for handling missing data (*describe the steps—do not just name a method; what statistical analysis was used; if no empirical analysis, provide justification)*

We can provide data once testing is completed at the next maintenance review.

2d3.3. What were the statistical results obtained from the analysis of missing data? (e.g., *results of sensitivity analysis of effect of various rules for missing data; if no empirical analysis, identify the approaches for handling missing data that were considered and pros and cons of each*)

N/A

2d3.4. What is your interpretation of the results in terms of demonstrating that the approach used for missing data minimizes bias? (i.*e., what do the results mean in terms of supporting the selected approach for missing data; if no empirical analysis, provide rationale for the selected approach for missing data*)

We can provide data once testing is completed at the next maintenance review.

3. Feasibility

Extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

3a. Byproduct of Care Processes

For clinical measures, the required data elements are routinely generated and used during care delivery (e.g., blood pressure, lab test, diagnosis, medication order).

3a.1. **Data Elements Generated as Byproduct of Care Processes.**

Coded by someone other than person obtaining original information (e.g., DRG, ICD-9 codes on claims)

If other:

3b. Electronic Sources

The required data elements are available in electronic health records or other electronic sources. If the required data are not in electronic health records or existing electronic sources, a credible, near-term path to electronic collection is specified.

3b.1. **To what extent are the specified data elements available electronically in defined fields?** *(i.e., data elements that are needed to compute the performance measure score are in defined, computer-readable fields)*

ALL data elements are in defined fields in electronic clinical data (e.g., clinical registry, nursing home MDS, home health OASIS)

3b.2. **If ALL the data elements needed to compute the performance measure score are not from electronic sources, specify a credible, near-term path to electronic capture, OR provide a rationale for using other than electronic sources.**

3b.3. **If this is an eMeasure, provide a summary of the feasibility assessment in an attached file or make available at a measure-specific URL.**

Attachment:

3c. Data Collection Strategy

Demonstration that the data collection strategy (e.g., source, timing, frequency, sampling, patient confidentiality, costs associated with fees/licensing of proprietary measures) can be implemented (e.g., already in operational use, or testing demonstrates that it is ready to put into operational use). For eMeasures, a feasibility assessment addresses the data elements and measure logic and demonstrates the eMeasure can be implemented or feasibility concerns can be adequately addressed.

3c.1. **Describe what you have learned/modified as a result of testing and/or operational use of the measure regarding data collection, availability of data, missing data, timing and frequency of data collection, sampling, patient confidentiality, time and cost of data collection, other feasibility/implementation issues.**

IF a PRO-PM, consider implications for both individuals providing PROM data (patients, service recipients, respondents) and those whose performance is being measured.

The National Quality Forum (NQF) first endorsed this measure in September 2010. This measure provides information on the hospital risk-standardized rates of complications following the implantation of an ICD in Medicare fee-for-service (FFS) patients at least 65 years of age. In developing the measure, we used clinical data from the National Cardiovascular Data Registry (NCDR) ICD Registry for risk adjustment, and linked that data to CMS administrative claims data. The claims data were used to identify ICD-related complications via ICD-9-CM diagnosis and procedure codes.

Considering that the administrative database may be subject to coding errors and variation in coding practices within and across care settings, the ICD measure development team at YNHHSC/CORE chose to conduct a chart validation study. The goal was to determine whether ICD-9-CM diagnosis and procedure codes reported on Medicare claims and used in the measure specifications accurately identify patients experiencing ICD complications within 30 or 90 days of ICD implantation as reported in the medical charts. This approach required obtaining medical records of patients who had an ICD implanted from participating hospitals, abstracting data related to ICD complications (including number of complications, timing, severity and treatment), conducting a head-to-head comparison of data between Medicare claims and medical records to assess the degree of agreement, and finally, where appropriate, adjusting the list of codes and/or the cohort definition in the ICD measure specifications to improve the agreement.

We calculated the sample size requirement based on the desired degree of agreement between medical records and claims data, which can be categorized as fair, moderate, substantial, or almost perfect depending on the magnitude of the kappa coefficient2. Our initial calculation was based on achieving a “substantial” degree of agreement, and accounting for a within-hospital correlation coefficient of 0.03. This would have required approximately 860 medical records. To compensate for missing charts, we added 10-20 percent to the required sample size. This increased the required number to nearly 1000 charts, which would have resulted in

doubling our budgetary allotment. We therefore decided to keep the sample size at 500 medical records from 9 candidate hospitals. This sample size would allow a qualitative assessment of the ICD-9-CM codes used in the claims model while meeting NQF review committee standards, considering budgetary and time constraints.

Thus, our approach was to recruit 9 hospitals and request copies of medical charts for approximately 60 Medicare FFS patients who had an ICD implanted between 2005 and 2007, 30 with and 30 without complications at each hospital. This number also accounted for 10 to 20 percent of medical records that may be missing. Given the low ICD complication rate, we selected sites that had a minimum of 25 cases with complications over the three-year period.

Although we planned to review approximately 540 charts from 9 hospitals, the final sample size was 411. One of the 9 hospitals withdrew from the project and did not provide the charts, though it previously signed both, a data use agreement (DUA) and a business associate agreement (BAA). Because they withdrew 9 months into the study, there was insufficient time remaining in the contract to recruit a replacement hospital. The remaining 8 hospitals provided 411 charts out of the 480 requested, with 69 (14.4%) missing charts.

Summary of Study and Findings:

- 9 Hospitals agreed to participate in the study; 8 completed the study and one withdrew
- Of the 480 charts requested, 411 were obtained from 8 hospitals (14.4% of missing charts)
- Charts were abstracted by professional chart abstractors at an independent company, Information Collection Enterprises, LLC (ICE)
- We excluded 95 cases because they had a previous ICD (consistent with current measure specifications). Thus, the study was based on 316 patients
- We identified 149 patients with complications (1 or more complication) in the chart, while administrative codes identified 166 patients with complications; 144 patients with complications were identified by both charts and codes; 22 by codes only; and 5 by charts only.

- These findings resulted in an overall agreement between chart and claims (based on all paired ratings) of 91.5% [Yes/Yes(144) + No/No(145) / total (316)=0.915] with a kappa coefficient of 0.83 (0.7865 – 0.8907) which is in the “almost perfect” range. A depiction of the overall agreement can be found in section 2b2.2 of the testing form (figure 1. and table 2).

We examined all cases of disagreement between the charts and the claims for each complication. Complications reported in the charts but not identified in the claims were due to either missing codes from our measure specifications or a failure to report the complication in the claims (e.g. evacuation of a hematoma). Examination of cases where the complication was reported in the claims but not in the charts, revealed that the complication was not related to the ICD but to another procedure, device, or medical condition. Based on these results, we made the following changes to the cohort and definitions of complications:

- Added the following administrative claim codes to the measure specifications to capture more mechanical complications with revision: 996.72; 39.94; 37.77

- Excluded patients with a previous pacemaker from the cohort, considering the lack of availability of present-on-admission codes at this time

3c.2. Describe any fees, licensing, or other requirements to use any aspect of the measure as specified *(e.g., value/code set, risk model, programming code, algorithm)*.

The ACCF’s program the National Cardiovascular Data Registry (NCDR) provides evidence based solutions for cardiologists and other medical professionals committed to excellence in cardiovascular care. NCDR hospital participants receive confidential benchmark reports that include access to measure macro specifications and micro specifications, the eligible patient population, exclusions, and model variables (when applicable). In addition to hospital sites, NCDR Analytic and Reporting Services provides consenting hospitals’ aggregated data reports to interested federal and state regulatory agencies, multi-system provider groups, third-party payers, and other organizations that have an identified quality improvement initiative that supports NCDR-participating facilities. Lastly, the ACCF also allows for licensing of the measure specifications outside of the Registry.

It should be noted that the centers already have to participate in this specific registry for reimbursement purposes so that currently almost all hospitals that implant ICDs in Medicare populations already participate. Hence there is no additional cost.

Measures that are aggregated by ACCF and submitted to NQF are intended for public reporting and therefore there is no charge for a standard export package. However, on a case by case basis, requests for modifications to the standard export package will be available for a separate charge.

4. Usability and Use

Extent to which potential audiences (e.g., consumers, purchasers, providers, policy makers) are using or could use performance results for both accountability and performance improvement to achieve the goal of high-quality, efficient healthcare for individuals or populations.

4a. Accountability and Transparency

Performance results are used in at least one accountability application within three years after initial endorsement and are publicly reported within six years after initial endorsement (or the data on performance results are available). If not in use at the time of initial endorsement, then a credible plan for implementation within the specified timeframes is provided.

4.1. **Current and Planned Use**

NQF-endorsed measures are expected to be used in at least one accountability application within 3 years and publicly reported within 6 years of initial endorsement in addition to performance improvement.

Planned	Current Use (for current use provide URL)
Public Reporting Quality Improvement with Benchmarking (external benchmarking to multiple organizations) Quality Improvement (Internal to the specific organization)	

4a.1. **For each CURRENT use, checked above, provide:**

- Name of program and sponsor
- Purpose
- Geographic area and number and percentage of accountable entities and patients included

N/A, not being publicly reported.

4a.2. **If not currently publicly reported OR used in at least one other accountability application (e.g., payment program, certification, licensing) what are the reasons?** (*e.g., Do policies or actions of the developer/steward or accountable entities restrict access to performance results or impede implementation?*)

N/A, not being publicly reported.

4a.3. **If not currently publicly reported OR used in at least one other accountability application, provide a credible plan for implementation within the expected timeframes -- any accountability application within 3 years and publicly reported within 6 years of initial endorsement.** (*Credible plan includes the specific program, purpose, intended audience, and timeline for implementing the measure within the specified timeframes. A plan for accountability applications addresses mechanisms for data aggregation and reporting.*)

ACC is committed to implementing this measure. ACC is an authorized organization to receive CMS data through the ResDAC application process. Unfortunately, it has been determined by ResDAC that this authorization does not permit use of CMS for performance measure reporting purposes, either to hospitals or for public display. ACC is currently in process of applying to be a Qualified Entity. It is unclear if this pathway will permit measure implementation. ACC also is commenting on and tracking proposed language in 21st Century Cures legislation, which does appear to create a pathway for use of CMS data for this type of reporting purpose.

4b. Improvement

Progress toward achieving the goal of high-quality, efficient healthcare for individuals or populations is demonstrated. If not in use for performance improvement at the time of initial endorsement, then a credible rationale describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.

4b.1. **Progress on Improvement. (Not required for initial endorsement unless available.)**

Performance results on this measure (current and over time) should be provided in 1b.2 and 1b.4. Discuss:

- **Progress (trends in performance results, number and percentage of people receiving high-quality healthcare)**
- **Geographic area and number and percentage of accountable entities and patients included**

Due to the changes to this measure since its endorsement, a direct comparison of results of the measure over time would not provide a true reflection of the extent of improvement. The development of the parsimonious model is described in more detail in section 2b4.3 of the testing form as well as the process of selection of clinically significant variables in the updated model.

4b.2. **If no improvement was demonstrated, what are the reasons? If not in use for performance improvement at the time of initial endorsement, provide a credible rationale that describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.**
N/A

4c. Unintended Consequences

The benefits of the performance measure in facilitating progress toward achieving high-quality, efficient healthcare for individuals or populations outweigh evidence of unintended negative consequences to individuals or populations (if such evidence exists).

4c.1. **Were any unintended negative consequences to individuals or populations identified during testing; OR has evidence of unintended negative consequences to individuals or populations been reported since implementation? If so, identify the negative unintended consequences and describe how benefits outweigh them or actions taken to mitigate them.**
As noted earlier, publicly reporting hospital risk-standardized ICD complication rates requires that the data submitted by hospitals be complete, consistent, and accurate. A protocol that assures accurate data for public reporting should be established prior to implementation. Steps to ensure data quality could include monitoring data for variances in case mix, chart audits, and possibly adjudicating cases that are vulnerable to systematic misclassification.

As an example of some of the methods that could be used to ensure data quality, we describe the NCDR's existing Data Quality Program (DQP). The two main components of the DQP are complementary and consist of the Data Quality Report (DQR) and the Data Audit Program (DAP). The DQR process assesses the completeness and validity of the electronic data submitted by participating hospitals. Hospitals must achieve >95% completeness of specific data elements identified as 'core fields' to be included in the registry's data warehouse for analysis. The 'core fields' capture many of the variables included in our risk adjustment models. The process is iterative, providing hospitals with the opportunity to correct errors and resubmit data for review and acceptance into the data warehouse. The DAP consists of annual on-site chart review and data abstraction. Among participating hospitals that pass the DQR for a minimum of two quarters, at least 5% are randomly selected to participate in the DAP. At individual sites, on-site auditors review charts of 10% of submitted cases. The NCDR audit focuses on variables used to determine whether patients meet accepted criteria for ICD implantation. However, the scope of the audit could be expanded to include additional fields. The DAP includes an appeals process that allows hospitals to reconcile audit findings.

5. Comparison to Related or Competing Measures

If a measure meets the above criteria and there are endorsed or new related measures (either the same measure focus or the same target population) or competing measures (both the same measure focus and the same target population), the measures are compared to address harmonization and/or selection of the best measure.

5. Relation to Other NQF-endorsed Measures

Are there related measures (conceptually, either same measure focus or target population) or competing measures (conceptually both the same measure focus and same target population)? If yes, list the NQF # and title of all related and/or competing measures.
Yes

5.1a. **List of related or competing measures (selected from NQF-endorsed measures)**

5.1b. **If related or competing measures are not NQF endorsed please indicate measure title and steward.**
HRS is expected to submit a complications measure that is attributable at the physician level. ACC and HRS staff have been in close contact and the specifications should mirror in both consensus standards applications.

5a. Harmonization

The measure specifications are harmonized with related measures;
OR

The differences in specifications are justified

5a.1. **If this measure conceptually addresses EITHER the same measure focus OR the same target population as NQF-endorsed measure(s):**
Are the measure specifications completely harmonized?
Yes

5a.2. **If the measure specifications are not completely harmonized, identify the differences, rationale, and impact on interpretability and data collection burden.**
Yes. ACC and HRS have met and ensured the specifications are aligned as closely as possible. The inclusion and exclusion criteria are identical.

5b. Competing Measures

The measure is superior to competing measures (e.g., is a more valid or efficient way to measure);
OR
Multiple measures are justified.

5b.1. **If this measure conceptually addresses both the same measure focus and the same target population as NQF-endorsed measure(s):**
Describe why this measure is superior to competing measures (e.g., a more valid or efficient way to measure quality); OR provide a rationale for the additive value of endorsing an additional measure. (Provide analyses when possible.)
HRS is expected to submit a complications measure that is attributable at the physician level. ACC and HRS staff have been in close contact and the specifications should mirror in both consensus standards applications.

Appendix

A.1 Supplemental materials may be provided in an appendix. All supplemental materials (such as data collection instrument or methodology reports) should be organized in one file with a table of contents or bookmarks. If material pertains to a specific submission form number, that should be indicated. Requested information should be provided in the submission form and required attachments. There is no guarantee that supplemental materials will be reviewed.

Additional Information

Ad.1 **Workgroup/Expert Panel involved in measure development**
Provide a list of sponsoring organizations and workgroup/panel members' names and organizations. Describe the members' role in measure development.
For this particular topic those individuals who were involved in identifying the key attributes and variables for this outcome measure were leaders and experts in the field of electrophysiology and data management. Serial phone calls were held to both define the eligible population and given process. These clinical leaders are noted below.

Working Group:
Jim Beachy, RCIS
Barbara Christensen, R.N., M.H.A.
Susan Fitzgerald, R.N., M.B.A.
Stephen Hammill, M.D.
Paul Heidenreich, M.D.
Kathleen Hewitt, R.N., M.S.N., C.P.H.Q.
Alan Kadish, M.D.
Christie Lang
Isabelle LeBlanc

Frederick Masoudi, M.D.
Kristi Mitchell, M.P.H.
Kathy Pontzer
John Rumsfeld, M.D., Ph.D
Lara Slattery, M.H.S.
John Spertus, M.D., M.P.H.
Al Woodward, Ph.D., M.B.A.

Technical Expert Panel:
Francis Ferdinand, M.D.
Ziad Issa, M.D.
Neil Jensen, MHA, MBA
Alan Kadish, M.D.
Bradley Knight, M.D.
Bruce Koplan, M.D., M.P.H.
Frederick Masoudi, M.D.
John Onufer, M.D.
Russell Robbins, M.D., MBA
John Rumsfeld, M.D., Ph.D
Andrea Russo, M.D.
Stuart Winston, D.O.

NCDR Clinical Subworkgroup ensured the measure demonstrated an opportunity for improvement, had strong clinical evidence, and was a reliable and valid measure. These members included the below individuals: Drs. Jeptha Curtis (Chair), Frederick Masoudi, John Rumsfeld, Matt Reynolds, and Mark Kremers.

NCDR Scientific Quality and Oversight Committee—a committee that served as the primary resource for crosscutting scientific and quality of care methodological issues. These members included Drs. Frederick Masoudi (Chair) , David Malenka, Thomas Tsai, Matthew Reynolds, David Shahian, John Windle, Fred Resnic, John Moore, Deepak Bhatt, James Tcheng, Jeptha Curtis, Paul Chan, Matthew Roe, and John Rumsfeld.

Measure Developer/Steward Updates and Ongoing Maintenance

Ad.2 **Year the measure was first released:** 2011

Ad.3 **Month and Year of most recent revision:** 02, 2015

Ad.4 **What is your frequency for review/update of this measure?** With dataset revisions and based on new evidence.

Ad.5 **When is the next scheduled review/update for this measure?** 02, 2016

Ad.7 **Disclaimers:** ACC realizes the various NCDR endorsed measures are not readily available on their own main webpage. However, ACCF plans to update their main webpage (acc.org) to include the macrospecifications of the NQF endorsed measures. ACC hopes to work collaboratively with NQF to create a consistent and standard format would be helpful for various end users. In the interim, the supplemental materials include the details needed to understand this model. In addition, interested parties are always able to contact comment@acc.org to reach individuals at the ACC Quality Measurement Team.

Ad.8 **Additional Information/Comments:** ACC appreciates the opportunity to submit measures for this NQF endorsement maintenance project.

MEASURE WORKSHEET

This document summarizes the evaluation of the measure as it progresses through NQF's Consensus Development Process (CDP). The information submitted by measure developers/stewards is included after the Brief Measure Information, Preliminary Analysis, and Pre-meeting Public and Member Comments sections.

To navigate the links in the worksheet: Ctrl + click link to go to the link; ALT + LEFT ARROW to return

Brief Measure Information

NQF #: 0730
Measure Title: Acute Myocardial Infarction (AMI) Mortality Rate (IQI15)
Measure Steward: Agency for Healthcare Research and Quality
Brief Description of Measure: In-hospital deaths per 1,000 hospital discharges with acute myocardial infarction (AMI) as a principal diagnosis for patients ages 18 years and older.
Developer Rationale: Acute Myocardial Infarction (AMI) is an emergent condition for which significant morbidity and mortality may result from delayed, inappropriate or low quality treatment. Processes that have been identified to lower AMI mortality include: timely electrocardiography (ECG), early percutaneous coronary intervention (PCI) for ST-elevation MI, or fibrinolytic therapy if PCI is not available, aspirin administration at arrival, afterload reduction with renin-angiotensin system blockade among patients with impaired left ventricular function, and aspirin/statin prescription initiation during hospitalization with continuation at discharge. The 30-day risk-standardized AMI mortality rate is currently a CMS quality metric. In-hospital risk-adjusted mortality rates allow users without access to post-hospitalization death data, to assess and compare AMI outcomes.

Numerator Statement: Number of in-hospital deaths among cases meeting the inclusion and exclusion rules for the denominator.
Denominator Statement: Discharges, for patients ages 18 years and older, with a principal ICD-9-CM diagnosis code for AMI.
Denominator Exclusions: Exclude cases:

- transferred to another short-term hospital, for whom the outcome at hospital discharge was unknown
- admitted for treatment of pregnancy, childbirth, and puerperium
- with missing discharge disposition, gender, age, quarter, year, or principal diagnosis

Measure Type: Outcome
Data Source: Administrative claims
Level of Analysis: Facility
Is this an eMeasure? ☐ Yes ☒ No **If Yes, was it re-specified from a previously endorsed measure?** ☐ Yes ☐ No

Is this a MAINTENANCE measure submission? ☒ Yes ☐ **No, this is a NEW measure submission.**
For MAINTENANCE, state the Original Endorsement Date: Mar 28, 2011 **Most Recent Endorsement Date:** Mar 28, 2011

Previous Measure Evaluation - Public & Member Comments, Developer Responses & Steering Committee Recommendations from (National Voluntary Consensus Standards for Patient Outcomes 2009):

This measure provides a rate of in-hospital AMI mortality using administrative data. It was compared to another endorsed in-hospital AMI mortality measure from The Joint Commission (161 AMI inpatient mortality). The Joint Com- mission is no longer reporting their in-hospital AMI mortality measure5 on their website in favor of CMS's NQF-endorsed 230 AMI 30-day mortality measure. This candidate AMI mortality measure from AHRQ differs from measure 161 in that the risk-adjustment model is based on all patient refined diagnosis related groups (APR DRGs), uses administrative coding rather than manual medical record abstraction, and does include transfers into the facility. Reliability of the coding was demonstrated to be 93 percent to 98 percent. The population measured is determined by the principal diagnosis, and the definition of AMI is harmonized with the endorsed 30-day AMI mortality measure from CMS. The Committee considered the differences in the measures and the benefits of having both inpatient and 30-day mortality measures. Unlike the 30-day mortality measure, which includes only patients aged >65 years, this candidate standard includes all patients experiencing AMI as a primary diagnosis. The inpatient measure is more feasible for some implementers since tracking out-of-hospital deaths can be difficult. Members of the Steering Committee also felt that knowing the proportion of in-hospital deaths was important in addition to the 30-day mortality data and that the two measures are complementary. Committee members asked the developers about the 30 percent of AMI patients who are excluded with a secondary AMI diagnosis and are not

captured in the measure currently. The developer clarified that most excluded patients experienced an AMI postoperatively, and the Committee suggested that future measures should address this population.

Preliminary Analysis

The preliminary analysis was developed in response to recommendations from NQF's Consensus Task Force and measurement stakeholders as a way to enhance and streamline the measures evaluation and voting processes. The preliminary analysis will help to guide the Standing Committee evaluation of each measure by summarizing the measure developer submission, guide measure evaluation discussion, and identify topic areas for additional input. **NQF staff would like to stress that the preliminary analysis is intended to be used as a guide to facilitate the Committee's discussion and evaluation.**

Criteria 1: Importance to Measure and Report

1a. Evidence

1a. Evidence. The evidence requirements for a health outcomes measure include providing rationale that supports the relationship of the health outcome to processes or structures of care. The guidance for evaluating the clinical evidence asks if health outcomes measures agree the relationship between the measured health outcome and at least one clinical action is identified and supported by the stated rationale.

- This is a risk-adjusted (by gender, age & clinical co-morbidities) outcomes measure that assesses the occurrence of in-hospital deaths per 1,000 hospital discharges with acute myocardial infarction (AMI) as a principal diagnosis for patients ages 18 years and older. The developer states there are numerous health care processes that lower AMI mortality.
- This measure is a component for the Inpatient Quality Indicators #91 (IQI #91) Mortality for Selected Conditions measure, which also includes individual component measures for Heart Failure, Acute Stroke, Gastrointestinal Hemorrhage, Hip Fracture and Pneumonia Mortality Rates.
- In addition to demonstrating links between processes and outcomes, the developer provides numerous clinical practice guidelines for the evaluation, management and treatment of AMI, as well as a formalized environmental scan of AMI literature related to health system characteristics and processes, relationship to 30-day mortality, geographic and temporal variation, risk adjustment, and scientific acceptability.

Questions for the Committee (as appropriate):

- *Are there structures or processes of care that can affect this outcome?*

1b. Gap in Care/Opportunity for Improvement and 1b. Disparities

1b. Performance Gap. The performance gap requirements include demonstrating quality problems and opportunity for improvement.

- The developer provided a robust reference population demonstrating an improvement opportunity of overall AMI inpatient mortalities per 1000 discharges (disposition = 20) for over 2800 hospitals with statistically significant declining annual mortalities of 68.94 to 56.37 from 2008 to 2012 using data from the Healthcare Cost and Utilization Project (HCUP) State Inpatient Databases (SID). For IQI 15, 24,890 patients died among 441,557 AMI patients at 2,978 hospitals in 2012. Observed rates from 2008-2010 are not provided as the AMI diagnosis data element was not "Present on Admission" (POA) or collected consistently during that time. In hospital complications, for risk adjustment purposes, are also excluded as they would not be POA. Distributions, mean, standard deviation (SD) of the observed rates are included, and 5th, 25th, 50th (median), 75th, and 95th percentile are also provided.
- 2012 HCUP SID patient characteristic disparities data are provided by age, gender, zip code median income, NCHS patient residence location, and expected payment source, with disparities increasing with age (expected), female, highest and lowest zip code median income, large central metropolitan and micropolitan residences, and Medicare payer. Hospital characteristic disparities data includes Northeast, Midwest, South & West locations of care, noting disparities in the Northeast and West regions.

Questions for the Committee:

○ *Should this measure be indicated as disparities sensitive?*

1c. Priority

1c. High Priority (previously "High Impact") requires measures to address national health goal/priority or a demonstrated high-impact aspect of care.

○ *Beginning in 2015, priority is no longer an NQF measure evaluation criterion.*

Committee pre-evaluation comments

Criteria 1: Importance to Measure and Report (including 1a, 1b, 1c)

1. ***Committee's Overview Comments***:
   - There is excellent evidence for this Outcome Measure

1a. ***Committee's Comments on Evidence to Support Measure Focus:***
   - Not Applicable

1b. ***Committee's Comments on Performance Gap:***
   - There is a performance GAP and disparity for this measure.

1c. ***Committee's Comments on Composite Performance Measure:***
   - Not Applicable

Criteria 2: Scientific Acceptability of Measure Properties

2a. Reliability

2a1. Reliability Specifications

2a1. Specifications requires the measure, as specified, to produce consistent (reliable) and credible (valid) results about the quality of care when implemented.

- This measure is specified at the facility level of analysis exclusively using electronic administrative claims as the data source to calculate the measure performance rate, with better quality equaling lower scores. The measure utilizes "all payer" discharges (disposition = 20) for the calendar year for patients ages 18 years and older, with a principal ICD-9-CM diagnosis code for AMI for all hospitals, except for psychiatric facilities, alcohol and drug dependency facilities and military hospitals. The data elements are clearly defined, and ICD-9 & ICD-10 codes are provided. A peer-reviewed ICD-9 and ICD-10 conversion methodology is discussed and was validated through literature review and IQI15 annual use review & measure maintenance activities. The developer utilizes patient age, sex, disposition, principal diagnosis for AMI, procedural, quarter and year codes to calculate the measure.
- The developer standardizes 4 provider-level indicators groups including demographics, severity of illness, comorbidities and transfer-in status for clinical factors covariates or potential risk adjusters.
- This outcome measure is risk-adjusted using a statistical risk model by gender, age, comorbidities and transfer in status. The calculation algorithm provided by the developer is informative and understandable. Additional details for the risk model are provided in the supplemental spreadsheet attachment.
- The measure is risk adjusted, and the developer provides descriptions and covariates for the risk variables used in the risk-adjustment model are included in the specifications (*gender, age, Major Diagnostic Categories (MDC), All Payer Refined Diagnosis Related Group (APR-DRG) with Risk of Mortality (ROM) scores, patient point-of-origin and whether they were transferred from another facility).* Other than gender and age, no other SDS factors were included in the risk-adjustment approach.
- Predicted values for each case are computed using logistic regression and hospital random effect, with the defined measure covariates. Descriptions of the reference population, expected rates, risk adjusted rates and observed rates are provided, with the risk adjusted rate calculated with the following equation:

Risk Adjusted Rate = Reference Population X (Observed Rate / Expected Rate)

Questions for the Committee:

- *Are all the data elements clearly defined? Are all appropriate codes included?*
- *Is the logic or calculation algorithm clear?*
- *Is it likely this measure can be consistently implemented?*

2a2. Reliability Testing Testing attachment

2a2. Reliability testing demonstrates if the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise enough to distinguish differences in performance across providers.

- The developer completed *performance measure score* testing using a signal-to-noise analysis, which is appropriate for this measure, which assesses differences in performance between hospitals ("the signal") to stability within hospitals (random measurement error or "the noise"). Hospital size is calculated by number of discharges per year, which is weighted to reduce impact of small denominators. The signal-to-noise method results in a reliability statistic that ranges from 0 to 1 for each facility. A value of 0 indicates that all variation is due to measurement error and a value of 1 indicates that all variation is due to real differences in between hospital performance. A value of 0.7 is often regarded as a minimum acceptable reliability value, though the developer provides guidance for lower acceptable reliability scores.
- Performance score testing results are provided by deciles of 266 and 267 hospitals from 2012 HCUP SID data, with an overall signal-to-noise ratio of 0.75 for 2664 hospitals with an average of 165.6 discharges per year, and range from 0.169 for hospitals with 4.2 average discharges per year to 0.899 for hospitals with 672.2 average discharges per. Hospitals with greater than 28 discharges per year were risk adjusted 0.48 to .090 reliability.
- Individual cases not meeting denominator definitions, or with missing data described in 2b.7 of the Measure Worksheet are removed from the calculation.

Questions for the Committee:

- *Is the test sample adequate to generalize for widespread implementation?*
- *Do the results demonstrate sufficient reliability so that differences in performance can be identified?*

2b. Validity

2b1. Validity: Specifications

2b1. Validity Specifications. This section should determine if the measure specifications are consistent with the evidence.

- Because this is an outcome measure, the rationale that is presented for subcriterion 1a does not necessarily have to address all of the variables used to calculate the measure.
- The measure was initially released in 2003, has been in use since that time, and undergoes annual maintenance and implementation updates as needed.
- A literature review of potential SDS factors indicates that race, ethnicity, and income are associated with in-hospital mortality after AMI. However, this literature also suggests that these relationships may be mediated by the quality of care provided (e.g., higher door-to-balloon time for Black patients, lower utilization of circulatory support devices among poorer patients). Accordingly, the developer has chosen not to include these factors in their risk-adjustment approach.

Question for the Committee:

- *Are the specifications consistent with the evidence?*
- *Does the Committee agree that the conceptual relationship between SDS factors and AMI in-hospital mortality as outlined by the developer does not warrant inclusion of SDS factors in the risk adjustment model? Are these variables available and generally accessible for the measured patient population?*

2b2. Validity testing

2b2. Validity Testing should demonstrate the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality.

- Validity testing was conducted with critical data elements, and performance measure score using empirical validity testing.
- Critical data element testing included a systematic review of alternative peer-reviewed definitions for AMI with ICD-9 coding, applied to a Canadian inpatient records from 2003, using ICD-9 & ICD-10 definitions resulting in the highest positive predictive value (PPV) of 84.0% and sensitivity of 81.1%. Seven studies validated the findings with patient data from 1984 through 2009.
- Empirical validity testing was performed between hospital-level Spearman rank correlation between IQI 15 risk-adjusted rates and adherence for 6 process measures; risk adjusted and risk standardized 30-day AMI mortality measures for all patients and for Medicare FFS beneficiaries; and 3 alternative cardiovascular care IQI measures with measure data for all measures from 2011 and/or 2012 generally demonstrating favorable correlations between the measures' performance and adjusted AMI mortality rates.
- As the measure has been in use for a more than 10 years, the developer states that along with data element validity testing and parallel finding and empirical validity testing from the literature cited, the measure's ability to differentiate quality of care between hospitals should be assumed.

Questions for the Committee:

- *Is the test sample adequate to generalize for widespread implementation?*
- *Do the results demonstrate sufficient validity so that conclusions about quality can be made?*
- *Do you agree that the score from this measure as specified is an indicator of quality?*

2b3-2b7. Threats to Validity

2b3. Exclusions:

- Excluded patients include:
  - transferred to another short-term hospital, for whom the outcome at hospital discharge was unknown
  - admitted for treatment of pregnancy, childbirth, and puerperium.
  - with missing discharge disposition, gender, age, quarter, year, or principal diagnosis that is not "Present on Admission" (POA).

Questions for the Committee:

- *Are the exclusions consistent with the evidence?*
- *Are any patients or patient groups inappropriately excluded from the measure?*
- *Are the exclusions/exceptions of sufficient frequency and variation across providers to be needed (and outweigh the data collection burden)?*

2b4. Risk adjustment:

- The risk model includes 23 risk factors under 4 covariate categories including gender, age, Major Diagnostic Categories (MDC), All Payer Refined Diagnosis Related Group (APR-DRG) with Risk of Mortality (ROM) scores, patient point-of-origin, and whether they were transferred from another facility. The developer describes the process for including risk factors based on AHRQ QI Empirical Methods Report, which outlines 4 steps in estimating risk modes (1. Construct candidate covariates, 2. Select model covariate, 3. Estimate the models, and 4. Evaluate the models)
- Measure discrimination assessing the risk model's ability to distinguish performance between hospitals is conducted with c-statistics with findings above 0.70 and below 0.80 have moderate discrimination, and above 0.80 as having high discrimination. Again, using 2012 HCUP SID inpatient data of approximately 44,000 discharges, a c-statistic of 0.8867, with deciles ranging between 0.85 – 1.04, and hospitals with fewer discharges resulting in lower predictive value. "Goodness of fit" tests were not performed due to large sample size, which is appropriate. The developer states the model has very strong predictive power.

The risk model includes clinical patient factors and does not include SDS factors beyond age and gender. The developer describes SDS factors, such as race/ethnicity, within the context of the measure focus; however, they note that these factors are confounded by the quality of care provided by the accountable entity.

Questions for the Committee:

For outcome measures:

- *Is an appropriate risk-adjustment strategy included in the measure?*
- *Are all of the risk adjustment variables present at the start of care? If not, describe the rationale provided.*

2b5. Meaningful difference:

- Using smoothed indicator rates that assume each hospital has a Gamma distribution, 20th percentile benchmarks for the reference population, and 80th percentile thresholds, decile results are provided by hospital size (# of discharges) to demonstrate meaningful differences in performance. The results demonstrate the measure has strong discrimination for identify low performing and moderate to large hospitals above and below benchmarks.

Question for the Committee:

- *Does this measure identify meaningful differences about quality?*

2b6. Comparability of data sources/methods:

- As there is only one data source used for measure calculation (administrative claims), comparability of data sources or methods is not applicable.

Question for the Committee:

-

2b7. Missing Data

- All state hospital data with 36 of 45 participating states (or ~82%) of national community hospital inpatient discharges are included for 2012 analysis.
- Patients with gender, age, quarter, year or principal diagnosis that are not "Present on Arrival" (POA) are excluded accounting for < 0.01%.

Questions for the Committee:

- *Do the missing records pose a threat to validity?*

Committee pre-evaluation comments

Criteria 2: Scientific Acceptability of Measure Properties (including all 2a, 2b, and 2d)

2a1. &2b1.: ***Committee's Comments on Reliability-Specifications:***

- Specifications are clearly defined

2a2.: ***Committee's Comments on Reliability-Testing:***

- No concerns with Reliability

2b1.: ***Committee's Comments on Validity-Specifications***:

- Not Applicable

2b2.: ***Committee's Comments on Validity-Testing:***

- No concerns with Validity

2b3-7.: ***Committee's Comments on Threats to Validity:***

- No Concerns

2d.: ***Committee's Comments on Composite Performance Measure:***

- Not Applicable

Criterion 3. Feasibility

3. Feasibility is the extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

- All measure elements are readily available in electronic sources via administrative claims data, and coded by someone other than the person obtaining the original information (e.g., DRG, ICD-9 codes on claims).
- Users have over ten years of experience using the AHRQ QI software in SAS and Windows, which has been available at no cost since 2001. The IQI15 software is freely available from the AHRQ Quality Indicators website.
- This is not an eMeasure.

Questions for the Committee:

- *Are the required data elements routinely generated and used during care delivery?*
- *Are the required data elements available in electronic form, e.g., EHR or other electronic sources?*
- *Is the data collection strategy ready to be put into operational use?*

Committee pre-evaluation comments

Criteria 3: Feasibility

3.: ***Committee's Comments on Feasibility:***

- Administrative Claims Data, no concerns

Criterion 4: Usability and Use

4. Usability and Use evaluate the extent to which audiences (e.g., consumers, purchasers, providers, policymakers) use or could use performance results for both accountability and performance improvement activities.

- The measure was first released in 2003 and is broadly used in public and private accountability and quality improvement programs, and is publically reported.
- The developer also states, when this measure is used in conjunction with 30-day risk-standardized AMI mortality rate, the in-hospital risk-adjusted mortality rates allow users without access to post-hospitalization death data, to assess and compare AMI outcomes.
- The developer found no noted unintended consequences, though theoretically expedited transfers to other levels of care could be found in dying patients. Though "transfer to another short-term hospital, for which the outcome at hospital discharge was unknown discharge" is a denominator exclusion, the developer states that in those instances, reporting the 30-day mortality rate measure would discourage such transfers.

Questions for the Committee*:*

- *For maintenance measures – is the measure used in at least one accountability application?*
- *How can the performance results be used to further the goal of high-quality, efficient healthcare?*
- *Do the benefits of the measure outweigh any potential unintended consequences?*

Committee pre-evaluation comments

Criteria 4: Usability and Use

4.: ***Committee's Comments on Usability and Use:***

- Tested and in use for over 10 years, no concerns.

Criterion 5: Related and Competing Measures

0230 : Hospital 30-day, all-cause, risk-standardized mortality rate (RSMR) following acute myocardial infarction (AMI) hospitalization for patients 18 and older
2473 : Hospital 30-Day Risk-Standardized Acute Myocardial Infarction (AMI) Mortality eMeasure

The indicators referenced above include 30-day mortality 1) for patients age 18 years and older 2) specified as an e-measure and 3) for patients age 65 and older. Inpatient mortality and 30-day mortality are different concepts, although capturing the same ultimate outcome. Harmonization is not appropriate.

IQI 15 and the Centers for Medicare & Medicaid Services' NQF-endorsed measures concerning AMI mortality (0230 and 2473) use the same ICD-9-CM codes to identify AMI, but they differ in two important respects: (1) whereas the CMS measures concern only Medicare fee-for-service and VA beneficiaries 65 years or older, IQI 15 measures mortality among hospitalizations of patients 18 years or older at non-federal acute care hospitals for all payers; and (2) while the CMS measures evaluate 30-day mortality, IQI 15—because it is based only on UB-04 data elements—is limited to inpatient mortality. The latter difference is a potential disadvantage in that the time at risk is not uniform for all patients and 30-day mortality is typically greater than inpatient mortality, but the former difference is an advantage because IQI 15 encompasses a greater proportion of the entire population at risk. We therefore believe that #0730 complements #0230 by offering an alternative specification for users who are interested in patients of all ages and all payers, just as #2473 offers an alternative e-measure specification for those with electronic health data.

Pre-meeting public and member comments

NATIONAL QUALITY FORUM—Evidence (subcriterion 1a)

Measure Number (*if previously endorsed*)**:** 0730

Measure Title: Acute Myocardial Infarction (AMI) Mortality Rate (IQI15)

IF the measure is a component in a composite performance measure, provide the title of the Composite Measure here: Inpatient Quality Indicators #91 (IQI #91)

Date of Submission: 6/30/2015

Instructions

- *For composite performance measures:*
  - *A separate evidence form is required for each component measure unless several components were studied together.*
  - *If a component measure is submitted as an individual performance measure, attach the evidence form to the individual measure submission.*
- Respond to all questions as instructed with answers immediately following the question. All information needed to demonstrate meeting the evidence subcriterion (1a) must be in this form. An appendix of *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 10 pages (*incudes questions/instructions*; minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the evidence for this measure meets NQF's evaluation criteria.

1a. Evidence to Support the Measure Focus

The measure focus is evidence-based, demonstrated as follows:

- Health outcome: [3] a rationale supports the relationship of the health outcome to processes or structures of care. Applies to patient-reported outcomes (PRO), including health-related quality of life/functional status, symptom/symptom burden, experience with care, health-related behavior.
- Intermediate clinical outcome: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured intermediate clinical outcome leads to a desired health outcome.
- Process: [5] a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured process leads to a desired health outcome.
- Structure: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured structure leads to a desired health outcome.
- Efficiency: [6] evidence not required for the resource use component.

Notes

3. Generally, rare event outcomes do not provide adequate information for improvement or discrimination; however, serious reportable events that are compared to zero are appropriate outcomes for public reporting and quality improvement.

4. The preferred systems for grading the evidence are the U.S. Preventive Services Task Force (USPSTF) grading definitions and methods, or Grading of Recommendations, Assessment, Development and Evaluation (GRADE) guidelines.

5. Clinical care processes typically include multiple steps: assess → identify problem/potential problem → choose/plan intervention (with patient input) → provide intervention → evaluate impact on health status. If the measure focus is one step in such a multistep process, the step with the strongest evidence for the link to the desired outcome should be selected as the focus of measurement. Note: A measure focused only on collecting PROM data is not a PRO-PM.

6. Measures of efficiency combine the concepts of resource use and quality (see NQF's Measurement Framework: Evaluating Efficiency Across Episodes of Care; AQA Principles of Efficiency Measures).

1a.1.This is a measure of: (*should be consistent with type of measure entered in De.1*)

Outcome

☒ Health outcome: mortality

☐ Patient-reported outcome (PRO): Click here to name the PRO

PROs include HRQoL/functional status, symptom/symptom burden, experience with care, health-related behaviors

☐ Intermediate clinical outcome (*e.g., lab value*): Click here to name the intermediate outcome

☐ Process: Click here to name the process

☐ Structure: Click here to name the structure

☐ Other: Click here to name what is being measured

HEALTH OUTCOME/PRO PERFORMANCE MEASURE *If not a health outcome or PRO, skip to 1a.3*

1a.2. Briefly state or diagram the path between the health outcome (or PRO) and the healthcare structures, processes, interventions, or services that influence it.

1a.2.1. State the rationale supporting the relationship between the health outcome (or PRO) to at least one healthcare structure, process, intervention, or service (*i.e., influence on outcome/PRO*).

Acute Myocardial Infarction (AMI) is an emergent condition for which significant morbidity and mortality may result from delayed, inappropriate or low quality treatment. Processes that have been identified to lower AMI mortality include: timely electrocardiography (ECG), early percutaneous coronary intervention (PCI) for ST-

elevation MI, or fibrinolytic therapy if PCI is not available, aspirin administration at arrival, afterload reduction with renin-angiotensin system blockade among patients with impaired left ventricular function, and aspirin/statin prescription initiation during hospitalization with continuation at discharge. The 30-day risk-standardized AMI mortality rate is currently a CMS quality metric. In-hospital risk-adjusted mortality rates allow users without access to post-hospitalization death data, to assess and compare AMI outcomes.

Please see clinical practice guidelines cited below for specific evidence supporting this rationale statement.

Note: For health outcome/PRO performance measures, no further information is required; however, you may provide evidence for any of the structures, processes, interventions, or service identified above.

INTERMEDIATE OUTCOME, PROCESS, OR STRUCTURE PERFORMANCE MEASURE

1a.3. Briefly state or diagram the path between structure, process, intermediate outcome, and health outcomes. Include all the steps between the measure focus and the health outcome.

Not applicable

1a.3.1. What is the source of the systematic review of the body of evidence that supports the performance measure?

☐ Clinical Practice Guideline recommendation – ***complete sections 1a.4, and 1a.7***

☐ US Preventive Services Task Force Recommendation – ***complete sections 1a.5 and 1a.7***

☐ Other systematic review and grading of the body of evidence (*e.g., Cochrane Collaboration, AHRQ Evidence Practice Center*) – ***complete sections 1a.6 and 1a.7***

☒ Other – ***complete section 1a.8***

Please complete the sections indicated above for the source of evidence. You may skip the sections that do not apply.

Please note that this is an outcome measure, so a systematic review of the body of evidence that supports the performance measure is not required. However, information is provided in 1a.4.1 and 1a.8 below, to provide additional context and support for IQI 15.

1a.4. CLINICAL PRACTICE GUIDELINE RECOMMENDATION

1a.4.1. Guideline citation (*including date*) and **URL for guideline** (*if available online*):

1a.7. FINDINGS FROM SYSTEMATIC REVIEW OF BODY OF THE EVIDENCE SUPPORTING THE MEASURE

If more than one systematic review of the evidence is identified above, you may choose to summarize the one (or more) for which the best information is available to provide a summary of the quantity, quality, and consistency of the body of evidence. Be sure to identify which review is the basis of the responses in this section and if more than one, provide a separate response for each review.

Not applicable

1a.7.1. What was the specific structure, treatment, intervention, service, or intermediate outcome addressed in the evidence review?

Not applicable

1a.7.2. Grade assigned for the quality of the quoted evidence with definition of the grade:

Not applicable

1a.7.3. Provide all other grades and associated definitions for strength of the evidence in the grading system.

Not applicable

1a.7.4. What is the time period covered by the body of evidence? (*provide the date range, e.g., 1990-2010*).
Date range: Click here to enter date range

Not applicable

QUANTITY AND QUALITY OF BODY OF EVIDENCE

1a.7.5. How many and what type of study designs are included in the body of evidence? (*e.g., 3 randomized controlled trials and 1 observational study*)

Not applicable

1a.7.6. What is the overall quality of evidence across studies in the body of evidence? (*discuss the certainty or confidence in the estimates of effect particularly in relation to study factors such as design flaws, imprecision due to small numbers, indirectness of studies to the measure focus or target population*)

Not applicable

ESTIMATES OF BENEFIT AND CONSISTENCY ACROSS STUDIES IN BODY OF EVIDENCE

1a.7.7. What are the estimates of benefit—magnitude and direction of effect on outcome(s) across studies in the body of evidence? (*e.g., ranges of percentages or odds ratios for improvement/ decline across studies, results of meta-analysis, and statistical significance*)

Not applicable

1a.7.8. What harms were studied and how do they affect the net benefit (benefits over harms)?

Not applicable

UPDATE TO THE SYSTEMATIC REVIEW(S) OF THE BODY OF EVIDENCE

1a.7.9. If new studies have been conducted since the systematic review of the body of evidence, provide for each new study: 1) citation, 2) description, 3) results, 4) impact on conclusions of systematic review.

Not applicable

1a.8 OTHER SOURCE OF EVIDENCE

If source of evidence is NOT from a clinical practice guideline, USPSTF, or systematic review, please describe the evidence on which you are basing the performance measure.

1a.8.1 What process was used to identify the evidence?

Formal environmental scans of the literature, including routine PubMed searches are performed to continually update evidence. The current evidence review results presented below constitute the most recent update, conducted in January 2015. Search terms included relevant MeSH terms (Myocardial Infarction/mortality). We combined this clinical search string with MeSH terms (quality indicator, hospital mortality) to identify studies examining quality of inpatient care. The search was limited to English publications. For completeness we also tested more inclusive search strings. Below we have provided a summary of the most up-to-date evidence.

1a.8.2. Provide the citation and summary for each piece of evidence.

Association with health system characteristics and processes

Three studies examined the association between hospital teaching status and IQI15 rates. One found that major teaching hospitals in the same Medicare data set had 20% lower risk-adjusted 30-day mortality than nonteaching hospitals; half of this difference was attributable to greater use of beneficial therapies.[1] Two other studies found that in-hospital AMI mortality was significantly lower in major teaching hospitals than in minor and non-teaching hospitals.[1,2] A fourth study by Jena et al. used Healthcare Cost and Utilization Project (HCUP) National Inpatient Sample (NIS) data (2002-2008) to examine the effect of resident physician turnover and subsequent influx of inexperienced new physicians in the month of July in teaching (n=98) and non-teaching hospitals (n=1353).[3] They found the adjusted in-hospital mortality rates of high-risk AMI patients in teaching hospitals to be lower in May than in July (18.8% vs. 22.7%, $p < 0.01$) but also found in-hospital mortality in the lower-risk AMI cohort to be similar in May and June for both teaching (2.1% vs. 1.9%, $p = 0.45$) and non-teaching (2.7% vs. 2.8%, $p = 0.21$) hospitals, respectively.

One study of Medicare data by Patel et al. found that there were no significant differences in 30-day mortality rates for AMI between more intensive vs. less-intensive teaching hospitals (odds ratio 1.05, 95% CI 0.97 to 1.14; p=0.20) following Accreditation Council for Graduate Medical Education (ACGME) resident work hour limit reforms in 2011.[4] Hospital teaching intensity in the study was represented by the change in odds of an event for every 1-unit change in the resident-to-bed ratio.

Multiple studies have examined the relationship between hospital volume and IQI15 rates. Carretta et al. used AHRQ IQI measures and 2008 patient-level discharge files (n=30,843 records of AMI inpatient mortality) from Florida to investigate the impact of hospital characteristics on IQI mortality rates and found that increased hospital volume (as measured by a log-transformed value) was associated with decreased in-hospital AMI mortality (OR 0.89; $p < 0.001$) and overall 30-day mortality (OR 0.91; $p < 0.0001$) while other hospital characteristics had little impact on AMI death outcomes.[5] Various studies also found that for primary percutaneous transluminal coronary angioplasty (PTCA), high volume hospitals had lower AMI mortality than lower volume hospitals.[6-12] For example, in the 1995 New York State Coronary Angioplasty Reporting System Registry, in-hospital mortality was reduced 57% among patients who underwent primary angioplasty by high-volume, as opposed to low-volume, physicians (adjusted relative risk 0.43; 95% CI 0.21 to 0.83). When patients with AMI were treated with primary angioplasty in high-volume hospitals rather than low-volume institutions, the relative risk reduction for in-hospital mortality was 44% (adjusted relative risk 0.56; 95% CI 0.29 to 1.1). When compared with patients treated at low-volume hospitals by low-volume physicians, patients treated at high-volume hospitals by high-volume physicians had a 49% reduction in the risk of in-hospital mortality (adjusted relative risk 0.51; 95% CI 0.26 to 0.99).[7]

Other studies have examined the impact of various factors such as hospital spending and accreditation. Analyzing NIS data (2003-2007) from over 1,200 hospitals, Romley et al found that patients treated at hospitals in the highest spending quintile had lower risk-adjusted inpatient mortality for AMI (OR 0.65; 95% CI 0.56 to 0.76) compared with hospitals in the lowest spending quintile.[15] Chen et al. examined the association between accreditation of hospitals by The Joint Commission, quality of care, and survival among Medicare patients hospitalized for AMI. They found that hospitals not accredited by The Joint Commission had, on average, lower quality (less likely to use aspirin, beta-blockers, and reperfusion therapy) and higher thirty-day mortality rates than accredited hospitals.[6]

Finally, several studies have explored associations between in-hospital risk-adjusted mortality rates and process adherence rates for AMI patients. Meehan et al. evaluated coding accuracy, severity of illness, and process-based quality of care in Connecticut hospitals. Three process measures were selected by an expert panel based on medical literature and local practice patterns: 1) administration of thrombolytic therapy, 2) discharged on aspirin if no contraindication, and 3) discharged on a beta blocker if no contraindication. Hospitals with the highest risk-adjusted mortality had significantly lower utilization of these therapies than other hospitals in the sample. Although the Medicare Prospective Payment System Quality of Care study did not focus on specific therapeutic interventions, it also demonstrated significantly higher risk-adjusted mortality (using risk factors derived by chart review) among hospitals with "poor" processes of care than among hospitals with "good" or "medium" processes of care (30.1% versus 22.0% and 23.9%, respectively). Chen showed that the hospitals designated by US News as "America's Best Hospitals" in cardiology, based on risk-adjusted in-hospital mortality (using APR-DRGs) and reputation among physicians, had lower risk-adjusted mortality using clinical predictors among Medicare patients (15.6% versus 18.3-18.6%), and used aspirin and beta blockers more often, than hospitals that were not so designated. Similar findings were reported using HealthGrades' approach to estimating risk-adjusted in-hospital mortality.[13] In another study, quality improvement interventions lowered the risk of in hospital death in patients with AMI about 40%. In the California Hospital Outcomes Project, hospitals with low risk-adjusted AMI mortality were more likely to give aspirin within 6 hours of arrival in the emergency department, more likely to perform cardiac catheterization and revascularization within 24 hours, and more likely to give heparin to prevent thromboembolic

complications. However, there were no differences between low and high-mortality hospitals in the use or timing of thrombolytic or beta blocker therapy.

To clarify these somewhat conflicting findings, Mant and Hicks systematically reviewed the literature to estimate effect sizes for therapies proven effective for AMI patients, based on clinical trials and meta-analyses (i.e., beta blockade, aspirin, fibrinolysis, and angiotensin converting enzyme inhibitors). Using these estimates and the proportion of patients eligible for treatment, the authors simulated the number of patients required to detect differences in care using either a "perfect system" for risk-adjusted mortality or a process-based quality of care audit. Plausible differences in lives lost were detectable with one year of data collection on mortality, consistent with AHRQ's recommendation to use a one-year minimum data collection period for IQI 15.

Relationship with 30-day mortality

Three studies compared adjusted in-hospital and 30-day mortality for AMI. Kristofferson et al., examined Norwegian hospital data (n=55 hospitals and n = 48,048 AMI patients) from 1997-2001 and found the adjusted mortality measures for in-hospital and 30-day AMI mortality to be highly correlated ($0.82 \leq r \leq 0.94$).[16] Borzecki et al. used AHRQ IQI (version 3.1) software and Veterans Health data from 2004-2007, for 119 facilities, to compare in-hospital and 30-day mortality rates for AMI.[17] They also found a strong correlation ($r \geq 70$, $p < 0.05$) between in-hospital and 30-day mortality, but the observed 30-day mortality rate (11.1%) for AMI was significantly higher than in-hospital mortality (7.2%). A third study by Drye et al. used Medicare claims data for admissions to non-federal acute care hospitals to investigate differences between in-hospital and 30-day mortality rates.[18] They found that the mean absolute risk-standardized difference between 30-day and in-hospital mortality was 6.0% for AMI. Moreover, of 3,135 hospitals studied, 8.2% had differing performance classifications for in-hospital and 30-day mortality. An increase in length-of-stay of one day was associated with an estimated absolute increase of 0.33% in risk-standardized AMI mortality.

Geographic and temporal variation

Studies have also examined geographic and temporal variation in IQI 15 rates. Kolte et al. used the 2003-2010 NIS to quantify regional differences in ST-elevation myocardial infarction treatment and in-hospital mortality.[19] They found risk-adjusted mortality to be higher in the Midwest (Odds Ratio [OR] 1.07; 95% Confidence Interval [CI] 1.05 to 1.09; p<0.001), South (OR 1.03; 95% C 1.01 to 1.05; p=0.001), and West (OR 1.06; 95% CI 1.04 to 1.08; p<0.001)), compared to the Northeast. Another study by Menees and colleagues addressed trends in door-to-balloon time for patients undergoing percutaneous coronary interventions (PCI) against in-hospital mortality using data on 96,738 patients admitted for ST-elevated myocardial infarction from the CathPCI Registry from July 2005-June 2009.[20] They found a significant decline between July 2005 – June 2006 and July 2008 – June 2009 in door-to-balloon times, as measured both by median times (83 minutes vs. 67 minutes, p<0.001) and by the percentage of patients with door-to-balloon times of 90 minutes or less (59.7% vs. 83.1%, p<0.001). However, despite these changes, there was no significant change in risk-adjusted in-hospital mortality over this time period (5.0% vs. 4.7%, p=0.34).

Risk adjustment

Numerous studies have established the importance of risk adjustment for AMI patients. As a result, researchers have developed a number of risk adjustment models. Normand et al. developed and validated two models, one of which was based on conditions likely to be present on admission and therefore applicable to comparisons of hospital-based care.[21] The claims-based model included 25 comorbidities not related to treatment. Hypertension (18.3%), diabetes (13.8%), and pulmonary disease (11.2%) were the most frequent

comorbidities in an AMI Medicare cohort of 164,427 patients. Frequently occurring comorbidities that were considered possibly related to hospital treatment, and therefore omitted, included congestive heart failure (33.9%), chronic angina (27.4%), and arrhythmias (25.2%). The same team developed another model using the clinical predictors available from the Cooperative Cardiovascular Project. From these and numerous other studies, the most important predictors of short-term AMI mortality have been shown to include age, previous AMI, tachycardia, pulmonary edema and other signs of congestive heart failure, hypotension and cardiogenic shock, anterior wall and Q-wave infarction, cardiac arrest, and serum creatinine or urea nitrogen.

Krumholz et al. compared seven models including a newly developed 7-variable clinical/demographic risk adjustment model for 30-day mortality in AMI patients.[22] The models based on clinical data demonstrated modestly better discrimination and calibration than two models based on ICD-9-CM codes (area under the receiver operating curve 0.74-0.78 versus 0.70-0.71, respectively). In addition, the clinical models classified hospital performance somewhat differently than the models based on administrative data. Such differences were further explored by Iezzoni et al., who used several proprietary products to estimate risk-adjusted AMI mortality, and found 40-60% disagreement in identifying the 10 best and 10 worst hospitals in a nationwide sample.[23,24] Adding full clinical data to administrative data for risk-adjustment, Pine found that 73% of Cleveland hospitals' expected mortality rates changed by less than one standard deviation, and none changed by more than two.[25] In St. Louis, 95% of hospitals' expected mortality rates changed by less than 0.5 standard deviations, and none changed by more than one. These estimates were better than those for other major medical conditions, including pneumonia, stroke, and congestive heart failure.[26] In the California Hospital Outcomes Project, the addition of clinical risk factors to a re-estimated model based on re-abstracted ICD-9-CM codes had a minimal effect on the difference in risk-adjusted mortality between low-mortality and high-mortality hospitals, although individual hospitals were affected.[27] In summary, these studies found that the method of risk-adjustment does affect which specific hospitals are identified as mortality outliers, but that the correlations within pairs of risk-adjusted or expected mortality rates are generally high (e.g., 0>0.80)[13] to 0.94,[26] and higher for AMI than for other medical conditions.

When risk adjustment models include ICD-9-CM conditions that may represent consequences of poor care, then discrimination is exaggerated.[22] Romano and Chan compared an administrative data set to a re-abstraction of diagnoses present on admission (POA), with two versions of the All Patient Refined-Diagnosis-Related Groups (APR-DRG), Risk of Mortality (ROM) and Severity of Illness (SOI).[28] The authors showed empirically that APR-DRGs predicted in-hospital mortality better when all diagnoses were included than when only POA diagnoses were included. Hospitals' expected mortality rates based on all re-abstracted ICD-9-CM codes were moderately correlated (r=0.72-0.77) with expected mortality rates based only on POA diagnoses. However, 2 of the 3 hospitals classified as having higher than expected mortality, 8 of the 23 hospitals classified as having neither higher nor lower than expected mortality, and 0 of the 4 hospitals classified as having lower than expected mortality, switched categories when diagnoses not present on admission were excluded from risk-adjustment. IQI 15 risk adjustment therefore only considers POA secondary diagnoses.

Scientific Acceptability

Metcalfe et al., searched Ovid Medline from 1950-2010 to identify studies (26 articles) that validated ICD-9, ICD-9-CM, and ICD-10 AMI case definitions. They then applied these ICD-based definitions to an ICD-9-CM/ICD-10 dual-coded dataset (n=4,008 inpatient records) to assess the criterion validity of the definitions (using chart review as the criterion standard) and to assess the impact of varied AMI case definitions on AMI in-hospital mortality estimates.[29] They found that AMI code 410 (ICD-9-CM) had the highest sensitivity (94%) and specificity (99%). The use of codes 410 (ICD-9-CM) and I21-I22 (ICD-10) to define AMI had high sensitivity (83.3%, 82.8% for ICD-9-CM and ICD-10, respectively) and positive predictive value (82.8%, 82.2%). The

percentage of in-hospital AMI mortality identified in the chart review, using these specific case definitions, was 7.6% (ICD-9-CM) and 6.6% (ICD-10).

Another study suggested that patients transferred to a second hospital may be counted twice for one episode of AMI (if these patients are not excluded, as in IQI 15), and sought to describe the impact of such double counting and transfer bias on the estimation of incidence rates and outcomes of AMI in the United States. Analyzing hospital discharge data from eight states, the study estimated that double count rates range from 10% to 15% for all states and increased over the 3 years. Moderate sized rural counties had the highest estimated double count rates at 15% to 20% with a few counties having estimated double count rates a high as 35% to 50%. Older patients and females were less likely to be double counted ($p < 0.05$).[30] This problem is addressed in the design of IQI 15 by excluding inter-hospital transfers from the transferring facility, and adjusting for their marginal risk at the receiving facility.

1. Evidence, Performance Gap, Priority – Importance to Measure and Report

Extent to which the specific measure focus is evidence-based, important to making significant gains in healthcare quality, and improving health outcomes for a specific high-priority (high-impact) aspect of healthcare where there is variation in or overall less-than-optimal performance. ***Measures must be judged to meet all subcriteria to pass this criterion and be evaluated against the remaining criteria.***

1a. Evidence to Support the Measure Focus – See attached Evidence Submission Form
AHRQ_IQI15_NQF_0730_Measure_Evidence_Form.docx

1b. Performance Gap
Demonstration of quality problems and opportunity for improvement, i.e., data demonstrating:

- considerable variation, or overall less-than-optimal performance, in the quality of care across providers; and/or
- disparities in care across population groups.

1b.1. Briefly explain the rationale for this measure *(e.g., the benefits or improvements in quality envisioned by use of this measure)*
Acute Myocardial Infarction (AMI) is an emergent condition for which significant morbidity and mortality may result from delayed, inappropriate or low quality treatment. Processes that have been identified to lower AMI mortality include: timely electrocardiography (ECG), early percutaneous coronary intervention (PCI) for ST-elevation MI, or fibrinolytic therapy if PCI is not available, aspirin administration at arrival, afterload reduction with renin-angiotensin system blockade among patients with impaired left ventricular function, and aspirin/statin prescription initiation during hospitalization with continuation at discharge. The 30-day risk-standardized AMI mortality rate is currently a CMS quality metric. In-hospital risk-adjusted mortality rates allow users without access to post-hospitalization death data, to assess and compare AMI outcomes.

1b.2. Provide performance scores on the measure as specified (current and over time) at the specified level of analysis. *(This is required for endorsement maintenance. Include mean, std dev, min, max, interquartile range, scores by decile. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities included). This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*
This table is also included in the supplemental files.

Table 1. Reference Population Rate and Distribution of Hospital Performance of IQI 15 Acute Myocardial Infarction (AMI) Mortality Rate

Overall Reference Population Rate

Year	Number Hospitals (Numerator)1	Population at Risk (Denominator)1	Outcome of Interest Observed Rate Per 10001	
2012	2,978	24,890	441,557	56.37
2011	2,835	23,995	411,209	58.35
20103	4,063	30,917	512,422	60.34
20093	4,023	31,543	503,971	66.41
20083	4,029	34,093	513,338	68.94

Distribution of Hospital-level Observed Rates in Reference Population

Year	Number of Hospitals	Distribution of Observed Hospital-level Rates per 1000 (p=percentile)2						
		Mean	SD	p5	p25	Median	p75	p95
2012	2,978	104.33	150.90	0.00	33.90	58.82	115.38	375.00
2011	2,835	111.90	153.88	0.00	36.91	63.45	125.00	400.00

Source: HCUP State Inpatient Databases (SID). Healthcare Cost and Utilization Project (HCUP). 2008-2012. Agency for Healthcare Research and Quality, Rockville, MD. www.hcup-us.ahrq.gov/sidoverview.jsp. (AHRQ QI Software Version 4.5 and 5.0)
1The observed rate refers to the total rate for all observations included in the reference population data (numerator) divided by the total combined population of all hospitals included in the reference population data (denominator).
2The distribution of hospital rates reports the mean and standard deviation (SD) of the observed rates for all hospitals included in the dataset, as well as the observed rate for hospitals in the 5th, 25th, 50th (median), 75th, and 95th percentile.
32008-2010 data are calculated using Version 4.5 of the QI Software and all states included in the SID for those years. Version 4.5 includes a "prediction module" which is used to account for missing present on admission flags. In Version 5.0, the "prediction module" has been removed and the reference population is limited to states and hospitals with present on admission data. These differences may lead to some discontinuity in the observed rates between 2010 and 2011, since many states did not report POA data prior to 2011. The number of states reporting consistent POA has increased from 2008-2012.

1b.3. If no or limited performance data on the measure as specified is reported in 1b2, then provide a summary of data from the literature that indicates opportunity for improvement or overall less than optimal performance on the specific focus of measurement.
Not applicable

1b.4. Provide disparities data from the measure as specified (current and over time) by population group, e.g., by race/ethnicity, gender, age, insurance status, socioeconomic status, and/or disability. *(This is required for endorsement maintenance. Describe the data source including number of measured entities; number of patients; dates of data; if a sample, characteristics of the entities include.) This information also will be used to address the subcriterion on improvement (4b.1) under Usability and Use.*

This table is also included in the supplemental files.

Table 2. Observed AMI Mortality Rates per 1,000 (IQI 15), by patient and hospital characteristics, 2012

Patient Characteristics	Estimate	Std Error	p-value	(Ref Grp = *)
Total U.S.	56.296	0.351		
Patient Characteristics				
Age Groups:				
18-44*	18.064	0.878

1b.5. **If no or limited data on disparities from the measure as specified is reported in 1b4, then provide a summary of data from the literature that addresses disparities in care on the specific focus of measurement. Include citations.**
Not applicable

1c. High Priority (previously referred to as High Impact)

The measure addresses:

- a specific national health goal/priority identified by DHHS or the National Priorities Partnership convened by NQF; OR
- a demonstrated high-priority (high-impact) aspect of healthcare (e.g., affects large numbers of patients and/or has a substantial impact for a smaller population; leading cause of morbidity/mortality; high resource use (current and/or future); severity of illness; and severity of patient/societal consequences of poor quality).

1c.1. **Demonstrated high priority aspect of healthcare**

Affects large numbers, A leading cause of morbidity/mortality, Patient/societal consequences of poor quality

1c.2. **If Other:**

1c.3. **Provide epidemiologic or resource use data that demonstrates the measure addresses a high priority aspect of healthcare. List citations in 1c.4.**

Table 1 in section 1.b.2 shows that the total U.S. observed rate for AMI mortality in 2012 was 56.4 per 1000, representing an estimated total of 24,890 deaths. From 2008-2012, rates decreased from 68.9 in 2008 to 56.4 in 2012. Note that between 2010 and 2011, the reference population changed substantially, notably limiting to states with strong POA data and to community hospitals (i.e., excluding children's hospitals, rehabilitation hospitals, etc.).

1c.4. **Citations for data demonstrating high priority provided in 1a.3**

HCUP State Inpatient Databases (SID). Healthcare Cost and Utilization Project (HCUP). 2008-2012. Agency for Healthcare Research and Quality, Rockville, MD. www.hcup-us.ahrq.gov/sidoverview.jsp. (AHRQ QI Software Version 4.5 and 5.0)

1c.5. **If a PRO-PM (e.g. HRQoL/functional status, symptom/burden, experience with care, health-related behaviors), provide evidence that the target population values the measured PRO and finds it meaningful.** *(Describe how and from whom their input was obtained.)*

Not applicable

2. Reliability and Validity—Scientific Acceptability of Measure Properties

Extent to which the measure, as specified, produces consistent (reliable) and credible (valid) results about the quality of care when implemented. ***Measures must be judged to meet the subcriteria for both reliability and validity to pass this criterion and be evaluated against the remaining criteria.***

2a.1. Specifications The measure is well defined and precisely specified so it can be implemented consistently within and across organizations and allows for comparability. eMeasures should be specified in the Health Quality Measures Format (HQMF) and the Quality Data Model (QDM).

De.5. **Subject/Topic Area** *(check all the areas that apply):*

Cardiovascular, Cardiovascular : Acute Myocardial Infarction

De.6. **Cross Cutting Areas** *(check all the areas that apply):*

S.1. **Measure-specific Web Page** *(Provide a URL link to a web page specific for this measure that contains current detailed specifications including code lists, risk model details, and supplemental materials. Do not enter a URL linking to a home page or to general information.)*

http://www.qualityindicators.ahrq.gov/Modules/iqi_resources.aspx

S.2a. **If this is an eMeasure**, HQMF specifications must be attached. Attach the zipped output from the eMeasure authoring tool (MAT) - if the MAT was not used, contact staff. (Use the specification fields in this online form for the plain-language description of the specifications)

This is not an eMeasure **Attachment:**

S.2b. **Data Dictionary, Code Table, or Value Sets** *(and risk model codes and coefficients when applicable) must be attached. (Excel or csv file in the suggested format preferred - if not, contact staff)*

Attachment **Attachment:** Technical_Specs_IQI15_v5.0.xlsx

S.3. **For endorsement maintenance**, please briefly describe any changes to the measure specifications since last endorsement date and explain the reasons.

As standard protocol, the AHRQ QI program annually updates all measures with Fiscal Year coding changes, refinements based on stakeholder input, refinements to improve specificity and sensitivity based on additional analyses, and necessary software changes. In addition, approximately every two years, AHRQ updates the risk adjustment parameter estimates and composite weights based

on the most recent year of data (i.e., the most current reference population possible). The refined measures are tested and confirmed to be valid and reliable prior to release of the updated software.

Since the last endorsement (version 4.3), no changes have been made to the specification of IQI 15.

In Version 5.0 (released April 2015), the reference population has been updated to limit the population to states with strong present on admission (POA) data and community hospitals. The software no longer supports the "prediction module" for POA imputation, and instead requires user supplied POA data.

S.4. **Numerator Statement** *(Brief, narrative description of the measure focus or what is being measured about the target population, i.e., cases from the target population with the target process, condition, event, or outcome)*
IF an OUTCOME MEASURE, state the outcome being measured. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
Number of in-hospital deaths among cases meeting the inclusion and exclusion rules for the denominator.

S.5. **Time Period for Data** *(What is the time period in which data will be aggregated for the measure, e.g., 12 mo, 3 years, look back to August for flu vaccination? Note if there are different time periods for the numerator and denominator.)*
The time period is one year for users with a complete sample of hospital discharges (i.e., "all payer" data). Note that the signal variance parameters assume a one-year time period. Users may use longer time periods if desired.

S.6. **Numerator Details** *(All information required to identify and calculate the cases from the target population with the target process, condition, event, or outcome such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
IF an OUTCOME MEASURE, describe how the observed outcome is identified/counted. Calculation of the risk-adjusted outcome should be described in the calculation algorithm.
Number of deaths (DISP=20 in AHRQ's Healthcare Cost and Utilization Project datasets) among cases meeting the inclusion and exclusion rules for the denominator.

S.7. **Denominator Statement** *(Brief, narrative description of the target population being measured)*
Discharges, for patients ages 18 years and older, with a principal ICD-9-CM diagnosis code for AMI.

S.8. **Target Population Category** *(Check all the populations for which the measure is specified and tested if any):*
Populations at Risk

S.9. **Denominator Details** *(All information required to identify and calculate the target population/denominator such as definitions, specific data collection items/responses , code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
ICD-9-CM AMI diagnosis codes (initial or unspecified episode of care):

41000 AMI ANTEROLATERAL, UNSPEC
41001 AMI ANTEROLATERAL, INIT
41010 AMI ANTERIOR WALL, UNSPEC
41011 AMI ANTERIOR WALL, INIT
41020 AMI INFEROLATERAL, UNSPEC
41021 AMI INFEROLATERAL, INIT
41030 AMI INFEROPOST, UNSPEC
41031 AMI INFEROPOST, INITIAL
41040 AMI INFERIOR WALL, UNSPEC
41041 AMI INFERIOR WALL, INIT
41050 AMI LATERAL NEC, UNSPEC
41051 AMI LATERAL NEC, INITIAL
41060 TRUE POST INFARCT, UNSPEC
41061 TRUE POST INFARCT, INIT
41070 SUBENDO INFARCT, UNSPEC
41071 SUBENDO INFARCT, INITIAL
41080 AMI NEC, UNSPECIFIED
41081 AMI NEC, INITIAL

41090 AMI NOS, UNSPECIFIED
41091 AMI NOS, INITIAL

S.10. **Denominator Exclusions** *(Brief narrative description of exclusions from the target population)*
Exclude cases:

- transferred to another short-term hospital, for whom the outcome at hospital discharge was unknown
- admitted for treatment of pregnancy, childbirth, and puerperium
- with missing discharge disposition, gender, age, quarter, year, or principal diagnosis

S.11. **Denominator Exclusion Details** *(All information required to identify and calculate exclusions from the denominator such as definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format at S.2b)*
Exclude cases:

- transferred to another short-term hospital (DISP=2)
- with Major Diagnosis Category (MDC) 14 (pregnancy, childbirth, and puerperium)
- with missing discharge disposition (DISP=missing), gender (SEX=missing), age (AGE=missing), quarter (DQTR=missing), year (YEAR=missing) or principal diagnosis (DX1=missing)

S.12. **Stratification Details/Variables** *(All information required to stratify the measure results including the stratification variables, definitions, specific data collection items/responses, code/value sets – Note: lists of individual codes with descriptors that exceed 1 page should be provided in an Excel or csv file in required format with at S.2b)*
Not applicable

S.13. **Risk Adjustment Type** (Select type. Provide specifications for risk stratification in S.12 and for statistical model in S.14-15)
Statistical risk model
If other:

S.14. **Identify the statistical risk model method and variables** *(Name the statistical method - e.g., logistic regression and list all the risk factor variables. Note - risk model development and testing should be addressed with measure testing under Scientific Acceptability)*
The predicted value for each case is computed using a hierarchical model (logistic regression with hospital random effect) and covariates for gender, age (in 5-year age groups), All Patient Refined Diagnosis Related Groups (APR DRGs) with Risk of Mortality (ROM) scores, Major Diagnosis Categories (MDC) based on the principal diagnosis, and transfer in from another acute care hospital. The expected rate is computed as the sum of the predicted value for each case divided by the number of cases for the unit of analysis of interest (i.e., hospital). The risk adjusted rate is computed using indirect standardization as the observed rate divided by the expected rate, multiplied by the reference population rate.

The specific covariates for this measure are as follows:

Parameter	Label
Age	18 to 39
Age	40 to 44
Age	45 to 49
Age	50 to 54
Age	55 to 59
Age	65 to 79
Age	80 to 84
Age	85+
APR-DRG	161-(1-2) CARDIAC DEFIBRILLATOR & HEART ASSIST IMPLANT, Risk of mortality (ROM) 1 - 2
APR-DRG	161-(3-4) CARDIAC DEFIBRILLATOR & HEART ASSIST IMPLANT, Risk of mortality (ROM) 3 - 4
APR-DRG	162-(1,2)CARDIAC VALVE PROCEDURES W CARDIAC CATHETERIZATION, ROM 1 and 2
APR-DRG	162-3 CARDIAC VALVE PROCEDURES W CARDIAC CATHETERIZATION, ROM 3
APR-DRG	162-4 CARDIAC VALVE PROCEDURES W CARDIAC CATHETERIZATION, ROM 4
APR-DRG	165-(1,2) CORONARY BYPASS W CARDIAC CATH OR PERCUTANEOUS CARDIAC PROC, ROM 1 and 2
APR-DRG	165-3 CORONARY BYPASS W CARDIAC CATH OR PERCUTANEOUS CARDIAC PROC, ROM 3
APR-DRG	165-4 CORONARY BYPASS W CARDIAC CATH OR PERCUTANEOUS CARDIAC PROC, ROM 4
APR-DRG	173-(1-4) OTHER VASCULAR PROCEDURES, ROM 1-4

APR-DRG 174-2 PERCUTANEOUS CARDIOVASCULAR PROCEDURES W AMI, ROM 2

S.15. **Detailed risk model specifications** *(must be in attached data dictionary/code list Excel or csv file. Also indicate if available at measure-specific URL identified in S.1.)*
Note: Risk model details (including coefficients, equations, codes with descriptors, definitions), should be provided on a separate worksheet in the suggested format in the Excel or csv file with data dictionary/code lists at S.2b.
Available in attached Excel or csv file at S.2b

S.15a. **Detailed risk model specifications** (*if not provided in excel or csv file at S.2b*)

S.16. **Type of score:**
Rate/proportion
If other:

S.17. **Interpretation of Score** *(Classifies interpretation of score according to whether better quality is associated with a higher score, a lower score, a score falling within a defined interval, or a passing score)*
Better quality = Lower score

S.18. **Calculation Algorithm/Measure Logic** *(Describe the calculation of the measure score as an ordered sequence of steps including identifying the target population; exclusions; cases meeting the target process, condition, event, or outcome; aggregating data; risk adjustment; etc.)*
The observed rate is the number of discharge records where the patient experienced the QI adverse event divided by the number of discharge records at risk for the event. The expected rate is a comparative rate that incorporates information about a reference population that is not part of the user's input dataset – what rate would be observed if the expected level of care observed in the reference population and estimated with risk adjustment regression models, were applied to the mix of patients with demographic and comorbidity distributions observed in the user's dataset? The expected rate is calculated only for risk-adjusted indicators.

The expected rate is estimated for each person using a generalized estimating equations (GEE) approach to account for correlation at the hospital or provider level.

The risk-adjusted rate is a comparative rate that also incorporates information about a reference population that is not part of the input dataset – what rate would be observed if the level of care observed in the user's dataset were applied to a mix of patients with demographics and comorbidities distributed like the reference population? The risk adjusted rate is calculated using the indirect method as observed rate divided by expected rate multiplied by the reference population rate. The smoothed rate is the weighted average of the risk-adjusted rate from the user's input dataset and the rate observed in the reference population; the smoothed rate is calculated with a shrinkage estimator to result in a rate near that from the user's dataset if the provider's rate is estimated in a stable fashion with minimal noise, or to result in a rate near that of the reference population if the variance of the estimated rate from the input dataset is large compared with the hospital-to-hospital variance estimated from the reference population. Thus, the smoothed rate is a weighted average of the risk-adjusted rate and the reference population rate, where the weight is the signal-to-noise ratio. In practice, the smoothed rate brings rates toward the mean, and tends to do this more so for outliers (such as rural hospitals).

For additional information, please see supporting information in the Quality Indicator Empirical Methods.

S.19. **Calculation Algorithm/Measure Logic Diagram URL or Attachment** *(You also may provide a diagram of the Calculation*

Algorithm/Measure Logic described above at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)
No diagram provided

S.20. **Sampling** *(If measure is based on a sample, provide instructions for obtaining the sample and guidance on minimum sample size.)*
IF a PRO-PM, identify whether (and how) proxy responses are allowed.
Not applicable

S.21. **Survey/Patient-reported data** *(If measure is based on a survey, provide instructions for conducting the survey and guidance on minimum response rate.)*
IF a PRO-PM, specify calculation of response rates to be reported with performance measure results.
Not applicable

S.22. **Missing data** (specify how missing data are handled, e.g., imputation, delete case.)
Required for Composites and PRO-PMs.
Exclude cases with missing gender (SEX=missing), age (AGE=missing), quarter (DQTR=missing), year (YEAR=missing), or principal diagnosis (DX1=missing). Missingness on these variables, in aggregate, almost never exceeds 1% of eligible records.

S.23. **Data Source** *(Check ONLY the sources for which the measure is SPECIFIED AND TESTED).*
If other, please describe in S.24.
Administrative claims

S.24. **Data Source or Collection Instrument** *(Identify the specific data source/data collection instrument e.g. name of database, clinical registry, collection instrument, etc.)*
IF a PRO-PM, identify the specific PROM(s); and standard methods, modes, and languages of administration.
While the measure is tested and specified using data from the Healthcare Cost and Utilization Project (HCUP) (see section 1.1 and 1.2 of the measure testing form), the measure specifications and software are specified to be used with any ICD-9-CM-coded administrative billing/claims/discharge dataset with Present on Admission (POA) information. Note that in Version 5.0, the AHRQ QI software no longer supports prediction of POA status using an embedded prediction module. Users are expected to provide POA data.

S.25. **Data Source or Collection Instrument** *(available at measure-specific Web page URL identified in S.1 OR in attached appendix at A.1)*
Available at measure-specific web page URL identified in S.1

S.26. **Level of Analysis** *(Check ONLY the levels of analysis for which the measure is SPECIFIED AND TESTED)*
Facility

S.27. **Care Setting** *(Check ONLY the settings for which the measure is SPECIFIED AND TESTED)*
Hospital/Acute Care Facility
If other:

S.28. **COMPOSITE Performance Measure** - Additional Specifications *(Use this section as needed for aggregation and weighting rules, or calculation of individual performance measures if not individually endorsed.)*
Not applicable

AHRQ_IQI15_Measure_Testing_Form.docx

NATIONAL QUALITY FORUM—Measure Testing (subcriteria 2a2, 2b2-2b7)

Measure Number (*if previously endorsed*)**:** 0730
Measure Title: Acute Myocardial Infarction (AMI) Mortality Rate
Date of Submission: 6/30/2015
Type of Measure:

☐ Composite – ***STOP – use composite testing form***	☒ Outcome (*including PRO-PM*)
☐ Cost/resource	☐ Process
☐ Efficiency	☐ Structure

Instructions

- Measures must be tested for all the data sources and levels of analyses that are specified. ***If there is more than one set of data specifications or more than one level of analysis, contact NQF staff*** about how to present all the testing information in one form.
- **For all measures, sections 1, 2a2, 2b2, 2b3, and 2b5 must be completed.**
- **For outcome and resource use measures**, section **2b4** also must be completed.
- If specified for **multiple data sources/sets of specificaitons** (e.g., claims and EHRs), section **2b6** also must be completed.
- Respond to all questions as instructed with answers immediately following the question. All information on testing to demonstrate meeting the subcriteria for reliability (2a2) and validity (2b2-2b6) must be in this form. An appendix for *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 20 pages (*incuding questions/instructions;* minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.
- For information on the most updated guidance on how to address sociodemographic variables and testing in this form refer to the release notes for version 6.6 of the Measure Testing Attachment.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the testing results for this measure meet NQF's evaluation criteria for testing.

2a2. Reliability testing [10] demonstrates the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise. For **PRO-PMs and composite performance measures**, reliability should be demonstrated for the computed performance score.

2b2. Validity testing [11] demonstrates that the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality. For **PRO-PMs and composite performance measures**, validity should be demonstrated for the computed performance score.

2b3. Exclusions are supported by the clinical evidence; otherwise, they are supported by evidence of sufficient frequency of occurrence so that results are distorted without the exclusion; [12]

AND

If patient preference (e.g., informed decision making) is a basis for exclusion, there must be evidence that the exclusion impacts performance on the measure; in such cases, the measure must be specified so that the information about patient preference and the effect on the measure is transparent (e.g., numerator category computed separately, denominator exclusion category computed separately). [13]

2b4. For outcome measures and other measures when indicated (e.g., resource use):

- **an evidence-based risk-adjustment strategy** (e.g., risk models, risk stratification) is specified; is based on patient factors (including clinical and sociodemographic factors) that influence the measured outcome and are present at start of care; [14,15] and has demonstrated adequate discrimination and calibration

OR

- rationale/data support no risk adjustment/ stratification.

2b5. Data analysis of computed measure scores demonstrates that methods for scoring and analysis of the specified measure allow for **identification of statistically significant and practically/clinically meaningful [16] differences in performance**;

OR

there is evidence of overall less-than-optimal performance.

2b6. If multiple data sources/methods are specified, there is demonstration they produce comparable results.

2b7. For **eMeasures, composites, and PRO-PMs** (or other measures susceptible to missing data), analyses identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias.

Notes

10. Reliability testing applies to both the data elements and computed measure score. Examples of reliability testing for data elements include, but are not limited to: inter-rater/abstractor or intra-rater/abstractor studies; internal consistency for multi-item scales; test-retest for survey items. Reliability testing of the measure score addresses precision of measurement (e.g., signal-to-noise).

11. Validity testing applies to both the data elements and computed measure score. Validity testing of data elements typically analyzes agreement with another authoritative source of the same information. Examples of validity testing of the measure score include, but are not limited to: testing hypotheses that the measures scores indicate quality of care, e.g., measure scores are different for groups known to have differences in quality assessed by another valid quality measure or method; correlation of measure scores with another valid indicator of quality for the specific topic; or relationship to conceptually related measures (e.g., scores on process measures to scores on outcome measures). Face validity of the measure score as a quality indicator may be adequate if accomplished through a systematic and transparent process, by identified experts, and explicitly addresses whether performance scores resulting from the measure as specified can be used to distinguish good from poor quality.

12. Examples of evidence that an exclusion distorts measure results include, but are not limited to: frequency of occurrence, variability of exclusions across providers, and sensitivity analyses with and without the exclusion.

13. Patient preference is not a clinical exception to eligibility and can be influenced by provider interventions.

14. Risk factors that influence outcomes should not be specified as exclusions

15. With large enough sample sizes, small differences that are statistically significant may or may not be practically or clinically meaningful. The substantive question may be, for example, whether a statistically significant difference of one percentage point in the percentage of patients who received smoking cessation counseling (e.g., 74 percent v. 75 percent) is clinically meaningful; or whether a statistically significant difference of $25 in cost for an episode of care (e.g., $5,000 v. $5,025) is practically meaningful. Measures with overall less-than-optimal performance may not demonstrate much variability across providers.

1. DATA/SAMPLE USED FOR ALL TESTING OF THIS MEASURE

Often the same data are used for all aspects of measure testing. In an effort to eliminate duplication, the first five questions apply to all measure testing. If there are differences by aspect of testing,(e.g., reliability vs. validity) be sure to indicate the specific differences in question 1.7.

1.1. What type of data was used for testing? (*Check all the sources of data identified in the measure specifications and data used for testing the measure. Testing must be provided for all the sources of data specified and intended for measure implementation.* ***If different data sources are used for the numerator and denominator, indicate N [numerator] or D [denominator] after the checkbox.***)

Measure Specified to Use Data From: (***must be consistent with data sources entered in S.23***)	**Measure Tested with Data From:**
☐ abstracted from paper record	☐ abstracted from paper record
☒ administrative claims	☒ administrative claims
☐ clinical database/registry	☐ clinical database/registry
☐ abstracted from electronic health record	☐ abstracted from electronic health record
☐ eMeasure (HQMF) implemented in EHRs	☐ eMeasure (HQMF) implemented in EHRs
☐ other: Click here to describe	☐ other: Click here to describe

1.2. If an existing dataset was used, identify the specific dataset (*the dataset used for testing must be consistent with the measure specifications for target population and healthcare entities being measured; e.g., Medicare Part A claims, Medicaid claims, other commercial insurance, nursing home MDS, home health OASIS, clinical registry*).

All analyses were completed using data from the Healthcare Cost and Utilization Project (HCUP) State Inpatient Databases (SID), 2008-2012. HCUP is a family of health care databases and related software tools and products developed through a Federal-State-Industry partnership and sponsored by the Agency for Healthcare Research and Quality (AHRQ).[1] HCUP databases bring together the data collection efforts of State data organizations, hospital associations, private data organizations, and the Federal government to create a national information resource of encounter-level health care data. The HCUP SID contain the universe of the inpatient discharge abstracts in participating States, translated into a uniform format to facilitate multi-State comparisons and analyses. All states provide data for community hospitals and together, the SID encompasses about 97 percent of all U.S. community hospital discharges. For the analyses presented here, we use 36 of the 45 states that participated in 2012, and 82 percent of the U.S. community hospital discharges, for a total of about 30 million hospital discharges from community hospitals. As defined by the American Hospital Association, community hospitals are all non-Federal, short-term, general or other specialty hospitals, excluding hospital units of institutions. Included among community hospitals are public and academic medical centers, specialty hospitals such as obstetrics–gynecology, ear–nose–throat, orthopedic and pediatric institutions. Short-stay rehabilitation, long-term acute care hospitals are excluded from the data used for the reported analyses.

Each of the 36 states included in the dataset report information about whether a diagnosis was present on admission (POA) and information on the timing of procedures during the hospitalization. POA data[1] is important to distinguish complications that occur in-hospital from diagnoses that existed prior to hospitalization. For all PSIs, the POA flag is used to exclude cases from the numerator when the condition of interest is present on admission and to exclude complications that occur in-hospital from risk adjustment. Edit

[1] Present-on -Admission was added as a data element to the uniform bill form (UB-04) effective October 1, 2007, and hospitals incurred a payment penalty for not including POA on Medicare records beginning October 1, 2008. Each of the several diagnoses in a discharge record can be flagged as "present at the time the order for inpatient admission occurs" or not (see http://www.cdc.gov/nchs/icd/icd9cm_addenda_guidelines.htm).

checks on POA were developed using a separate analysis of HCUP databases that examined POA coding in the 2011 SID at hospitals that were required to report POA to CMS. The edits identify general patterns of suspect reporting of POA. The edits do not evaluate whether a valid POA value (e.g., Y or N) is appropriate for the specific diagnosis. There are three hospital-level edit checks:

1. Indication that a hospital has POA reported as Y on all diagnoses on all discharges
2. Indication that a hospital has POA reported as missing on all non-Medicare discharges
3. Indication that a hospital reported POA as missing on all nonexempt diagnoses for 15 percent or more of discharges. The cut-point of 15 percent was determined by 2 times the standard deviation plus the mean of the percentage for hospitals required to report POA to CMS.

Hospitals that failed any of the edit checks were excluded from the dataset.

The SID data elements include ICD-9-CM coded principal and secondary diagnoses and procedures, additional detailed clinical and service information based on revenue codes, admission and discharge status, patient demographics, expected payment source (Medicare, Medicaid, private insurance as well as the uninsured), total charges and length of stay (www.hcup-us.ahrq.gov).

[1]HCUP State Inpatient Databases (SID). Healthcare Cost and Utilization Project (HCUP). 2008-2012. Agency for Healthcare Research and Quality, Rockville, MD. www.hcup-us.ahrq.gov/sidoverview.jsp. (AHRQ QI Software Version 5.0)

1.3. What are the dates of the data used in testing? 2008-2012

1.4. What levels of analysis were tested? (*testing must be provided for all the levels specified and intended for measure implementation, e.g., individual clinician, hospital, health plan*)

Measure Specified to Measure Performance of: (***must be consistent with levels entered in item S.26***)	**Measure Tested at Level of:**

1.5. How many and which measured entities were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of measured entities included in the analysis (e.g., size, location, type); if a sample was used, describe how entities were selected for inclusion in the sample*)

Table 1. Reference Population Rate and Distribution of Hospital Performance IQI 15 Acute Myocardial Infarction (AMI) Mortality Rate

Overall Reference Population Rate				
Year	**Number**	**Outcome of Interest**	**Population at Risk**	**Observed Rate**

	Hospitals	(Numerator)[1]	(Denominator)[1]	Per 1000[1]
2012	2,978	24,890	441,557	56.37
2011	2,835	23,995	411,209	58.35
2010[3]	4,063	30,917	512,422	60.34
2009[3]	4,023	31,543	503,971	66.41
2008[3]	4,029	34,093	513,338	68.94

Distribution of Hospital-level Observed Rates in Reference Population

Year	Number of Hospitals	Distribution of Observed Hospital-level Rates per 1000 (p=percentile)[2]						
		Mean	SD	p5	p25	Median	p75	p95
2012	2,978	104.33	150.90	0.00	33.90	58.82	115.38	375.00
2011	2,835	111.90	153.88	0.00	36.91	63.45	125.00	400.00

Source: HCUP State Inpatient Databases (SID). Healthcare Cost and Utilization Project (HCUP). 2008-2012. Agency for Healthcare Research and Quality, Rockville, MD. www.hcup-us.ahrq.gov/sidoverview.jsp. (AHRQ QI Software Version 4.5 and 5.0)

[1]The observed rate refers to the total rate for all observations included in the reference population data (numerator) divided by the total combined population of all hospitals included in the reference population data (denominator).

[2]The distribution of hospital rates reports the mean and standard deviation (SD) of the observed rates for all hospitals included in the dataset, as well as the observed rate for hospitals in the 5th, 25th, 50th (median), 75th, and 95th percentile.

[3]2008-2010 data are calculated using Version 4.5 of the QI Software and all states included in the SID for those years. Version 4.5 includes a "prediction module" which is used to account for missing present on admission flags. In Version 5.0, the "prediction module" has been removed and the reference population is limited to states and hospitals with present on admission data. These differences may lead to some discontinuity in the observed rates between 2010 and 2011, since many states did not report POA data prior to 2011. The number of states reporting consistent POA has increased from 2008-2012.

1.6. How many and which <u>patients</u> were included in the testing and analysis (by level of analysis and data source)? (*identify the number and descriptive characteristics of patients included in the analysis (e.g., age, sex, race, diagnosis); if a sample was used, describe how patients were selected for inclusion in the sample*)

See 1.5 (Table 1)

1.7. If there are differences in the data or sample used for different aspects of testing (e.g., reliability, validity, exclusions, risk adjustment), identify how the data or sample are different for each aspect of testing reported below.

Some tests require comparisons of two years of data (2011-2012). When no comparisons are required for the test, only 2012 data are used. For the sake of providing 5-year comparisons, we also provide rates from 2008-2010 using Version 4.5 of the software. Version 5.0 could not be calculated for 2008-2010 due to missing POA data. POA data is used in the risk adjustment model.

1.8 What were the patient-level sociodemographic (SDS) variables that were available and analyzed in the data or sample used? For example, patient-reported data (e.g., income, education, language), proxy variables when

SDS data are not collected from each patient (e.g. census tract), or patient community characteristics (e.g. percent vacant housing, crime rate).

Age and sex were the only patient-level sociodemographic variables that were available and analyzed in the data used for measure development and testing. The development data sets generally include race/ethnicity, principal expected source of payment, and zip code of residence, which could be used to capture socioeconomic characteristics at an ecological (community) level. However, these variables were not used in our analyses, based on our conceptual description (logical rationale or theory informed by literature and content experts) of the causal pathway between these factors, patient clinical factors, quality of care, and outcome, described in Section 2b4.3 below.

2a2. RELIABILITY TESTING

***Note**: If accuracy/correctness (validity) of data elements was empirically tested, separate reliability testing of data elements is not required – in 2a2.1 check critical data elements; in 2a2.2 enter "see section 2b2 for validity testing of data elements"; and skip 2a2.3 and 2a2.4.*

2a2.1. What level of reliability testing was conducted? (*may be one or both levels*)

☐ **Critical data elements used in the measure** (*e.g., inter-abstractor reliability; data element reliability must address ALL critical data elements*)

☒ **Performance measure score** (e.g., *signal-to-noise analysis*)

2a2.2. For each level checked above, describe the method of reliability testing and what it tests (*describe the steps—do not just name a method; what type of error does it test; what statistical analysis was used*)

Signal-to-noise. The signal-to-noise ratio refers to the entire population of US hospitals, comparing the degree to which rates are different from hospital to hospital (the signal) to how stable the rates are within hospitals (the noise). This metric is a stringent measure of reliability that takes into account the observed distribution of rates within a reference population. An indicator with a low signal-to-noise ratio may not be able to distinguish differences in quality between hospitals, or may identify differences inconsistently within the same time period. An indicator with a high signal-to-noise ratio will be more likely to consistently distinguish performance differences between hospitals (e.g. one hospital performs better than others).

The signal-to-noise ratio is estimated for each hospital. The overall signal-to-noise estimate is an average of hospital-level signal to noise ratios weighted by hospital size. Hospital size is calculated as the number of eligible discharges for IQI15. Weighting by hospital size reduces the impact of hospitals that have very small denominators (the number of patients at risk). Small hospitals admit very few patients at risk for AMI mortality.

Because the signal-to-noise ratio quantifies the ability to consistently discriminate one hospital's performance from the other hospitals in the population, it is sensitive to the distribution of hospital sizes as well as the distribution of observed rates in the reference population. If the hospitals in a population all have performance in a narrow range, it is more difficult to reliably distinguish between hospitals' performance than when hospital performance is spread out over a much wider range. For example, if all hospitals have nearly perfect performance, it will be impossible to distinguish between them. As a consequence, if the distribution of hospital rates changes over time, the signal-to-noise ratio will also change.

There is no universally accepted threshold of "adequate" signal to noise ratio. Different methods of calculating reliability and signal-to-noise result in different distributions of reliability scores. In addition, "adequate" depends on the specific application and judgment of the user. For instance, if a complication such as mortality is very important (e.g. leads to great harm to the patient) a lower reliability may be acceptable. However, the AHRQ QI program generally considers ratios between 0.4 – 0.8 as acceptable. It is rare to achieve reliability above 0.8. To account for the uncertainty (noise) in a hospital's performance due to reliability concerns stemming from low volume, smoothed rates can be calculated.

2a2.3. For each level of testing checked above, what were the statistical results from reliability testing? (e.g., *percent agreement and kappa for the critical data elements; distribution of reliability statistics from a signal-to-noise analysis*)

Table 2. Signal-to-Noise Ratio by Size Decile IQI 15 Acute Myocardial Infarction (AMI) Mortality

Size Decile	Number of Hospitals	Avg. Number of Discharges per Hospital in Decile	Avg. Signal-to-Noise Ratio for Hospitals in Decile
1	266	4.2	0.16937
2	266	8.2	0.24352
3	267	14.9	0.3386
4	266	27.7	0.47658
5	267	51.5	0.58262
6	266	100.8	0.66445
7	267	166.2	0.73103
8	266	249.1	0.78999
9	267	361.3	0.83704
10	266	672.2	0.89988
Overall	2664	165.6	0.74937

Source: HCUP State Inpatient Databases (SID). Healthcare Cost and Utilization Project (HCUP). 2012. Agency for Healthcare Research and Quality, Rockville, MD. www.hcup-us.ahrq.gov/sidoverview.jsp. (AHRQ QI Software Version 5.0)

2a2.4 What is your interpretation of the results in terms of demonstrating reliability? (i.e., *what do the results mean and what are the norms for the test conducted?*)

Signal to noise ratios were smaller for hospitals with fewer than 15 qualifying discharges per year (average signal-to-noise ratio less than 0.34). Smoothed rates, which are recommended for all hospitals (and are implemented in the AHRQ software), address reliability concerns particularly for small hospitals. Hospitals with more than 28 discharges on average have risk adjusted rates with moderate to high reliability (average signal-to-noise ratio of 0.48 to 0.90). Overall, the signal to noise ratio for this indicator is strong with an overall signal-to-noise ratio of 0.75.

2b2. VALIDITY TESTING

2b2.1. What level of validity testing was conducted? (*may be one or both levels*)

☒ **Critical data elements** (*data element validity must address ALL critical data elements*)

☒ **Performance measure score**

☒ **Empirical validity testing**

☐ **Systematic assessment of face validity of performance measure score as an indicator** of quality or resource use (*i.e., is an accurate reflection of performance on quality or resource use and can distinguish good from poor performance*)

2b2.2. For each level of testing checked above, describe the method of validity testing and what it tests (*describe the steps—do not just name a method; what was tested, e.g., accuracy of data elements compared to*

authoritative source, relationship to another measure as expected; what statistical analysis was used)

Critical Data Elements

The most critical data element for IQI 15 is the principal diagnosis field, which is used to identify patients admitted principally for treatment of AMI. Several published studies have reported on the sensitivity, specificity, and/or positive predictive value (PPV) of hospital administrative data for the purpose of identifying patients with a principal diagnosis of AMI (ICD-9-CM 410.x0 or 410.x1):

1: Metcalfe A, Neudam A, Forde S, Liu M, Drosler S, Quan H, Jetté N. Case definitions for acute myocardial infarction in administrative databases and their impact on in-hospital mortality rates. Health Serv Res. 2013 Feb;48(1):290-318.
2: Meehan TP, Hennen J, Radford MJ, Petrillo MK, Elstein P, Ballard DJ. Process and outcome of care for acute myocardial infarction among Medicare beneficiaries in Connecticut: a quality improvement demonstration project. Ann Intern Med. 1995 Jun 15;122(12):928-36.
3: Choma NN, Griffin MR, Huang RL, Mitchel EF Jr, Kaltenbach LA, Gideon P, Stratton SM, Roumie CL. An algorithm to identify incident myocardial infarction using Medicaid data. Pharmacoepidemiol Drug Saf. 2009 Nov;18(11):1064-71.

Empirical Validity

We tested the empirical validity of IQI 15 in a variety of ways:

1. Previous studies have demonstrated a relatively high correlation between inpatient and 30-day mortality for AMI, with a moderate kappa value. We empirically compared CMS 30-day risk-standardized mortality rates (RSMR) for AMI to IQI 15 rates (restricted to hospitalizations meeting the CMS measure's denominator criteria) by estimating Spearman rank correlations.
2. We evaluated the association between process measures involving AMI care and IQI 15 rates with the expectation that the two should generally be inversely related. The process measures included: (1) Median time to ECG (OP-5); (2) Fibrinolytic therapy received within 30 minutes of emergency department arrival (OP-2); (3) Fibrinolytic therapy received within 30 minutes of hospital arrival (AMI-7a); (4) Timing of receipt of primary percutaneous coronary intervention (AMI-8a); (5) Aspirin prescribed at discharge (AMI-2); and (6) Statin prescribed at discharge (AMI-10). We estimated Spearman rank correlations between these process measures and IQI 15 rates at the hospital level.
3. Teaching hospitals have been associated with improved outcomes from AMI, probably by virtue of closer adherence to current evidence-based guidelines. We determined the association between hospital teaching status and IQI 15 rates.
4. Assuming that hospitals that perform a high volume of percutaneous coronary intervention procedures are adept at management of patients with AMI, we assessed the relationship between

percutaneous coronary intervention (PCI) volume (as expressed by AHRQ's IQI 6) and IQI 15 rates. We tested for differences in rates across quartiles of PCI volume.

5. IQI 15 performance should be associated with performance on AHRQ's other IQIs that involve mortality from cardiovascular conditions or procedures. We assessed the relationship between IQIs 12 (Coronary Artery Bypass Graft Mortality Rate), 16 (Heart Failure Mortality Rate), and 30 (Percutaneous Coronary Intervention Mortality Rate) and IQI 15 rates. We estimated Spearman rank correlations among these measures.
6. Previous evidence suggests a meaningful volume-outcome association for AMI. For this reason, IQI 15 performance should be associated with volume of AMI hospitalizations. We assessed the relationship between AMI volume, as expressed by the IQI 15 denominator, and IQI 15 rates using the Spearman rank correlation coefficient.

2b2.3. What were the statistical results from validity testing? (*e.g., correlation; t-test*)

Critical Data Elements

In a systematic review of alternative case definitions for AMI in administrative databases, Metcalfe et al. identified 8 ICD-9-CM based definitions that have been validated in peer-reviewed studies. When these 8 definitions were applied to a Canadian (Calgary, Alberta) database with 4,008 inpatient records from 2003 that had been independently coded in both ICD-9-CM and ICD-10, the codes used in the current IQI 15 definition (410.x0 and 410.x1) had the highest PPV (84.0%) and acceptable sensitivity of 81.1%. However, these authors did not focus on the principal diagnosis position, and did not limit their "gold standard" to patients admitted for treatment of AMIs that occurred in the community.

The following authors have validated this case definition (or a slightly broader case definition including all 410 codes) based only on the principal diagnosis field in US data:

1. Fisher et al., 1992: sensitivity = 94.0%, PPV = 92.0% in 1984-1985 data (using 410.x)
2. Meehan et al., 1995; PPV = 95.7% in 1988-1991 data (using 410.x)
3. Petersen et al., 1999: PPV = 96.9% in 1994-1995 data (also applied LOS ≥3 days)
4. Kiyota et al., 2004: PPV = 95.1% in 1999-2000 data
5. Choma et al., 2009: PPV = 92.8% in 1999-2004 data (using 410.x, also required LOS ≥3 days)
6. Yeh et al., 2010: PPV = 96.7% in 1999-2008 data
7. Cutrona et al., 2013: PPV =86.0% in 2009 data

Empirical Validity

The following analyses address the hospital-level Spearman rank correlation between IQI 15 risk-adjusted rates and process measure adherence. Unless otherwise specified, the first estimate is based on 2011 data and the second estimate is based on 2012 data.

1. CMS OP-2, Fibrinolytic therapy received within 30 minutes (NQF 0288) – R=-0.102 and -0.263 (i.e., hospitals with higher IQI15 mortality have less timely use of fibrinolytic therapy, or worse process performance, but only 763 hospitals were eligible for this analysis).
2. CMS OP-5, Median time to ECG (NQF 0289) – R=-0.062 and -0.051 (i.e., hospitals with higher IQI15 mortality have shorter median time to electrocardiogram (ECG), or better process performance, but correlations are weak).
3. AMI-2, Aspirin prescribed at discharge (NQF 0142) – R=-0.192 and -0.217 (i.e., hospitals with higher IQI15 mortality have less use of aspirin at discharge, or worse process performance).
4. AMI-7a, Fibrinolytic (thrombolytic) agent received within 30 minutes of hospital arrival (NQF 0164) – R=-0.018 (i.e., no significant correlation between IQI15 mortality and timely fibrinolytic therapy, but only 293 hospitals were eligible for this analysis).

5. AMI-8a, Receipt of primary percutaneous coronary intervention (PCI) within 90 minutes of hospital arrival (NQF 0163) – R=-0.207 and -0.238 (i.e., hospitals with higher IQI15 mortality have less timely use of PCI, or worse process performance).
6. AMI-10, Statin prescribed at discharge (NQF 0639) – R=-0.333 (i.e., hospitals with higher IQI15 mortality have less use of statin at discharge, or worse process performance).

With respect to hospital-level Spearman rank correlations between IQI 15 risk-adjusted rates and risk-standardized 30-day mortality rates for Medicare FFS patients (from the Yale-CMS model), analyses are limited to 13 states in the reference population for which Medicare FFS records could be identified:
1. Comparisons involving IQI 15 estimates based on ALL patients (i.e., all payers, all ages) are modest but statistically significant (r=0.161 and 0.144).
2. Comparisons involving IQI 15 estimates limited to Medicare FFS beneficiaries are similar to all patient-comparisons (r=0.147 and 0.139).

With respect to teaching status, teaching hospitals had significantly and substantially lower IQI 15 risk-adjusted mortality rates than non-teaching hospitals (i.e., weighted means 6.2% versus 12.4% in 2011, 6.0% versus 11.5% in 2012).

With respect to PCI volume, high-volume (top quartile by volume) PCI hospitals had significantly and substantially lower IQI 15 risk-adjusted mortality rates than low-volume (bottom quartile) PCI hospitals (i.e., weighted means 3.6% versus 7.0% in 2011, 3.5% versus 7.1% in 2012). Similarly, hospitals meeting the American College of Cardiology threshold for sufficient PCI volume (200 cases/year) had lower IQI 15 risk-adjusted mortality than PCI-performing hospitals with lower PCI volume (3.4% versus 4.2% in 2011, 3.3% versus 3.9% in 2012).

With respect to hospital-level Spearman rank correlations between IQI 15 risk-adjusted rates and risk-adjusted inpatient mortality rates for other cardiovascular diseases and procedures:
1. IQI 12 – Among the 913 hospitals that performed coronary artery bypass graft (CABG) surgery, Spearman rank correlations with CABG mortality were 0.222 (2011) and 0.226 (2012).
2. IQI 16 – Among the 2574 hospitals that treated both AMI and heart failure (HF), Spearman rank correlations with HF mortality were 0.172 (2011) and 0.130 (2012).
3. IQI 30 – Among the 1333 hospitals that performed PCI, Spearman rank correlations with PCI mortality were 0.406 (2011) and 0.407 (2012).

With respect to the volume-mortality relationship for acute inpatient AMI care, high-volume (top quartile by volume) AMI hospitals had significantly and substantially lower IQI 15 risk-adjusted rates than low-volume (bottom quartile) AMI hospitals (i.e., weighted means 3.8% versus 20.1% in 2011).

2b2.4. What is your interpretation of the results in terms of demonstrating validity? (i.*e., what do the results mean and what are the norms for the test conducted?*)

Most studies have estimated the accuracy of the current IQI 15 case definition in ICD-9-CM coded administrative data from US hospitals in the range of 92.8-96.9%; one study reported a lower estimate (PPV=86.0%; 95% CI 79.2-91.2%) but this study had relatively low inter-rater reliability for its gold standard of cardiologist review (kappa=0.60; 95% CI: 0.42, 0.78). Variation across hospitals was nonsignificant when tested.

Almost all of the expected construct validity relationships were supported. Specifically, hospitals with higher risk-adjusted inpatient mortality, according to IQI 15, also reported poorer adherence on most process measures (with the notable exception of median time to ECG), compared with hospitals with lower IQI 15 rates. As expected, teaching hospitals, high-volume hospitals for AMI care, and high-volume hospitals for PCI, had much lower risk-adjusted inpatient

mortality, according to IQI 15, than comparator facilities. Hospitals with higher risk-adjusted inpatient mortality, according to IQI 15, also had higher risk-standardized mortality for Medicare FFS patients with AMI, and higher risk-adjusted, all-payer inpatient mortality for CABG, PCI, and HF, compared with hospitals with lower IQI 15 rates. In other words, IQI 15 has the expected relationship with other IQIs at the hospital level.

2b3. EXCLUSIONS ANALYSIS
NA ☐ no exclusions — *skip to section 2b4*

2b3.1. Describe the method of testing exclusions and what it tests (*describe the steps—do not just name a method; what was tested, e.g., whether exclusions affect overall performance scores; what statistical analysis was used*)

Using the 2012 data from 36 states, we examined the percent of potential denominator cases excluded by each criterion. The percent of potential cases excluded by each criterion are reported.

2b3.2. What were the statistical results from testing exclusions? (*include overall number and percentage of individuals excluded, frequency distribution of exclusions across measured entities, and impact on performance measure scores*)

see Table 3

Table 3. Number and Percent of Discharges Excluded, by Denominator Exclusion Criteria, Acute Myocardial Infarction Mortality Rate (IQI 15)[1]

IQI15	Denominator			Potential Numerator[2]		
Exclusion Name	Exclusion Count	After Exclusions	% Change	Exclusion Count	After Exclusions	% Change
No Exclusions Applied	---	492,529	--	--	25,287	--
Missing DISP	66	492,563	0.0%	0	25,287	0.0%
Transfer to another Acute-care Hospital	43,450	449,079	8.8%	0	25,287	0.0%

[1]This indicator does not have numerator exclusion criteria.
[2]Potential numerator cases are those that would have qualified for the numerator if not for a particular denominator exclusion criterion.
Source: HCUP State Inpatient Databases (SID). Healthcare Cost and Utilization Project (HCUP). 2012. Agency for Healthcare Research and Quality, Rockville, MD. www.hcup-us.ahrq.gov/sidoverview.jsp. (AHRQ QI Software Version 5.0)

2b3.3. What is your interpretation of the results in terms of demonstrating that exclusions are needed to prevent unfair distortion of performance results? (*i.e., the value outweighs the burden of increased data collection and analysis. Note: **If patient preference is an exclusion**, the measure must be specified so that the effect on the performance score is transparent, e.g., scores with and without exclusion*)

The exclusion of patients with missing disposition is necessary because the outcome of the hospital stay (i.e., death versus survival) is unknown for these patients. The prevalence of missingness (approximately 0.01%) is

too low to justify multiple imputation, and stakeholders are unlikely to accept imputation of such an important outcome.

The exclusion of patients transferred to other acute care hospitals is necessary because most users of IQI 15 do not have the ability to link sequential hospitalizations on the same patient to ascertain the ultimate outcome of the inpatient episode of care. To avoid double counting the same AMI, it is necessary to exclude either the initial hospitalization or the subsequent (i.e., second) hospitalization for patients who are transferred from one hospital to another. Given that the outcome of the second hospitalization is known, and given that the second hospital is usually the hospital that provided the largest portion of the patient's care, it is most logical to exclude the initial hospitalization and then to adjust statistically for any difference in risk associated with transfers at the second hospital. (Although there is hypothetical concern that academic medical centers and other hospitals that receive AMI transfers might be disadvantaged by this approach, the empirical data summarized in 2b.2.3 above and Table 4 below do not support this concern. In fact, the Emergency Medical Treatment and Active Labor Act [EMTALA] generally requires that any patient with an "emergency medical condition," such as AMI, be stabilized prior to transfer, meaning that that "no material deterioration of the patient's condition is likely to result from the transfer or is likely to occur during the transfer." Consistent with this standard, the post-transfer, risk-adjusted outcomes of transferred AMI patients are not worse than the outcomes of AMI patients who are not transferred.)

2b4. RISK ADJUSTMENT/STRATIFICATION FOR OUTCOME OR RESOURCE USE MEASURES
If not an intermediate or health outcome, or PRO-PM, or resource use measure, skip to section 2b5.

2b4.1. What method of controlling for differences in case mix is used?
☐ **No risk adjustment or stratification**
☒ **Statistical risk model with 23 risk factors**
☐ **Stratification by** Click here to enter number of categories **risk categories**
☐ **Other,** Click here to enter description

2b4.2. If an outcome or resource use measure is not risk adjusted or stratified, provide rationale and analyses to demonstrate that controlling for differences in patient characteristics (case mix) is not needed to achieve fair comparisons across measured entities.
Not applicable

2b4.3. Describe the conceptual/clinical and statistical methods and criteria used to select patient factors (clinical factors or sociodemographic factors) used in the statistical risk model or for stratification by risk (*e.g., potential factors identified in the literature and/or expert panel; regression analysis; statistical significance of p<0.10; correlation of x or higher; patient factors should be present at the start of care*)

Clinical Factors
For the provider level indicators, each module has a standard set of covariates grouped into four categories: demographics, severity of illness, comorbidities and transfer-in status. The standard set is tailored to each indicator to create a parsimonious set of covariates for each indicator. Based on cross tabulations between each covariate and the outcome of interest, only those covariates with at least 30 cases with the outcome of interest are retained. For categories that are mutually exclusive, covariates with fewer than 30 cases are pooled into the next covariate along the risk gradient. For example, age 70 to 74 is combined with age 65 to 69, or risk of mortality subclass 3 is combined with subclass 2. For categories with no risk gradient, covariates are pooled into broader covariates. Covariates that are considered as potential risk adjusters for the Inpatient Quality Indicators include gender and age, Major Diagnostic Categories (MDC), All Payer Refined Diagnosis Related Group (APR-DRG), patient point-of-origin and whether they were transferred from another facility.

The omitted covariate within mutually exclusive categories is the reference group for those categories. Reference categories are usually 1) the most common and/or 2) the least risk.

The choice of omitted reference category does affect how one might use the model coefficients or odds ratios in an English language sentence, but it does not affect predicted probabilities or model performance.

Once the preliminary multivariable model is specified, it is estimated on the adult analytic data, as appropriate. Only those covariates that are statistically significant ($p<0.05$) are retained. For covariates that are not statistically significant in categories that are mutually exclusive, the pooling process described above is repeated until a complete, parsimonious model is specified.

Additional details are available in the AHRQ Quality Indicator Empirical Methods document, included in the supplemental file.

Sociodemographic Factors

The relevant literature on disparities in cardiovascular care was recently summarized by Lewey and Choudhry (Lewey J, Choudhry NK. The current state of ethnic and racial disparities in cardiovascular care: lessons from the past and opportunities for the future. Curr Cardiol Rep 2014;16(10):530). These authors make several key points:

1. "black and Hispanic patients presenting with an acute myocardial infarction (AMI) have significantly longer door-to-balloon times compared to white patients, a delay that contributes significantly to clinical outcomes [33, 34]. Differences in utilization are not fully explained by patient preference [35] or overuse among whites [36]."
2. "Several studies have demonstrated that black and Hispanic patients are less likely to receive evidence-based medications and counseling during an admission or at discharge for CHF or AMI. However, many of the differences are attenuated when confounders, such as socioeconomic status, comorbid conditions, and especially site of care, are taken into consideration [4, 14, 33, 43, 44]. Uptake of newer therapies and recommendations may occur more slowly among minority populations. The CRUSADE registry demonstrated that black patients were significantly less likely than whites to receive newer therapies for acute coronary syndrome, such as clopidogrel and glycoprotein IIb/IIIa inhibitors [29].
3. Despite living closer to higher quality hospitals than whites, black patients presenting with AMI or undergoing cardiac surgery are more frequently admitted to lower-quality hospitals [53] and experience higher mortality rates [54–57].
4. Cohen et al. evaluated more than 140,000 patients with AMI treated at one of the 443 participating (Get with The Guidelines, GTWG) hospitals between 2002 and 2007 [33]. During the first year of the study, black patients received lower quality of care compared to whites. But, by the end of the study, the small difference in quality had been eliminated such that all patients were receiving similar quality of care. Despite these improvements, some disparities do persist. A subsequent analysis of the GWTG-CAD cohort found that although time to revascularization in patients presenting with AMI decreased over time, black and Hispanic men continued to be at greater risk for a door-to-balloon time of greater than 90 min [89]."

These findings are supported by a more recent study by Agarwal et al. (Agarwal S, Garg A, Parashar A, et al. Outcomes and resource utilization in ST-elevation myocardial infarction in the United States: Evidence for socioeconomic disparities. J Am Heart Assoc 2014;3:e001057), not included in Lewey and Choudhry's review, that used the same HCUP data on which IQI 15 was developed and tested (specifically, the 2003-2011 Nationwide Inpatient Sample). These authors divided STEMI patients into quartiles based on the median household income of each patient's residential zip code. There was significantly higher inpatient risk-adjusted mortality among the lowest SES quartile as compared to the highest quartile (OR [95% CI]: 1.11 [1.06-1.17]). Similarly, there was a highly significant trend indicating progressively reduced timely reperfusion (i.e., day 0) among patients from lower quartiles (OR [95% CI]: 0.80 [0.74-0.88] comparing the lowest quartile to the

highest). Paradoxically, there was also lower utilization of circulatory support devices among patients from lower as compared to higher zip code quartiles (OR [95% CI]: 0.85 [0.75-0.97] comparing the lowest quartile to the highest).

Based on the evidence thoroughly summarized by Lewey and Choudhry, and recently extended by Agarwal et al., it appears likely that any relationship between socioeconomic factors (e.g., race, ethnicity, income) and inpatient AMI mortality is at least partially mediated by the quality of care provided. Although we cannot exclude the possibility that part of this relationship is independent of quality of care, or is mediated by pre-hospital care (which may not fall within the proper realm of hospital accountability), we have no mechanism by which to separate this component of the socioeconomic effect. Accordingly, consistent with the guidance provided by NQF in the SDS Trial Period FAQs, AHRQ believes that it would be inappropriate to include other SDS variables in the risk-adjustment approach for IQI 15, which is an in-hospital outcome measure.

2b4.4a. What were the statistical results of the analyses used to select risk factors?

The process to select risk factors is described in the AHRQ QI Empirical Methods report. The results of the analyses are provided in the PSI Parameter Estimates document. Both documents are available to reviewers in the supporting materials. The results of the analyses are provided in the tables below as well as on the submitted excel spreadsheet.

There are several steps involved in estimating the QI risk-adjustment models.
1. Construct candidate covariates
2. Select model covariates
3. Estimate the models
4. Evaluate the models

Covariates are coded for each discharge record based on the data elements, data values, and logic described in the technical specifications and the appendices of the risk-adjustment coefficient tables. For a given covariate, if the discharge meets the technical specification for that covariate a value of "1" is assigned to the discharge level covariate data element. Otherwise a value of "0" is assigned to the discharge level covariate data element.

Table 4. Risk Adjustment Coefficients for IQI 15 Acute Myocardial Infarction (AMI) Mortality

2b4.4b. Describe the analyses and interpretation resulting in the decision to select SDS factors (e.g. prevalence of the factor across measured entities, empirical association with the outcome, contribution of unique variation in the outcome, assessment of between-unit effects and within-unit effects)

Not applicable (see above)

2b4.5. Describe the method of testing/analysis used to develop and validate the adequacy of the statistical model or stratification approach (*describe the steps—do not just name a method; what statistical analysis was used*)

This analysis evaluates how strongly the risk adjustment model is associated with the event of interest (i.e. hospitalization for dehydration). The measure of discrimination, how well the risk adjustment model distinguishes events from non-events, is the c-statistic. The c-statistic is computed by assigning each observation a predicted probability of the outcome from the risk-adjustment model based on the value of the observations covariates from the risk-adjustment model. Two copies of the dataset are sorted, first from highest to lowest predicted probability and second from lowest to highest predicted probability. This creates a set of

pairs of observations. Pairs that consist of one event and one non-event (discordant pairs) are kept and concordant pairs are discarded. The c-statistic is a measure of the proportion of discordant pairs of observations for which the observation with the event had a higher predicted probability from the risk-adjustment model than the non-event. C-statistics above 0.70 and below 0.80 have moderate discrimination. Above 0.80 the discrimination is high. We did not employ common "goodness of fit" tests because these tests tend to not be informative with large samples.

We also evaluated the calibration of the risk adjustment model by evaluating how closely observed and predicted rates compare across deciles of the predicted rate. This analysis splits the sample into deciles based on predicted rates, and then compares these rates with the observed rates for the population in each decile. A well calibrated model, or one that does not over or under-estimate risk, will have comparable observed and predicted rates across the risk spectrum.

Provide the statistical results from testing the approach to controlling for differences in patient characteristics (case mix) below.

If stratified, skip to 2b4.9

2b4.6. Statistical Risk Model Discrimination Statistics (*e.g., c-statistic, R-squared*)**:**

Table 5. Risk adjustment Model Discrimination and Calibration IQI 15 Acute Myocardial Infarction (AMI) Mortality Rate

Source: HCUP State Inpatient Databases (SID). Healthcare Cost and Utilization Project (HCUP). 2012. Agency for Healthcare Research and Quality, Rockville, MD. www.hcup-us.ahrq.gov/sidoverview.jsp. (AHRQ QI Software Version 5.0)

2b4.7. Statistical Risk Model Calibration Statistics (*e.g., Hosmer-Lemeshow statistic*):

See Table 5 in 2b4.6

2b4.8. Statistical Risk Model Calibration – Risk decile plots or calibration curves:

2b4.9. Results of Risk Stratification Analysis:
Not applicable

2b4.10. What is your interpretation of the results in terms of demonstrating adequacy of controlling for differences in patient characteristics (case mix)? (i.*e., what do the results mean and what are the norms for*

the test conducted)

A model that is well calibrated will have observed values similar to predicted values across the predicted value deciles. This indicator is well calibrated and has good discrimination, as the observed to predicted values across the deciles range between 0.85 – 1.04 for all deciles except the lowest decile. For hospitals with very low predicted rates, the relative differences between observed and predicted values is greater, primarily due to the very small observed rates.

2b4.11. Optional Additional Testing for Risk Adjustment (*not required, but would provide additional support of adequacy of risk model, e.g., testing of risk model in another data set; sensitivity analysis for missing data; other methods that were assessed*)

2b5. IDENTIFICATION OF STATISTICALLY SIGNIFICANT & MEANINGFUL DIFFERENCES IN PERFORMANCE

2b5.1. Describe the method for determining if statistically significant and clinically/practically meaningful differences in performance measure scores among the measured entities can be identified (*describe the steps—do not just name a method; what statistical analysis was used? Do not just repeat the information provided related to performance gap in 1b)*

This analysis assesses the probability that a hospital is higher or lower than a benchmark or threshold, given hospital size. It reflects whether the indicator can discriminate the best performing hospitals from the lower performing hospitals.

For this analysis, "benchmark" refers to the smoothed indicator rate based on the 20th percentile of the reference population (i.e., 20% of hospitals have a lower mortality rate or better performance). "Threshold" refers to the indicator rate based on the 80th percentile (i.e., 80% have lower mortality or better performance).

The analysis is reported by size decile, based on the denominator cases, demonstrating performance across hospitals of various sizes. Each hospital is assumed to have an underlying distribution of smoothed rates that follows a Gamma distribution. The parameters of a Gamma distribution are shape and scale. For each hospital the shape is calculated as ((smoothed rate)^2/ smoothed rate variance), and the scale is calculated as (smoothed rate variance / smoothed rate). The smoothed rate variance (aka posterior variance) is calculated as the signal variance – (reliability weight * signal variance). The reliability weight is calculated as (signal variance / (signal variance + noise variance)). Hospitals are ranked by size and grouped into 10 equal categories of size (deciles). The Benchmark and Threshold are compared to the Gamma distribution of the smoothed rates for each hospital to determine if the hospital rate is better or worse than the Benchmark and Threshold rates with 95% probability. This provides a 95% confidence interval for the Benchmark and Threshold rate.

Table 6 reports the proportion of hospitals above (better than) and below (worse than) the Benchmark and Threshold rates and the proportion not classified as either above or below. The proportion of hospitals not classified as either better or worse have rates that fall within the 95% confidence interval.

2b5.2. What were the statistical results from testing the ability to identify statistically significant and/or clinically/practically meaningful differences in performance measure scores across measured entities? (e.g., *number and percentage of entities with scores that were statistically significantly different from mean or some benchmark, different from expected; how was meaningful difference defined*)

Table 6. Performance Categories by Hospital Size Decile IQI 15 Acute Myocardial Infarction (AMI) Mortality Rate

	Benchmark	Threshold

Size Decile	Number of Hospitals	Average Number of Denominator Discharges Per Hospital	Proportion Better	Proportion Worse	Proportion Unclassified	Proportion Better	Proportion Worse	Proportion Unclassified
1	266	4.2	0.0000	0.5075	0.4925	0.1015	0.1278	0.4060
2	266	8.2	0.0075	0.6090	0.3835	0.3496	0.2669	0.2669

10	266	672.2	0.0376	0.9511	0.0113	0.9436	0.0489	0.0451
Overall	2,664	165.6	0.0837	0.7571	0.1592	0.6276	0.1806	0.2132

Source: HCUP State Inpatient Databases (SID). Healthcare Cost and Utilization Project (HCUP). 2012. Agency for Healthcare Research and Quality, Rockville, MD. www.hcup-us.ahrq.gov/sidoverview.jsp. (AHRQ QI Software Version 5.0)

2b5.3. What is your interpretation of the results in terms of demonstrating the ability to identify statistically significant and/or clinically/practically meaningful differences in performance across measured entities? (i.e., *what do the results mean in terms of statistical and meaningful differences?*)

This indicator has strong discrimination for most hospitals to identify low performing hospitals; 79% of hospitals can be classified as better or worse than the threshold (the percentage classified as either above or below the threshold). The indicator has strong discrimination, particularly for moderate to large hospitals to identify high performing hospitals; 84% of hospitals can be classified as better or worse than the benchmark.

2b6. COMPARABILITY OF PERFORMANCE SCORES WHEN MORE THAN ONE SET OF SPECIFICATIONS

If only one set of specifications, this section can be skipped.

Note: *This item is directed to measures that are risk-adjusted (with or without SDS factors)* ***OR*** *to measures with more than one set of specifications/instructions (e.g., one set of specifications for how to identify and compute the measure from medical record abstraction and a different set of specifications for claims or eMeasures). It does not apply to measures that use more than one source of data in one set of specifications/instructions (e.g., claims data to identify the denominator and medical record abstraction for the numerator).* ***Comparability is not required when comparing performance scores with and without SDS factors in the risk adjustment model. However, if comparability is not demonstrated for measures with more than one set of specifications/instructions, the different specifications (e.g., for medical records vs. claims) should be submitted as separate measures.***

Not applicable

2b6.1. Describe the method of testing conducted to compare performance scores for the same entities across the different data sources/specifications (*describe the steps—do not just name a method; what statistical analysis was used*)
Not applicable

2b6.2. What were the statistical results from testing comparability of performance scores for the same entities when using different data sources/specifications? (*e.g., correlation, rank order*)
Not applicable

2b6.3. What is your interpretation of the results in terms of the differences in performance measure scores for the same entities across the different data sources/specifications? (i.*e., what do the results mean and what are the norms for the test conducted*)
Not applicable

2b7. MISSING DATA ANALYSIS AND MINIMIZING BIAS

2b7.1. Describe the method of testing conducted to identify the extent and distribution of missing data (or nonresponse) and demonstrate that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias (*describe the steps—do not just name a method; what statistical analysis was used*)

The AHRQ QIs use frequently reported administrative data variables. IQI 15 excludes cases with missing discharge disposition, age, sex, discharge quarter, discharge year, and principal diagnosis. These variables are required for indicator construction and are required of all hospital discharge records. The rate of missing data for each variable is available by state and year from the AHRQ HCUP website (http://www.hcup-us.ahrq.gov/cdstats/cdstats_search.jsp).

2b7.2. What is the overall frequency of missing data, the distribution of missing data across providers, and the results from testing related to missing data? (*e.g., results of sensitivity analysis of the effect of various rules for missing data/nonresponse; if no empirical sensitivity analysis, identify the approaches for handling missing data that were considered and pros and cons of each*)

For these variables, rates of missing data are typically less than 1% of the state database. It is unlikely the bias would occur from such a low rate of missing data.

2b7.3. What is your interpretation of the results in terms of demonstrating that performance results are not biased due to systematic missing data (or differences between responders and nonresponders) and how the specified handling of missing data minimizes bias**?** (i.*e., what do the results mean in terms of supporting the selected approach for missing data and what are the norms for the test conducted; if no empirical analysis, provide rationale for the selected approach for missing data*)

Exclusion of cases for missing data is appropriate.

3. Feasibility

Extent to which the specifications including measure logic, require data that are readily available or could be captured without undue

burden and can be implemented for performance measurement.

3a. Byproduct of Care Processes

For clinical measures, the required data elements are routinely generated and used during care delivery (e.g., blood pressure, lab test, diagnosis, medication order).

3a.1. **Data Elements Generated as Byproduct of Care Processes.**

Coded by someone other than person obtaining original information (e.g., DRG, ICD-9 codes on claims)

If other:

3b. Electronic Sources

The required data elements are available in electronic health records or other electronic sources. If the required data are not in electronic health records or existing electronic sources, a credible, near-term path to electronic collection is specified.

3b.1. **To what extent are the specified data elements available electronically in defined fields?** *(i.e., data elements that are needed to compute the performance measure score are in defined, computer-readable fields)*

ALL data elements are in defined fields in electronic claims

3b.2. **If ALL the data elements needed to compute the performance measure score are not from electronic sources, specify a credible, near-term path to electronic capture, OR provide a rationale for using other than electronic sources.**

3b.3. **If this is an eMeasure, provide a summary of the feasibility assessment in an attached file or make available at a measure-specific URL.**

Attachment:

3c. Data Collection Strategy

Demonstration that the data collection strategy (e.g., source, timing, frequency, sampling, patient confidentiality, costs associated with fees/licensing of proprietary measures) can be implemented (e.g., already in operational use, or testing demonstrates that it is ready to put into operational use). For eMeasures, a feasibility assessment addresses the data elements and measure logic and demonstrates the eMeasure can be implemented or feasibility concerns can be adequately addressed.

3c.1. **Describe what you have learned/modified as a result of testing and/or operational use of the measure regarding data collection, availability of data, missing data, timing and frequency of data collection, sampling, patient confidentiality, time and cost of data collection, other feasibility/implementation issues.**

IF a PRO-PM, consider implications for both individuals providing PROM data (patients, service recipients, respondents) and those whose performance is being measured.

Because the indicator is based on readily available administrative billing and claims data and U.S. Census data, feasibility is not an issue. This version of the indicator requires POA data for risk-adjustment (although not for specification of the numerator and denominator). Present-on-Admission indicators were added as data elements to the uniform bill form (UB-04) effective October 1, 2007. Hospitals incurred a payment penalty for not including POA status on Medicare records beginning October 1, 2008. Each of the secondary diagnoses in a discharge record can be flagged as "present at the time the order for inpatient admission occurs" or not (see http://www.cdc.gov/nchs/icd/icd9cm_addenda_guidelines.htm). The number of states reporting consistent POA has increased dramatically since 2008.

The AHRQ QI software has been publicly available at no cost since 2001; Users have over ten years of experience using the AHRQ QI software in SAS and Windows.

3c.2. **Describe any fees, licensing, or other requirements to use any aspect of the measure as specified** *(e.g., value/code set, risk model, programming code, algorithm)*.

There are no fees. The IQI15 software is freely available from the AHRQ Quality Indicators website (http://www.qualityindicators.ahrq.gov/).

4. Usability and Use

Extent to which potential audiences (e.g., consumers, purchasers, providers, policy makers) are using or could use performance results for both accountability and performance improvement to achieve the goal of high-quality, efficient healthcare for individuals or populations.

4a. Accountability and Transparency

Performance results are used in at least one accountability application within three years after initial endorsement and are publicly reported within six years after initial endorsement (or the data on performance results are available). If not in use at the time of initial endorsement, then a credible plan for implementation within the specified timeframes is provided.

4.1. Current and Planned Use

NQF-endorsed measures are expected to be used in at least one accountability application within 3 years and publicly reported within 6 years of initial endorsement in addition to performance improvement.

4a.2. If not currently publicly reported OR used in at least one other accountability application (e.g., payment program, certification, licensing) what are the reasons? (*e.g., Do policies or actions of the developer/steward or accountable entities restrict access to performance results or impede implementation?*)
Not applicable

4a.3. **If not currently publicly reported OR used in at least one other accountability application, provide a credible plan for implementation within the expected timeframes -- any accountability application within 3 years and publicly reported within 6 years of initial endorsement.** (*Credible plan includes the specific program, purpose, intended audience, and timeline for implementing the measure within the specified timeframes. A plan for accountability applications addresses mechanisms for data aggregation and reporting.*)
Not applicable

4b. Improvement

Progress toward achieving the goal of high-quality, efficient healthcare for individuals or populations is demonstrated. If not in use for performance improvement at the time of initial endorsement, then a credible rationale describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.

4b.1. **Progress on Improvement. (Not required for initial endorsement unless available.)**
Performance results on this measure (current and over time) should be provided in 1b.2 and 1b.4. Discuss:

- **Progress (trends in performance results, number and percentage of people receiving high-quality healthcare)**
- **Geographic area and number and percentage of accountable entities and patients included**

See Table 1 in response to question 1b.2.

The observed rate has decreased over time, from 68.9 cases per 1000 in 2008 to 56.4 cases per 1000 in 2012. The mean hospital-level rate in 2012 was 104.3 with a coefficient of variation of 1.44, and 111.90 in 2011 with a coefficient of variation of 1.38. The coefficient of variation suggests that further improvement may be possible if lower performing hospitals met the performance of higher performing hospitals.

These rates encompass 82 percent of all U.S. community hospital discharges from 36 of the 45 states that participated in the 2012 SID, for a total of about 30 million hospital discharges from community hospitals, which include all non-Federal, short-term, general or other specialty hospitals, excluding hospital units of institutions. Included among community hospitals are public and academic medical centers, specialty hospitals such as obstetrics–gynecology, ear–nose–throat, orthopedic and pediatric institutions. Short-stay rehabilitation and long-term acute care hospitals are excluded from the data used for the reported analyses. The remaining discharges not captured in these data are psychiatric facilities, alcohol and drug dependency facilities and military hospitals. The number and percentage of discharges captured in past years are similar. For IQI 15, 24,890 patients died among 441,557 AMI patients at 2,978 hospitals in 2012.

4b.2. **If no improvement was demonstrated, what are the reasons? If not in use for performance improvement at the time of initial endorsement, provide a credible rationale that describes how the performance results could be used to further the goal of high-quality, efficient healthcare for individuals or populations.**
Not applicable

4c. Unintended Consequences

The benefits of the performance measure in facilitating progress toward achieving high-quality, efficient healthcare for individuals or populations outweigh evidence of unintended negative consequences to individuals or populations (if such evidence exists).

4c.1. **Were any unintended negative consequences to individuals or populations identified during testing; OR has evidence of unintended negative consequences to individuals or populations been reported since implementation? If so, identify the negative unintended consequences and describe how benefits outweigh them or actions taken to mitigate them.**
None identified or reported. In theory, the use of this metric could encourage premature transfer of dying patients to lower levels of care, such as skilled nursing or intermediate care facilities, but the widespread use of 30-day risk-standardized mortality measures for Medicare beneficiaries(which are immune to this unintended consequence) makes such behavior unlikely.

5. Comparison to Related or Competing Measures

If a measure meets the above criteria and there are endorsed or new related measures (either the same measure focus or the same target population) or competing measures (both the same measure focus and the same target population), the measures are compared to address harmonization and/or selection of the best measure.

5. Relation to Other NQF-endorsed Measures
Are there related measures (conceptually, either same measure focus or target population) or competing measures (conceptually both the same measure focus and same target population)? If yes, list the NQF # and title of all related and/or competing measures.
Yes

5.1a. **List of related or competing measures (selected from NQF-endorsed measures)**
0230 : Hospital 30-day, all-cause, risk-standardized mortality rate (RSMR) following acute myocardial infarction (AMI) hospitalization for patients 18 and older
2473 : Hospital 30-Day Risk-Standardized Acute Myocardial Infarction (AMI) Mortality eMeasure

5.1b. **If related or competing measures are not NQF endorsed please indicate measure title and steward.**

5a. Harmonization
The measure specifications are harmonized with related measures;
OR
The differences in specifications are justified

5a.1. **If this measure conceptually addresses EITHER the same measure focus OR the same target population as NQF-endorsed measure(s):**
Are the measure specifications completely harmonized?
No

5a.2. **If the measure specifications are not completely harmonized, identify the differences, rationale, and impact on interpretability and data collection burden.**
The indicators referenced above include 30-day mortality 1) for patients age 18 years and older 2) specified as an e-measure and 3) for patients age 65 and older. Inpatient mortality and 30-day mortality are different concepts, although capturing the same ultimate outcome. Harmonization is not appropriate.

5b. Competing Measures
The measure is superior to competing measures (e.g., is a more valid or efficient way to measure);
OR
Multiple measures are justified.

5b.1. **If this measure conceptually addresses both the same measure focus and the same target population as NQF-endorsed measure(s):**
Describe why this measure is superior to competing measures (e.g., a more valid or efficient way to measure quality); OR provide a rationale for the additive value of endorsing an additional measure. (Provide analyses when possible.)
IQI 15 and the Centers for Medicare & Medicaid Services' NQF-endorsed measures concerning AMI mortality (0230 and 2473) use the same ICD-9-CM codes to identify AMI, but they differ in two important respects: (1) whereas the CMS measures concern only Medicare fee-for-service and VA beneficiaries 65 years or older, IQI 15 measures mortality among hospitalizations of patients 18 years or older at non-federal acute care hospitals for all payers; and (2) while the CMS measures evaluate 30-day mortality, IQI 15—because it is based only on UB-04 data elements—is limited to inpatient mortality. The latter difference is a potential disadvantage in that the time at risk is not uniform for all patients and 30-day mortality is typically greater than inpatient mortality, but the former difference is an advantage because IQI 15 encompasses a greater proportion of the entire population at risk. We therefore believe that #0730 complements #0230 by offering an alternative specification for users who are interested in patients of all ages and all payers, just as #2473 offers an alternative e-measure specification for those with electronic health data.

Appendix

A.1 Supplemental materials may be provided in an appendix. All supplemental materials (such as data collection instrument or methodology reports) should be organized in one file with a table of contents or bookmarks. If material pertains to a specific submission form number, that should be indicated. Requested information should be provided in the submission form and required attachments. There is no guarantee that supplemental materials will be reviewed.

Brief Measure Information

NQF #: 0965
Measure Title: Discharge Medications (ACE/ARB and beta blockers) in Eligible ICD Implant Patients
Measure Steward: American College of Cardiology
Brief Description of Measure: Proportion of patients undergoing ICD implant who received prescriptions for all medications (ACE/ARB and beta blockers) for which they are eligible for at discharge.
Developer Rationale: This measure is intended to assess the extent to which eligible patients receive evidence-based medications that are indicated at hospital discharge following ICD implantation.
Composite performance measures have a variety of uses.
Data reduction. A large and growing array of individual indicators makes it possible for users to become overloaded with data. A composite measure reduces the information burden by distilling the available indicators into a simple summary.
Scope expansion. The information in a composite measure is highly condensed, making it feasible to track a broader range of metrics than would be possible otherwise. Composite measures have been described as a tool for making provider assessments more comprehensive
Provider performance valuation. Performance indicators are used for various decisions about providers, including the allocation of pay-for-performance incentives, designation of preferred provider status, and assignment of letter grades and star rating categories. If a decision is to be based on multiple indicators instead of a single indicator, a method of translating several variables into a single decision is needed. Composite measures serve this function by assigning providers to 1 position on a scale of better-to-worse performance.
Given all these uses, NCDR believes that while we will continue to report these measures at the individual level there is a distinctive value of having a composite measure endorsed at NQF.

Numerator Statement: Patients who receive ACE/ARB and Beta blockers for which they are eligible.
1. ACE/ARB prescribed at discharge (if eligible for ACE/ARB as described in denominator)
AND
2. Beta blockers prescribed at discharge (if eligible for beta blockers as described in denominator)

Denominator Statement: All patients with an ICD implant surviving hospitalization who are eligible to receive any one of the two medication classes:
1) Eligiblility for ACE/ARB: Patients who have an ejection fraction (EF) of <40% AND do not have a documented contraindication to ACE/ARB documented
OR
2) Eligibility for beta blockers: Patients who do not have a documented contraindication to beta blocker therapy and have either:
a. EF of <40% OR
b. a previous myocardial infarction (MI)

Denominator Exclusions: Discharge status of expired; not eligible for either ACE/ARB or beta blockers

Measure Type: Composite

Data Source: Electronic Clinical Data : Registry

Level of Analysis: Facility

Is this an eMeasure? ☐ **Yes** ☒ **No** **If Yes, was it re-specified from a previously endorsed measure?** ☐ **Yes** ☐ **No**

IF this measure is included in a composite, NQF Composite#/title: n/a – 0965 is the composite measure.

Composite Measure Construction: all-or-none measures (e.g., all essential care processes received, or outcomes experienced, by each patient)

Component Measures (if endorsed or submitted for endorsement): n/a

The *non-endorsed* component measures for this composite measure include:

1. ACE/ARB prescribed at discharge (if eligible for ACE/ARB as described in denominator)
2. Beta blockers prescribed at discharge (if eligible for beta blockers as described in denominator)

Is this a MAINTENANCE measure submission? ☒ **Yes** ☐ **No, this is a NEW measure submission.**

For MAINTENANCE, state the Original Endorsement Date: 1/17/12 **Most Recent Endorsement Date:** 1/17/12

Previous Measure Evaluation - Public & Member Comments, Developer Responses & Steering Committee Recommendations from (Cardiology Project 2010):

Public and Member Comments:

- This measure is too specific to be generalized to the population.

Steering Committee:

- ICD patients are an important population that has a special clinical registry to track the performance. This all-or-none composite measure was specifically developed at the request of the Steering Committee to increase the number of composite measures.

Preliminary Analysis

The preliminary analysis was developed in response to recommendations from NQF's Consensus Task Force and measurement stakeholders as a way to enhance and streamline the measures evaluation and voting processes. The preliminary analysis will help to guide the Standing Committee evaluation of each measure by summarizing the measure developer submission, guide measure evaluation discussion, and identify topic areas for additional input. **NQF staff would like to stress that the preliminary analysis is intended to be used as a guide to facilitate the Committee's discussion and evaluation.**

Criteria 1: Importance to Measure and Report

1a. Evidence

1a. Evidence. The evidence requirements for a *process* measure is that it is based on a systematic review (SR) and grading of the body of empirical evidence where the specific focus of the evidence matches what is being measured.

- This composite measure has two process measure components. Evidence for each component measure should include a systematic review of the body of evidence that describes the quantity, quality and consistency (QQC) of the evidence that relates the process of care to desired health outcomes. Evidence for this measure should link receipt of each medication to patient outcomes. (algorithm Box 3)
- This composite measure has 2 component measures that assess if all patients with an ICD implant surviving hospitalization who are eligible to receive any one of the two medication classes, beta-blockade and ACE/ARBs. Because the beta-blocker component may be applied to two separate patient populations (patients with previous MI and patients with LVSD), the developer has provided evidence supporting the use of beta blockers in each of these populations separately. The developer provides diagrams demonstrating how receiving beta-blockers for a previous MI, LVSD and ACEI/ARBs for LVSD are linked to patient outcomes.

Beta-blocker for previous MI

- The developer provides 4 guidelines with 6 guideline statements that recommend beta-blocker therapy for patients with HF or prior MI and the Quantity/Quality/Consistency for the 2012 ACCF/AHA/ACP/AATS/PCNA/SCAI/STS guideline (Level of Evidence A or B).
- One prospective cohort study and one meta-analysis were published after the publication of the 2012 ACCF/AHA/ACP/AATS/PCNA/SCAI/STS guideline. The analysis concluded that the use of beta-blockers in patients with stable CAD was associated with a lower risk of cardiovascular mortality.

Beta-blocker for LVSD

- The developer provides 2 guidelines with 4 guideline statements that recommend beta-blocker therapy for patients with LVSD, with or without prior MI and the Quantity/Quality/Consistency for the 2013 ACCF/AHA Guideline for the Management of Heart Failure (Level of Evidence A, B, or C).
- One RCT, one prospective cohort study, and two meta-analyses were published after the publication of the 2013 ACCF/AHA Guideline for the Management of Heart Failure. The analysis concluded that the use of beta-blockers in patients with stable CAD was associated with a lower risk of cardiovascular mortality.

ACE/ARBs for LVSD

- The developer provides 2 guidelines with 6 guideline statements that recommend that recommend ACE/ARBs for patients with LVSD, with or without prior MI and the Quantity/Quality/Consistency for the 2013 ACCF/AHA Guideline for the Management of Heart Failure (Level of Evidence A or B).
- One meta-analysis was published after the publication of the 2013 ACCF/AHA Guideline for the Management of Heart Failure.

Questions for the Committee:

- *For process measures:*
  - *Is the evidence directly applicable to the process of care being measured?*
  - *Is the process of care proximal and closely related to desired outcomes?*
- *For possible exception to the evidence criteria:*
  - *Are there, or could there be, performance measures of a related health outcome, OR evidence-based intermediate clinical outcomes, intervention/treatment?*
  - *Is there evidence of a systematic assessment of expert opinion beyond those involved in developing the measure?*
  - *Does the SC agree that it is acceptable (or beneficial) to hold providers accountable without empiric evidence?*

1b. Gap in Care/Opportunity for Improvement and 1b. Disparities

1b. Performance Gap. The performance gap requirements include demonstrating quality problems and opportunity for improvement.

- In 2011-2012 a total of 243,186 patients at 1552 hospitals were analyzed and 195,563 patients at 1606 hospitals in 2013-14. Data from 2011-12 indicated a mean of 74% and 50th percentile results at 76%. Data from 2013-14 indicated a mean of 78% and 50th percentile results at 79%.
- The developers currently collect data on race and insurance type but do not provide statistical analysis and results of these data elements. Instead, the developer provides the # and % of the following hospital characteristics by age, sex, race and insurance type.
- The developers do not provide a summary from the literature that addresses disparities in care on the specific focus of this measure.
- The developers provide the following rationale for the composite:
  - This measure is intended to assess the extent to which eligible patients receive evidence-based medications that are indicated at hospital discharge following ICD implantation.
  - Each of the components of this measure address appropriate medication prescribing at discharge for ICD patients. Combining the individual process measures into a single composite provides patients, physicians, and hospitals with a perspective of the overall quality of medical therapy provided to patients undergoing ICD implantation.

- The composite measure is an "all-or-none measure" meaning all essential care processes are received by each patient.

Questions for the Committee:

- *Is there a gap in care that warrants a national performance measure?*
- *If no disparities information is provided, are you aware of evidence that disparities exist in this area of healthcare?*
- *Should this measure be indicated as disparities sensitive?*

1c. Priority

1c. High Priority (previously "High Impact") requires measures to address national health goal/priority or a demonstrated high-impact aspect of care.

- *Beginning in 2015, priority is no longer an NQF measure evaluation criterion.*

Committee pre-evaluation comments

Criteria 1: Importance to Measure and Report (including 1a, 1b, 1c)

1. ***Committee's Overview Comments***:
   - I think that there is not significant evidence to support this measure. There is very good evidence that patients with AMI and depressed LV function or CAD and depressed LV fxn benefit from beta blockers, but there is not significant evidence in a purely ICD population of patients.

1a. ***Committee's Comments on Evidence to Support Measure Focus:***

- I think that there is not significant evidence to support this measure. There is very good evidence that patients with AMI and depressed LV function or CAD and depressed LV fxn benefit from beta blockers, but there is not significant evidence in a purely ICD population of patients.

1b. ***Committee's Comments on Performance Gap:***

- There is a performance gap

1c. ***Committee's Comments on Composite Performance Measure:***

- I could go either way on this one. It is not clear to me there is a significant advantage of a composite measure.

Criteria 2: Scientific Acceptability of Measure Properties

2a. Reliability

2a1. Reliability Specifications

2a1. Specifications requires the measure, as specified, to produce consistent (reliable) and credible (valid) results about the quality of care when implemented.

- The measure's data source is the National Cardiovascular Data Registry (NCDR) ICD Registry with the data dictionary and collection tool provided. The data elements and the calculation algorithm are described. The developer does not provide ICD-9, ICD-10 codes and the specific beta-blockers and ACE/ARBs are not specified - this was brought up in CV2 with 0964. The developer explained that the measure aligns with the guidelines which are at a drug class-level. There is no specific recommendation in the guidelines for one BB/ACE/ARB over another.
- Denominator exclusions include "discharge status of expired patients" and "not eligible for either ACE/ARB or beta-blockers". "Not eligible" includes patients in a clinical trial and with a contraindication; types of acceptable contraindications are not provided.

Questions for the Committee:

- *Are all the data elements clearly defined? Are all appropriate codes included?*

○ *Is the logic or calculation algorithm clear?*

○ *Is it likely this measure can be consistently implemented?*

2a2. Reliability Testing Testing attachment

2a2. Reliability testing demonstrates if the measure data elements are repeatable, producing the same results a high proportion of the time when assessed in the same population in the same time period and/or that the measure score is precise enough to distinguish differences in performance across providers.

- Empirical testing was carried out using the National Cardiovascular Data Registry for ICD Registry from 1,606 hospitals. The patient characteristics are described.
- Reliability testing of the measure score was performed using a correlation of random split halves. The correlation coefficient of 0.87 is high.
- The developers provide a description of the registry's Data Quality Program that includes onsite audits and Inter-Rater Reliability Assessment conducted to validate the audit. The kappa scores were calculated with a 95% CI; a kappa > .70 is considered acceptable inter-rater reliability. The developers state that "The kappa score for all medication elements demonstrate substantial or almost perfect reliability."

Questions for the Committee:

○ *Is the test sample adequate to generalize for widespread implementation?*

○ *Do the results demonstrate sufficient reliability so that differences in performance can be identified?*

2b. Validity

2b1. Validity: Specifications

2b1. Validity Specifications. This section should determine if the measure specifications are consistent with the evidence.

- The specifications include the specific medications described in the evidence for PCI patients.

Question for the Committee:

○ *Are the specifications consistent with the evidence?*

2b2. Validity testing

2b2. Validity Testing should demonstrate the measure data elements are correct and/or the measure score correctly reflects the quality of care provided, adequately identifying differences in quality.

- Empiric testing was conducted at the level of the data element and measure score using 93,971 Medicare FFS patients who were at least 65 years of age and underwent ICD implantation in 2010 or 2011.
- The analyses included the association of patient and hospital performance on the composite measure with adverse outcomes, specifically mortality and readmission at 6 months following hospital discharge and the association between hospital-level performance on the measure and the combination of mortality or readmission at 6 months. The developer provides patient-level and hospital level results:
    - A significantly smaller proportion of patients discharged on the appropriate medical therapy died or were readmitted within 6 months of hospital discharge (without meds = 28.37% vs. with meds = 36.28%).
    - Patients treated at hospitals that performed better on the measure had better unadjusted outcomes that those treated at hospitals that performed worse on the measure (correlation coefficient (-0.0998), $p<0.001$).
- Face validity was described as "Content validity of this process was achieved by the specialized expertise" of various ACC committee members involved in the development or approval of the measure.

Questions for the Committee:

- *Is the test sample adequate to generalize for widespread implementation?*
- *Do the results demonstrate sufficient validity so that conclusions about quality can be made?*
- *Do you agree that the score from this measure as specified is an indicator of quality?*

2b3-2b7. Threats to Validity

2b3. Exclusions:

- The only exclusions for this measure are noted under S.10. (Discharge status of expired; not eligible for either ACE/ARB or beta blockers). These exclusions are relatively rare and firmly supported by the clinical rationale.
- The developer provides data on the frequency of exclusions.

Questions for the Committee:

- *Are the exclusions consistent with the evidence?*
- *Are any patients or patient groups inappropriately excluded from the measure?*
- *Are the exclusions/exceptions of sufficient frequency and variation across providers to be needed (and outweigh the data collection burden)?*

2b4. Risk adjustment:

- The measure is not risk-adjusted.
- The developer states that they do not currently collect many of the socio-demographic status (SDS) variables listed as examples in the submission form, but note that they do collect data on race as well as insurance type.
- However, the developer did not consider either clinical or SDS adjustment for this measure.

Questions for the Committee:

- *Do you agree with the developer that risk-adjustment for clinical or SDS factors is not necessary for this measure?*

2b5. Meaningful difference:

- Detailed performance results are presented for many subpoulations. Results vary among different groups.

Question for the Committee:

- *Does this measure identify meaningful differences about quality?*

2b6. Comparability of data sources/methods:

- N/A

2b7. Missing Data

- The developer reports that missing data defaults to performance not met. This measure assumes that missing documentation on the process results in a failure of meeting evidence based therapy.

2d.Composite measure: construction

- The developer reports that the empirical analysis demonstrating the individual component measures fit the overall quality construct is currently being researched. This research is expected to be published in the medical literature.

Questions for the Committee:

- *Are the quality construct and rationale for the composite explicitly stated and logical?*
- *Is the method for aggregation and weighting of the components explicitly stated and logical?*

Committee pre-evaluation comments

Criteria 2: Scientific Acceptability of Measure Properties (including all 2a, 2b, and 2d)

2a1. &2b1.: ***Committee's Comments on Reliability-Specifications:***

- This would be enhanced if they used ICD-9 or ICD10 codes but they have been capturing everything in NCDR so I think it meets the bar.

2a2.: ***Committee's Comments on Reliability-Testing:***

- The developers state that there is substantial or almost perfect reliability

2b1.: ***Committee's Comments on Validity-Specifications***:

- This is based upon face validity and i agree it meets that criteria

2b2.: ***Committee's Comments on Validity-Testing:***

- I have no concerns regarding validity.

2b3-7.: ***Committee's Comments on Threats to Validity:***

- My biggest concern here is the failure to adjust for SDS. Patients may or may not be able to afford these classes of drugs and without adjustment for factors related to SDS at an institution, there would be a reporting bias.

2d.: ***Committee's Comments on Composite Performance Measure:***

- They say "currently being researched"

Criterion 3. Feasibility

3. Feasibility is the extent to which the specifications including measure logic, require data that are readily available or could be captured without undue burden and can be implemented for performance measurement.

- The developer reports that the data are available via several methods: electronic transfer to the registry from the procedure/care setting; web-based tool for manual data entry or from an EHR.
- The developer states that centers already have to participate in this specific registry for reimbursement purposes therefore there is no additional cost and there is no charge for a standard export package.

Questions for the Committee:

- *Are the required data elements routinely generated and used during care delivery?*
- *Are the required data elements available in electronic form, e.g., EHR or other electronic sources?*
- *Is the data collection strategy ready to be put into operational use?*

Committee pre-evaluation comments

Criteria 3: Feasibility

3.: ***Committee's Comments on Feasibility:***

- Seems fine and easy enough

Criterion 4: Usability and Use

4. Usability and Use evaluate the extent to which audiences (e.g., consumers, purchasers, providers, policymakers) use or could use performance results for both accountability and performance improvement activities.

- The measure is not currently reported publically. The individual component measures are used in ACC's NCDR Registry.
- Planned use: public reporting, QI with external benchmarking to multiple organizations and internal to the

specific organization.

- Improvement: The developers note that comparing 2011-2012 data with 2013-2014 data – "While the top 10% of performers saw slight performance improvement, the hospitals in the lower percentiles (below the median) improved significantly."
- Unintended consequences: The developer states that inaccuracies may occur due to incorrectly exported data and during the transmission of data from medical record to paper form and/or online data collection tool and some sites may over-code medication exclusions.

***Questions for the Committee**:*

- *Is the measure publicly reported?*
- *How can the performance results be used to further the goal of high-quality, efficient healthcare?*
- *Do the benefits of the measure outweigh any potential unintended consequences?*

Committee pre-evaluation comments

Criteria 4: Usability and Use

4.: ***Committee's Comments on Usability and Use:***

- No issues

Criterion 5: Related and Competing Measures

- 0066 : Coronary Artery Disease (CAD): Angiotensin-Converting Enzyme (ACE) Inhibitor or Angiotensin Receptor Blocker (ARB) Therapy - Diabetes or Left Ventricular Systolic Dysfunction (LVEF < 40%)
- 0070 : Coronary Artery Disease (CAD): Beta-Blocker Therapy-Prior Myocardial Infarction (MI) or Left Ventricular Systolic Dysfunction (LVEF < 40%)
- 0071 : Persistence of Beta-Blocker Treatment After a Heart Attack
- 0081 : Heart Failure (HF): Angiotensin-Converting Enzyme (ACE) Inhibitor or Angiotensin Receptor Blocker (ARB) Therapy for Left Ventricular Systolic Dysfunction (LVSD)
- 0083 : Heart Failure (HF): Beta-Blocker Therapy for Left Ventricular Systolic Dysfunction (LVSD)
- 0117 : Beta Blockade at Discharge
- 0236 : Coronary Artery Bypass Graft (CABG): Preoperative Beta-Blocker in Patients with Isolated CABG Surgery
- 0594 : Post MI: ACE inhibitor or ARB therapy
- 0696 : The STS CABG Composite Score (Composite Measure)
- The developer did not harmonize measure specifications and report that the listed measures are not in direct competition with 0965.

Pre-meeting public and member comments

-

NATIONAL QUALITY FORUM—Evidence (subcriterion 1a)

Measure Number (*if previously endorsed*)**:** 1528

Measure Title: Beta Blocker at Discharge for ICD Implant Patients with a Previous MI

IF the measure is a component in a composite performance measure, provide the title of the Composite Measure here: 965 Patients with an ICD implant who receive ACE-I/ARB and beta blocker therapy at discharge

Date of Submission: Click here to enter a date

Instructions

- *For composite performance measures:*
  - *A separate evidence form is required for each component measure unless several components were studied together.*
  - *If a component measure is submitted as an individual performance measure, attach the evidence form to the individual measure submission.*
- Respond to all questions as instructed with answers immediately following the question. All information needed to demonstrate meeting the evidence subcriterion (1a) must be in this form. An appendix of *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 10 pages (*incudes questions/instructions*; minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the evidence for this measure meets NQF's evaluation criteria.

1a. Evidence to Support the Measure Focus

The measure focus is evidence-based, demonstrated as follows:

- Health outcome: [3] a rationale supports the relationship of the health outcome to processes or structures of care. Applies to patient-reported outcomes (PRO), including health-related quality of life/functional status, symptom/symptom burden, experience with care, health-related behavior.
- Intermediate clinical outcome: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured intermediate clinical outcome leads to a desired health outcome.
- Process: [5] a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured process leads to a desired health outcome.
- Structure: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured structure leads to a desired health outcome.
- Efficiency: [6] evidence not required for the resource use component.

Notes

3. Generally, rare event outcomes do not provide adequate information for improvement or discrimination; however, serious reportable events that are compared to zero are appropriate outcomes for public reporting and quality improvement.

4. The preferred systems for grading the evidence are the U.S. Preventive Services Task Force (USPSTF) grading definitions and methods, or Grading of Recommendations, Assessment, Development and Evaluation (GRADE) guidelines.

5. Clinical care processes typically include multiple steps: assess → identify problem/potential problem → choose/plan intervention (with patient input) → provide intervention → evaluate impact on health status. If the measure focus is one step in such a multistep process, the step with the strongest evidence for the link to the desired outcome should be selected as the focus of measurement. Note: A measure focused only on collecting PROM data is not a PRO-PM.

6. Measures of efficiency combine the concepts of resource use and quality (see NQF's Measurement Framework: Evaluating Efficiency Across Episodes of Care; AQA Principles of Efficiency Measures).

1a.1.This is a measure of: (*should be consistent with type of measure entered in De.1*)

Outcome

☐ Health outcome: Click here to name the health outcome

☐ Patient-reported outcome (PRO): Click here to name the PRO

PROs include HRQoL/functional status, symptom/symptom burden, experience with care, health-related behaviors

☐ Intermediate clinical outcome (*e.g., lab value*): Click here to name the intermediate outcome

☒ Process: Beta-blocker therapy for patients with a prior MI receiving an ICD

☐ Structure: Click here to name the structure

☐ Other: Click here to name what is being measured

HEALTH OUTCOME/PRO PERFORMANCE MEASURE *If not a health outcome or PRO, skip to 1a.3*

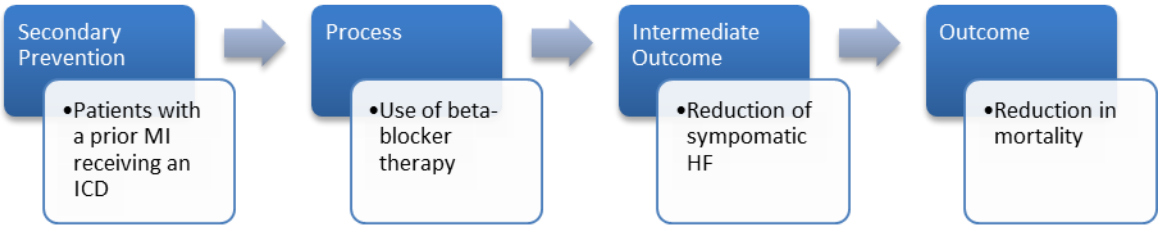
1a.2. Briefly state or diagram the path between the health outcome (or PRO) and the healthcare structures, processes, interventions, or services that influence it.

1a.2.1. State the rationale supporting the relationship between the health outcome (or PRO) to at least one healthcare structure, process, intervention, or service (*i.e., influence on outcome/PRO*).

Note: For health outcome/PRO performance measures, no further information is required; however, you may provide evidence for any of the structures, processes, interventions, or service identified above.

INTERMEDIATE OUTCOME, PROCESS, OR STRUCTURE PERFORMANCE MEASURE

1a.3. Briefly state or diagram the path between structure, process, intermediate outcome, and health outcomes. Include all the steps between the measure focus and the health outcome.



Beta-blockers reduce morbidity, mortality, and hospitalizations for patients who had a prior myocardial infarction (MI).

1a.3.1. What is the source of the systematic review of the body of evidence that supports the performance measure?

☒ Clinical Practice Guideline recommendation – ***complete sections 1a.4, and 1a.7***

☐ US Preventive Services Task Force Recommendation – ***complete sections 1a.5 and 1a.7***

☐ Other systematic review and grading of the body of evidence (*e.g., Cochrane Collaboration, AHRQ Evidence Practice Center*) – ***complete sections 1a.6 and 1a.7***

☐ Other – ***complete section 1a.8***

Please complete the sections indicated above for the source of evidence. You may skip the sections that do not apply.

1a.4.2. Identify guideline recommendation number and/or page number and **quote verbatim, the specific guideline recommendation**.

2014 AHA/ACC guideline for the management of patients with non–ST-elevation acute coronary syndromes (p. e 159)

1. In patients with concomitant NSTE-ACS, stabilized HF, and reduced systolic function, it is recommended to continue beta-blocker therapy with 1 of the 3 drugs proven to reduce mortality in patients with HF: sustained-release metoprolol succinate, carvedilol, or bisoprolol. **Class I: Level of Evidence: C**

2013 ACCF/AHA guideline for the management of ST-elevation myocardial infarction (p. e104)

2. Beta blockers should be continued during and after hospitalization for all patients with STEMI and with no contraindications to their use. **Class I: Level of Evidence: B**

AHA/ACCF secondary prevention and risk reduction therapy for patients with coronary and other atherosclerotic vascular disease: 2011 update (p. e2435)

3. Beta-blocker therapy should be used in all patients with left ventricular systolic dysfunction (ejection fraction <40%) with heart failure or prior myocardial infarction, unless contraindicated. (Use should be limited to carvedilol, metoprolol succinate, or bisoprolol, which have been shown to reduce mortality.) **Class I: Level of Evidence: A**
4. Beta-blocker therapy should be started and continued for 3 years in all patients with normal left ventricular function who have had myocardial infarction or ACS. **Class I: Level of Evidence: B**

2012 ACCF/AHA/ACP/AATS/PCNA/SCAI/STS guideline for the diagnosis and management of patients with stable ischemic heart disease (p. e96)

5. Beta-blocker therapy should be started and continued for 3 years in all patients with normal LV function after MI or ACS. **Class I: Level of Evidence: B**

6. Beta-blocker therapy should be used in all patients with LV systolic dysfunction (EF <40%) with heart failure or prior MI, unless contra- indicated. (Use should be limited to carvedilol, metoprolol succinate, or bisoprolol, which have been shown to reduce risk of death.). **Class I: Level of Evidence: A**

1a.4.3. Grade assigned to the quoted recommendation <u>with definition</u> of the grade:

Guideline Statement # (see 1a.4.2 above)	Class of Recommendation/Level of Evidence (for definitions see 1a.4.4 below)
1	Class Ic
2	Class Ib
3	Class Ia
4	Class Ib
5	Class Ib
6	Class Ia

1a.4.4. Provide all other grades and associated definitions for recommendations in the grading system. (*Note: If separate grades for the strength of the evidence, report them in section 1a.7.*)

Class of Recommendation (COR) is an estimate of the size of the treatment effect considering risks versus benefits in addition to evidence and/or agreement that a given treatment or procedure is or is not useful/effective or in some situations may cause harm.

Class I: Procedure/Treatment should be performed/administered

Class IIa: It is reasonable to perform procedure/administer treatment

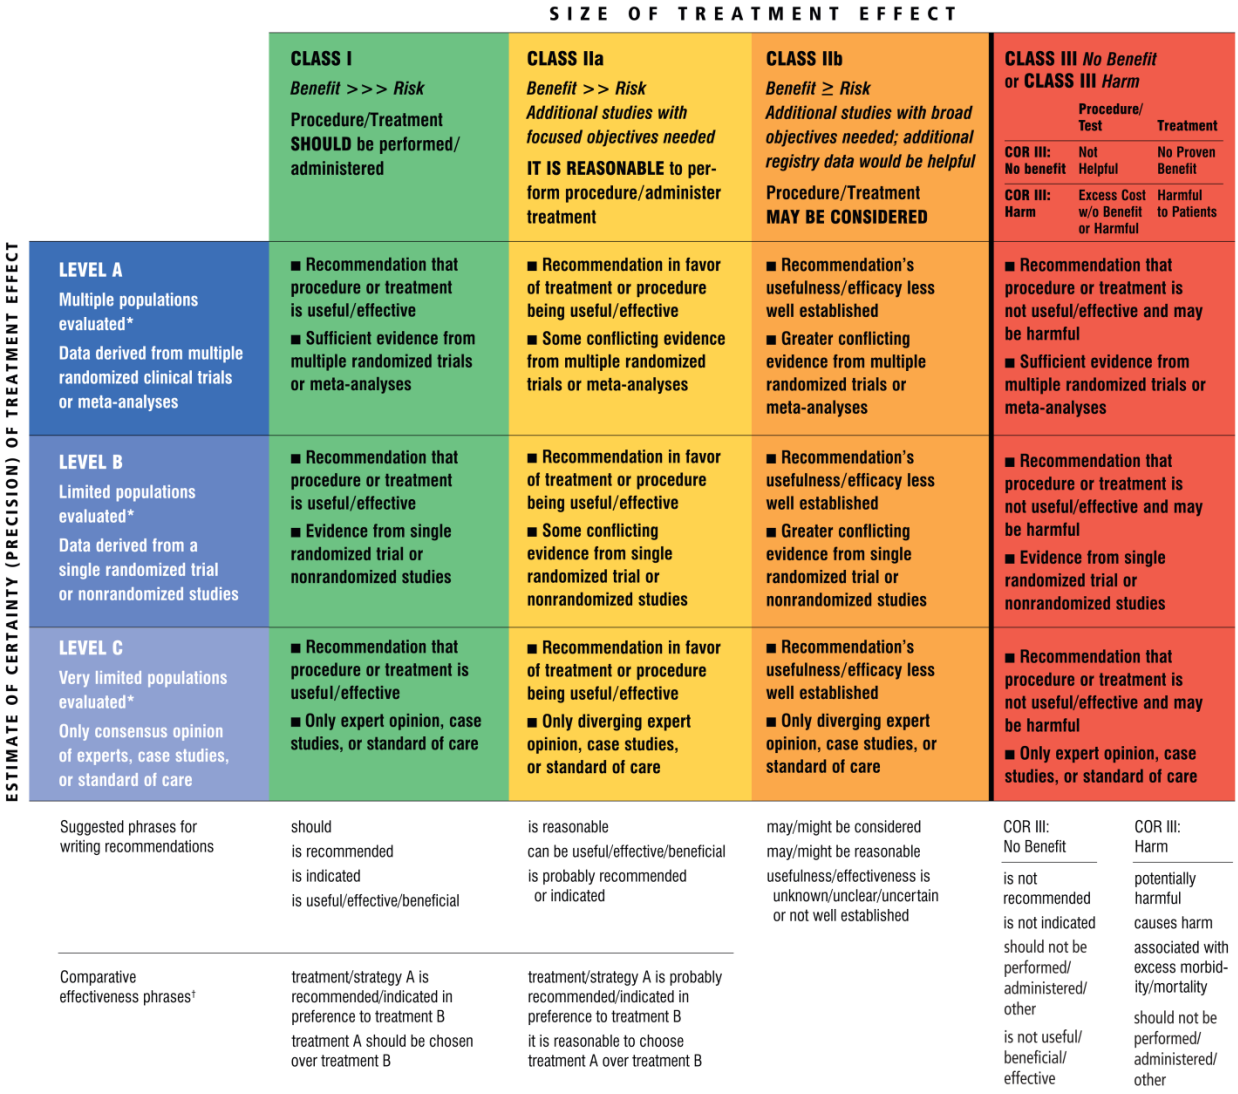
Class IIb: Procedure/Treatment may be considered

Class III: No benefit (Not helpful or No proven benefit)

Class III: Harm (Excess cost w/o benefit or Harmful to patients)

Specific COR definitions are included in Table 1 below.

Table 1. Applying Classification of Recommendation and Level of Evidence



Note: A recommendation with Level of Evidence B or C does not imply that the recommendation is weak. Many important clinical questions addressed in the guidelines do not lend themselves to clinical trials. Although randomized trials are unavailable, there may be a very clear clinical consensus that a particular test or therapy is useful or effective. *Data available from clinical trials or registries about the usefulness/efficacy in different subpopulations, such as sex, age, history of diabetes, history of prior myocardial infarction, history of heart failure, and prior aspirin use. †For comparative effectiveness recommendations (Class I and IIa; Level of Evidence A and B only), studies that support the use of comparator verbs should involve direct comparisons of the treatments or strategies being evaluated.

_____

1a.7. FINDINGS FROM SYSTEMATIC REVIEW OF BODY OF THE EVIDENCE SUPPORTING THE MEASURE

If more than one systematic review of the evidence is identified above, you may choose to summarize the one (or more) for which the best information is available to provide a summary of the quantity, quality, and consistency of the body of evidence. Be sure to identify which review is the basis of the responses in this section and if more than one, provide a separate response for each review.

1a.7.1. What was the specific structure, treatment, intervention, service, or intermediate outcome addressed in the evidence review?

2012 ACCF/AHA/ACP/AATS/PCNA/SCAI/STS guideline for the diagnosis and management of patients with stable ischemic heart disease

This guideline covers multiple management issues for the adult patient with stable known or suspected ischemic heart disease (SIHD) including the guideline-directed medical therapy (GDMT) such as beta-blocker therapy.

1a.7.2. Grade assigned for the quality of the quoted evidence with definition of the grade:

An overall grade for the quality of evidence was not assigned. Rather, the quality of a study (or set of studies) supporting a recommendation was graded on an estimate of the certainty or precision of the treatment effect (see 1a.4.3).

Recommendations used to support this measure have a:

- Level of Evidence A: Data derived from multiple randomized clinical trials or meta- analyses. References used to determine level of evidence must be provided and cited with the recommendation.

OR

- Level of Evidence B: Data derived from a single randomized trial, or nonrandomized studies. References used to determine level of evidence must be provided and cited with the recommendation

1a.7.3. Provide all other grades and associated definitions for strength of the evidence in the grading system.

Level of Evidence (LOE) is an estimate of the certainty or precision of the treatment effect.

Level of Evidence A: Data derived from multiple randomized clinical trials or meta- analyses. References used to determine level of evidence must be provided and cited with the recommendation.

Level of Evidence B: Data derived from a single randomized trial, or nonrandomized studies. References used to determine level of evidence must be provided and cited with the recommendation.

Level of Evidence C: Consensus opinion of experts, case studies, or standard of care.

Specific LOE definitions are included in Table 1 in 1a.4.4.

1a.7.4. What is the time period covered by the body of evidence? (*provide the date range, e.g., 1990-2010*). Date range: An extensive evidence review was conducted through December 2008 and includes selected other references through December 2011.

QUANTITY AND QUALITY OF BODY OF EVIDENCE

1a.7.5. How many and what type of study designs are included in the body of evidence? (*e.g., 3 randomized controlled trials and 1 observational study*)

2012 ACCF/AHA/ACP/AATS/PCNA/SCAI/STS guideline for the diagnosis and management of patients with stable ischemic heart disease

The body of evidence supporting the recommendations on beta-blocker therapy with patients with a prior MI includes randomized controlled trials and meta-analyses. The number of which is not provided in the guideline.

1a.7.6. What is the overall quality of evidence <u>across studies</u> in the body of evidence? (*discuss the certainty or confidence in the estimates of effect particularly in relation to study factors such as design flaws, imprecision due to small numbers, indirectness of studies to the measure focus or target population*)

2012 ACCF/AHA/ACP/AATS/PCNA/SCAI/STS guideline for the diagnosis and management of patients with stable ischemic heart disease

All of the recommendations for this process are rated as Level of Evidence A or B, meaning that the data was derived from one or more RCTs or meta-analyses. Additional information on the overall quality of evidence across the RCTs is not provided.

ESTIMATES OF BENEFIT AND CONSISTENCY ACROSS STUDIES IN BODY OF EVIDENCE

1a.7.7. What are the estimates of benefit—magnitude and direction of effect on outcome(s) across studies in the body of evidence? (*e.g., ranges of percentages or odds ratios for improvement/ decline across studies, results of meta-analysis, and statistical significance*)

2012 ACCF/AHA/ACP/AATS/PCNA/SCAI/STS guideline for the diagnosis and management of patients with stable ischemic heart disease (p. e96-97)

Decreases in the rate–BP product, AV nodal conduction, and myocardial contractility from beta blockers reduce myocardial oxygen demand, counteracting beta- receptor activity and contributing to a reduction in angina onset, with improvement in the ischemic threshold during exercise and in symptoms. These agents significantly reduce deaths and recurrent MIs in patients who have suffered a MI and are especially effective when a STEMI is complicated by persistent or recurrent ischemia or tachyarrhythmias early after the onset of infarction. However, no large trials have assessed effects of beta blockers on survival or coronary event rates in patients with SIHD.

Two large long-term follow-up studies investigating the prognostic importance of heart rate showed that all-cause mortality rate progressively increases with higher resting heart rate after adjustment for exercise capacity, age, diabetes mellitus, systolic arterial pressure, BMI, and level of physical activity. Therefore, it is recommended that beta-blocker dosing be adjusted to limit the heart rate to 55 to 60 beats per minute at rest.

In large prospective studies, bisoprolol, carvedilol, and metoprolol, when administered on a background of ACE inhibitors and diuretics with or without digoxin, have been shown to reduce the risk of death and to improve symptoms, clinical status, and quality of life in patients with chronic systolic heart failure. Importantly, these benefits were seen in patients with and without IHD.

1a.7.8. What harms were studied and how do they affect the net benefit (benefits over harms)?

2012 ACCF/AHA/ACP/AATS/PCNA/SCAI/STS guideline for the diagnosis and management of patients with stable ischemic heart disease (p. e96-97)

Absolute contraindications to beta blockers are severe bradycardia, preexisting high-degree AV block, sick sinus syndrome (without a pacemaker in place), and refractory heart failure. Relative contraindications include bronchospastic disease or active PAD (beta blockers without vasodilating properties or selective agents at low doses may be used). Because they can mask symptoms of hypoglycemia, beta blockers should be used with caution in patients with insulin-dependent diabetes mellitus. Abrupt beta-blocker withdrawal should be avoided because heightened beta- receptor density and sensitivity can result in a rebound phenomenon associated with an increased risk for AMI and sudden death.

The principle adverse effects of beta blockers are fatigue, exercise intolerance, lethargy, insomnia, nightmares, and impotence.

UPDATE TO THE SYSTEMATIC REVIEW(S) OF THE BODY OF EVIDENCE

1a.7.9. If new studies have been conducted since the systematic review of the body of evidence, provide for <u>each</u> new study: 1) citation, 2) description, 3) results, 4) impact on conclusions of systematic review.

One prospective cohort study and one meta-analysis were published after the publication of the 2012 ACCF/AHA/ACP/AATS/PCNA/SCAI/STS guideline for the diagnosis and management of patients with stable ischemic heart disease.

Note: Text below for description and results is verbatim from the article abstract.

Bangalore S, Makani H, Radford M, Thakur K, Toklu B, Katz SD, DiNicolantonio JJ, Devereaux P, Alexander KP, Wettersley J, Messerli FH. Clinical outcomes with β-blockers for myocardial infarction: a meta-analysis of randomized trials. Am J Med. 2014;127:939-53.

Description: We conducted a MEDLINE/EMBASE/CENTRAL search for randomized trials evaluating β-blockers in myocardial infarction enrolling at least 100 patients. The primary outcome was all-cause mortality. Analysis was performed stratifying trials into reperfusion-era (> 50% undergoing reperfusion or receiving aspirin/statin) or pre-reperfusion-era trials.

Results: Sixty trials with 102,003 patients satisfied the inclusion criteria. In the acute myocardial infarction trials, a significant interaction (Pinteraction = .02) was noted such that β-blockers reduced mortality in the pre-reperfusion (incident rate ratio [IRR] 0.86; 95% confidence interval [CI], 0.79-0.94) but not in the reperfusion era (IRR 0.98; 95% CI, 0.92-1.05). In the pre-reperfusion era, β-blockers reduced cardiovascular mortality (IRR 0.87; 95% CI, 0.78-0.98), myocardial infarction (IRR 0.78; 95% CI, 0.62-0.97), and angina (IRR 0.88; 95% CI, 0.82-0.95), with no difference for other outcomes. In the reperfusion era, β-blockers reduced myocardial infarction (IRR 0.72; 95% CI, 0.62-0.83) (number needed to treat to benefit [NNTB] = 209) and angina (IRR 0.80; 95% CI, 0.65-0.98) (NNTB = 26) at the expense of increase in heart failure (IRR 1.10; 95% CI, 1.05-1.16) (number needed to treat to harm [NNTH] = 79), cardiogenic shock (IRR 1.29; 95% CI, 1.18-1.41) (NNTH = 90), and drug discontinuation (IRR 1.64; 95% CI, 1.55-1.73), with no benefit for other outcomes. Benefits for recurrent myocardial infarction and angina in the reperfusion era appeared to be short term (30 days).

Conclusion: In contemporary practice of treatment of myocardial infarction, β-blockers have no mortality benefit but reduce recurrent myocardial infarction and angina (short-term) at the expense of increase in heart failure, cardiogenic shock, and drug discontinuation. The guideline authors should reconsider the strength of recommendations for β-blockers post myocardial infarction.

Bauters C, Lemesle G, Meurice T, Tricot O, de Groote P, Lamblin N. Prognostic impact of ß-blocker use in patients with stable coronary artery disease. Heart. 2014;100:1757-61.

Description: We analysed the data of 4184 outpatients included in a prospective cohort study on stable CAD. Two groups were formed based on ß-blocker use at enrollment. Two propensity score analyses were performed to control for differences in covariates: one with adjustment among the entire cohort, and the other with propensity score matching. The outcome variable was cardiovascular mortality after a 2-year follow-up.

Results: There were 3320 patients with ß-blocker use. Younger age, hypertension, diabetes, prior myocardial infarction, multivessel CAD, prior coronary revascularisation, prior stroke, prior hospitalisation for heart failure and a low LVEF were associated with ß-blocker use. Clinical follow-up data were obtained for 4149 patients (99.2%). When adjusted on propensity score, ß-blocker use was associated with a HR for cardiovascular mortality of 0.64 (0.42-0.98) in the whole cohort (p=0.04). After one-to-one propensity score matching, both groups (n=839 in each group) were well matched on covariates. The cardiovascular mortality rate in the propensity-matched cohort was significantly lower in patients with ß-blocker use with a HR of 0.43 (0.22-0.82) (p=0.011). Non-cardiovascular mortality was similar in both groups. These results were consistent across different subgroups.

Conclusions: In this observational study of patients with stable CAD, the use of ß-blockers was associated with a lower risk of cardiovascular mortality.

Impact on conclusions of systematic review:

These observational study does further support the recommendations and level of evidence ratings for this process of care. However, the other reviews do demonstrate that doing further guideline updates, careful review will need to be considered as to the utility of including this beta blocker measure after MI and including this subcomponent in the composite 0965 application.

1a.8 OTHER SOURCE OF EVIDENCE

If source of evidence is NOT from a clinical practice guideline, USPSTF, or systematic review, please describe the evidence on which you are basing the performance measure.

1a.8.1 What process was used to identify the evidence?

1a.8.2. Provide the citation and summary for each piece of evidence.

NATIONAL QUALITY FORUM—Evidence (subcriterion 1a)

Measure Number (*if previously endorsed*)**:** 1529

Measure Title: Beta Blocker at Discharge for ICD Implant Patients with LVSD

IF the measure is a component in a composite performance measure, provide the title of the Composite Measure here: 965 Patients with an ICD implant who receive ACE-I/ARB and beta blocker therapy at discharge

Date of Submission: Click here to enter a date

Instructions

- *For composite performance measures:*
  - *A separate evidence form is required for each component measure unless several components were studied together.*
  - *If a component measure is submitted as an individual performance measure, attach the evidence form to the individual measure submission.*
- Respond to all questions as instructed with answers immediately following the question. All information needed to demonstrate meeting the evidence subcriterion (1a) must be in this form. An appendix of *supplemental* materials may be submitted, but there is no guarantee it will be reviewed.
- If you are unable to check a box, please highlight or shade the box for your response.
- Maximum of 10 pages (*incudes questions/instructions*; minimum font size 11 pt; do not change margins). ***Contact NQF staff if more pages are needed.***
- Contact NQF staff regarding questions. Check for resources at Submitting Standards webpage.

Note: The information provided in this form is intended to aid the Steering Committee and other stakeholders in understanding to what degree the evidence for this measure meets NQF's evaluation criteria.

1a. Evidence to Support the Measure Focus

The measure focus is evidence-based, demonstrated as follows:

- Health outcome: [3] a rationale supports the relationship of the health outcome to processes or structures of care. Applies to patient-reported outcomes (PRO), including health-related quality of life/functional status, symptom/symptom burden, experience with care, health-related behavior.
- Intermediate clinical outcome: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured intermediate clinical outcome leads to a desired health outcome.
- Process: [5] a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured process leads to a desired health outcome.
- Structure: a systematic assessment and grading of the quantity, quality, and consistency of the body of evidence [4] that the measured structure leads to a desired health outcome.
- Efficiency: [6] evidence not required for the resource use component.

Notes

3. Generally, rare event outcomes do not provide adequate information for improvement or discrimination; however, serious reportable events that are compared to zero are appropriate outcomes for public reporting and quality improvement.

4. The preferred systems for grading the evidence are the U.S. Preventive Services Task Force (USPSTF) grading definitions and methods, or

Grading of Recommendations, Assessment, Development and Evaluation (GRADE) guidelines.
5. Clinical care processes typically include multiple steps: assess → identify problem/potential problem → choose/plan intervention (with patient input) → provide intervention → evaluate impact on health status. If the measure focus is one step in such a multistep process, the step with the strongest evidence for the link to the desired outcome should be selected as the focus of measurement. Note: A measure focused only on collecting PROM data is not a PRO-PM.
6. Measures of efficiency combine the concepts of resource use and quality (see NQF's Measurement Framework: Evaluating Efficiency Across Episodes of Care; AQA Principles of Efficiency Measures).

1a.1.This is a measure of: (*should be consistent with type of measure entered in De.1*)

Outcome

☐ Health outcome: Click here to name the health outcome

☐Patient-reported outcome (PRO): Click here to name the PRO

PROs include HRQoL/functional status, symptom/symptom burden, experience with care, health-related behaviors

☐ Intermediate clinical outcome (*e.g., lab value*): Click here to name the intermediate outcome

☒ Process: Beta-blocker therapy for patients with LVSD receiving an ICD

☐ Structure: Click here to name the structure

☐ Other: Click here to name what is being measured

HEALTH OUTCOME/PRO PERFORMANCE MEASURE *If not a health outcome or PRO, skip to 1a.3*

1a.2. Briefly state or diagram the path between the health outcome (or PRO) and the healthcare structures, processes, interventions, or services that influence it.

1a.2.1. State the rationale supporting the relationship between the health outcome (or PRO) to at least one healthcare structure, process, intervention, or service (*i.e., influence on outcome/PRO*).

Note: For health outcome/PRO performance measures, no further information is required; however, you may provide evidence for any of the structures, processes, interventions, or service identified above.
